

## Configuring Mobile-Specific Compiling Settings

---

In general, compilation process for mobile application consists of the following events:

- **Compilation:** this is done by common compiler such as javac. To learn how to configure settings for this compilation part refer to [Configuring Compiler Settings](#) section.
- **Preverify:** this stage is conducted by a preverify utility with emulator provided for the given mobile Java SDK. This section describes how to configure preverify settings.
- **Packaging.**

### To configure preverify settings

1. [Open the Project Structure dialog \(Ctrl+Alt+Shift+S\)](#).
2. Go to **SDKs** section and select your mobile SDK in the list.
3. If you are using WTK, you can specify whether you want to use default profile (MIDP) and configuration (CLDC) versions for the given emulator, or profile and/or configuration versions different from default. In the second case, select the profile and/or configuration version using the corresponding drop-down list.
4. For both WTK and DoJa, specify parameters for the preverify utility.
