

Executing Maven Goal

There are two ways to execute a Maven goal:

- [Use Run Goal command](#), which produces the same result as launching `mvn` from the command line.
- [Run the Maven goal as an application](#) with a Maven-specific run/debug configuration, which can be stored and reused for debugging Maven plugins.

Results are displayed in the console of the [Run tool window](#).

To build a lifecycle phase or a plugin

1. Select the desired node in the [Maven Projects](#) tool window.
2. Choose **Run Goal** on the context menu of the selection.

To run a maven goal as an application, do one of the following

- Perform the regular procedure, as described in the section [Running Applications](#).
- Perform the *shortcut* procedure, which uses a Maven-specific run/debug configuration for each goal:

Select the desired node in the [Maven Projects](#) tool window, and choose **Run <goal> [run/debug configuration]** on the context menu, or press `Ctrl+Shift+F10`.
