

## Creating Maven Run/Debug Configuration

IntelliJ IDEA provides Maven-specific form of run/debug configuration. When a Maven project is imported, each goal gets its own configuration, with the pre-defined name, project file, profiles, goals, and other settings.

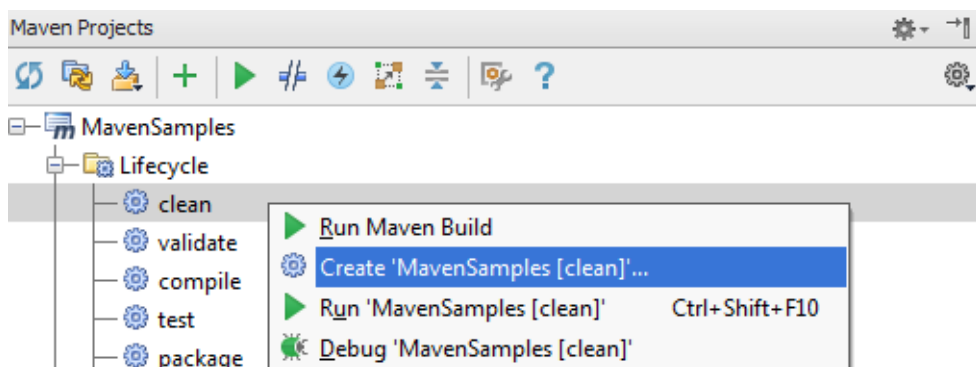

You can save such configuration for future reuse, or create your own ones. When a configuration is created, it is added to the list of permanent configurations and becomes available from the drop-down list on the main toolbar:

In general, working with run/debug configurations follows the same procedure as described in the section [Creating and Editing Run/Debug Configurations](#). This section provides a *shortcut* procedure, specially tailored for Maven integration.

### To create a run/debug configuration for a maven goal

1. In the Maven Projects tool window, expand a project and right-click the desired goal.
2. On the context menu of the selection, choose **Create "<project>[goal]"**:

The [Run/Debug Configuration](#) dialog box for Maven opens, with the current Maven project, goal, profiles and other settings.

3. Edit the run/debug configuration as required, and click **OK**.
