

## Move Attribute in

The *Move Attribute In* refactoring allows you to move attributes defined on a set of XML tags inward to a set of subtags. If this refactoring is invoked, all attributes matching the selected attribute name on tags with the selected tag name may be moved inward toward a subtag of a given name. This bulk modification of attribute values may be useful as XML schemas evolve.

### Moving attribute in

1. Position the caret on the attribute to modify in the editor, right-click, and select **XML Refactorings | Move Attribute In...** menu item.

2. Determine the subtag to move the attribute to.
3. Determine the scope of the change. All attributes matching the name of the attribute selected on the tag selected will be modified, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the **Recursively** check box is selected. If the **Limit to files with DTD:...** check box is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
4. Press **Preview** button to make IntelliJ IDEA to search for usages of the selected attribute **Find** window.
5. Click **OK** to continue. If you do not select the **Preview** option, all usages will be changed immediately.

Pressing **Preview** opens the **Refactoring preview** window displaying all found usages of the attributes to be changed. In this window you can exclude/include usages you want to refactor.

Pressing **Show XSLT...** opens the **XSLT preview** window displaying an small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.
