Note that adding a constructor is required, as there is no default constructor defined for the parent class.

### 3. Add a test method

In the editor, right-click the `HelloDroidTest` test class and click Generate (alternatively, click `Alt+Insert`). From the popup menu that opens, select Test Method :

IntelliJ IDEA creates a new method stub named `testName` where you can easily change the `Name` suffix into something more meaningful in the context:

```
public void testStringForDisplay() throws Exception {
```

The `test` prefix in the method name is required if you are using [JUnit 3](#), the default testing framework in Android. With [JUnit 4](#), you have to use method name annotations to indicate that a given method must be processed as a test method.

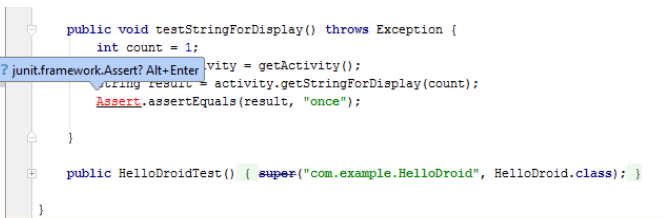

### 4. Write the logic for a test method

Internally, the test method first gets a reference to the activity it is trying to test, then it calls the target method, and, finally, compares the effective results with the expected results.

Add the following code to the test method:

```
public void testStringForDisplay() throws Exception {
    int count = 1;
    HelloDroid activity = getActivity();
    String result = activity.getStringForDisplay(count);
    Assert.assertEquals(result, "once");
}
```

Assertions are implemented through the services of the JUnit framework and need to be properly referenced in the source file. Press **Alt+Enter** when the intention action pops up to reference it:

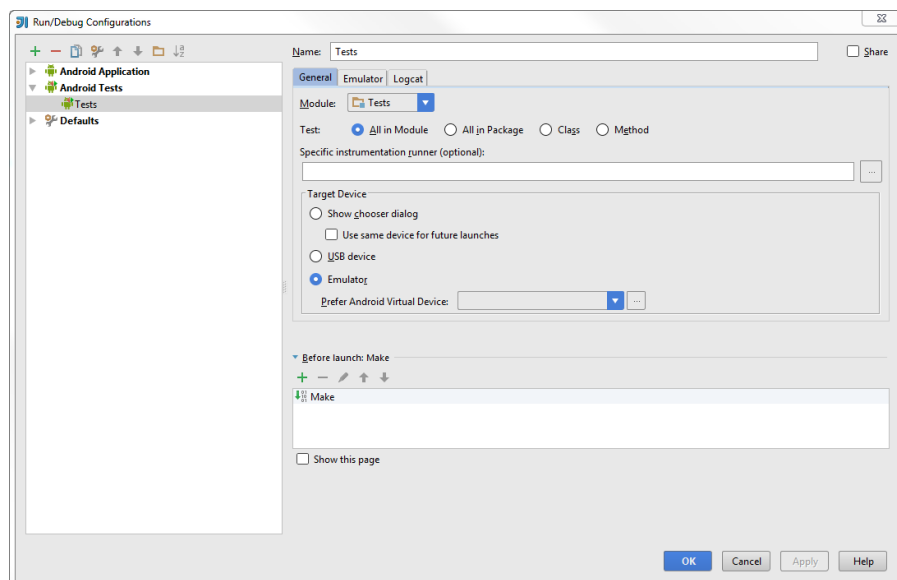

```
public void testStringForDisplay() throws Exception {
    int count = 1;
    ? junit.framework.Assert? Alt+Enter vity = getActivity();
    String result = activity.getStringForDisplay(count);
    Assert.assertEquals(result, "once");
}

public HelloDroidTest() { super("com.example.HelloDroid", HelloDroid.class); }
}
```

## 5. Create a run/debug configuration for tests

In order to run tests, you need to create a dedicated run/debug configuration. A default configuration is created for you automatically when you set up a test module.

To edit its settings, in the main menu select **Run | Edit Configurations** and select **Tests** under **Android Tests** in the left pane:

You can select to run all tests in the module, or limit the test to the methods in a given class.

## 6. Run a test

To run your tests, make sure the appropriate run/debug configuration is selected in the drop-down list in the top-right corner of the editor, and click the **Run** button next to it:

Test results are displayed in the **Test Runner** tab of the **Run tool window** that is activated automatically. If a test is completed successfully, a green square icon appears in the top right corner of the editor. If there are warnings, the icon is yellow, and if a test fails - it is red. You can click the icon to get more details.

You can export a test report to a variety of formats by clicking the **Export Test Results** icon in the **Tests** tab toolbar.

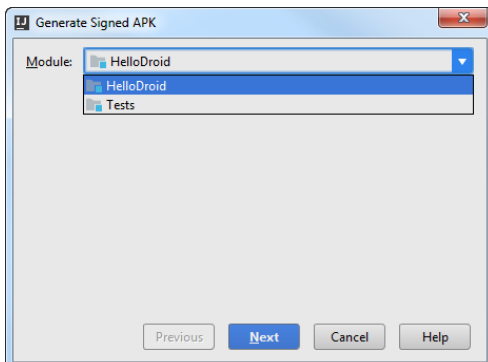

Once ready, an Android application is packaged as an [.apk file](#) . The package contains binaries as well as resources.

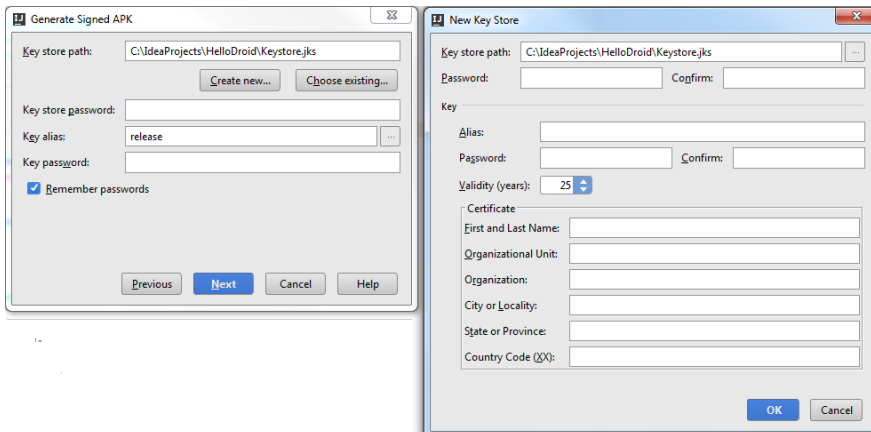

Android applications can be published in an application store, such as [Google Play](#) . To publish an application, you need to [sign it digitally](#) . Based on this signature, the Android system identifies the author of every deployed application. You do not need to apply for a personal signature to any authority, a signature generated by IntelliJ IDEA is quite sufficient.

To package and sign the application, perform the following steps:

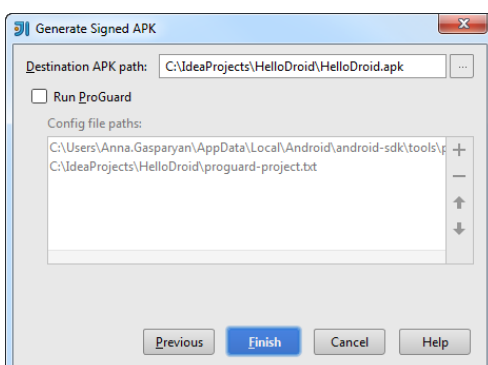

1. From the main menu, select Build | Generate Signed APK . The [Generate Signed APK Wizard](#) starts.
2. On the first page, select the module that you want to package ( [HelloDroid](#) ) and click Next :

3. On the next page, click the Create new button to create a new keystore file with a new key.
  - In the [New Key Store](#) dialog box that opens, click the Browse button (...), select the folder where the newly generated keystore file will be located, and enter the name of the file.
  - Specify and confirm the password to access the keystore.
  - Configure the new release key by filling in the data in the Key area.

4. On the next step, in the Destination APK path text box, specify the folder where the [.apk](#) file will be saved. Optionally, select the Run ProGuard option if you want IntelliJ IDEA to [obfuscate the application](#) during the packaging procedure.

5. Click Finish to generate and sign the application package.

You can upload the resulting [HelloDroid.apk](#) file to an application store, or install it directly on devices configured to install applications from unknown sources.

This feature is only supported in the Ultimate edition.

This guide shows main IntelliJ IDEA features for writing and running [Arquillian](#) tests.

- [Before you start](#)
- [Creating a project with Arquillian JUnit support](#)
- [Creating a class](#)
- [Developing code for the Greeter class](#)
- [Defining javax-inject.jar as a library](#)
- [Creating a folder for test sources](#)
- [Creating a test class](#)
- [Completing the code for the GreeterTest class](#)
- [Creating a run configuration for running the test](#)
- [Running the test in an embedded container](#)
- [Editing the run configuration: adding a managed container](#)
- [Creating the arquillian.xml configuration file](#)
- [Running the test in a managed container](#)
- [Modifying arquillian.xml](#)
- [Running the test: deploying to a running server](#)

## Before you start

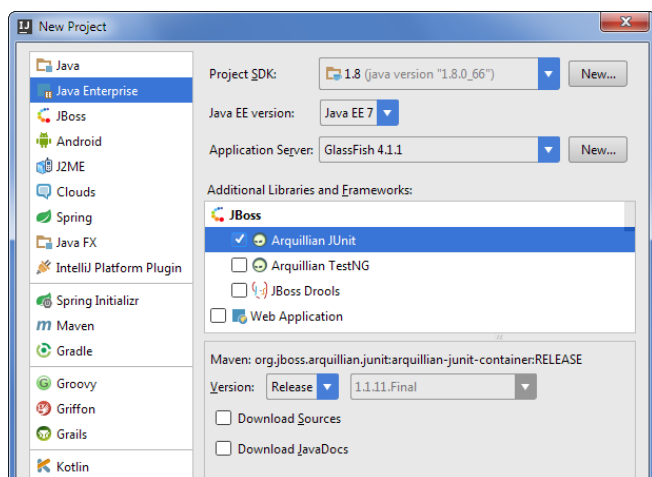

Make sure that the following software is installed on your computer:

- IntelliJ IDEA ULTIMATE Edition. Also check if the JBoss Arquillian Support [plugin](#) is enabled.
- Java SE Development Kit (JDK), version 8. [Download Oracle JDK](#) .
- GlassFish Server, version 4. The server will be used as a managed Arquillian container. [Download GlassFish](#) .

You should also [download javax-inject.jar](#) . This file will be used as a [library](#) when developing our sample test class.

## Creating a project with Arquillian JUnit support

1. Click Create New Project on the Welcome screen, or select File | New | Project .  
The New Project wizard opens.
2. In the left-hand pane, select Java Enterprise .
3. If the JDK that you want to use is already defined in IntelliJ IDEA, select that JDK from the Project SDK list. Otherwise, click New , select JDK , and select the JDK installation folder in the dialog that opens.
4. If GlassFish is not defined in IntelliJ IDEA yet, click New to the right of the Application Server field and select Glassfish Server .  
In the Glassfish Server dialog, specify the GlassFish Server installation directory.
5. Under Additional Libraries and Frameworks , select the Arquillian JUnit checkbox.

Click Next .

6. Specify the name for your new project (e.g. `HelloArquillian` ) and click Finish .

When the project is created, you'll see something similar to this in the Project tool window.

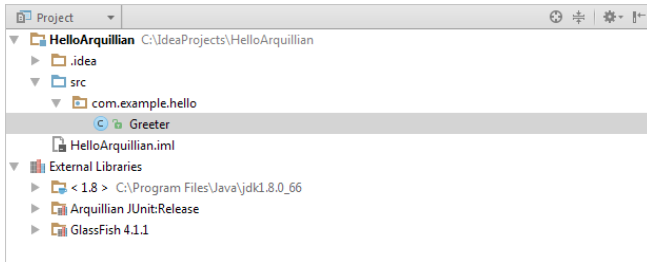

(To add Arquillian JUnit support for an existing project: in the Project tool window, right-click your project or module folder and select Add Framework Support . Then, select the Arquillian JUnit checkbox in the dialog that opens.)

## Creating a class

Now we are going to create a class that we'll test. Let the class name be `com.example.hello.Greeter` .

1. In the Project tool window, right-click the `src` folder, point to New and select Java Class .
  2. In the Create New Class dialog that opens, type `com.example.hello.Greeter` in the Name field and press `Enter` .
- The package `com.example.hello` and the class `Greeter` are shown in the Project tool window.

At the same time, the file `Greeter.java` opens in the editor.

## Developing code for the Greeter class

Here is the code for the `Greeter` class.

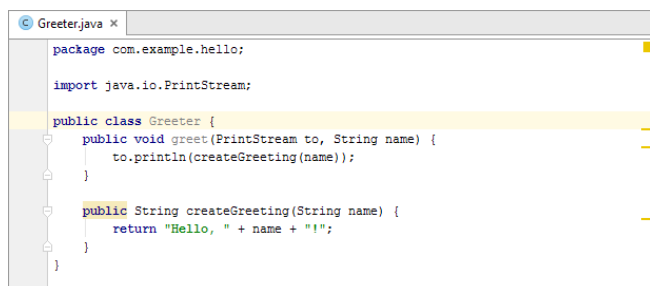

```
package com.example.hello;

import java.io.PrintStream;

public class Greeter {
    public void greet(PrintStream to, String name) {
        to.println(createGreeting(name));
    }

    public String createGreeting(String name) {
        return "Hello, " + name + "!";
    }
}
```

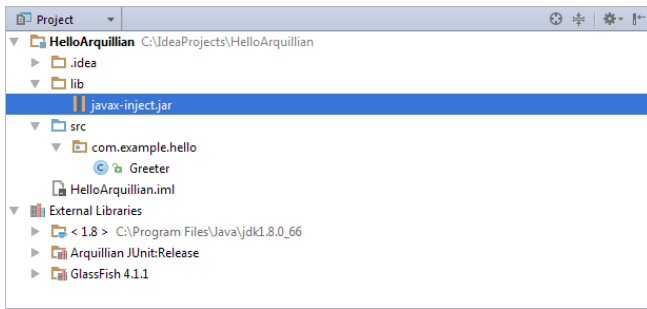

Copy the code into the editor.

## Defining javax-inject.jar as a library

To be able to write and run our Arquillian test, we need `javax-inject.jar` as a library.

1. In the project root folder, create the folder `lib` ( New | Directory ) and copy `javax-inject.jar` into that folder.

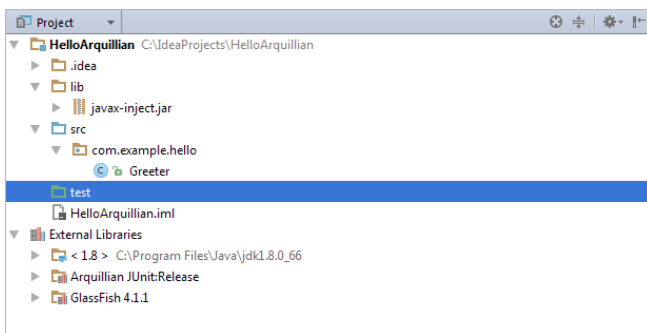

2. Open the Project Structure dialog ( `Ctrl+Shift+Alt+S` ) and select Libraries .
3. Click `+`, select Java and select `javax-inject.jar` in the dialog that opens.
4. Click OK in the Choose Modules dialog.

5. Click OK in the Project Structure dialog.

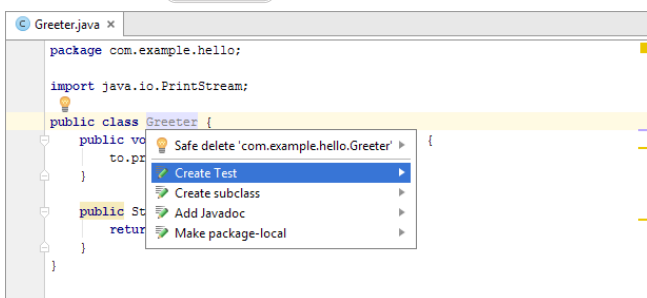

## Creating a folder for test sources

1. In the project root folder, create the folder `test` .
2. Right-click that folder, point to Mark Directory As and select Test Sources Root .

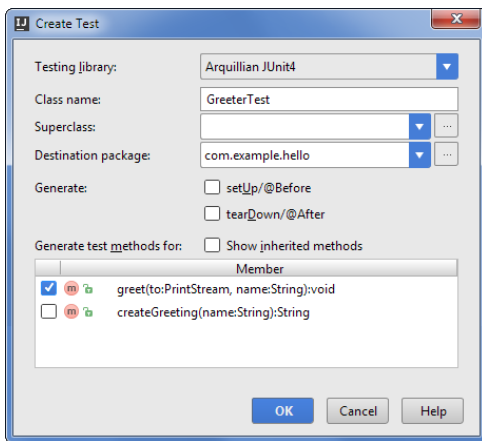

## Creating a test class

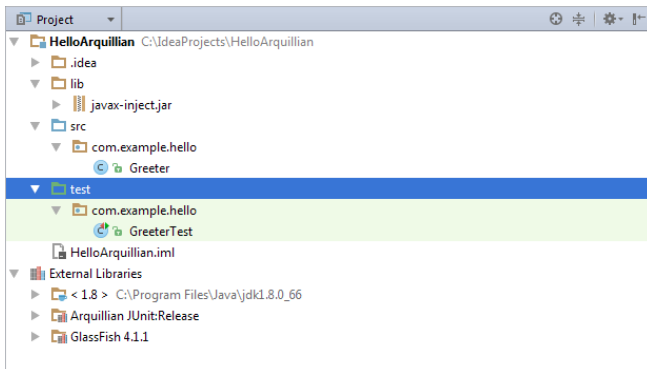

1. In the editor, place the cursor within the name of the class ( `Greeter` ) .
2. Click the light bulb ( `Alt+Enter` ) and select Create Test .

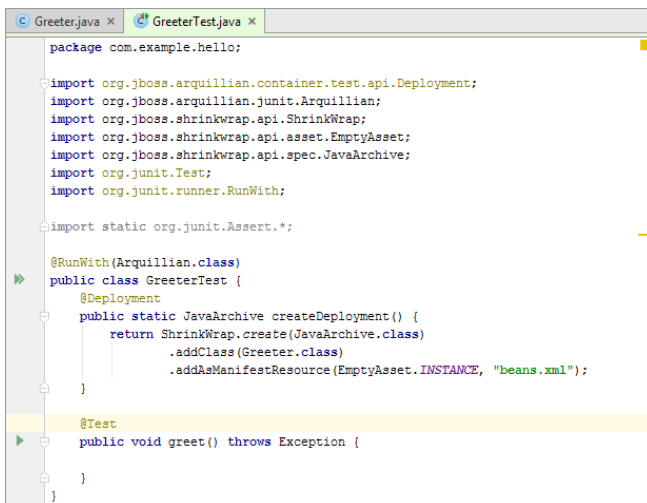

3. In the Create Test dialog that opens, select Arquillian JUnit4 from the Testing library list. Under Create test methods for , select the method that doesn't return a value ( `greet` ) . Click OK .

The new test class is shown in the Project tool window.

At the same time, the file `GreeterTest.java` opens in the editor.

The initial content of the test class is defined by the corresponding template. You can edit that template on the Code tab of the File and Code Templates page in the Settings / Preferences dialog (`Ctrl+Alt+S` | Editor | File and Code Templates).

## Completing the code for the GreeterTest class

Here is the code for the test class in its final state:

```

package com.example.hello;

import org.jboss.arquillian.container.test.api.Deployment;
import org.jboss.arquillian.junit.Arquillian;
import org.jboss.shrinkwrap.api.ShrinkWrap;
import org.jboss.shrinkwrap.api.asset.EmptyAsset;
import org.jboss.shrinkwrap.api.spec.JavaArchive;
import org.junit.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

import javax.inject.Inject;

import static org.junit.Assert.*;

@RunWith(Arquillian.class)
public class GreeterTest {

    @Deployment
    public static JavaArchive createDeployment() {
        return ShrinkWrap.create(JavaArchive.class)
            .addClass(Greeter.class)
            .addAsManifestResource(EmptyAsset.INSTANCE, "beans.xml");
    }

    @Inject
    Greeter greeter;

    @Test
    public void greet() throws Exception {
        String name="Arquillian";
        Assert.assertEquals("Hello, Arquillian!", greeter.createGreeting(name));
        greeter.greet(System.out, name);
    }
}

```

1. To insert a proper `import` statement for `@Inject`, type `@Inj` and select `@Inject (javax.inject)`.

```

package com.example.hello;

import org.jboss.arquillian.container.test.api.Deployment;
import org.jboss.arquillian.junit.Arquillian;
import org.jboss.shrinkwrap.api.ShrinkWrap;
import org.jboss.shrinkwrap.api.asset.EmptyAsset;
import org.jboss.shrinkwrap.api.spec.JavaArchive;
import org.junit.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

import static org.junit.Assert.*;

@RunWith(Arquillian.class)
public class GreeterTest {

    @Deployment
    public static JavaArchive createDeployment() {
        return ShrinkWrap.create(JavaArchive.class)
            .addClass(Greeter.class)
            .addAsManifestResource(EmptyAsset.INSTANCE, "beans.xml");
    }

    @Inject
    Greeter greeter;

    @Test
    public void greet() throws Exception {
        String name="Arquillian";
        Assert.assertEquals("Hello, Arquillian!", greeter.createGreeting(name));
        greeter.greet(System.out, name);
    }
}

```

2. Add the remaining code by copying.

```

package com.example.hello;

import org.jboss.arquillian.container.test.api.Deployment;
import org.jboss.arquillian.junit.Arquillian;
import org.jboss.shrinkwrap.api.ShrinkWrap;
import org.jboss.shrinkwrap.api.asset.EmptyAsset;
import org.jboss.shrinkwrap.api.spec.JavaArchive;
import org.junit.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

import javax.inject.Inject;

import static org.junit.Assert.*;

@RunWith(Arquillian.class)
public class GreeterTest {

    @Deployment
    public static JavaArchive createDeployment() {
        return ShrinkWrap.create(JavaArchive.class)
            .addClass(Greeter.class)
            .addAsManifestResource(EmptyAsset.INSTANCE, "beans.xml");
    }

    @Inject
    Greeter greeter;

    @Test
    public void greet() throws Exception {
        String name="Arquillian";
        Assert.assertEquals("Hello, Arquillian!", greeter.createGreeting(name));
        greeter.greet(System.out, name);
    }
}

```

## Creating a run configuration for running the test

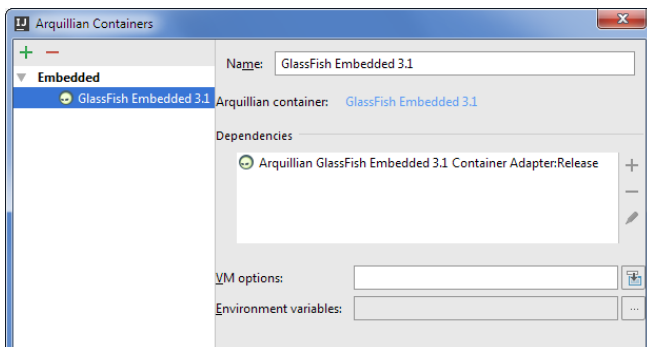

1. To the left of `public class GreeterTest`, click  and select Run 'GreeterTest'.

2. In the Edit configuration dialog that opens, click Configure.

3. In the Arquillian Containers dialog, click , point to Embedded and select GlassFish Embedded 3.1. (We'll start by running the test in an embedded container.)

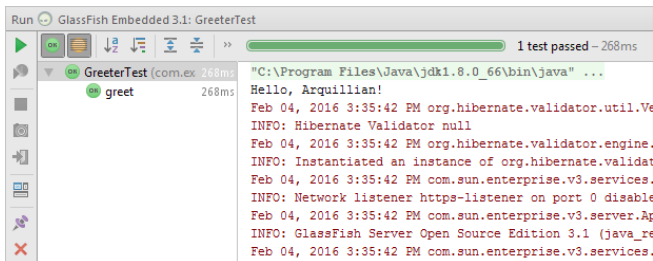

4. In the Edit configuration dialog, select GlassFish Embedded 3.1.

## Running the test in an embedded container

1. In the Edit configuration dialog, click Run.

The Run tool window opens and, after some time, the test result is shown there.

2. Close the Run tool window by clicking .

## Editing the run configuration: adding a managed container

Now let's change our run configuration so that it could be used for running the test in a managed container.

1. Click the run configuration selector and select Edit Configurations .

2. In the Run/Debug Configurations dialog, click Configure .

3. In the Arquillian Containers dialog, click  and select Manual container configuration .

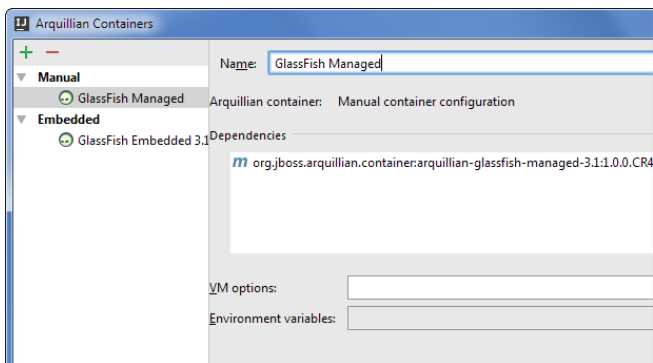

4. Change the name of the configuration (e.g. to `GlassFish Managed` ).

5. Under Dependencies , click  and select Add maven dependency .

6. In the Download Library From Maven Repository dialog, type `arquillian-glassfish-managed-3.1` and click  . Then select `org.jboss.arquillian.container:arquillian-glassfish-managed-3.1:1.0.0.CR4` from the list. Select the Download to checkbox and click OK .

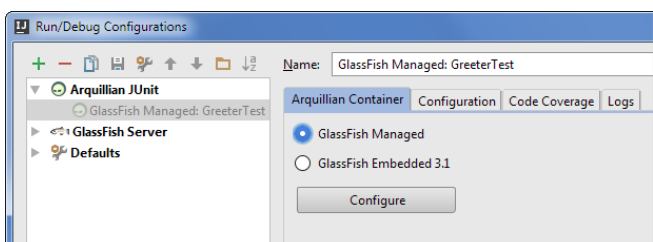

At this step, your Arquillian Containers dialog should look something like this:

Click OK .

7. In the Run/Debug Configurations dialog, select GlassFish Managed and click OK .

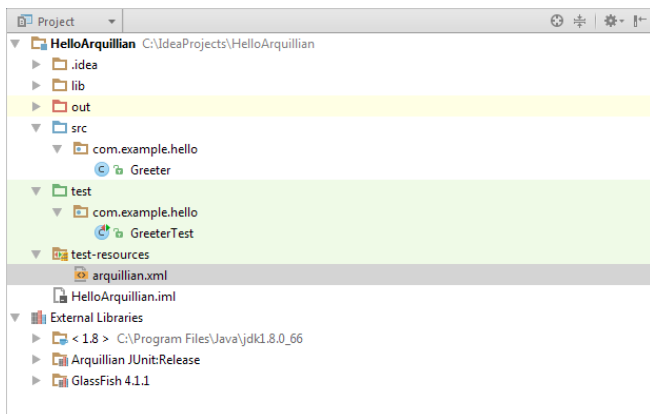

## Creating the arquillian.xml configuration file

To be able to run an Arquillian test in a managed container, the container adapter needs to know the container location. So let's create the `arquillian.xml` configuration file with the necessary info.

1. In the project root folder, create the folder `test-resources`.
2. Right-click the new folder, point to Mark Directory As and select Test Resources Root.
3. In the test-resources folder, create a new file `arquillian.xml`.

4. Copy the following into the file:

```
<?xml version="1.0"?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns="http://jboss.org/schema/arquillian"
  xsi:schemaLocation="http://jboss.org/schema/arquillian
  http://jboss.org/schema/arquillian/arquillian_1_0.xsd">

  <container qualifier="glassfish" default="true">
    <configuration>
      <property name="glassFishHome">C:\GlassFish\glassfish4</property>
    </configuration>
  </container>

</arquillian>
```

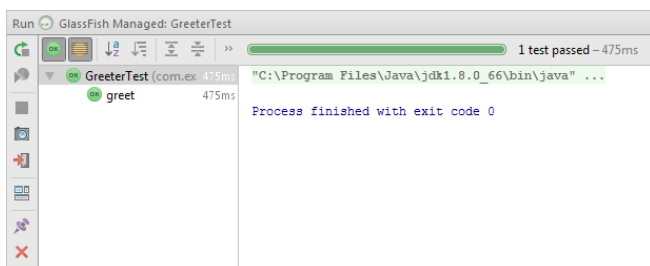

Use your actual path to the GlassFish Server installation folder in place of `C:\GlassFish\glassfish4`.

## Running the test in a managed container

1. To the right of the run configuration selector, click .

The Run tool window opens and the test result is shown there.

2. Close the tool window .

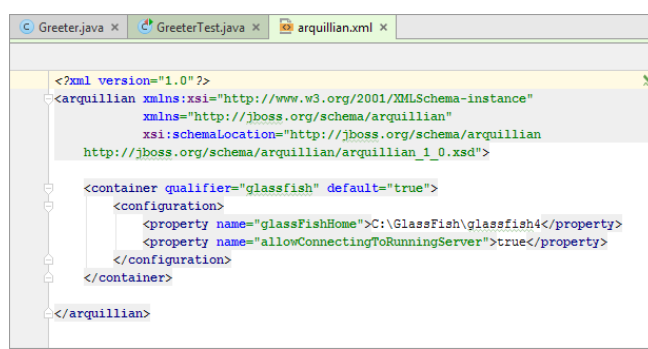

## Modifying arquillian.xml

Sometimes, you need to deploy your test to a container that is already running. In such cases, you can just change the

container configuration file a little and continue using the managed container adapter.

Add the following to `arquillian.xml` :

```
<property name="allowConnectingToRunningServer">true</property>
```

The screenshot shows an IDE with three tabs: Greeter.java, GreeterTest.java, and arquillian.xml. The arquillian.xml file is open and shows the following XML structure:

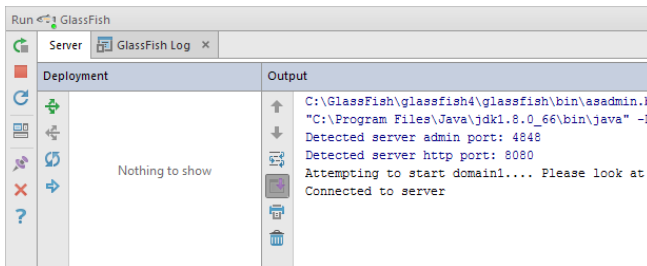

```
<?xml version="1.0" ?>
<arquillian xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns="http://jboss.org/schema/arquillian"
  xsi:schemaLocation="http://jboss.org/schema/arquillian
    http://jboss.org/schema/arquillian/arquillian_1_0.xsd">
  <container qualifier="glassfish" default="true">
    <configuration>
      <property name="glassFishHome">C:\GlassFish\glassfish4</property>
      <property name="allowConnectingToRunningServer">true</property>
    </configuration>
  </container>
</arquillian>
```

## Running the test: deploying to a running server

1. Start GlassFish Server: select GlassFish and click ▶.

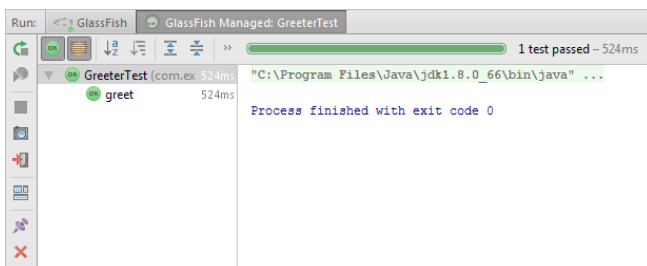

When the server is started, you'll see something like this in the Run tool window.

2. Select GlassFish Managed: GreeterTest and click ▶.

After some time, the test result is shown in the Run tool window.

This feature is only supported in the Ultimate edition.

In this section:

- AspectJ
  - [Introduction](#)
  - [Overview of AspectJ support](#)
  - [Overview of using AspectJ support](#)
- [Enabling AspectJ Support Plugins](#)
- [Creating a Library for aspectjrt.jar](#)
- [Creating Aspects](#)
- [Using the Push ITDs In Refactoring](#)
- [Using the AspectJ Compiler \(ajc\)](#)

## Introduction

[AspectJ](#) support in IntelliJ IDEA Ultimate is based on the following [plugins](#) that are bundled with the IDE:

- Spring AOP/@AspectJ
- AspectJ Support

An AspectJ [facet](#) which you can add to your Java [modules](#) lets you fine-tune the use of the AspectJ compiler at a module level.

## Overview of AspectJ support

AspectJ support in IntelliJ IDEA Ultimate includes:

- Ability to create aspects in two forms: as `.aj` files and `.java` files containing classes annotated with `@Aspect` .
- Coding assistance (including [code completion](#) ) when writing aspect code. For annotation-style aspects, the coding assistance is provided in full; for code-style aspects, the assistance is limited to [inter-type declarations](#) .
- Ability to perform basic aspect refactorings such as [Rename](#) and [Move](#) , and also the [Push ITDs In refactoring](#) for inter-type declarations.
- Integration with the AspectJ compiler `ajc` which you can run right from the IDE. (This compiler is part of the AspectJ distribution which you can download from the [AspectJ website](#) .)
- Ability to configure `ajc` at the project level with an option of fine-tuning its use at the level of individual modules.

## Overview of using AspectJ support

The tasks that are specific to AspectJ are outlined below.

1. Make sure that:
  - You are using the Ultimate Edition of IntelliJ IDEA. AspectJ is not supported in the Community Edition.
  - The Spring AOP/@AspectJ and the AspectJ Support plugins are enabled. See [Enabling AspectJ Support Plugins](#) .
2. [Download](#) and install AspectJ.
3. Create a library containing `aspectjrt.jar` and add this library to dependencies of the modules in which you are going to develop your aspects. Once you have installed AspectJ, you can find `aspectjrt.jar` in `<AspectJ installation directory>\lib` . See [Creating a Library for aspectjrt.jar](#) .
4. [Create aspect files](#) and develop the code. Note that code- and annotation-style aspects are supported.
5. If necessary, [refactor the aspect code](#) .
6. To use the AspectJ compiler, [configure the compiler settings](#) . The compiler (`ajc` ) is in `aspectjtools.jar` which is located in `<AspectJ installation directory>\lib` .
7. To fine-tune the use of `ajc` at the level of individual modules, add AspectJ facets to corresponding modules and [adjust the facet settings](#) accordingly.

This feature is only supported in the Ultimate edition.

To be able to use the AspectJ support in IntelliJ IDEA Ultimate, you have to make sure that the following [plugins](#) are enabled:

- Spring AOP/@AspectJ
- AspectJ Support

In addition to that, you should also [create a library for aspectjrt.jar](#) .

### Making sure that the necessary plugins are enabled

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S` ).
2. In the left-hand part of the dialog, in the search box, type `plugins` . Then, select Plugins in the pane below the search box.
3. On the [Plugins page](#) that opens in the right-hand part of the dialog, make sure that All plugins is selected in the Show box, and type `aspectj` in the search field.
4. Make sure that the checkboxes to the right of AspectJ Support and Spring AOP/@AspectJ are selected.
5. Click OK in the Settings dialog.
6. If asked, restart IntelliJ IDEA.

This feature is only supported in the Ultimate edition.

To be able to use the AspectJ support, in addition to [enabling AspectJ support plugins](#) , you should create a [library](#) containing `aspectjrt.jar` and add this library to dependencies of the [modules](#) in which you are going to develop your aspects.

`aspectjrt.jar` is included in the AspectJ distribution which you can download from the [AspectJ website](#) .

## Creating a library for aspectjrt.jar and adding it to module dependencies

By the time you start to perform this task, you must have already downloaded and installed AspectJ.

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Depending on whether you want to create the new library at the project or the IDE level, select Libraries or Global Libraries .
3. Click `+` and select Java .
4. In the [dialog that opens](#) , find and select `aspectjrt.jar` . (This file is located in `<AspectJ installation directory>\lib` .)
5. In the Choose Modules dialog, select the modules in which you want to use this library and click OK .  
As a result, the library is added to dependencies of the corresponding modules.
6. Click OK in the Project Structure dialog.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA lets you create aspects in two forms: as `.aj` files and `.java` files containing classes annotated with `@Aspect` .

Note that by the time you start to create your aspects, you must have already [enabled the AspectJ support plugins](#) and [defined aspectjrt.jar as a library](#) .

## Creating an aspect

1. In the [Project Tool Window](#) , do one of the following:
  - Select your source directory or the package in which you want to create a new aspect, and select File | New .
  - Select the source directory or package, and press `Alt+Insert` .
  - Right-click the source directory or package to open the context menu, and select New .
2. Select Aspect .
3. In the dialog that opens:
  1. Specify the name of the aspect in the Name field.
  2. Select one of the following options from the Kind list:
    - Aspect to create a `.aj` file with the specified name.
    - `@Aspect` to create a `.java` file containing a class annotated with `@Aspect` .
  3. Click OK .

This feature is only supported in the Ultimate edition.

For aspects, IntelliJ IDEA supports most of the basic refactorings such as [Move](#) and [Rename](#) . In addition to that, you can also perform the Push ITDs In refactoring for [inter-type declarations](#) .

The Push ITDs In refactoring lets you move the definitions of fields and methods from aspects to corresponding classes. (The ITDs in the refactoring name stands for [Inter-Type Declarations](#) .)

The refactoring may be performed for an individual field or method, for an aspect as a whole, or for all aspects in a package.

If when performing the refactoring certain aspects become "empty" (this may be the case when the corresponding aspects contain nothing but inter-type declarations), you can select to automatically delete all such aspects.

– [Examples](#)

– [Performing the Push ITDs In refactoring](#)

## Examples

The following table shows examples of the Push ITDs In refactoring.

In the first example, the declaration of the field `closed` is moved from the aspect `MyAspect` to the class `Account` .

In the second example, the method `close()` is also moved from `MyAspect` to `Account` .

Note that both these declarations (that is, the declarations of `closed` and `close()` ) may be moved to the class `Account` at once if the refactoring is performed for the aspect `MyAspect` as a whole.

### Before/After

<pre>aspect myAspect {     boolean Account.closed = false;     void Account.close() {         closed = true;     }     // some code here } class Account {     // some code here }</pre>	<pre>aspect myAspect {     void Account.close() {         closed = true;     }     // some code here } class Account {     // some code here     boolean closed = false; }</pre>
<pre>aspect MyAspect {     void Account.close() {         closed = true;     }     // some code here } class Account {     // some code here     boolean closed = false; }</pre>	<pre>aspect MyAspect {     // some code here } class Account {     // some code here     boolean closed = false;     void close() {         closed = true;     } }</pre>

## Performing the Push ITDs In refactoring

- Depending on the intended scope of the refactoring:
  - To perform the refactoring for an individual field or method, open the aspect of interest in the editor and place the cursor within the declaration of the field or method.
  - To perform the refactoring for an aspect as a whole, select the aspect of interest in the Project tool window. Alternatively, open the aspect in the editor and place the cursor somewhere outside of individual inter-type declarations (e.g. within the declaration of the aspect).
  - To perform the refactoring for all aspects in a package, select the package in the Project tool window.
- Select Refactor | Push ITDs In in the main or the context menu.
- In the Push Inter-Type Declarations In dialog that opens:
  1. Select or clear the Delete empty aspects checkbox.
  2. Click Refactor to perform the refactoring right away, or Preview to be able to study the expected changes prior to actually performing the refactoring.
- If at the previous step you clicked Preview , the [Find tool window](#) opens showing the inter-type declarations that are going to be affected. If happy with the expected result, click Do Refactor .

This feature is only supported in the Ultimate edition.

By default, IntelliJ IDEA uses the `javac` compiler. To use the AspectJ compiler `ajc` (instead of or in combination with `javac`), you should make changes to [corresponding IDE settings](#).

The `ajc` settings specified at the project level can be fine-tuned at the level of individual modules. AspectJ facets associated with the modules are used for that purpose.

Note that `ajc` is not bundled with IntelliJ IDEA and should be downloaded separately.

`ajc` is available as part of the AspectJ distribution which you can download from the [AspectJ website](#).

- [Optimizing compilation performance: Using ajc in combination with javac](#)
- [Controlling the ajc aspectpath](#)
- [Selecting ajc as the project compiler and specifying its settings](#)
- [Fine-tuning the use of ajc at a module level](#)

## Optimizing compilation performance: Using ajc in combination with javac

IntelliJ IDEA lets you use `ajc` in combination with `javac` without the need to switch the compilers in the IDE settings.

First of all, you should select `ajc` as your project compiler (the [Use compiler field](#) on the [Java Compiler page](#)).

If you want `javac` to be also used, turn on the [Delegate to Javac option](#). If this option is on, the modules without aspects are compiled with `javac` (which is, generally, faster), and the modules that contain aspects are compiled with `ajc`. (If this option is off, `ajc` is used for all the modules in your project.)

You can fine-tune the distribution of tasks between the compilers (`ajc` and `javac`) at the level of individual modules. For modules that contain aspects only in the form of `@Aspect`-annotated Java classes (in `.java` files), you can specify that `ajc` should be used only for post-compile weaving. If you do so, `javac` will be used to compile all the source files, and then `ajc` will be applied to the compiled class files for weaving. As a result, the overall process (compilation + weaving), will take less time.

Provided that the Delegate to Javac option is on, the post-compile weaving mode for `ajc` is enabled by turning on the corresponding option in an [AspectJ facet](#) associated with a module.

Note that you shouldn't turn on this option for modules that contain code-style aspects (ones defined in `.aj` files).

## Controlling the ajc aspectpath

You can control the `ajc aspectpath` option separately for each of your modules, see [Fine-tuning the use of ajc at a module level](#).

The module `aspectpath` may be set automatically as a result of importing an appropriately configured [Maven](#) project into IntelliJ IDEA.

## Selecting ajc as the project compiler and specifying its settings

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S`).
2. In the left-hand part of the dialog, in the search box, type `compiler`. Then, select Java Compiler in the pane below the search box.
3. On the [Compiler > Java Compiler page](#) that opens in the right-hand part of the dialog:
  1. Select Ajc from the Use compiler list.
  2. If necessary, specify the bytecode versions. (Roughly, these are the minimum target JVM versions.)
  3. Specify the path to the compiler in the Path to Ajc compiler field.  
You can type the path in the field, or click `...` and select the necessary file in the [corresponding dialog](#).  
  
(The file that you want is `aspectjtools.jar` which is located in `<AspectJ installation directory>\lib`.)
  4. If necessary, specify the [command-line options](#) to be passed to the compiler in the Command line parameters field.  
You can type the parameters right in the field, or click `...` to open the Command line parameters dialog where the text entry area is larger.
  5. Click Test to check if the specified settings are correct.
  6. If you want to use `javac` to compile the modules that contain no aspects, select the Delegate to Javac checkbox.  
Note that the distribution of tasks between `ajc` and `javac` can be fine-tuned at the level of individual modules.
4. Click OK in the Settings dialog.

## Fine-tuning the use of ajc at a module level

To be able to fine-tune the use of `ajc` at a module level, you should add an AspectJ facet to corresponding module or modules.

Once you've done that, you can specify that `ajc` should be used only for post-compile weaving. You can also specify the `aspectpath` for the module.

1. Add an AspectJ facet to the module of interest. For corresponding instructions, see [Configuring projects](#).
2. On the [page that opens](#) in the right-hand part of the [Project Structure dialog](#), under Compiler, specify the settings as necessary (see below).

3. If you want to use `ajc` only to weave the compiled class files (the source code in this case is compiled with `javac` ), select the Post-compile weave mode checkbox.  
IMPORTANT: Don't select this checkbox if the module contains `.aj` files.
4. To form the `aspectpath` for the module:
  - Use `+` (`Alt+Insert`) to add libraries and other modules. Select the necessary libraries and modules in the dialog that opens. (To choose from, dependencies of the module are suggested.)
  - Use `-` (`Alt+Delete`) to remove the selected items from the list.
  - Use `↑` (`Alt+Up`) to move the selected item one line up in the list.
  - Use `↓` (`Alt+Down`) to move the selected item one line down in the list.
5. Click OK in the Project Structure dialog.

IntelliJ IDEA supports the following build scripting tools:

- [Ant](#)
- [Gant](#)
- [Gradle](#)
- [Maven](#)

Ant is a flexible, platform-independent build tool from [Apache Ant Project](#). IntelliJ IDEA integrates with Ant to provide a comprehensive build process, that includes compilation, packaging with the documentation and source code, committing to version control and much more.

Ant integration is shipped with IntelliJ IDEA, and you do not need to perform any additional actions to install it. However, it is also possible to use the other Ant installations.

Ant support in IntelliJ IDEA imposes certain prerequisites, and includes the following features:

- Ant
  - [Dedicated tool window](#)
  - [Ant build files](#)
  - [Ant build target](#)
  - [Coding assistance](#)
  - [Path-like structures](#)
- [Creating Ant Build File](#)
- [Generating Ant Build File](#)
- [Adding Build File to Project](#)
- [Controlling Behavior of Ant Script with Build File Properties](#)
- [Running the Build](#)
- [Working with Ant Properties File](#)

**Tip** IntelliJ IDEA implements the Ant functionality with a bundled plugin, which can be completely disabled by clearing the Ant support check box on the the Plugins page of IntelliJ IDEA settings ([Ctrl+Alt+S](#)).

## Dedicated tool window

[Ant Build tool window](#) enables adding Ant build scripts to IntelliJ IDEA project, control behavior of the build, and execute Ant build targets.

## Ant build files

Ant works with the XML build file. Normally, the name of the build file is `build.xml`. Build file describes the steps, or build targets, required to build a project. The root element of the build file is `<project>`. IntelliJ IDEA makes it possible to work with existing build files, create new build files from scratch, or generate them automatically.

IntelliJ IDEA is aware of specific Ant syntax. However, you have to let IntelliJ IDEA know that a certain XML file is in fact an Ant build file. To be recognized as a build file and enable all advanced editing features, an Ant build file should meet at least one of the following requirements:

- The file should be properly [added to the project](#).
- The `<project>` root element should have `default` attribute.

Otherwise such files are treated as regular XML files with basic editing support. Once a build file is added to a project, it can be used to run the build and modify its properties.

## Ant build target

A build target is identified with a unique name and defines a procedure that should be executed to accomplish a certain task, for example, create a JAR file, or generate API documentation. A target specified in the `default` attribute of the `<project>` element is considered the default target, which is executed when no other target is specified. This target is called the primary target, and is marked with bold font in the [Ant Build tool window](#).

## Coding assistance

When editing Ant build files in IntelliJ IDEA, you can enjoy the following advanced editing features:

- Syntax highlighting.
- Code completion. In particular, code completion is provided for the properties of the File type.
- Navigating to declaration ([Ctrl+B](#)).
- Using Structure view.
- Rename refactoring.
- Code folding.
- Reformatting.
- Validation.
- Viewing parameter information ([Ctrl+P](#)).
- Viewing quick info ([Ctrl+Q](#)). In particular, if classpath is defined as a path-like structures, the View Quick Info command for the `fileset` or `dirset` directives displays the actual files and directories on the disk, to which these directives are resolved.

## Path-like structures

IntelliJ IDEA enables using path-like structures in the task definitions. If a classpath is defined as a path-like structure, the paths in the `fileset` and `dirset` directives are resolved into the actual files and directories on the disk. All JARs, required for performing the task, should be placed to the same place that contains the JAR with task definitions.

This section describes how to create the Ant build file manually.

IntelliJ IDEA provides a framework for editing build files, but it is the developer's responsibility to populate the build file with targets.

## Creating Ant build file

1. In the Project window, select the directory, where the build file should be created.
2. Right-click the directory and choose New | File on the context menu, or press `Alt+Insert` .
3. In the New File dialog, specify the name of the new file with `.xml` extension, for example, `build.xml` . The new file opens in the editor.
4. Specify the build targets. You can use the path-like structures in the `fileset` or `dirset` directives to define You have to enter at least a root tag in the `build.xml` file. Otherwise the file will not be added to the Ant Build tool window.
5. [Add the build file to the project](#) .

IntelliJ IDEA provides the possibility to automatically generate Ant build files for a project, or several build files per each module comprising the project. Once the build file is generated, you can add it to the [Ant Build tool window](#) . You can edit and manage such build file as a regular file.

## Generating Ant build file

1. On the main menu, choose Build | Generate Ant Build .
2. In the [Generate Ant Build dialog](#) , specify the generation options.
  - Choose to generate a single-file or multiple-file build.
  - Choose to preserve or overwrite the previously generated files.

Refer to the topic [Generate Ant Build Dialog](#) for detailed description of controls.

3. Click OK .

A build file should be added to a project to enable running the build, filtering targets, or defining properties. One project can have several build files. The build files are grouped in the Ant Build tool window by names, specified in the root element of each build file, for example `<project name="acme">` .

When a build file is generated, it is automatically added to the project. If you create a build file manually, or reuse an existing one, you might need to add it to the [Ant Build Tool Window](#) .

### Adding a build file to a project

1. Open the [Ant Build Tool Window](#) . To do that, choose View | Ant Build on the main menu, or click the Ant Build button in the right toolbar of the tool windows.
2. In the Ant Build tool window, click **+** .
3. In the Select Path dialog, navigate to the desired `build.xml` file, and click OK .

A build file should have at least a root element to be added to the Ant Build tool window.

You can control the way IntelliJ IDEA executes Ant scripts. If you want to perform execution in the background, change amount of memory allocated to the build process, or set other execution options, you'll need to open the [Build File Properties](#) dialog. This section describes how to do it.

## Opening the Build File properties dialog

1. In the [Ant Build Tool Window](#) , select the desired build file.
2. Do one of the following:
  - On the context menu of the selection, choose Properties .
  - Click  button on the Ant Build toolbar.
  - Press  .

For specific tasks refer to the following procedures:

- [Increasing memory heap](#) .
- [Executing Build File In Background](#) .
- [Defining Runtime Properties](#) .
- [Defining Additional Ant Classpath](#) .
- [Defining Ant Execution Options](#) .
- [Defining Ant Filters](#) .

Ant build scripts require classpaths that are independent from IntelliJ IDEA, or additional libraries for proper functioning. This section describes how to add directories and archives to the classpath, and change the order in which Ant loads the resources.

## Configuring Ant classpaths

1. [Open the Build File Properties dialog](#).
2. Select the Additional Classpath tab.
3. Click Add , and in the Select Path dialog box select an archive or a directory to be added to the classpath.  
If you want to add the contents of a whole directory, click the Add All In Directory button, and select the desired directory in the Select Path dialog box.
4. Use Move Up and Move Down buttons to change the order of classpath entries.

Using the Build File Properties dialog, you can control how IntelliJ IDEA launches the Ant build process. In particular, you can define which version of Ant should be used, add command line arguments, and specify the SDK to be used for running Ant.

## Defining execution options

1. Open the [Build File Properties](#) dialog box.
2. Select the Execution tab.
3. In the Run With Ant section, specify whether you want to use project default or custom Ant version. If you want to use custom Ant version rather than the bundled one, select it from the drop-down list, or click the ellipsis button and configure Ant [by adding classpaths](#).
4. In the Ant command line field, type the command line arguments, using the standard Ant syntax: precede arguments with dashes, and separate with spaces. For the lengthy command lines, click  and type the text in the Ant Command Line dialog.
5. In the Run under JDK field, specify a SDK to be used for Ant process: select the SDK from the list, or click the ellipsis button and configure an individual SDK.

By default, the [Ant Build Tool Window](#) shows all targets of a build file. Filtering enables you to show or hide targets as desired. The default filter displays the primary targets only. You can change this behavior and configure your own filter with custom set of targets that should be visible when the filter is applied.

## Configuring custom filter for build targets

1. [Open the Build File Properties](#) dialog box.
2. In the Filters tab, clear the checkboxes next to the build targets you want to hide, and select the checkboxes next to the targets you want to show.

Now, when you apply filter by pressing the filter button , only the targets selected in the Filters list will be displayed.

Use the Properties tab of the [Build File Properties Dialog](#) to pass properties to the build script at runtime. The specified values are equivalent to those defined after the `-D` option of the command line launcher.

In addition to plain values, you can use macros that are evaluated at runtime. Such macros are helpful, when you have to pass specific paths and other varying information to the build script. Macros are character strings surrounded with dollar signs. Build File Properties dialog provides the complete list of macros, available for the selected build file, with the previews that show, how these macros will be evaluated at runtime.

## Defining the runtime properties

1. [Open the Build File Properties dialog](#) .
2. In the Properties tab, click Add .
3. In the Name column, type the property name.
4. In the Value column, type the desired value. If you use a macro as the property value, type the name of the desired macro.  
If you don't know the name, click the `+` button, select the desired macro from the Macros dialog box, and click OK .
5. Use Add and Remove buttons to make up the complete list of properties.

By default, during the build process Ant displays a modal dialog that shows the progress of the build. It is possible to execute the build in the background, and use this time to work on other things.

**Warning!** Background execution may slow down performance.

## Enabling background execution of a build file

1. [Open the Build File Properties](#) dialog box.
2. Check the Make build in background option.

To prevent the build process from running out of memory, you can increase the amount of memory allocated to the process. By default, the memory heap is 128 MB, but for large projects you may need more.

In this section:

- [Increasing memory heap of the build process](#)
- [Important notes](#)

## Increasing memory heap of the build process

1. [Open the Build File Properties](#) dialog box.
2. In the Maximum heap size field, type the required amount of memory.

## Important notes

Please note the following:

The memory heap of the build process is independent of IntelliJ IDEA memory heap, and is released after the build process is complete.

The memory heap available to IntelliJ IDEA may be changed by editing the corresponding VM options.

To avoid editing files in the IntelliJ IDEA installation folder, do one of the following:

- From the main menu, choose Help | Edit Custom VM Options to create a copy of the `idea.vmoptions` file in the user home directory.
- Copy the existing file from the IntelliJ IDEA installation folder somewhere and save the path to this location in the `IDEA_VM_OPTIONS` environment variable ( `IDEA64_VM_OPTIONS` for 64 bit systems ).
- Copy the existing `<IntelliJ IDEA installation folder>/bin/idea.exe.vmoptions` or the `<IntelliJ IDEA installation folder>/bin/idea64.exe.vmoptions` file from the IntelliJ IDEA installation folder into your user home directory.

Then edit this file in the new location.

If the `IDEA_VM_OPTIONS` ( `IDEA64_VM_OPTIONS` for 64 bit systems ) environment variable is defined, or the `*.vmoptions` file exists, this file is used instead of the one located in the IntelliJ IDEA installation folder.

This section describes how to prepare and perform Ant build:

- [Assign a keyboard shortcut to an Ant target](#) .
- [Configure triggers for the Ant targets](#) .
- [Execute an Ant target](#) .

You can associate a build target with a keyboard shortcut and execute commonly-used targets with a single key-stroke. If an Ant build file is added to the project, its targets appear under the Ant Targets node in the [Keymap](#) dialog box.

### Associating a keyboard shortcut with a build target

- In the [Ant Build Tool Window](#) , right-click the desired build target.
- On the context menu, choose Assign.Shortcut . [Keymap](#) dialog is opened.
- Configure keymap, as described in the section [Configuring Keyboard Shortcuts](#) .

You can configure triggers that run Ant targets before or after certain events, for example, compiling, running, or testing. These triggers are called compilation trigger and execution trigger respectively.

### Setting up a compilation trigger

1. On the [Ant Build Tool Window](#), right-click the desired build target.
2. On the context menu of the target, choose Execute on .
3. On the submenu, choose Before Compilation or After Compilation , as required. Note that you can set up both options.

### Setting up an execution trigger

1. On the Ant Build tool window, right-click the desired build target.
2. On the context menu of the target, choose Execute on .
3. On the submenu, choose Before Run/Debug . Execute Target Before Run/Debug dialog appears, presenting the list of possible execution types.
4. In the dialog, select checkboxes next to the types of execution that should trigger the selected Ant target, and click OK .

With IntelliJ IDEA you can run the build targets, review results of compilation and build, and navigate to the point of origin of each error.

Build targets can be executed from:

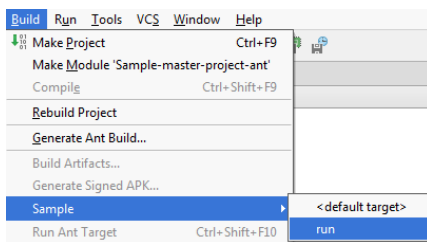

- [The Ant Build tool window](#) .
- [The main](#) Build menu that contains the list of all targets defined in the build files, added to a project.

### Executing a build target from the Ant Build tool window

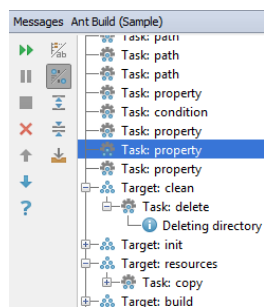

1. In the [Ant Build Tool Window](#) , select the desired target.
2. Do one of the following:
  - On the context menu of the selected target, choose Run target (or Run build , if you execute the entire build file).
  - Click the  button on the toolbar of the [Ant Build Tool Window](#) .
  - Double-click the selected target.

### Executing a build target from the main menu

1. On the main menu, click Build .
2. Click the submenu that corresponds to the desired build file.
3. Select the desired build target.

In both cases, results are displayed in the [Messages tool window](#) :

IntelliJ IDEA lets you create a meta target for your Ant build file. A meta target can contain several different targets of your choosing. Those targets will be executed in the specified order. In this case, you don't need to change the Ant build script itself.

You can treat your meta target as a regular Ant target and assign shortcuts to it, configure triggers for running the target, etc.

## Creating a Meta Target

- In the [Ant Build Tool Window](#), press `Ctrl` and simultaneously click the desired Ant targets to mark them as selected.
- Right-click on one of the targets to open a context menu.
- From the context menu, select `Create Meta Target`.  
(If you need to remove the created meta target, select `Remove Meta Target`.)
- In the `Create Meta Target` dialog, check the order of your targets and the name of your meta target. If you need, you can edit the specified information accordingly. Click `OK`.

Ant properties files let you move properties out of your build.xml file.

You create `.properties` file for all the properties that are defined outside the build file. For example, properties that you define in build settings. IntelliJ IDEA keeps those properties in one place and you don't need to edit the generated build file.

IntelliJ IDEA generates `.properties` file automatically if you [generate the Ant build file](#) . If you [create build.xml manually](#) then to use a `.properties` file in your Ant build.xml file do the following:

- Include a property in your build.xml file with the name of the properties file specified by the file attribute. For example, `<property file="build.properties"/>` .

In this section:

- Gant
  - [Prerequisite](#)
  - [Gant support](#)
- [Running Gant Targets](#)
- [Adding Gant Scripts](#)

## Prerequisite

Before you start working with Gant files, make sure that [Gant](#) is downloaded and installed on your computer.

## Gant support

IntelliJ IDEA provides [Gant](#) support. IntelliJ IDEA recognizes `*.gant` files, and allows editing them.

Gant files are marked with  icon.

Gant support includes:

- Code completion for Gant tasks.
- Execution of a whole script.
- Selective run of the individual targets.
- Groovy script [run/debug configuration](#) .

On this page:

- [Introduction](#)
- [Running a Gant script](#)
- [Running a Gant target](#)

## Introduction

With IntelliJ IDEA, it is possible to run an entire Gant script, or each target separately, using the temporary run/debug configurations. Temporary run configuration for a script or target can be saved as a permanent one.

Results display in the [Run tool window](#).

## Running a Gant script

1. Select the desired Gant script, and [run it](#) with the default run/debug configuration.

## Running a Gant target

1. Open the desired Gant script in the editor, and place the caret at the Gant target to be executed.
2. On the context menu, choose Run "<script><target>"

IntelliJ IDEA lets you add Gant scripts for Groovy, Grails and Griffon projects.

**Note** For Groovy projects you need to specify the location of the [Gant home directory](#) in Project Settings | Gant before adding the Gant scripts.

## Adding Gant Scripts

1. In the Project tool window, right click the directory where you want to create a Gant script file.
2. Select New | Gant Script from the context menu.
3. In the New Gant Script dialog, specify the name of the script and click OK .
4. IntelliJ IDEA creates a Gant file with the default target.

## Creating a new Gradle project

1. Launch the [New Project wizard](#) . If no project is currently opened in IntelliJ IDEA, click Create New Project on the welcome screen. Otherwise, select File | New | Project from the main menu.
2. Select Gradle from the options on the left.
3. Specify the project SDK and an additional framework or a library (IntelliJ IDEA adds the appropriate plugin to the `build.gradle` file). Click Next .
4. On the next page of the wizard, specify the fields which resemble [Maven naming conventions](#) . These settings might be helpful if you decide to deploy your project to a Maven repository. The fields you specify are added to the `build.gradle` file.
  - GroupId - `groupId` of the new project. You can omit this field if you plan to deploy your project locally.
  - ArtifactId - `artifactId` that is added as a name of your new project.
  - Version - `version` of the new project. By default, this field is specified automatically.

If a parent Gradle project is specified, the specified fields can be inherited (click Inherit ) from the parent.

Click Next .
5. On the next page of the wizard, configure [Auto-import](#) , [source-sets](#) , and a [Gradle version](#) for your project.

You can also select the Store generated project files externally option, so that generated `.iml` and library files are stored in `idea.system.path` instead of the `.idea` directory. It might be helpful for sharing your project via version control.

Click Next .

6. Specify the name and location settings. Click Finish .

## Configuring a Gradle version for a project

IntelliJ IDEA lets you use different options to configure a Gradle version when you create or import your Gradle project. You can use the default Gradle wrapper, use a Gradle wrapper as a task, or configure a local Gradle distribution.

**TIP** Select  in the Gradle projects tool window to quickly access the Gradle settings page.

1. On the Gradle settings page when you create or import a Gradle project, choose one of the following options:
  - Use default gradle wrapper (recommended) - select this option to use [Gradle wrapper](#) . In this case you delegate the update of Gradle versions to Gradle and get an automatic Gradle download for the build. It also lets you build with a precise Gradle version. The Gradle version is saved in the `gradle-wrapper.properties` file in the Gradle directory of your project. We recommend that you use this option to eliminate any Gradle version problems in your project.
  - Use gradle task configuration - select this option to configure a Gradle wrapper according to the `wrapper` task configuration. It might be convenient if you don't want to work with the `gradle-wrapper.properties` file for some reason or you want to control which Gradle version you want your project to use. Note that if you initially used the default Gradle wrapper option and then decided to use the Gradle wrapper task configuration when you change anything in the task such as changing the Gradle version, you don't need to run the wrapper task manually, since the `gradle-wrapper.properties` file update is done implicitly by IntelliJ IDEA during importing.

Also, note that if, for example, you use VCS in your project and each team member syncs the project via gradle, the `gradle/wrapper/gradle-wrapper.properties` file will be updated and might have inconsistencies if you use this type of wrapper configuration.
  - Use Gradle local distribution - select this option if you want to manually download and use a specific Gradle version. Specify the location of your Gradle installation and JVM under which IntelliJ IDEA will run Gradle when you import the specified Gradle project and when you execute its tasks.
2. Press OK (in the wizard, press Next ).

## Adding a new Gradle module to an existing project

You can add a Gradle module to a project in which you are already working.

1. In a project, on the main menu, select File| New | Module to open the New Module wizard.
2. If the existing project is not the Gradle project then the process of adding a module is the same as [Creating a new Gradle project](#) .

If the existing project is a Gradle project then the process of adding a new module is shorter. You need to specify the name of your module in the ArtifactId field. The rest of the information is added automatically and you can use either the default settings or change them according to your preferences.

Also, note that Add as module to field, by default, displays the name of your project to which you are trying to add a module. You can click  to select a different name if you have other linked Gradle projects.

## Importing a project from a Gradle model

1. Launch the [New Project wizard](#) . If no project is currently opened in IntelliJ IDEA, click Import Project on the welcome screen. Otherwise, select File | New | Project from Existing Sources from the main menu.

Note that you can also select File | Open from the main menu and choose the `build.gradle` file or a directory containing the `build.gradle` file. IntelliJ IDEA will import a Gradle project even if the project was not opened or imported before.

2. In the dialog that opens, select the directory that contains the project you want to import or a file that contains a Gradle project description ( `build.gradle` ). Click OK .
3. On the first page of the Import Project wizard, in Import Project from External model , select Gradle and click Next .  
(This page is not displayed if IntelliJ IDEA has guessed what you are importing.)
4. On the next page of the Import Project wizard, specify [Gradle project settings](#) that are the same as when you [create a Gradle project](#) .

Also, specify the following global Gradle settings:

- Offline work - use this checkbox to work with Gradle in the offline mode. In this case Gradle will use dependencies from the cache. Gradle will not attempt to access the network to perform dependency resolution. If the required dependencies are not present in the cache, build execution will fail.
- Service directory path - use this field to override the default Gradle home location directory.
- Gradle VM options - use this field to specify VM options for your Gradle project.

Click Finish .

## Importing a Gradle module

1. You can start your module's import in one of the following ways:
  - From the main menu, select File | New | Module from Existing Sources .
  - In the Project Structure dialog, on the Module page, click **+** icon and select Import Module .
  - In the Gradle projects tool window, on the toolbar, click  icon.
2. In the dialog that opens, select a module you want to import and click OK .
3. If necessary, perform the steps described in the [Importing a Gradle project](#) section and click Finish .
4. If you have a multi-module project the Select Project Data to Import dialog opens.

In the Select Project Data to Import dialog, select the modules or data you want to include in your project and click OK .

## Working with Gradle projects

IntelliJ IDEA lets you manage [Gradle](#) projects. You can link, ignore projects and synchronize changes in Gradle and IntelliJ IDEA projects. Also, you can configure a Gradle composite build.

## Linking a Gradle project to the IntelliJ IDEA project

When a project is created by [importing from Gradle model](#) , the link of the project is established automatically and the Gradle Projects tool window is enabled.

If an IntelliJ IDEA project is not linked to a Gradle project, then the Gradle tool window is disabled.

In this case, IntelliJ IDEA displays a message with a link that quickly lets you import your Gradle project and enable the Gradle Projects tool window.

If the Gradle Projects tool window is active, then you have at least one Gradle project linked.

1. Open the Gradle Projects tool window.
2. In the Gradle Projects tool window, click **+** to attach a gradle project.
3. In the [dialog](#) that opens, select the desired `build.gradle` file, and click OK .
4. In the Import Module from Gradle window, specify options for the Gradle project that you are trying to link and click OK .  
The project is linked. The Gradle Projects tool window shows the toolbar and a tree view of Gradle entities.

Alternatively, you can link your Gradle project if you [import](#) your project as a Gradle module from existing sources. In this case, you can link your Gradle project even if the Gradle Projects tool window is not available.

## Navigating to the build.gradle file

1. In the Gradle projects tool window, right-click a linked project.
2. From the context menu, select  .  
IntelliJ IDEA navigates to the appropriate Gradle configuration file and the related `build.gradle` file opens in the editor.

## Detaching or ignoring a linked Gradle project

1. In the Gradle projects tool window, right-click a linked project.
2. From the context menu, select  ( `Delete` ). Alternatively, you can select the linked project and click  on the Gradle toolbar.
3. In the Import Gradle Projects pop-up window, clear the checkbox against the modules if you don't want to delete the project from the IntelliJ IDEA Project tool window.
4. Click OK .  
The Gradle project is detached from the IntelliJ IDEA project and is not synchronized anymore.

You can also de-activate a Gradle project using the Ignore Gradle Project option.

1. In the Gradle Projects tool window, right-click the project that you want to ignore.
2. On the context menu, select Ignore Gradle Project .

3. In the window that opens, select projects and modules that you want to de-activate and click OK .

In this case IntelliJ IDEA removes the selected projects and modules from the IntelliJ IDEA Project tool window and will not import them anymore. However, you would still be able to see the list of ignored Gradle modules and projects in the Gradle Projects tool window.

If you want to activate your Gradle projects or modules, select Unignore Gradle Projects from the context menu.

## Refreshing a linked Gradle project

1. In the Gradle projects tool window, right-click a linked project.

2. From the context menu, select .

On clicking this icon, IntelliJ IDEA parses the project structure in the Gradle projects tool window.

IntelliJ IDEA cannot refresh just a part of your project, it refreshes the whole project including modules and dependencies.

If you configure a dependency through the Project Structure dialog (click  on the main menu), the dependency will only appear in the IntelliJ IDEA Project tool window, not in the Gradle projects tool window. Note that the next time you refresh your project, IntelliJ IDEA will remove the added dependency since IntelliJ IDEA considers the Gradle configuration as a single source of truth.

If you selected Use auto-import when you created or imported a Gradle project, then the re-import of the project is done automatically every time you make changes to the project.

## Configuring Gradle Composite Build

Before you start configuring your composite build, make sure you have the Gradle version 3.1 or higher configured for your project.

Also, note that there are some [restrictions on using a Gradle composite build](#) .

You can use the `settings.gradle` file to include Gradle builds for your [Gradle composite build](#) .

1. Open the `settings.gradle` file in the editor.

2. Using the `includeBuild` command, specify the location of the builds you want to add as dependencies to your project.

You can also use the Gradle projects tool window to configure your composite build.

1. Open a Gradle project.

2. [Link](#) other Gradle projects that you want to use for the composite build.

3. In the Gradle projects tool window, right-click your main project and from the context menu select Composite Build Configuration .

4. In the Gradle Project Build Composite dialog, select projects that you want to include in your Gradle composite build.

5. Refresh your main Gradle project.

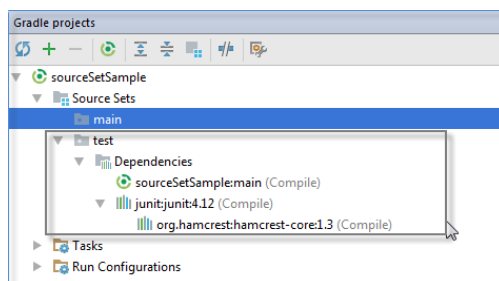

IntelliJ IDEA finds the included Gradle projects and treats them as IntelliJ IDEA modules.

## Using Gradle source sets

IntelliJ IDEA lets you use [Gradle source sets](#) in resolving Gradle projects. The source set is treated as a module in an IntelliJ IDEA project. You can declare a custom source set and IntelliJ IDEA adds it as a module to the project.

1. Select use separate module per source set when you create or import a Gradle project. Alternatively, click the  icon in the Gradle projects tool window and on the Gradle settings page, select the same option.

2. IntelliJ IDEA creates a main Source Sets directory that contains two source sets - *main* and *test* . For compiling the *test* sources there is a dependency to the *main* source set.

You can add a custom source set.

1. Open the `gradle.build` file in the editor.

2. Declare a custom source set. (In our example, it's `api`)

```

sourceSets {
    ...
    api
}
repositories {
    jcenter()
}
dependencies {
    ...
    compile sourceSets.api.output

    testCompile 'org.spockframework:spock-core:1.0-groovy-2.4'
}

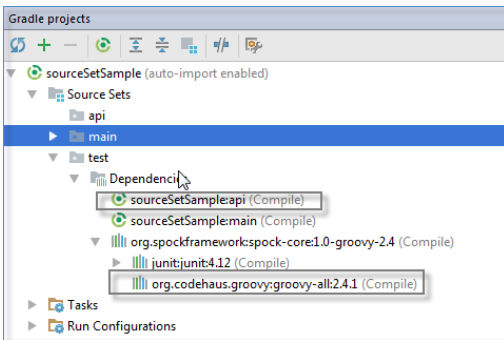

```

(This source set contains interfaces without implementations. The implementations for the interfaces are in the default *main* source set.)

- Open the Gradle projects tool window to see that IntelliJ IDEA added the `api` source set.

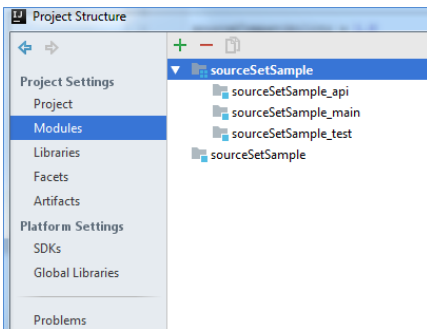

The test source set contains the appropriate dependencies.

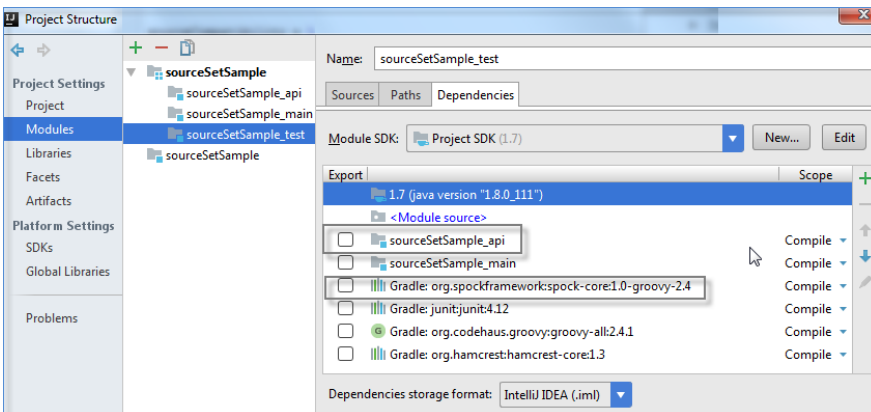

Note that the default *main* source set has the compile dependency on the output of the *api* source set. Gradle will invoke the `apiClasses` task automatically if you compile the sources in the *main* source set.

- Open project structure () . Notice that all source sets are represented as separate modules that are grouped into a single module.

If you click on the test module and select the Dependencies tab, you will see a list of dependencies for the source set.

You can also add custom tests and run them separately from the main ones using a source set feature.

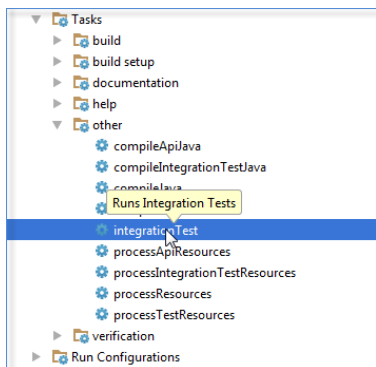

Declare a source set the same way as you would declare the `custom source set`. Besides the name of your source set

1. Declare a source set the same way as you would declare the `customSourceSet`. Besides the name of your source set, specify the output directory and the task that will run you test.

```
sourceSets {
    integrationTest {
        java {
            srcDir 'src/integrationtest/java'
        }
        resources {
            srcDir 'src/integrationtest/resources'
        }
        compileClasspath += sourceSets.main.runtimeClasspath
    }
}

task integrationTest(type: Test) {
    description = "Runs Integration Tests"
    testClassesDir = sourceSets.integrationTest.output.classesDir
    classpath += sourceSets.integrationTest.runtimeClasspath
}
```

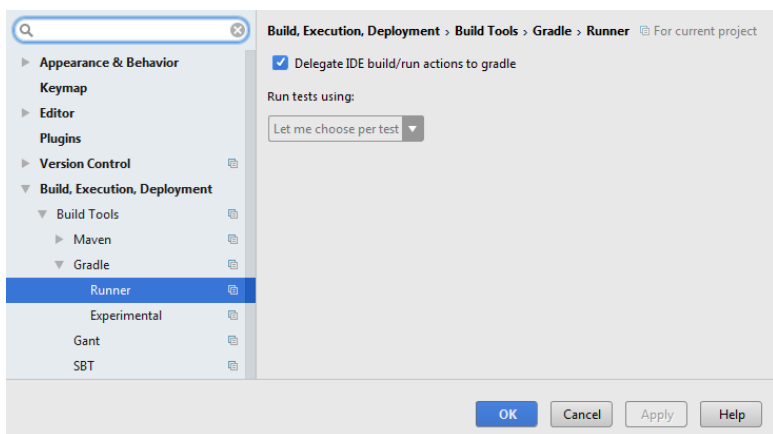

2. In the Gradle projects tool window, click `Tasks | other`.
3. In the list that opens, double-click the `integrationTest` to run your integration tests.

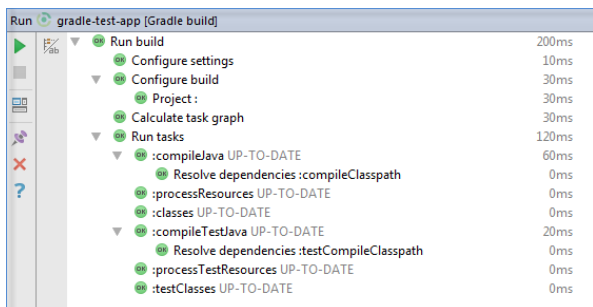

## Delegating build and run actions to Gradle

IntelliJ IDEA lets you delegate all your build and run actions to Gradle. When you build a project ( `Build | Build Project` ), IntelliJ IDEA invokes the correct tasks using Gradle. Also, the Run and Debug actions from the Run menu are executed with Gradle.

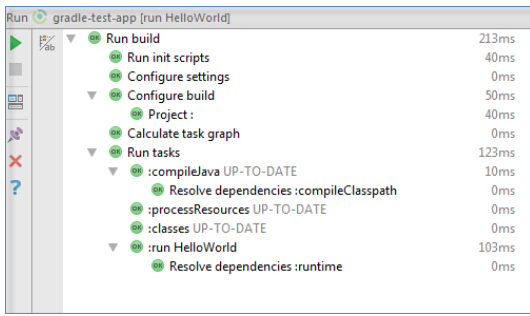

1. Click the `⚙️` icon in the Gradle projects tool window. Alternatively, on the main menu select `File | Settings | Build, Execution, Deployment | Build Tools | Gradle`.
2. Click `Gradle` and from the drop-down list, select `Runner`.
3. On the Runner page, select `Delegate IDE build/run actions to Gradle`.

4. Click `OK`.
5. Open any Java project with the `build.gradle` file.
6. Invoke the `Build Project` action ( `Ctrl+F9` ). Gradle compiles the code and displays it in the Run tool window.

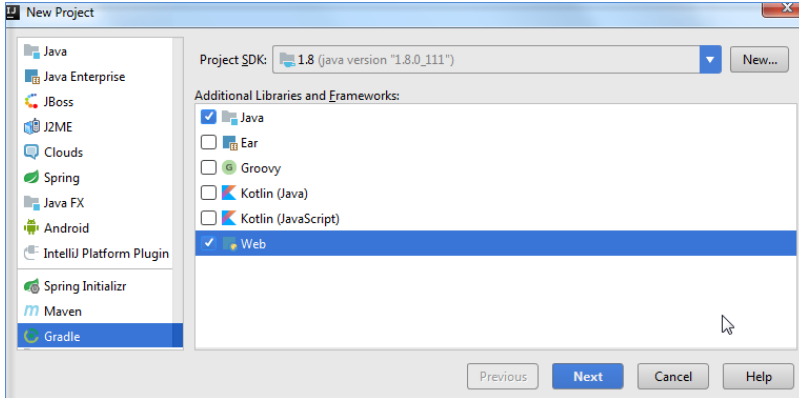

7. Run your main method ( `Ctrl+Shift+F10` ). You can see that IntelliJ IDEA uses the Gradle `JavaExec` task to run the class.

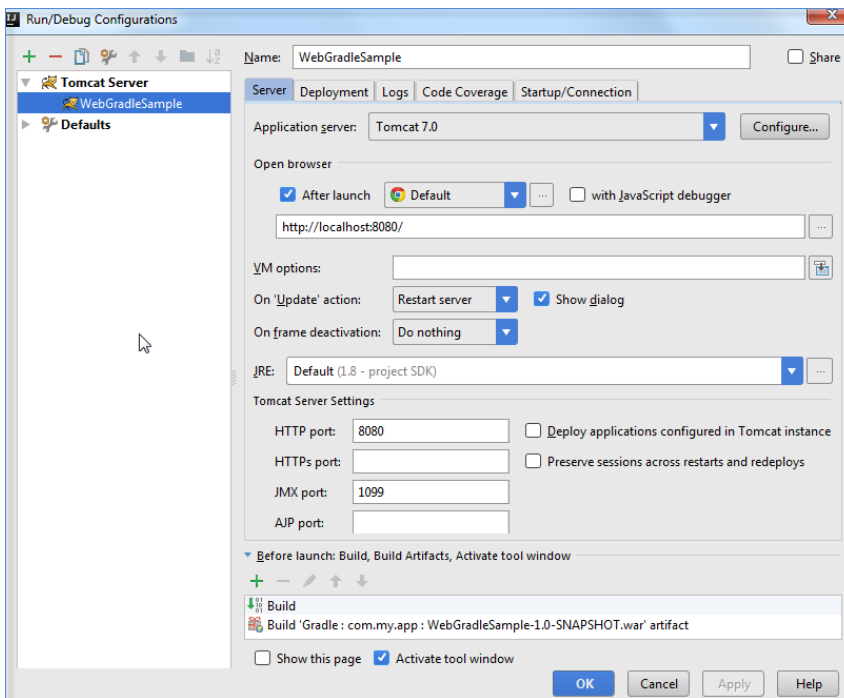

IntelliJ IDEA also lets you build WAR or EAR artifacts using Gradle.

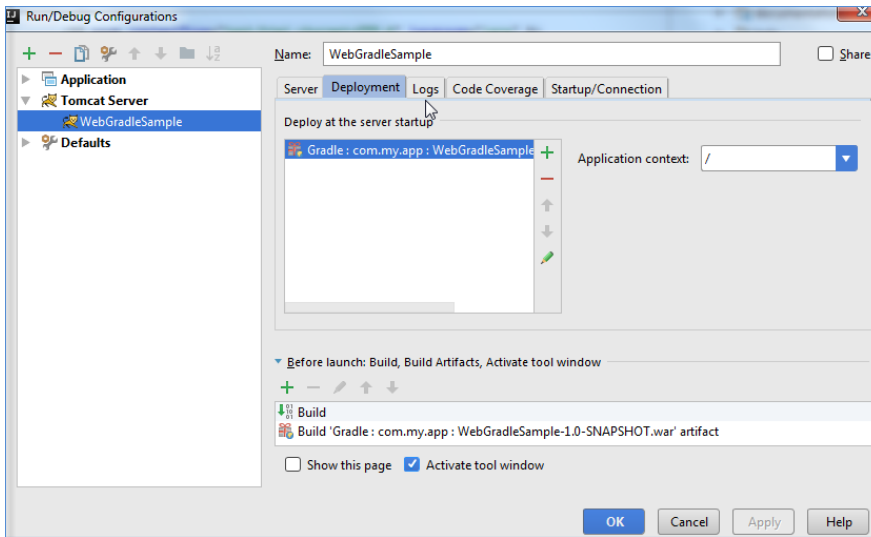

1. Create a Gradle Web project. (For more instructions, see [Creating a Gradle project](#).)

2. Create the Tomcat server run/debug configuration.

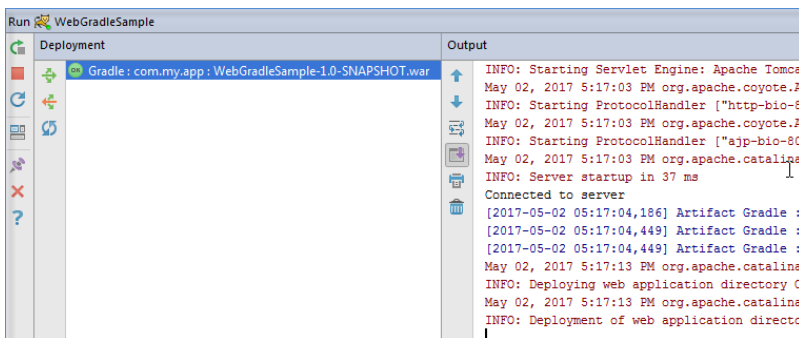

3. Click the Deployment tab and add an artifact for your deployment.

4. Click  to start the Tomcat server configuration.

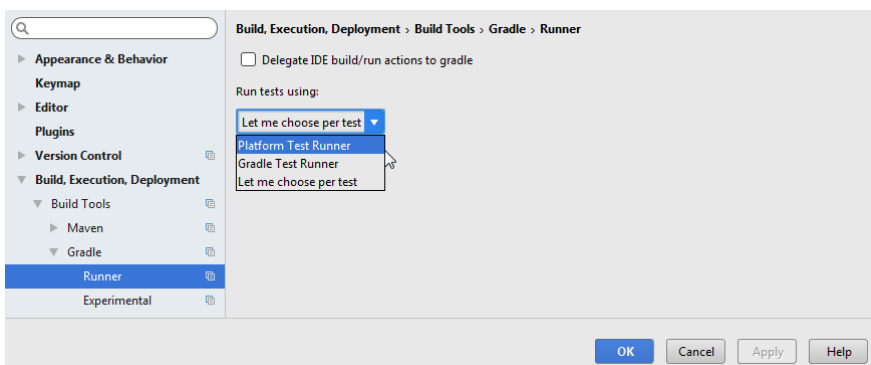

In the Run tool window you can see that the artifact is built by Gradle and deployed by the IntelliJ IDEA Tomcat's integration.

## Configuring and using a Gradle test runner

IntelliJ IDEA lets you use different test runners to execute tests in a Gradle project. You can use JUnit to run your tests. In this case tests are run much faster due to the incremental compilation. You can delegate the testing process to Gradle. In this case when you run your tests, you will get the same results on the continuous integration (CI) server. Also, no matter how difficult your Gradle project is, tests that are run in command line will always work in IDE. You can also decide which test runner to use specifically per each test.

1. In the Gradle projects tool window, click the  icon.
2. In the Settings dialog, right-click Gradle and from the drop-down list, select Runner .
3. On the page that opens, in the Run test using drop-down list, select an option that you want to use for your test run.

(The default value is *Platform Test Runner* .)

4. Click OK .
5. In your Gradle project, in the editor, create or select a test that you want to run.
6. From the context menu, select Run <test name> .

Alternatively, click the  icon in the left gutter.

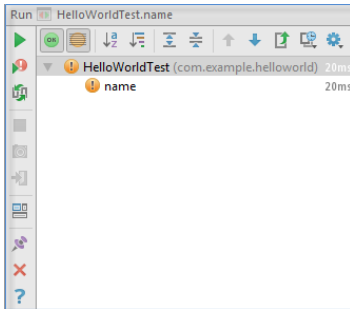

```

1 package com.example.helloworld;
2
3 import ...
10
11 /**...*/
14 public class HelloWorldTest {
15     @Test
16     public void name() throws Exception {
17         ByteArrayOutputStream out = new ByteArrayOutputStream();
18         HelloWorld.print(new PrintStream(out));
19         String s = out.toString();
20         Assert.assertEquals( expected: "Hello", s);
21     }
22
23 }

```

7. Depending on what you chose as your test runner, IntelliJ IDEA runs your tests in one of the following ways:

- If you selected *Platform Test Runner*, IntelliJ IDEA runs tests using a JUnit test runner and displays the output in the

Run JUnit tool window.

- If you selected *Gradle Test Runner*, IntelliJ IDEA runs tests using a Gradle test runner and displays the output in the

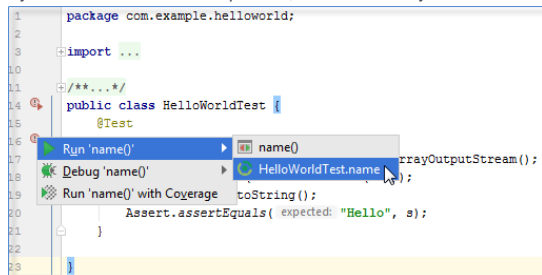

Run Gradle tool window.

You can also select Run 'name()' with

coverage to see the code coverage for your test.

Element	Class, %	Method, %	Line, %
com	100% (1/1)	50% (1/2)	40% (2/5)
com.HelloWorldPrinter	0% (0/1)	0% (0/2)	0% (0/4)
com.Main	0% (0/2)	0% (0/3)	0% (0/5)
com.MyClass	0% (0/1)	0% (0/1)	0% (0/3)
com.MyProperty	0% (0/1)	100% (0/0)	0% (0/1)
com.PrintAction	0% (0/1)	0% (0/2)	0% (0/6)
com.YourClass	0% (0/1)	0% (0/1)	0% (0/3)

- If you selected *Let me choose per test*, IntelliJ IDEA lets you choose between JUnit or Gradle to run your test.

Once you have selected the test runner,

IntelliJ IDEA will remember your selection and automatically will run your test using the option you've chosen.

You can change your selection, in the Runner settings page.

You can also select Run 'name()' with coverage to see the code coverage for your test.

Element	Class, %	Method, %	Line, %
com	100% (1/1)	50% (1/2)	40% (2/5)
com.HelloWorldPrinter	0% (0/1)	0% (0/2)	0% (0/4)
com.Main	0% (0/2)	0% (0/3)	0% (0/5)
com.MyClass	0% (0/1)	0% (0/1)	0% (0/3)
com.MyProperty	0% (0/1)	100% (0/0)	0% (0/1)
com.PrintAction	0% (0/1)	0% (0/2)	0% (0/6)
com.YourClass	0% (0/1)	0% (0/1)	0% (0/3)

It works for the platform test runner as well as for the Gradle test runner.

## Working with Gradle tasks

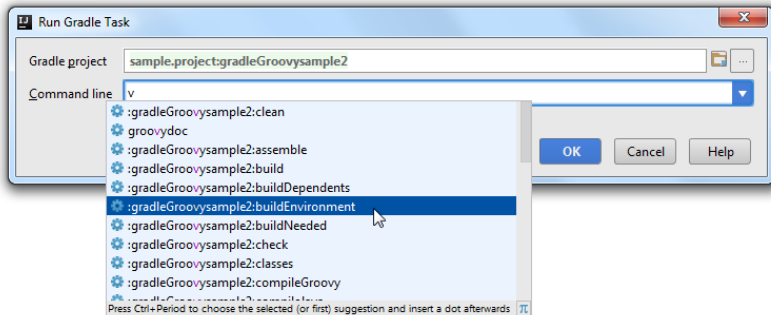

IntelliJ IDEA lets you create, debug and manage Gradle tasks in your project.

## Running Gradle tasks

IntelliJ IDEA lets you run Gradle tasks using several different ways such as using a toolbar in the Gradle tool window, using a run configuration, using a context menu, and even run several tasks using one run configuration.

## Running a Gradle task from the Gradle toolbar

1. In the Gradle projects tool window, on the toolbar, click .
2. In the Run Gradle Task dialog, in the Command line field, start entering the name of your task. You can see that IntelliJ IDEA displays the list of Gradle tasks from which you can select the appropriate one. Click OK.

3. IntelliJ IDEA runs the selected task and displays the result in the Run tool window.

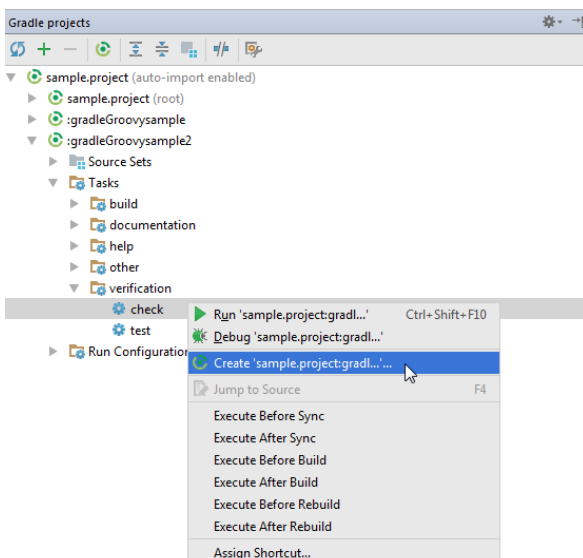

IntelliJ IDEA also saves the task in Gradle projects under the Run Configurations node.

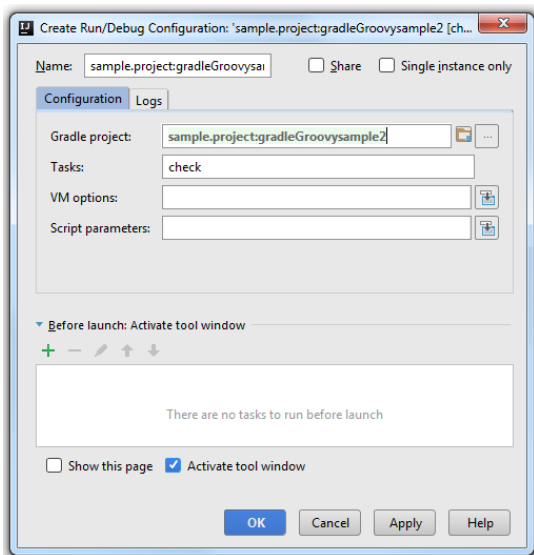

## Running a Gradle task via Run Configurations

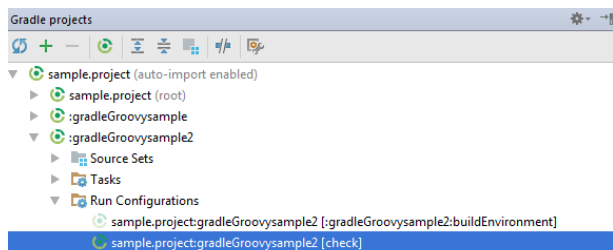

1. Open the Gradle projects tool window.
2. Right-click the task for which you want to create the Run configuration.
3. From the context menu select 'Create 'task name''.

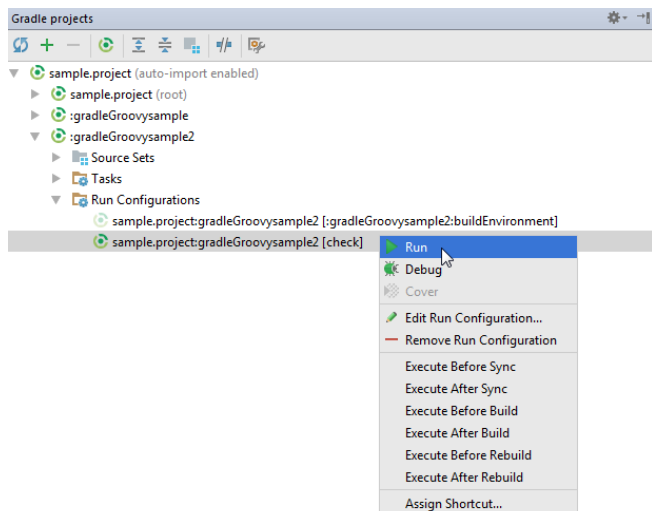

4. In Create Run/Debug Configuration: 'task name', specify the task settings and click OK.

IntelliJ IDEA displays the task under the Run Configurations node.

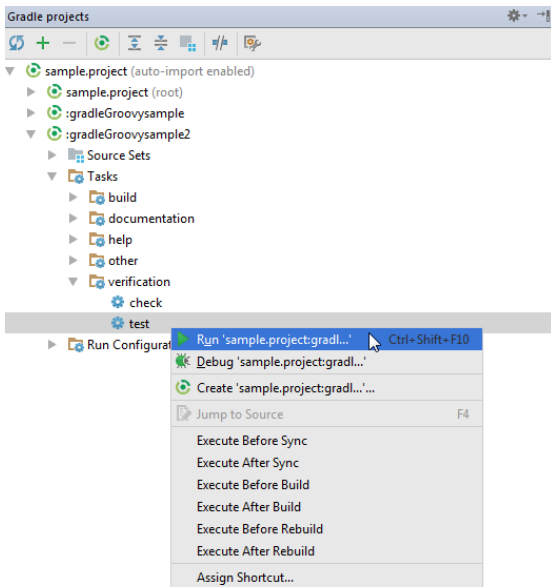

5. Double-click the task to run it or right-click the task and from the context menu select Run .

## Running a Gradle task from the context menu

1. Open the Gradle projects tool window.
2. Right-click a task that you want to run.
3. From the context menu select Run 'task name' .

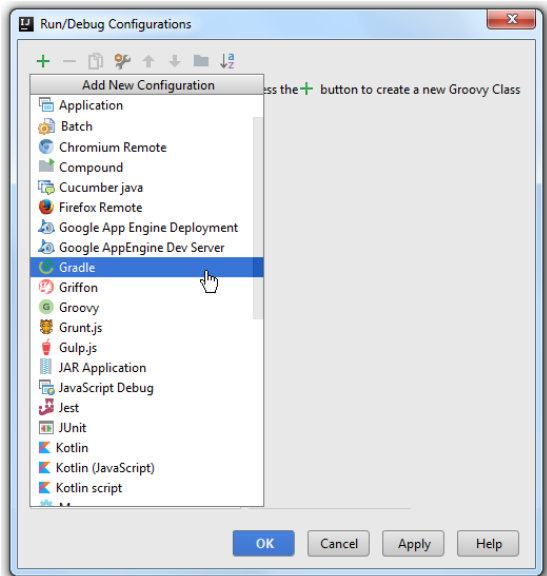

## Running several Gradle tasks with one Run/Debug configuration

1. Select Run | Edit Configurations ( `Shift+Alt+F10` ).

The [Run/Debug Configurations](#) dialog opens.

2. In the Run/Debug Configurations dialog, click the **+** icon and select Gradle to add a new configuration.

3. On the right side of the Run/Debug Configurations dialog, in the Name field, enter the name of your configuration.

As an example, specify the following settings:

- Gradle project - click  and select the registered Gradle project.

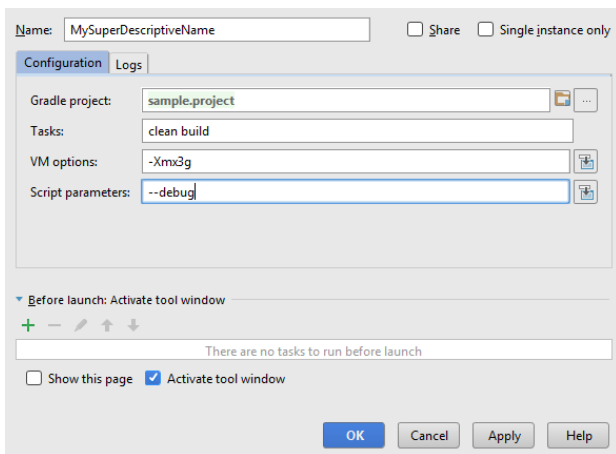

- Tasks - specify tasks you want to execute with this configuration. You can run more than one task.

For example, specify `clean` and `build` .

- VM options - you can customize VM options. For example, specify `-Xmx3g` .

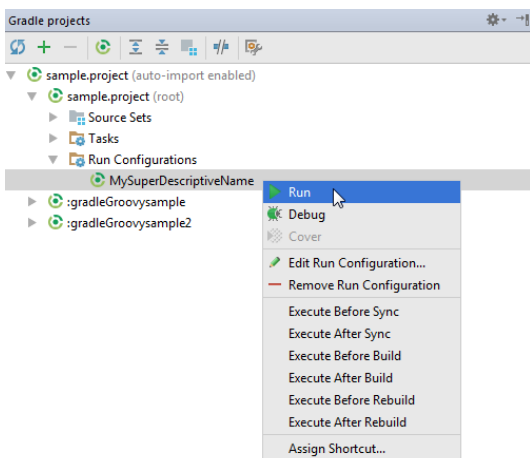

- Arguments - you can specify [Gradle command line parameters](#) . For example, specify `--debug` .

4. Click OK .

The created configuration is added to the Run Configurations node in the Gradle Projects tool window and is treated as a Gradle task.

5. Double-click the configuration to run the task or right-click the configuration and select Run .

## Debugging Gradle tasks in the Gradle projects tool window

Tasks available for debugging via the Gradle projects tool window are the ones that implement the `org.gradle.process.JavaForkOptions` interface, for example, `test` or `run` . For debugging Gradle script tasks themselves, use [Groovy run/debug configuration](#) that appears on the context menu when you right-click the script task in the editor.

1. In the Gradle projects tool window, in the Tasks area, double-click a Gradle project.

The list of tasks opens.

2. In the list of tasks, select the task which you want to debug, right-click it and from the context menu select Debug .

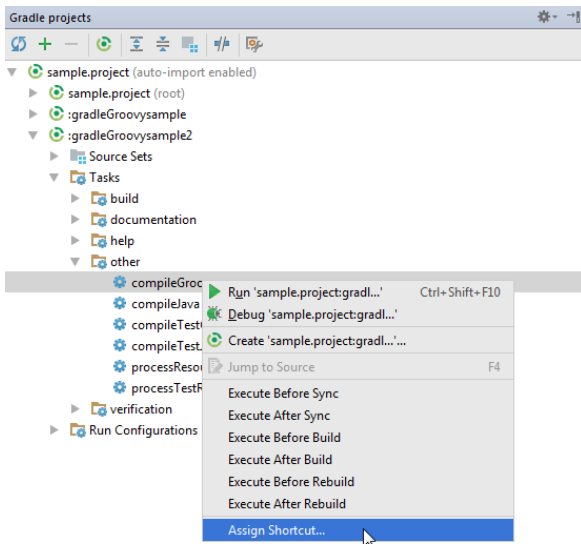

The debugging process is started and the task is added to the list of the recent tasks located under the Run Configurations node.

## Assigning a shortcut to a Gradle task

IntelliJ IDEA lets you assign shortcuts to Gradle tasks that can be run in several ways and execute those tasks with a single key-stroke. You can also assign a shortcut to the Gradle run/debug configuration that can contain more than one task.

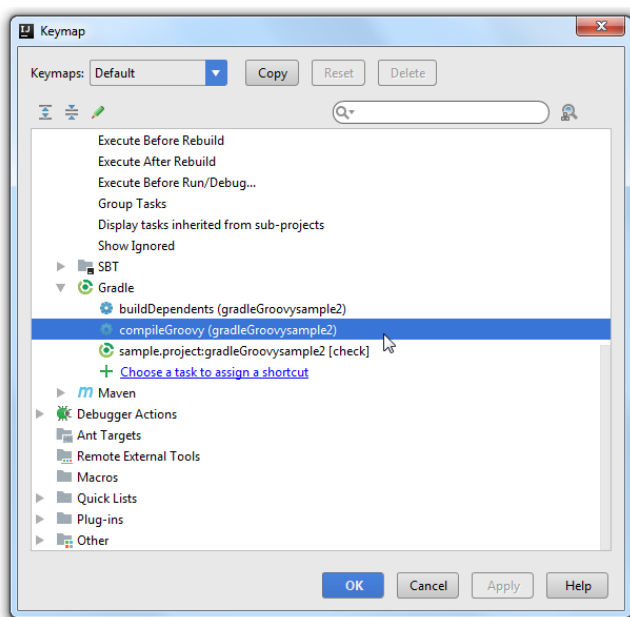

1. In the Gradle projects tool window, right-click the desired task.

2. From the context menu, choose Assign Shortcut .

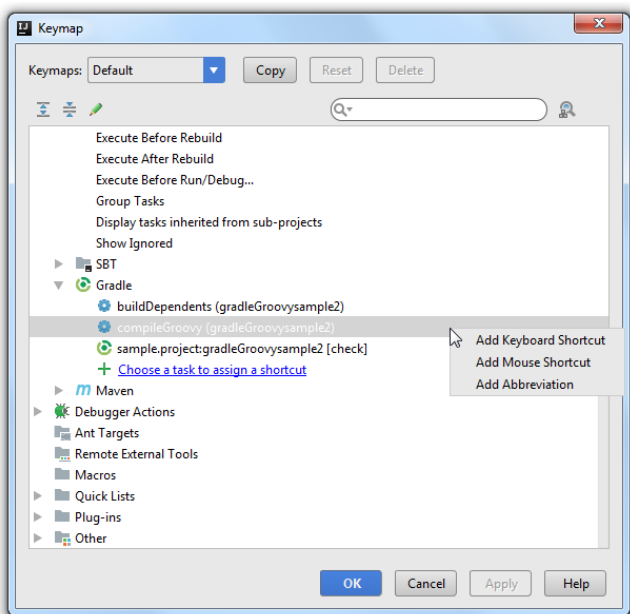

The **Keymap** dialog opens.

3. In the Keymap dialog, under the Gradle node navigate to your task.

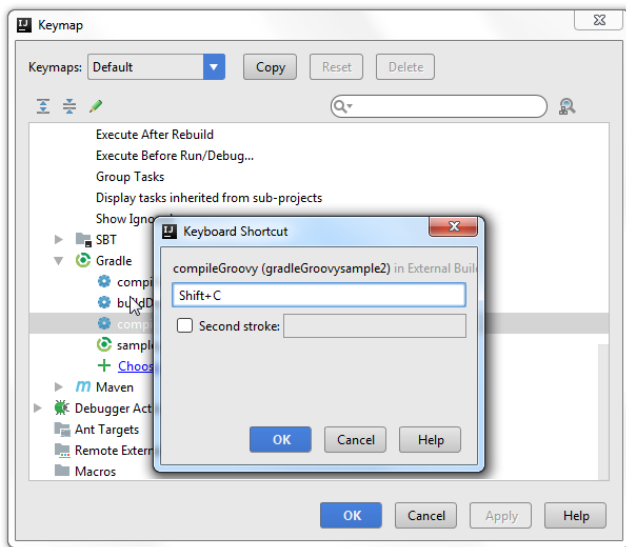

4. Right-click the task and from the list that opens, select a type of the shortcut you want to assign.

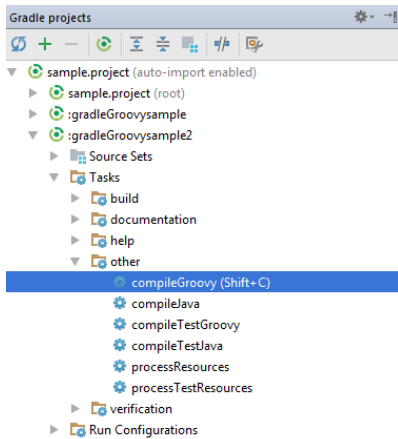

5. In the dialog that opens, depending on the shortcut's type, configure your shortcut and click OK .

In our case let's add a keyboard shortcut.

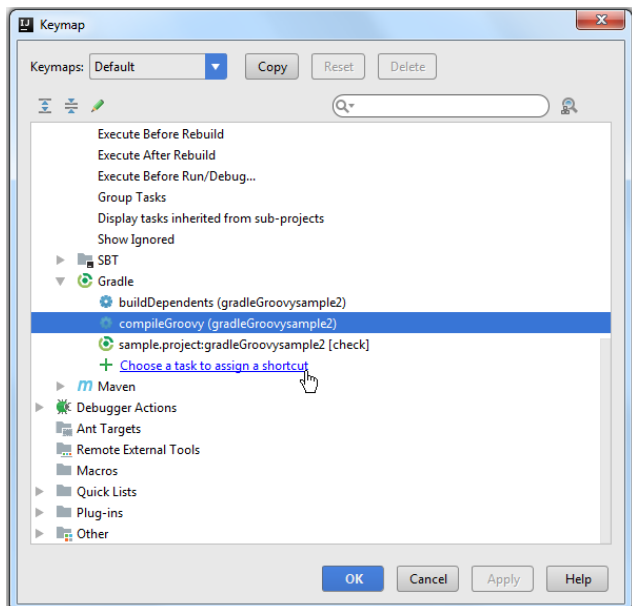

You can see that the shortcut is displayed against your task in the Gradle projects tool window.

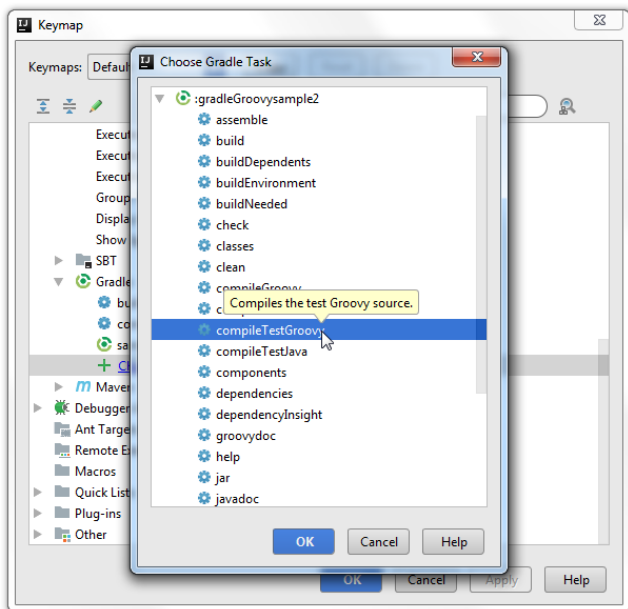

While in the Keymap dialog, you can add a new task to which you want to assign a shortcut.

1. In the Keymap dialog, under the Gradle node, click Choose a task to assign a shortcut .

2. In the dialog that opens, select a task you need and click OK .

The task is added to the list under the Gradle node. Now you can [configure the shortcut](#).

## Configuring running triggers for Gradle tasks

IntelliJ IDEA lets you run Gradle tasks before your project's execution or set other conditions using the task activation configuration.

1. In the Gradle projects tool window, right-click a Gradle project.
2. On the context menu, select Task Activation .
3. In the Task Activation dialog, click the **+** icon.
4. On the Choose activation phase menu, choose when to run your task, for example, *Before Build* , *After Sync* , etc.
5. On the Choose task menu, select the actual task.

The task and activation phase will be added to the list in the Task Activation dialog. You can also see the activation phase name against the selected task in the Gradle projects tool window.

Alternatively, you can select the activation phase name from the context menu when you right-click the task you want to execute in the Gradle projects tool window.

You can also create a run/debug configuration that would depend on a Gradle task.

1. On the main menu, select Run | Edit Configurations to open the run/debug configuration for your project.
2. In the Run/Debug Configurations dialog, in the Before Launch section, click the **+** icon.
3. In the list that opens, select Run Gradle task .
4. In the Select Gradle Task dialog, specify the project and the task that you want to execute before launching the project.  
You can specify a Gradle linked project or any other Gradle project. Note that if your Gradle project is not linked then IntelliJ IDEA will use the default configurations (for example, a bundled Gradle version) to run the task.
5. Click OK .

## Creating a new Gradle Project

1. Open [Project Wizard](#) , in the left-hand pane select Gradle .
2. In the right-hand pane, IntelliJ IDEA automatically adds a project **SDK** (JDK) and a default option Java in the Additional Libraries and Frameworks area. You can edit this information if you like.

Click Next .

3. On the next page of the wizard let's specify ArtifactId which basically is the name of our project. We can use the default information in the version field. Unless we plan to deploy our project in some Maven repository we don't need to specify a GroupId .

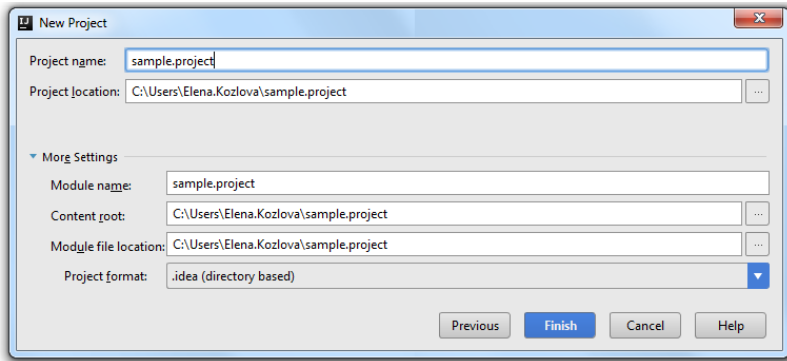

Click Next .

4. On the next page of the wizard, let's leave options Create separate module per source set and Use default gradle wrapper (recommended) selected. Let's also specify the Use auto-import option to resolve all the changes made to the Gradle project automatically every time we refresh our project.

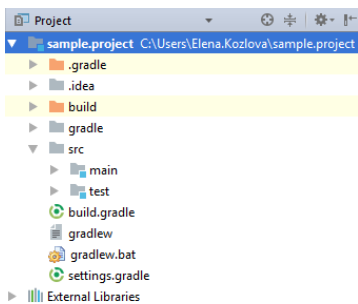

Click Next .

5. We've already specified our project's name, let's specify the location of our project and click Finish .

IntelliJ IDEA creates a project with the `build.gradle` file and the `src` folder with `main` and `test` subdirectories.

IntelliJ IDEA also creates a dedicated tool window with default tasks.

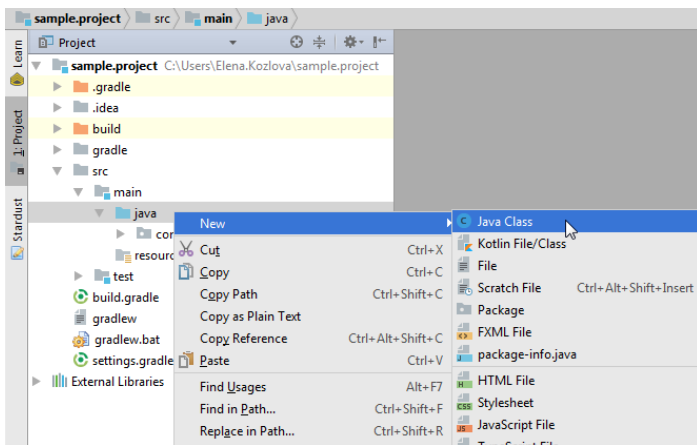

For more information on creating a Gradle project with the options that are out of this scope, see [Gradle](#) .

## Adding Java and test classes to a Gradle project

Let's add Java and test classes to our Gradle project.

1. In the Project tool window open the `src` folder.
2. Right-click the main or test directory then the java subdirectory and from the drop-down list select New | Java Class .

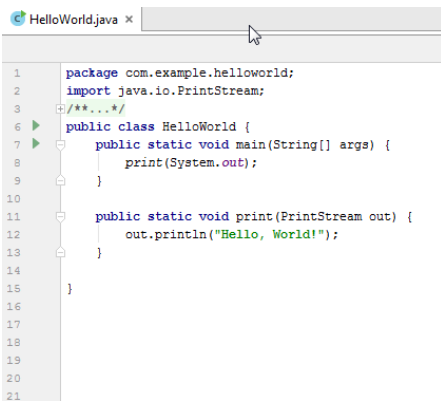

3. In the Create New Class dialog specify the name of your Java or test class and click OK .

Let's add the following code:

- for our `HelloWorld` class -

- for our `Test` class -

## Running tests in a Gradle project

We can run our test in several different ways:

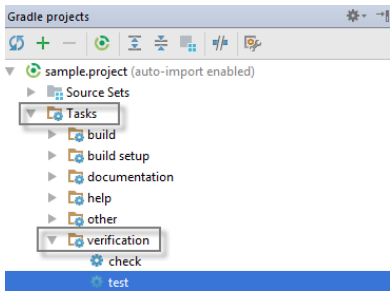

- using the editor - click  in the left gutter of the editor.

```

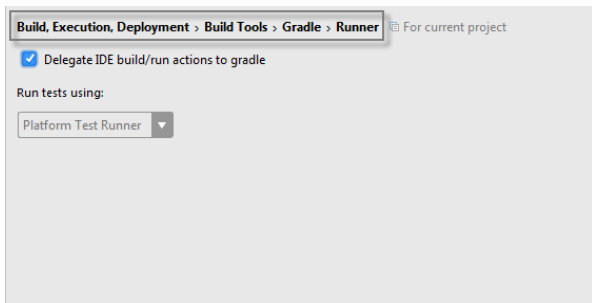

1  /**...*/
4
5  import com.example.helloworld.HelloWorld;
6  import org.junit.Assert;
7
8  import org.junit.Test;
9
10 import java.io.ByteArrayOutputStream;
11 import java.io.PrintStream;
12 public class MyTest {
13     @Test
14     public void test() throws Exception {
15         ByteArrayOutputStream out = new ByteArrayOutputStream();
16         HelloWorld.print(new PrintStream(out));
17         String s = out.toString();
18         Assert.assertEquals( expected: "Hello", s);
19     }
20 }
21

```

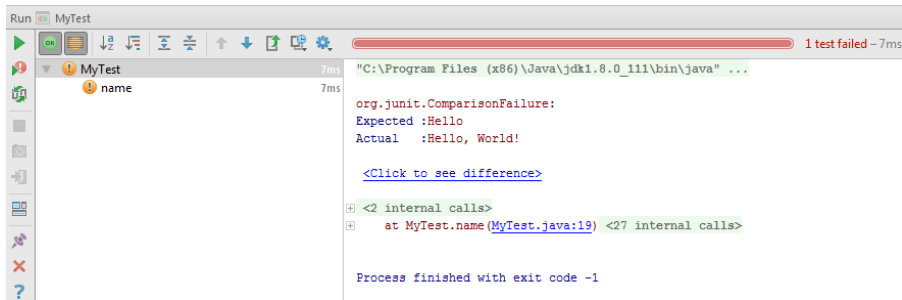

– using the Gradle task `test` - in the Gradle Projects tool window open the Tasks directory and then the verification subdirectory. In the list that opens, double-click test to run your test.

– using the Delegate all IDE builds/run actions to gradle option in the Settings dialog.

In all these cases the result of the test will be displayed in the Run tool window.

## Creating a new Maven project

IntelliJ IDEA lets you create a Maven project or add a Maven support to any existing project.

1. Launch the [New Project wizard](#) . If no project is currently opened in IntelliJ IDEA, click Create New Project on the Welcome screen: Otherwise, select File | New | Project from the main menu.
2. Select Maven from the options on the left.
3. Specify project's SDK (JDK) or use a default one and an archetype if you want to use a predefined project template (configure your own archetype by clicking Add Archetype ).

Click Next .

4. On the next page of the wizard, specify the following [Maven basic elements](#) that are added to the `pom.xml` file:
  - GroupId - a package of a new project.
  - ArtifactId - a name of your project.
  - Version - a version of a new project. By default, this field is specified automatically.

Click Next .

5. If you are creating a project using a Maven archetype, IntelliJ IDEA displays Maven settings that you can use to set the Maven home directory and Maven repositories. Also, you can check the archetype properties. Click Next .
6. Specify the name and location settings. Click Finish .

## Importing a Maven project

**Tip** You can select File | New | Project from Existing Sources on the main menu or click Import Project on the Welcome screen. Following the instructions of the Import Project wizard you can quickly import your Maven project.

1. On the main menu, select File | Open .
2. In the dialog that opens, select the `pom.xml` of the project you want to import. Click OK .
3. On the first page of the Import Project wizard, in the Import Project from External model select Maven and click Next .  
(This page is not displayed if you selected the `pom.xml` .)
4. Specify Maven settings or use the default selection.

The default settings are usually sufficient for a project. However, you can select the following (frequently used) options:

- Search for projects recursively - if you select this option, the sub projects (if any) are located and set up correctly.
- Import Maven projects automatically - if you select this option, the project is imported automatically every time you make changes to your POM file and you don't need to control manually when to import the changes. However, note that it might take some time to re-import a large project. Also, note that the changes made in the IntelliJ IDEA project (for example, adding a dependency to your project through the Project Structure dialog) will be overwritten on re-import by POM since IntelliJ IDEA considers the POM file as a single source of truth.

Click Next .

**Note** If IntelliJ IDEA detects [profiles](#) in your project, it displays them next.

5. IntelliJ IDEA displays the found projects and you can select the ones you need to import.

Click Next .

6. Specify the project's SDK and click Next .
7. Specify a name and the location of your project.

Click Finish .

## Adding a new Maven module to an existing project

You can add a Maven module to the project in which you are already working.

1. In the Project tool window, right-click the project folder and select New | Module . Alternatively, on the main menu, select File | New | Module to open the New Module wizard.
2. If you used main menu to add a module then the process of adding a module is the same as [Creating a new Maven project](#) .

If you are adding sub modules by right-clicking the root folder then the process of adding a new module is shorter. You need to specify the name of your module in the ArtifactId field. The rest of the information is added automatically and you can use either default settings or change them according to your preferences.

Also, note that Add as module to and Parent fields, by default, display the basic Maven attributes (groupId, artifactId, and version) of the project to which you are trying to add the module. You can click  to change the information displayed.

## Configuring a multi-module Maven project

IntelliJ IDEA lets you create a multi-module Maven project. The multi-module project is defined by a parent POM file with several sub modules.

1. [Create a Maven parent project](#) . IntelliJ IDEA creates a standard Maven layout including an `src` folder.
2. In the Project tool window, remove the `src` folder (you would need it for [very rare cases](#) for your general project you don't

need the `src` folder for the parent POM).

3. In the Project tool window, right-click your project (or in the main menu, click File ) and select New | Module to add a sub project.
4. In the New Module wizard following the instructions on [how to add a module](#) , specify the necessary information and click Finish .

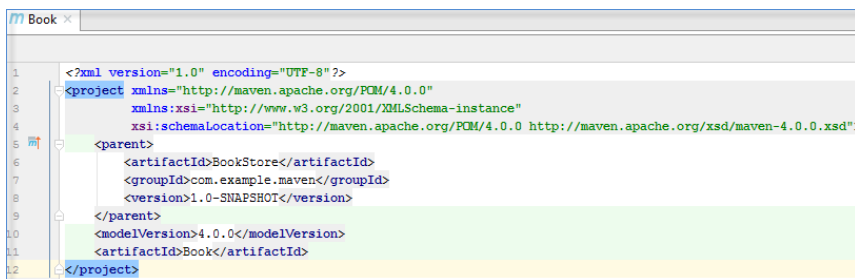

The `src` folder is created automatically and you can open POM and add a packaging that you need. IntelliJ IDEA adds the module to the parent project. IntelliJ IDEA also adds name and the description of the sub project to the parent POM.

```
1 <?xml version="1.0" encoding="UTF-8" ?>
2 <project xmlns="http://maven.apache.org/POM/4.0.0"
3         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
4         xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
5     <modelVersion>4.0.0</modelVersion>
6
7     <groupId>com.example.maven</groupId>
8     <artifactId>BookStore</artifactId>
9     <packaging>pom</packaging>
10    <version>1.0-SNAPSHOT</version>
11
12    <modules>
13        <module>Book</module>
14        <module>Author</module>
15    </modules>
16 </project>
```

Note that the `packaging` in the parent POM is defined as `pom` since it is an appropriate packaging for the parent project which refers to other sub projects.

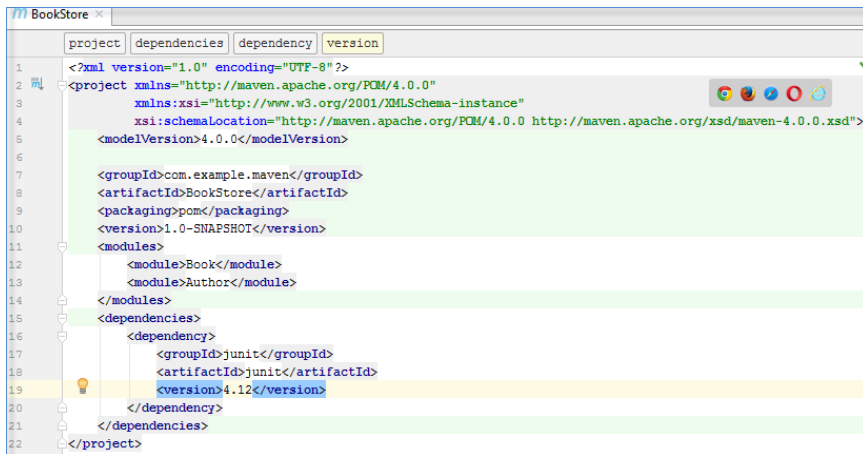

Last, but not least, IntelliJ IDEA adds the description of the parent POM to the sub project's POM.

```
1 <?xml version="1.0" encoding="UTF-8" ?>
2 <project xmlns="http://maven.apache.org/POM/4.0.0"
3         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
4         xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
5     <parent>
6         <artifactId>BookStore</artifactId>
7         <groupId>com.example.maven</groupId>
8         <version>1.0-SNAPSHOT</version>
9     </parent>
10    <modelVersion>4.0.0</modelVersion>
11    <artifactId>Book</artifactId>
12 </project>
```

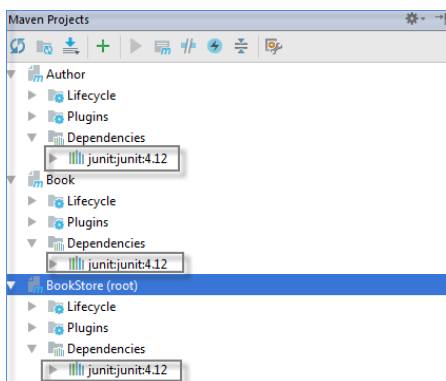

You can click  in the left gutter to quickly open the parent POM from your sub project.

5. You can also add dependencies to the parent POM that will be inherited by the sub projects.

```
1 <?xml version="1.0" encoding="UTF-8" ?>
2 <project xmlns="http://maven.apache.org/POM/4.0.0"
3         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
4         xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
5     <modelVersion>4.0.0</modelVersion>
6
7     <groupId>com.example.maven</groupId>
8     <artifactId>BookStore</artifactId>
9     <packaging>pom</packaging>
10    <version>1.0-SNAPSHOT</version>
11
12    <modules>
13        <module>Book</module>
14        <module>Author</module>
15    </modules>
16
17    <dependencies>
18        <dependency>
19            <groupId>junit</groupId>
20            <artifactId>junit</artifactId>
21            <version>4.12</version>
22        </dependency>
23    </dependencies>
24 </project>
```

6. Open Maven Projects tool window to see that all changes made in the parent POM are reflected in sub projects.

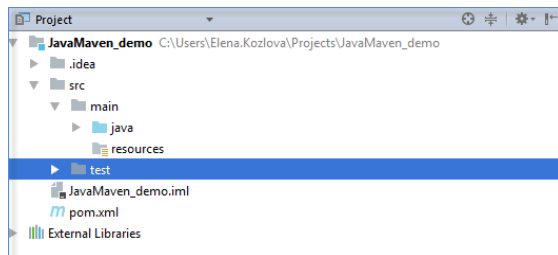

## Converting a regular project into a Maven project

You can open an existing non-Maven project and add a Maven support via IntelliJ IDEA UI.

Open an existing project for example a Java project

1. Open an existing project, for example, a Java project.
2. In the Project tool window, right-click your project and select Add Framework Support .
3. In the dialog that opens, select Maven from the options on the left and click OK .

IntelliJ IDEA adds a default POM to the project and generates the standard Maven layout in Project tool window.

IntelliJ IDEA also creates a corresponding structure with *Lifecycle* and *Plugins* in the Maven Projects tool window.

4. Open the generated POM and specify a `groupId` . The `artifactId` and `version` are specified automatically.

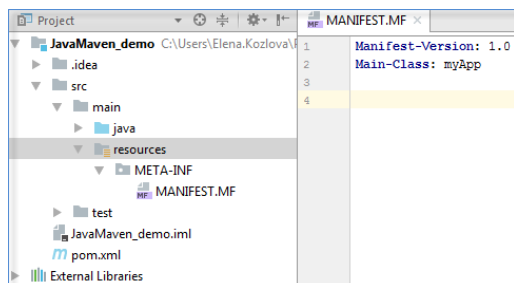

Every time you change the POM, IntelliJ IDEA displays a pop-up suggesting to import your changes.

At this point you can further develop your project using Maven. We recommend you to make all your project changes in POM since IntelliJ IDEA considers `pom.xml` as a single source of truth.

You can conclude the following optional steps to create an executable JAR.

1. Click  to build project. IntelliJ IDEA generates `target` folder. Note that IntelliJ IDEA only compiles sources and doesn't create either JAR file or Manifest file.
2. Create a Manifest file in the `resources` directory.

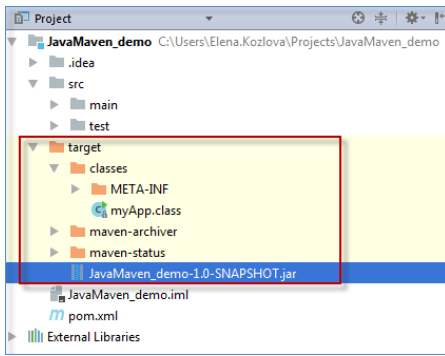

3. In your POM specify the [Manifest file](#) information, so you can use Maven to generate an executable `.jar` file.

4. In the Maven Projects tool window, in the Lifecycle drop-down list, double-click the `install` command to generate the `.jar` file.

IntelliJ IDEA generates an appropriate information in the target folder and an executable JAR in the Project tool window.

You can right-click the generated JAR and select Run to execute the file.

If your existing project is larger and contains more than one module, converting such project into a Maven project becomes quite challenging. Since IntelliJ IDEA recognizes project settings only from POM when you convert your project you need to check and adjust the following settings:

- Annotation settings - they are changed for the modules.
- Compiler output - it is changed for the modules.
- Resources settings - they are ignored and overwritten by POM.
- Module dependencies - they need to be checked.
- Language and Encoding settings - they are changed for modules.

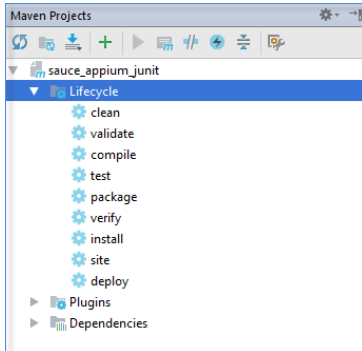

Also, there is no POM template generated. All dependencies (including module dependencies) need to be manually included into POM.

In this case we recommend that you create an external POM where you describe your project and [import](#) your POM as you would import a regular Maven project using File | New | Project from Existing Sources command.

IntelliJ IDEA adds POM to the project and a Maven layout for the existing elements.

IntelliJ IDEA also generates the corresponding structure in the Maven Projects tool window.

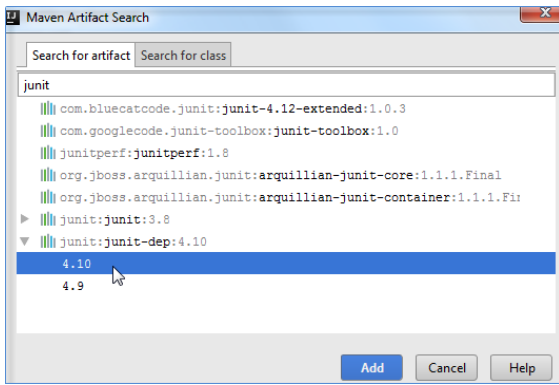

## Working with Maven dependencies

IntelliJ IDEA lets you manage Maven dependencies in your project. You can add, import Maven dependencies, and view them as diagrams.

### Adding a Maven dependency

IntelliJ IDEA lets you add a Maven dependency to your project. We recommend that you specify the dependency inside your POM. Dependencies that you set up manually inside IntelliJ IDEA module settings will be discarded on the next Maven project import.

1. Open your POM in the editor.
2. Press `Alt+Insert` to open the Generate context menu.
3. From the context menu, select Dependency or Dependency Template for quick search.
4. In the dialog that opens either search for artifacts or for classes if you switch to the Search for class tab.

Click Add . IntelliJ IDEA adds the dependency to your `pom.xml` .

```
<dependencies>
  <dependency>
    <groupId>junit</groupId>
    <artifactId>junit-dep</artifactId>
    <version>4.10</version>
  </dependency>
</dependencies>
```

IntelliJ IDEA also adds the dependency to the Dependencies node in the Maven Projects tool window and to the External Libraries in the Project tool window.

If the added dependency has its own transitive dependencies, IntelliJ IDEA displays them in both tool windows.

**Tip** When searching in artifacts, the search string can refer to the ArtifactId, GroupId, and version of an artifact. When searching in classes, IntelliJ IDEA searches through all the available artifacts, and adds all libraries, where the class with the specified name is detected.

## Centralizing dependency information

In a multi-module Maven project, the dependency in the parent POM will be inherited by all sub projects. You can use `dependencyManagement` to consolidate and centralize the management of the dependencies' versions.

1. Open your POM in the editor.
2. Press `Alt+Insert` to open the Generate context menu.
3. From the context menu, select the Managed Dependency option that will show you the list of the dependencies that are defined in the `dependencyManagement` section of your parent POM in a multi-module project.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>junit</groupId>
      <artifactId>junit</artifactId>
      <version>4.12</version>
    </dependency>
  </dependencies>
</dependencyManagement>
```

4. Select the desired dependency and click OK .

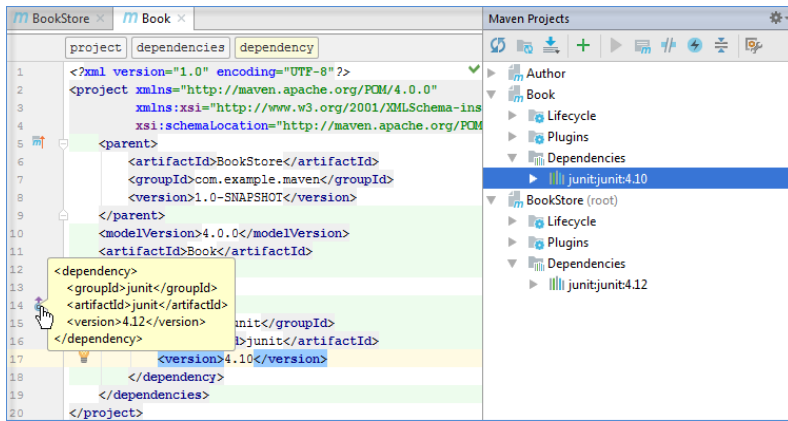

The dependency is added to the POM. You don't need to specify the version on the dependency it will be taken from the `DependencyManagement` .

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>junit</groupId>
      <artifactId>junit</artifactId>
      <version>4.12</version>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>junit</groupId>
    <artifactId>junit</artifactId>
  </dependency>
</dependencies>
```

However, if you want to overwrite the defined version, you need to include `version` when you add the managed dependency to the POM.

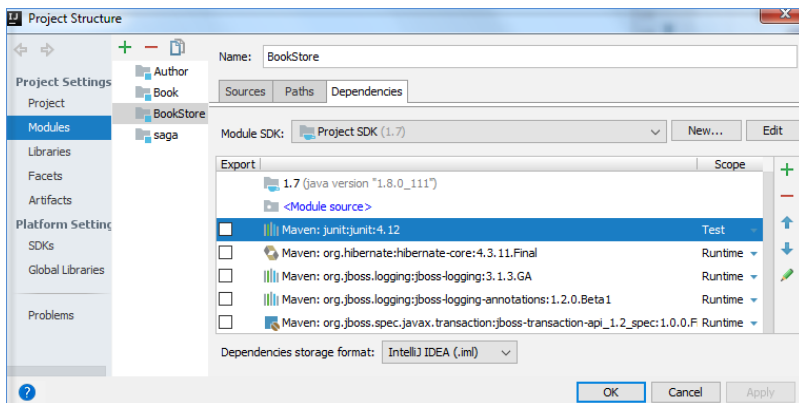

## Adding a scope for the Maven dependency

You can add a scope for your dependency using POM. In this case IntelliJ IDEA will execute the dependency at the specified phase.

1. In your POM, in the dependency description add `scope` and using the code completion add the name of the scope.

```
<dependency>
  <groupId>junit</groupId>
  <artifactId>junit</artifactId>
  <scope>test</scope>
</dependency>
```

2. Import your changes. The name of the scope is displayed in the Maven Projects tool window. In the Project Structure dialog, on the Modules page you can see that the scope of the dependency is also displayed.

Please note that changing dependency's scope in the Project Structure dialog will not affect the `pom.xml` file.

You can also add a custom `.jar` file as a dependency using the Maven scope `system` when you define your dependency. However, note that this dependency will only be available on your machine and you can use it only for the local deployment.

## Working with Maven transitive dependencies

IntelliJ IDEA lets you view transitive dependencies that were pulled in with the added or imported Maven dependency. You can check their versions, change them, or exclude those dependencies altogether.

The Maven Projects tool window displays the direct dependency and all its transitive dependencies that were pulled in.

1. In your project's POM, press `Ctrl` and hover the mouse over the dependency in question.

2. Click the dependency to open the dependency POM.
3. In the dependency POM, view the active dependency, its transitive dependencies and their versions.

```

4
5
6
7
8
9
10
11
12
13
14
15
16
<groupId>junit</groupId>
<artifactId>junit</artifactId>
<version>4.12</version>

<name>JUnit</name>
<description>JUnit is a unit testing framework for Java, </description>
<url>http://junit.org</url>
<inceptionYear>2002</inceptionYear>
<organization...>
<licenses>
  <license...>
</licenses>
<developers...>
<properties...>
<dependencies>
  <dependency>
    <groupId>org.hamcrest</groupId>
    <artifactId>hamcrest-core</artifactId>
    <version>1.3</version>
  </dependency>
</dependencies>

```

You can check the origin from which the dependency was pulled in.

```

<distributionManagement>
  <downloadUrl>https://github.com/junit-team/junit/wiki/Download-and-Install</downloadUrl>
  <snapshotRepository>
    <id>junit-snapshot-repo</id>
    <name>Nexus Snapshot Repository</name>
    <url>https://oss.sonatype.org/content/repositories/snapshots/</url>
  </snapshotRepository>
  <repository>
    <id>junit-releases-repo</id>
    <name>Nexus Release Repository</name>
    <url>https://oss.sonatype.org/service/local/staging/deploy/maven2/</url>
  </repository>
  <site>
    <id>junit.github.io</id>
    <url>git:git@github.com:junit-team/junit.git</url>
  </site>
</distributionManagement>

```

You can exclude a transitive dependency if you want.

**Tip** You can use Exclude command from the context menu in the [Maven dependency diagram](#) to quickly exclude the specified dependency from POM and the respective tool windows.

1. Open the dependency POM and find the transitive dependency you want to exclude. Copy `groupId` and `artifactId`.
2. In your project POM, underneath your active dependency, enter `exclusions` and using code completion paste the copied info of the dependency you want to exclude.

```

<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>junit</groupId>
      <artifactId>junit</artifactId>
      <version>4.12</version>
      <exclusions>
        <exclusion>
          <groupId>org.hamcrest</groupId>
          <artifactId>hamcrest-core</artifactId>
        </exclusion>
      </exclusions>
    </dependency>
  </dependencies>
</dependencyManagement>

```

The dependency is also excluded from the Project and Maven Projects tool windows.

## Importing Maven dependencies

IntelliJ IDEA lets you import dependencies to your Maven project. When IntelliJ IDEA imports added dependencies, it should parse the dependencies and set up the project automatically.

- In the Maven Projects tool window, click  icon to open the Maven | Importing settings and select the Import Maven projects automatically checkbox. Also, ensure that the JDK for importer matches the JDK version you are trying to use.

In this case the dependencies are updated automatically every time you change the POM.

- Press  in the Maven Projects tool window. In this case you manually trigger the re-import process and the update of dependencies.

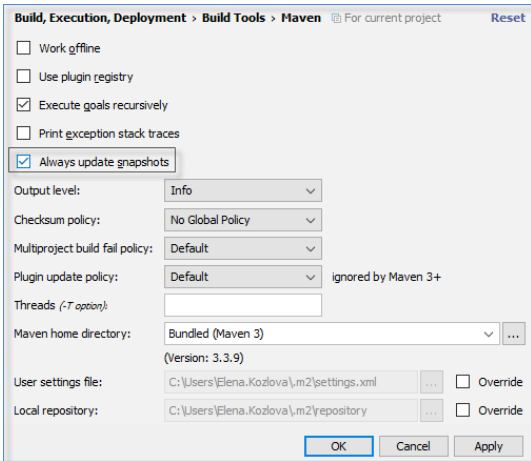

If for some reason the dependencies weren't imported correctly, try to perform the following actions:

- You can try to update Maven indices by updating the remote repository in the Maven | Repositories settings.

- You can check your local maven repository in the Maven | Repositories settings and try to updated it.

- You can check the `.jar` file of the local `.m2` repository to see if it was downloaded correctly.
- You can check the effective POM to determine which Maven repository was used as an origin of the dependency.
- You can select the Always update snapshots option in Maven settings. In this case IntelliJ IDEA checks the latest version of the downloaded dependency and updates it accordingly.

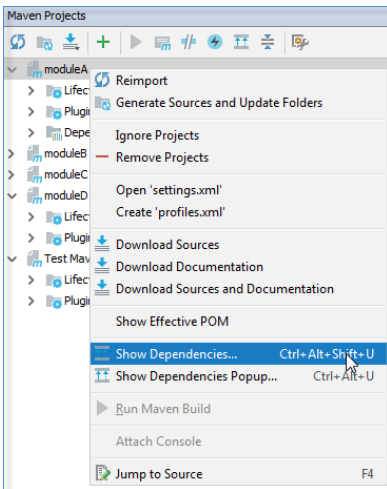

## Viewing Maven dependencies as a diagram

**Warning!** The Maven diagram support is available in IntelliJ IDEA Ultimate edition only. Please make sure that the *Maven Integration Extension* plugin is enabled.

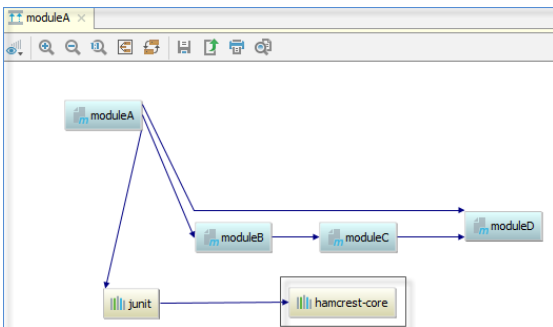

IntelliJ IDEA lets you view and work with Maven dependencies in a diagram format.

**Tip** In the POM in the editor, right-click to open context menu and select Maven | Show Dependencies to open the Maven dependencies diagram window. Alternatively, press `Ctrl+Shift+Alt+U` or `Ctrl+Alt+U`.

1. In the Maven Projects tool window, right-click the desired sub project and choose Show Dependencies, or Show Dependencies Popup.

2. In the diagram window, IntelliJ IDEA displays the sub project and all its dependencies including the transitive ones.

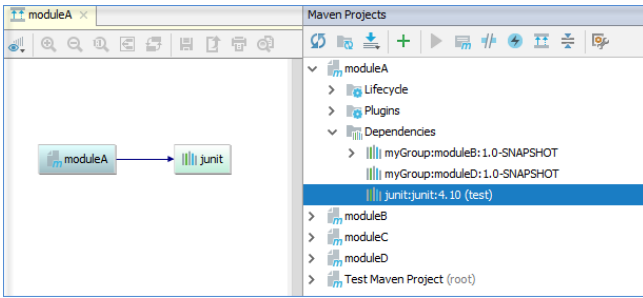

You can perform different actions while in the diagram window.

You can change the visibility level and, for example, view dependencies that have a specific scope (compile, test, etc.)

1. In the diagram window, select the sub project and click icon.
2. From the drop-down list, select the dependency scope you want to see.

IntelliJ IDEA displays only the specified dependency scope.

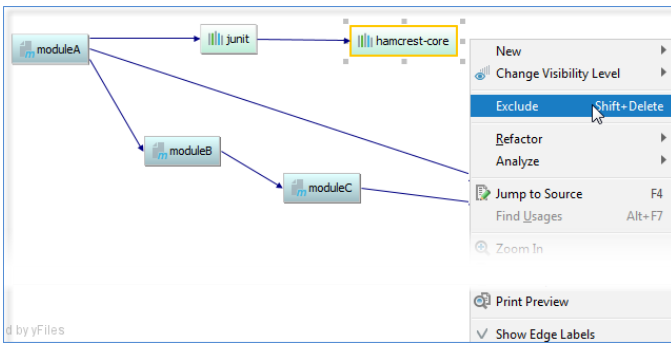

You can easily navigate to POM from the diagram window.

- Select the desired node, and press **F4**, or choose Jump to Source on its context menu. The corresponding file opens in the editor.

You can exclude a dependency from the diagram.

1. Select a dependency in the diagram window.
2. On the context menu, choose Exclude .

3. From the drop-down list, select the module where the exclusion definition will be added.

The selected dependencies will be removed from diagram, and the `exclusion` section will be added to the corresponding dependency in the module's POM.

**Tip** You can undo this operation by pressing **Ctrl+Z** before you import the changes.

## Working with Maven goals

IntelliJ IDEA lets you create, debug and manage Maven goals in your project.

### Running Maven goals

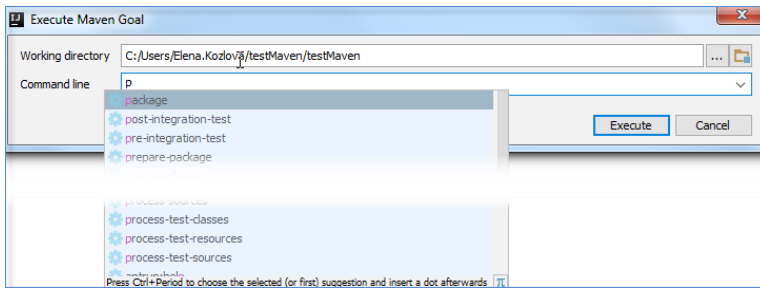

IntelliJ IDEA lets you run Maven goals using several ways. You can run a Maven goal from a command line , use the context menu in the Maven Projects tool window, or create a run/debug configuration to run one or several Maven goals.

### Running a Maven goal from the command line

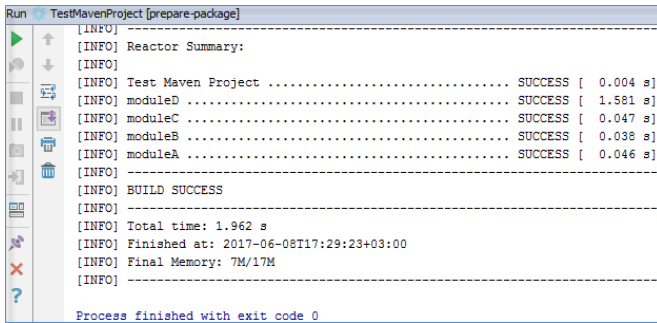

1. In the Maven Projects tool window, on the toolbar, click the  icon.

- In the Execute Maven Goal dialog, in the Command line field, start entering the name of your goal. You can see that IntelliJ IDEA displays the list of Maven goals from which you can select the appropriate one. Click Execute .

- IntelliJ IDEA runs the selected goal and displays the result in the Run tool window.

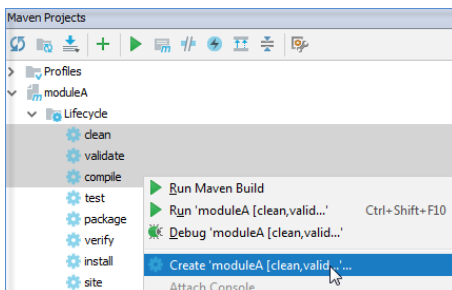

## Running a Maven goal from the context menu

- In the Maven Projects tool window, click Lifecycle to open a list of Maven goals.
- Right-click the desired goal and from the context menu select Run 'name of the goal' . IntelliJ IDEA runs the specified goal and adds it to the Run Configurations node.

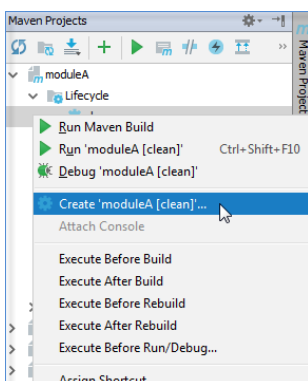

## Running a Maven goal or a set of goals via Run configuration

IntelliJ IDEA lets you create a run configuration for one specific goal or a set of several goals.

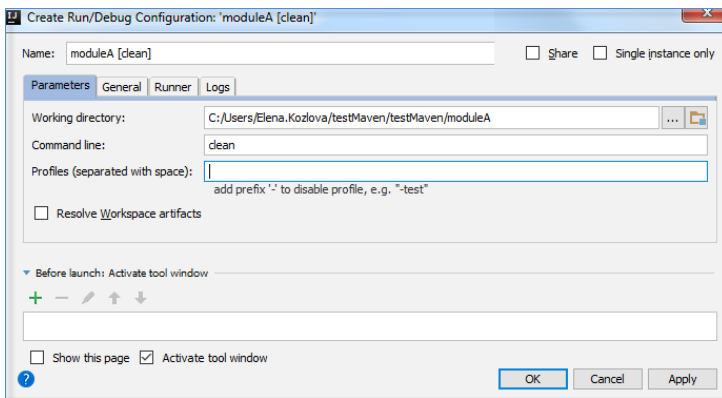

- In the Maven Projects tool window, click Lifecycle to open a list of Maven goals.
- Right-click a goal for which you want to create a Run configuration. (To select several Maven goals, press **Ctrl** and highlight the desired goals.)

- From the drop-down list select Create 'goal name' .

- In the Create Run/Debug Configuration: 'goal name' dialog, specify the goal settings (you can specify any Maven commands and arguments) and click OK .

IntelliJ IDEA displays the goal under the Run Configurations node.

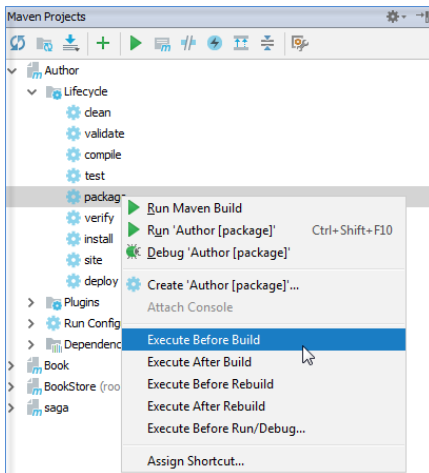

5. Double-click the goal to run it or right-click the goal and from the context menu select Run .

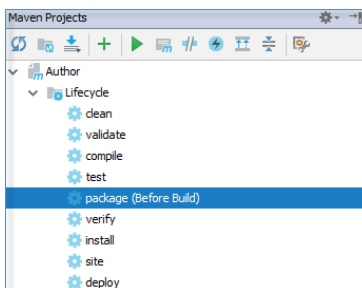

## Configuring triggers for Maven goals

IntelliJ IDEA lets you run Maven goals before your project's execution or set other conditions using the goal activation configuration.

1. In the Maven Projects tool window, click Lifecycle to open a list of goals.
2. In the list that opens, right-click the goal for which you want to set a trigger.
3. From the context menu, select an activation phase. For example, *Execute Before Build* .

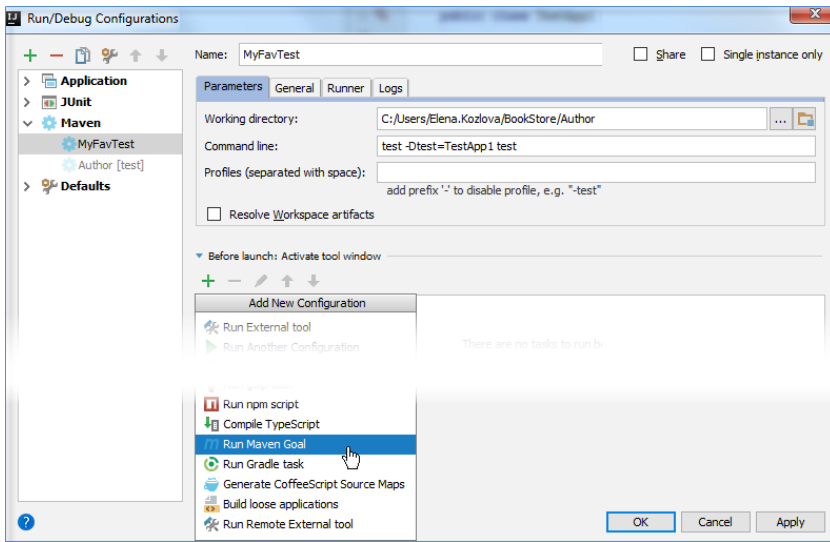

The name of activation phase is added to the selected goal in the Maven Projects tool window.

You can also create a run/debug configuration that would depend on a Maven goal.

1. On the main menu, select Run | Edit Configurations to open the run/debug configuration for your project.
2. In the Run/Debug Configurations dialog, in the Before Launch section, click the + icon.
3. In the list that opens, select Run Maven Goal .

4. In the Select Maven Goal dialog, specify a project and a goal that you want to execute before launching the project.

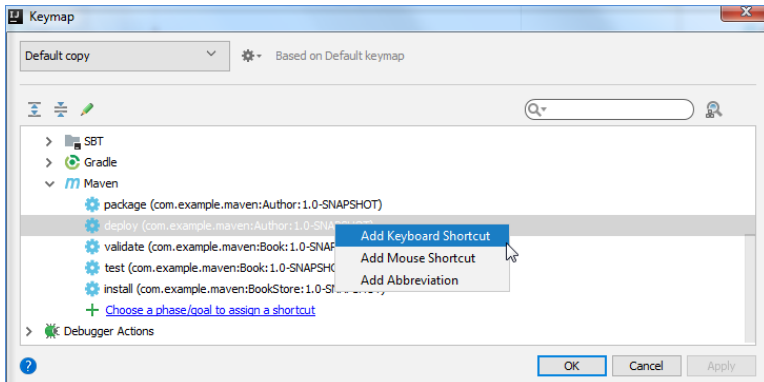

5. Click OK .

## Associating Maven goals with keyboard shortcuts

You can associate a Maven goal with a keyboard shortcut and execute goals with a single key-stroke.

1. In the Maven Projects tool window , right-click the desired goal.
2. On the context menu, choose Assign Shortcut . The **Keymap** dialog opens.
3. In the Keymap dialog, under the Maven node navigate to your goal.
4. Right-click the goal and from the list that opens, select a type of the shortcut you want to assign.

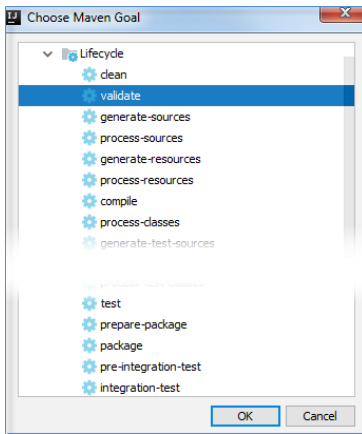

5. In the dialog that opens, depending on the shortcut's type, configure your shortcut and click OK .

The shortcut is displayed against your goal in the Maven Projects tool window.

While in the Keymap dialog, you can add a new goal to which you want to assign a shortcut.

1. In the Keymap dialog, under the Maven node, click Choose a phase/goal to assign a shortcut .
2. In the dialog that opens, select a goal you need and click OK .

The goal is added to the list under the Maven node. Now you can [configure the shortcut](#) .

## Debugging Maven goals

IntelliJ IDEA lets you create a debug configuration for one or several Maven goals or you can select a goal and start a debugging session.

1. On the main menu, select Run | Edit Configurations to create a Maven run/debug configuration.
2. In the dialog that opens, on the left side, click  to open the Add new Configuration list.
3. From the list that opens, select Maven to create a new Maven configuration.
4. On the right side of the dialog, specify the information, such as a name of your configuration, your project's directory, command line parameters, and profiles. You can leave default settings for the rest. Click OK .
5. On the main menu, click  to start your debugging session.

You can also start a debugging session for a single Maven goal or a Maven run configuration that may contain more than one Maven goal in the Maven Projects tool window.

1. Open the Maven Projects tool window.
2. Under the Lifecycle node, select a goal for which you want to start a debugging session. (Look for existing Maven run configurations under the Run Configurations node to start a debugging session for the run configuration.)
3. Right-click the goal and from the context menu select Debug [name of the goal] . IntelliJ IDEA starts a debugging session.

## Running tests in Maven projects

IntelliJ IDEA lets you run tests using default IntelliJ IDEA test runner. You can also pass [Maven Surefire plugin](#) parameters when you run JUnit or TestNg tests and [Maven Failsafe plugin](#) parameters for running integration tests. The Maven surefire plugin is declared in the super POM by default, but you can adjust its settings in your project's POM.

You can create and run tests as you normally would for your Java project. See [Testing](#) section.

You can run all your tests using the `test` Maven goal or use Maven commands to run a single test.

1. Open the Maven Projects tool window.
2. Under the Lifecycle node select test . Note that goals specified in the [Maven surefire plugin](#) will be activated at this phase and all tests in a project or in a module will be run.

If you want to run just a single test instead of all the tests declared in your project, use the Maven `-Dtest='TestName' test` command.

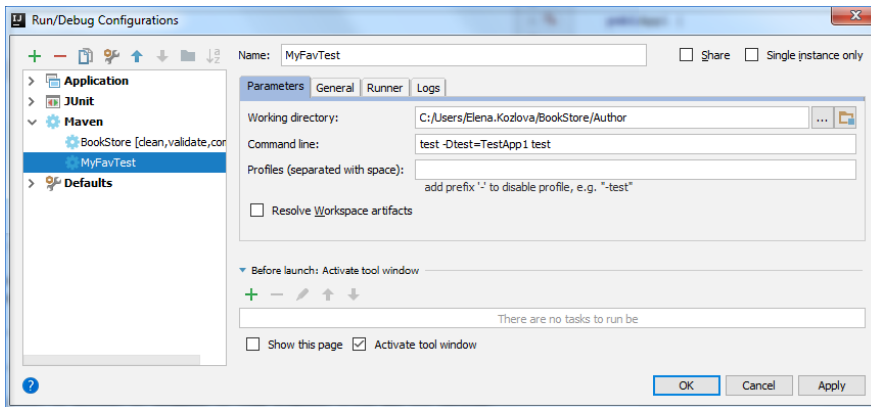

1. Open the Maven Projects tool window.
2. On the toolbar, click the  icon.
3. In the Select Maven Goal dialog, specify a project or a module that contains your test and in the Command line field, enter the `-Dtest='TestName' test` command. Click Execute .

Maven runs the specified test and displays the result in the Run tool window.

Alternatively, you can create a Maven run configuration to run a single test using the same Maven command. The run configuration will be saved under the Run Configurations node.

1. In the Maven Projects tool window, under the Lifecycle node, right-click the `test` goal.
2. From the context menu, select Create 'name of the module/project and name of a goal' .
3. In the dialog that opens, specify a working directory that contains test you want to run and in the Command line field, specify a phase (specified automatically) and the `-Dtest='TestName' test` command. Click OK .

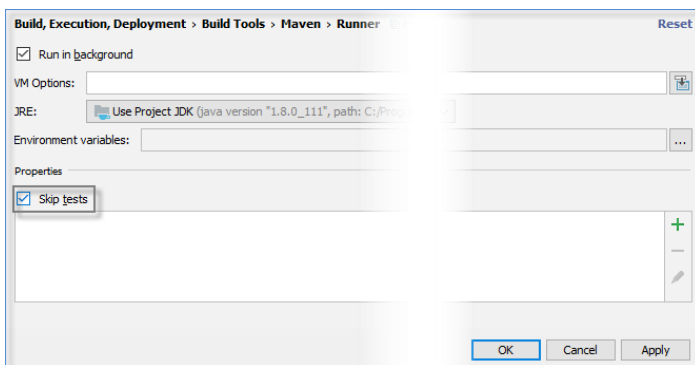

4. Open the Run Configurations node and double-click your configuration to run.

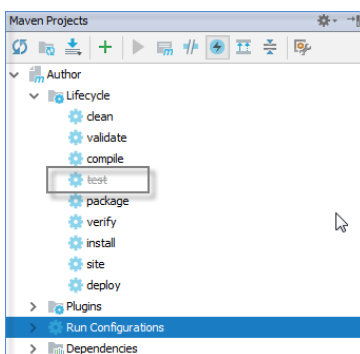

Maven runs the test and displays the result in the Run tool window.

You can skip running tests, for example, when you want to just compile your project and don't want to wait for Maven to complete the tests' execution.

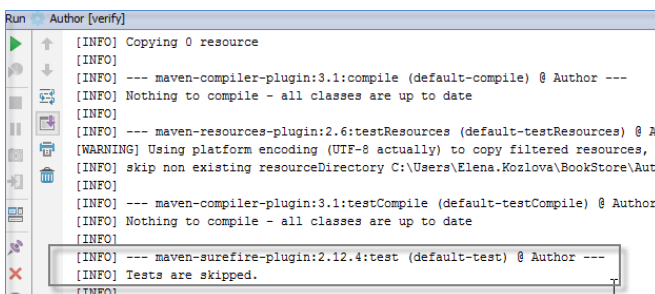

1. Click the  icon in the Maven Projects tool window to open Maven settings and select Runner from the options on the left.
2. On the Runner page, select Skip tests and click OK .

IntelliJ IDEA de-activates the `test` goal under the Lifecycle node.

The appropriate message notifying that tests are skipped is displayed in the Maven Run tool window when you execute other goals.

## Working with Maven profiles

IntelliJ IDEA lets you use [Maven build profiles](#) which can help you customize builds for a particular environment, for example, production or development.

## Declaring Maven profiles

IntelliJ IDEA lets you declare profiles explicitly in the POM of your project. Using code completion, you can place a number of different configurations inside the `<profiles>` tags and override default configurations specified in your POM for Maven plugins, dependencies, repositories, etc.

1. Open your POM in the editor.
2. Specify the `<profiles>` section and declare the profiles.

IntelliJ IDEA displays them in the Profiles list of the Maven Projects tool window.

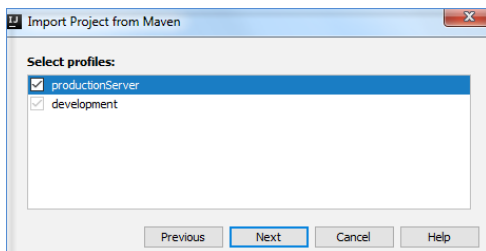

Alternatively, you can declare profiles using one of the following ways:

- You can define them locally in the Maven settings directory `%USER_HOME%/.m2/settings.xml`.
- You can define them globally in the global Maven settings `${maven.home}/conf/settings.xml`.
- You can define them in the profile descriptor located in the project's base directory (`profiles.xml`). Note that this option is not supported in Maven 3.0. Please see [Maven 3 compatibility notes](#).

## Activating Maven profiles

When IntelliJ IDEA imports a Maven project, it detects profiles and lets you activate them during importing.

1. Start [importing](#) your Maven project.
2. In the Import from Maven page where IntelliJ IDEA displays the profiles, activate the ones you need.

3. Click Next and finish your import.

You can activate a profile manually in the Maven Projects tool window using a `-P` command or using the Profiles node and the corresponding profiles' checkboxes.

1. Open the Maven Projects tool window.
2. On the toolbar, click the  icon.
3. In the dialog that opens, in the Command line field, enter `-P` and the name of your profile. If you need to exclude certain profiles, specify `!` in front of the name of the profile. The profile will be excluded even if it is activated by default. Click OK.

Alternatively, you can use Profiles node in the Maven Projects tool window to activate profiles.

1. Open the Maven Projects tool window.
2. Click the Profiles node to open a list of declared profiles.
3. Select the appropriate checkboxes to activate the profiles you need. You can have several active profiles. When they are activated, their configurations are merged based on the POM profile declaration.

You can also activate profiles automatically according to a range of contextual conditions for example, JDK version, OS name and version, presence or absence of a specific file or property, but you still need to specify all of the parameters inside your POM.

You can make a Maven profile to be activated automatically by default if you declare such profile with the `activeByDefault` tag in the POM.

```

<profiles>
  <profile>
    <id>development</id>
    <properties>
      <database.url>jdbc:hsqldb:mem:testdb</database.url>
    </properties>
    <activation>
      <activeByDefault>true</activeByDefault>
    </activation>
    <dependencies>
      <dependency>
        <groupId>org.hsqldb</groupId>
        <artifactId>hsqldb</artifactId>
        <version>2.3.3</version>
      </dependency>
    </dependencies>
  </profile>
  <profile>
    <id>productionServer</id>
    <properties>
      <database.url>jdbc:postgresql://databaseserver/database</database.url>
    </properties>
    <dependencies>
      <dependency>
        <groupId>postgresql</groupId>
        <artifactId>postgresql</artifactId>
        <version>9.0-801.jdbc4</version>
      </dependency>
    </dependencies>
  </profile>
</profiles>

```

IntelliJ IDEA displays the `activeByDefault` profile in the Maven Projects tool window with the selected checkbox that is greyed out.

You can manually de-activate this profile by clicking the checkbox. Also note that if you manually activate any other profile, the `activeByDefault` profile will be de-activated.

When you work with multi-module projects, keep in mind that if you specified the `activeByDefault` profile in your POM it will be de-activated when you manually activate any other profile even if it is declared in the POM of a different module.

**Note** Do not forget to sync every time you change your `pom.xml` file in order to view the changes in the Maven Projects tool window. When the `pom.xml` is changed, a pop-up window is displayed suggesting to import the changes. You can either enable Auto-import or click Import changes. You can also click the  button on the toolbar of the Maven Projects tool window.

If you encounter problems working with your Maven project you can check to see if the following solutions and workarounds can help you solve your issues.

## How to fix compiler version problems in Maven projects

In some cases when you import a Maven project, it might have compiler settings that will not match the expected settings in IntelliJ IDEA and when you compile your code, you might encounter a problem.

For example, you can get the following error:

This error usually indicates a problem with the compiler version compatibility and you can check few places to fix it.

– You can edit your POM and configure [Maven compiler plugin](#) to compile your Java code. You should set the compiler level explicitly, so it won't revert to the default settings when you re-import your project.

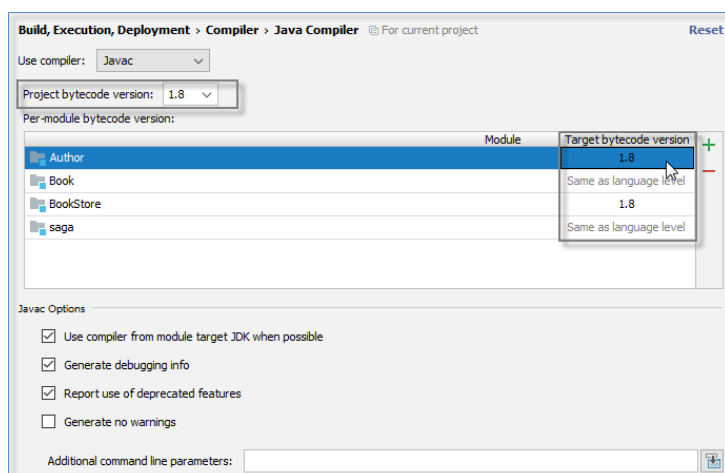

1. Open your POM in the editor.
2. Change the configuration for the [Maven compiler plugin](#).

```
<build>
  <plugins>
    <plugin>
      <groupId>org.apache.maven.plugins</groupId>
      <artifactId>maven-compiler-plugin</artifactId>
      <version>3.6.1</version>
      <configuration>
        <source>1.8</source>
        <target>1.8</target>
        <encoding>UTF-8</encoding>
      </configuration>
    </plugin>
  </plugins>
</build>
```

Click the icon to import your changes. Also note the configurations specified in your POM overrides any configurations specified in your project structure. So, now after this project is imported the language level should be picked up.

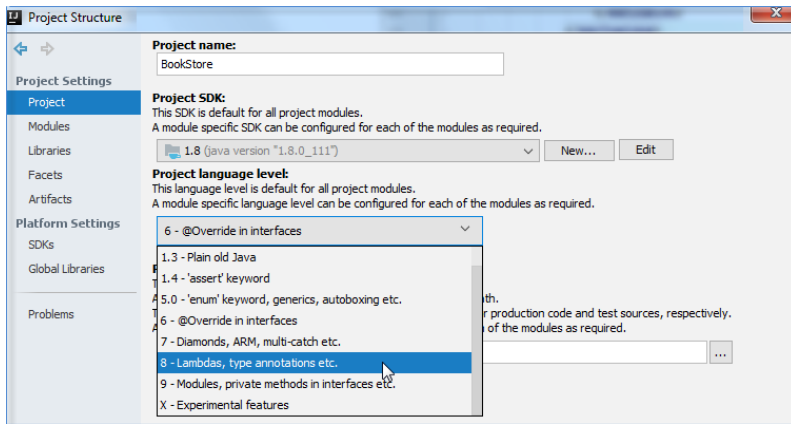

– Check Java compiler settings to see if bytecode versions match.

1. On the main menu, select File | Settings .
2. In the Settings dialog, select Build, Execution, Deployment | Compiler | Java Compiler from options on the left.
3. On the page that opens, check if Project bytecode version and Target bytecode version match, or leave the Target bytecode version option blank so it can be determined from JDK.

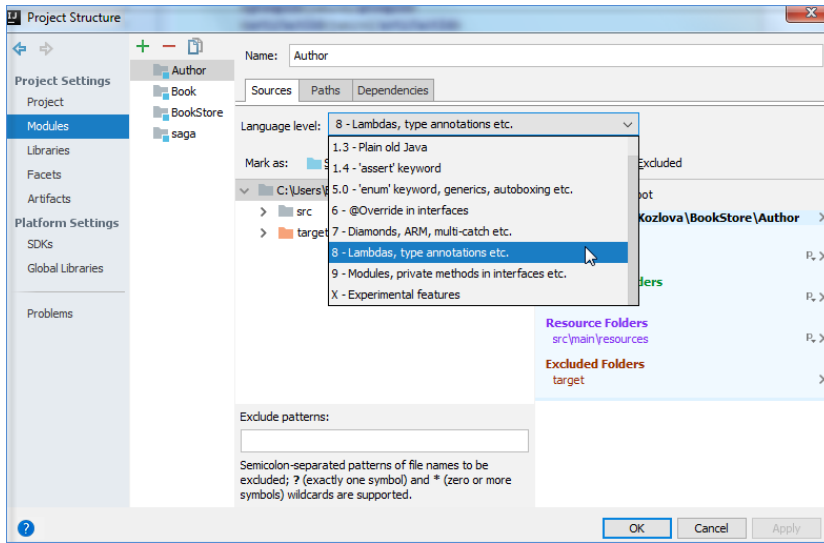

– If you have imported a multi-level project, you can check project structure settings for source language level configuration.

1. Open Project Structure dialog and select Project from the options on the left.
2. Check the source language level for your project.

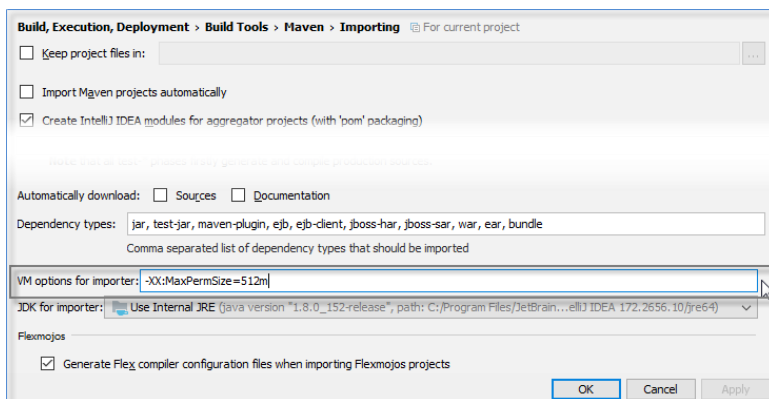

3. Check the source language level for each module (click the Sources tab).

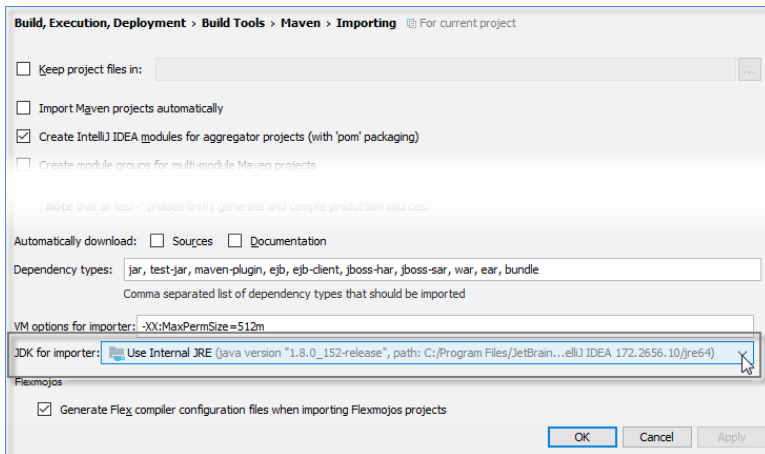

## How to fix problems with Maven projects that won't start

To fix issues that are related to the Maven projects that won't start or import, check the following:

- If you received the `OutOfMemory` error, try to increase heap size for the Maven importer.
  1. Open Settings dialog (click the  icon in the Maven Projects tool window).
  2. Select Maven | Importing from option on the left.
  3. On the Importing page, in the VM options for importer field, increase heap size for the Maven importer.

4. Also, in the JDK for importer field, increase [DE heap size](#) .

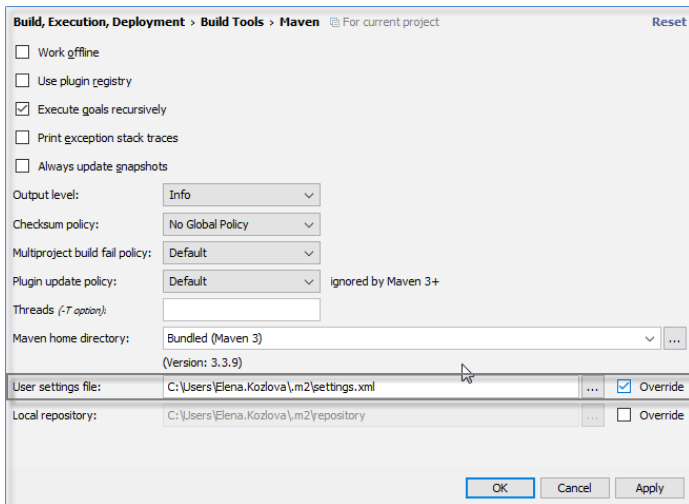

(Try not to exceed 750-1024m for -Xmx value if you are running on a 32-bit JVM (default), otherwise it may crash or fail to start.) If you need to use more heap, switch to 64-bit Java and specify the same 64-bit JVM for Maven JDK for importer .

- If you received the `Operation timed out` error or IDE connection failure to the Maven process, try to edit the `hosts` file.
- On some systems you need to edit the `hosts` file so that `localhost` resolves correctly. Try to have `127.0.0.1 localhost` in the `etc/hosts` file. Also make sure there are no other IP addresses mapped to `localhost` .
- If the error indicates the Maven repository issue, such as the `Failed to update Maven indices` error, try to check if Maven repositories were indexed correctly.

IntelliJ IDEA works with repository indexes. The indexes are fetched remotely from remote repositories. Some repositories do not provide indexes, or do not keep an updated index, for example, repositories from [Bintray](#) , in this case you can ignore the error.

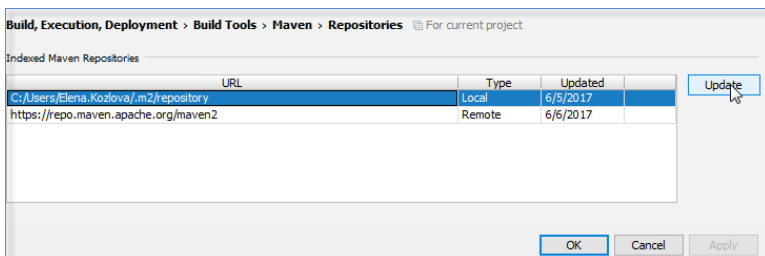

If you have an indexed repository, but still get a Maven repository error, check the following options:

1. Open the Maven Settings dialog (click the icon in the Maven Projects tool window).
2. On the Maven page, in the User settings file field, check if you defined proper credentials for the server in `settings.xml` .

You can try to restart IntelliJ IDEA and update Maven repositories.

1. Open the Maven Settings dialog (click the icon in the Maven Projects tool window).
2. Select Repositories from options on the left.
3. On the Repositories page, Update Maven repositories.

After the the update is finished, click OK .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with the [CoffeeScript compiler](#), recognizes \*.coffee files, and provides full range of coding assistance without any additional steps from your side. CoffeeScript files are marked with .

## Before you start

1. Download and install the [Node.js](#) runtime environment.
2. Configure the Node.js interpreter in IntelliJ IDEA as described in [Configuring a local Node.js interpreter](#).
3. Install and enable the **CoffeeScript** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Coding assistance

CoffeeScript support includes:

- [Code completion](#) for keywords, labels, variables, parameters and functions.
- Error and syntax highlighting.
- Code [formatting](#) and [folding](#).
- Refactoring: see [Rename Refactorings](#), [Move Refactorings](#), and [Refactoring JavaScript](#) for details.
- [Code generation](#)
  - Generating code stubs based on [file templates](#) during file creation.
  - Ability to create [line and block comments](#) ([Ctrl+Slash](#) / [Ctrl+Shift+Slash](#)).
- Navigation through source code
  - [Navigating with Structure View](#).
  - Navigate | Declaration ([Ctrl+B](#)).
  - Navigate | Implementation ([Ctrl+Alt+B](#)) from overridden method / subclassed class.
  - Navigate | Symbol ([Ctrl+Shift+Alt+N](#)).
- [Compiling to JavaScript](#) for further running, debugging, and testing, see [Running CoffeeScript](#) and [Debugging CoffeeScript](#).
- Executing CoffeeScript files involves:
  - Ability to [preview](#) results of CoffeeScript files compilation to JavaScript.
  - Ability to launch CoffeeScript files from the context menu.
  - [Run/debug configuration](#) for Node.js includes the ability to use CoffeeScript plugin.

This feature is only supported in the Ultimate edition.

CoffeeScript code is not processed by browsers that work with JavaScript code. Therefore to be executed, CoffeeScript code has to be translated into JavaScript. This operation is referred to as **compilation** and the tools that perform it are called **compilers**.

IntelliJ IDEA supports integration with the [coffee-script](#) compiler. The tool translates CoffeeScript code into JavaScript and creates [source maps](#) that set correspondence between lines in your CoffeeScript code and in the generated JavaScript code, otherwise your breakpoints will not be recognised and processed correctly. To use the compiler in IntelliJ IDEA, you need to configure it as a [File Watcher](#). For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template. To run a compiler in your project, create a project-specific File Watcher based on the relevant template.

The easiest way to install the CoffeeScript compiler is to use the **Node Package Manager (npm)**, which is a part of [Node.js](#). See [NPM](#) for details.

Depending on the desired location of the CoffeeScript compiler executable file, choose one of the following methods:

- Install the compiler **globally** at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.
- Install the compiler in a specific project and thus restrict its use to this project.
- Install the compiler in a project as a [development dependency](#).

In either installation mode, make sure that the parent folder of the CoffeeScript compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

IntelliJ IDEA provides user interface both for **global** and **project** installation as well as supports installation through the command line.

## Before you start

1. Download and install the [Node.js](#) runtime environment.

If you are going to use the command line mode, make sure the path to the parent folder of the `Node.js` executable file and the path to the `npm` folder are added to the `PATH` variable. This enables you to launch the CoffeeScript compiler and `npm` from any folder.

2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

3. Install and enable the File Watchers repository plugin.

The plugin is **not** bundled with IntelliJ IDEA, but it is available from the [IntelliJ IDEA plugin repository plugin repository](#). See [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) for details.

## Installing the CoffeeScript compiler globally

**Global** installation makes a compiler available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.

Moreover, during installation the parent folder of the compiler is automatically added to the `PATH` variable, which enables you to launch the compiler from any folder.

- Run the installation from the command line in the **global** mode:

1. Open the embedded Terminal ( View | Tool Windows | Terminal ) and switch to the directory where **NPM** is stored or define a `PATH` variable for it so it is available from any folder, see [Installing NodeJS](#).
2. Type the following command at the command prompt:

```
npm install -g coffee-script
```

The `-g` key makes the compiler run in the **global** mode. Because the installation is performed through **NPM**, the CoffeeScript compiler is installed in the `npm` folder. Make sure this parent folder is added to the `PATH` variable. This enables you to launch the compiler from any folder.

For more details on the **NPM** operation modes, see [npm documentation](#). For more information about installing the CoffeeScript compiler, see <https://npmjs.org/package/coffee-script>.

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Node.js and NPM under Languages & Frameworks.
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+`.
3. In the Available Packages dialog box that opens, select the required package to install.
4. Select the Options checkbox and type `-g` in the text box next to it.
5. Optionally specify the product version and click Install Package to start installation.

## Installing the CoffeeScript compiler in a project

**Local** installation in a specific project restricts the use of a compiler to this project.

- Run the installation from the command line:

1. Open the embedded Terminal ( View | Tool Windows | Terminal ) and switch to the project root folder.

2. At the command prompt, type `npm install coffee-script` .

– Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing **File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS**, and click **Node.js and NPM** under **Languages & Frameworks** .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+** .
3. In the Available Packages dialog box that opens, select the required package.
4. Optionally specify the product version and click **Install Package** to start installation.

**Project level** installation is helpful and reliable in **template-based projects** of the type **Node Boilerplate** or **Node.js Express** , which already have the `node_modules` folder. The latter is important because **NPM** installs the CoffeeScript compiler in a `node_modules` folder. If your project already contains such folder, the CoffeeScript compiler is installed there.

Projects of other types or **empty** projects may not have a `node_modules` folder. In this case **npm** goes upwards in the folder tree and installs the CoffeeScript compiler in the first detected `node_modules` folder. Keep in mind that this detected `node_modules` folder may be **outside** your current project root.

Finally, if no `node_modules` folder is detected in the folder tree either, the folder is created right under the current project root and the CoffeeScript compiler is installed there.

In either case, make sure that the parent folder of the CoffeeScript compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

## Creating a File Watcher

IntelliJ IDEA provides a common procedure and user interface for creating **File Watchers** of all types. The only difference is in the predefined templates you choose in each case.

1. To start creating a File Watcher, open the Settings/Preferences dialog box by choosing **File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS** on the main menu, and then click **File Watchers** under the **Tools** node. The **File Watchers page** that opens, shows the list of **File Watchers** that are already configured in the project.
2. Click the **Add** button **+** or press `Alt+Insert` and choose the CoffeeScript predefined template from the pop-up list. Your code will be translated to JavaScript and supplied with generated **source maps** .
3. In the Program text box, specify the path to the `coffee.cmd` file. Type the path manually or click the **Browse** button `...` and choose the file location in the dialog box that opens.
4. Proceed as described on page [Using File Watchers](#) .

## Examples of customizing the behaviour of a compiler

Any compiler is an external, third-party tool. Therefore the only way to influence a compiler is pass arguments to it just as if you were working in the command line mode. Below are two examples of customizing the default output location for the **CoffeeScript compiler** .

Suppose, you have a project with the following folder structure:

By default, the generated files will be stored in the folder where the original file is. You can change this default location and have the generated files stored in the `js` folder. Moreover, you can have them stored in a flat list or arranged in the folder structure that repeats the original structure under the `app` node.

– To have all the generated files stored in the output `js` folder without retaining the original folder structure under the `app` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir\js\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir\js\${FileNameWithoutExtension}.js:$ProjectFileDir\js\${FileNameWithoutExtension}.map
```

As a result, the project tree looks as follows:

- To have the original folder structure under the `app` node retained in the output `js` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir$\js\${FileDirRelativeToProjectRoot}\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir$\js\${FileDirRelativeToProjectRoot}\${FileNameWithoutExtension}.js:$ProjectFileDir$\js
```

As a result, the project tree looks as follows:

## Compiling the CoffeeScript code

When you open a CoffeeScript file, IntelliJ IDEA checks whether an applicable file watcher is available in the current project. If such file watcher is configured but disabled, IntelliJ IDEA displays a pop-up window that informs you about the configured file watcher and suggests to enable it.

If an applicable file watcher is configured and enabled in the current project, IntelliJ IDEA starts it automatically upon the event specified in the [New Watcher dialog](#).

- If the Auto-save edited files to trigger the watcher checkbox is selected, the File Watcher is invoked as soon as any changes are made to the source code.
- If the Auto-save edited files to trigger the watcher checkbox is cleared, the File Watcher is started upon save (File | Save All, `Ctrl+S`) or when you move focus from IntelliJ IDEA (upon frame deactivation).

The compiler stores the generated output in a separate file. The file has the name of the source **CoffeeScript** file and the extension `js` or `js.map` depending on the compiler type. The location of the generated files is defined in the Output paths to refresh text box of the [New Watcher dialog](#). Based on this setting, IntelliJ IDEA detects the compiler output. However, in the Project Tree, they are shown under the source `.coffee` file which is now displayed as a node.

## Previewing the compilation results without running a compiler

IntelliJ IDEA can perform static analyses of your CoffeeScript code without actually running a compiler and display the predicted compilation output in the dedicated read-only viewer.

1. Open the desired CoffeeScript file in the editor, and right-click the editor background.
2. On the context menu, choose Preview Compiled CoffeeScript File. The preview is opened in the dedicated read-only viewer: the left-hand pane shows the original CoffeeScript source code and the right-hand pane shows the JavaScript

code that will be generated by the compiler when it runs.

This feature is only supported in the Ultimate edition.

CoffeeScript code is not processed by browsers that work with JavaScript code. Therefore to be executed, CoffeeScript code has to be translated into JavaScript. This operation is referred to as **compilation** and the tools that perform it are called **compilers**.

For more details about **compilation** in IntelliJ IDEA, see the section [Using File Watchers](#).

In either case, running CoffeeScript is supported only in the **local** mode. This means that IntelliJ IDEA itself starts the Node.js engine and the target application according to a run configuration and gets full control over the session.

For more details about running Node.js applications, see [Running and Debugging Node.js](#).

There are two approaches to running CoffeeScript in IntelliJ IDEA:

- Compile the CoffeeScript code manually and then run the output JavaScript code as if it were a Node.js application.
- Run the original CoffeeScript code through the Node.js run configuration and have IntelliJ IDEA compile it on the fly.

## Compiling CoffeeScript manually and running the generated JavaScript code

1. [Compile the CoffeeScript code into Javascript](#).
2. [Start creating a Node.js run configuration](#) with the following mandatory settings:
  1. The Node.js engine to use. By default, the field shows the path to the interpreter specified on the [Node.js](#) page during Node.js configuration.
  2. In the Working directory field, specify the location of the files referenced from the starting CoffeeScript file to run, for example, `includes`. If this file does not reference any other files, just leave the field empty.
  3. In the Path to Node App JS File text box, specify the full path to the JavaScript file that was generated from the original CoffeeScript file during the compilation.
3. Save the configuration and click  on the toolbar.
4. Proceed as while [running a Node.js application](#).

## Compile CoffeeScript on the fly during run

1. This mode requires that the `register.js` file, which is a part of the `coffee-script` package, should be located inside the project. Therefore you need to install the `coffee-script` package on the [Node.js](#) page locally, as described in [NPM](#).
2. Open the starting CoffeeScript file in the editor or select in the Project tool window and choose Create `<CoffeeScript_file_name>` on the context menu. Alternatively, start creating a Node.js run configuration as described in [Running and Debugging Node.js](#). In the [Run/Debug Configuration: Node.js](#) dialog that opens, specify the following mandatory settings:
  1. The Node interpreter to use. Select the relevant interpreter configuration or create a new one, see By default, the field shows the path to the interpreter specified on the [Node.js](#) page during Node.js configuration.  
For Linux and macOS, this setting is overridden by the Node.js from the path to the CoffeeScript compiler executable file.
  2. In the Node parameters text box, type the following:

```
--require coffee-script/register
```
  3. In the Working directory field, specify the [working directory](#) of the application. All references in the **starting CoffeeScript file**, for example, `imports`, will be resolved relative to this folder, unless such references use full paths.  
By default, the field shows the **project root folder**. To change this predefined setting, choose the desired folder from the drop-down list, or type the path manually, or click the Browse button  and select the location in the dialog box, that opens.
  4. In the JavaScript file text box, specify the full path to the CoffeeScript file to run.

Note that all the mandatory fields will be filled in automatically if you create a run configuration directly from the required CoffeeScript file.

3. Save the configuration and click  on the toolbar.
4. Proceed as while [running a Node.js application](#).

This feature is only supported in the Ultimate edition.

CoffeeScript code is not processed by browsers that work with JavaScript code. Therefore to be executed, CoffeeScript code has to be translated into JavaScript. This operation is referred to as **compilation** and the tools that perform it are called **compilers**.

To debug CoffeeScript in IntelliJ IDEA, you need **source maps** generated in addition to the JavaScript code. [Source maps](#) set correspondence between lines in your CoffeeScript code and in the generated JavaScript code, otherwise your breakpoints will not be recognised and processed correctly. JavaScript and source maps are generated by compiling the CoffeeScript code manually using the File Watcher of the type **CoffeeScript**. After that you can debug the output JavaScript code as if it were a Node.js application.

For more details about **compilation** in IntelliJ IDEA, see the section [Using File Watchers](#).

Debugging CoffeeScript is supported only in the **local** mode. This means that IntelliJ IDEA itself starts the Node.js engine and the target application according to a run configuration and gets full control over the session.

For more details about debugging Node.js applications, see [Running and Debugging Node.js](#).

## Debugging

To debug a CoffeeScript code, follow these general steps:

1. Set the [breakpoints](#) in the CoffeeScript code where necessary.
2. [Compile the CoffeeScript code into Javascript](#) using the File Watcher of the type **CoffeeScript Source Map**.
3. [Start creating a Node.js run configuration](#) with the following mandatory settings:
  1. The Node.js engine to use. By default, the field shows the path to the interpreter specified on the [Node.js](#) page during Node.js configuration.
  2. In the Working directory field, specify the location of the files referenced from the starting CoffeeScript file to run, for example, **includes**. If this file does not reference any other files, just leave the field empty.
  3. In the Path to Node App JS File text box, specify the full path to the JavaScript file that was generated from the original CoffeeScript file during the compilation.
4. Save the configuration and click  on the toolbar.
5. Proceed as while [debugging a Node.js application locally](#).

IntelliJ IDEA provides extensive editing support for ColdFusion files, and facilities for deploying applications to the [ColdFusion](#) server.

On this page:

- [ColdFusion Support](#)
- [Configuring deployment to ColdFusion server](#)

**Tip** IntelliJ IDEA implements the ColdFusion functionality with a bundled plugin, which can be completely disabled by clearing the CFML Support check box on the the Plugins page of IntelliJ IDEA settings ( [Ctrl+Alt+S](#) ).

[ColdFusion server](#) should be downloaded and installed on your machine.

## ColdFusion Support

ColdFusion files are marked with  icon.

ColdFusion support includes:

1. Coding assistance:

- [Code completion](#) for tags, attributes, attribute values, functions and variable of the current scope, function arguments, functions of Java classes and components created through 'createObject' function, for components' and Java classes' names in 'createObject', for inherited methods of a component.
- Error and syntax highlighting.
- Code [formatting](#) and [folding](#) .

2. Numerous ways to [navigate](#) through the source code, among them:

- Ability to open a [file or component with the specified name](#) .
- [Navigating with Structure View](#) .
- [Navigate | Declaration](#) ( [Ctrl+B](#) ).

3. Advanced facilities to [search through the source code](#) .

4. [Code generation](#)

- Generating code stubs based on [file templates](#) during file creation.
- Inserting, expanding, and generating code blocks using [live templates](#) .
- Creating various applications elements via [intention actions](#) .
- Ability to create [line and block comments](#) ( [Ctrl+Slash](#) / [Ctrl+Shift+Slash](#) ).

5. [Viewing method parameters](#) information.

6. [Run/debug configuration](#) for ColdFusion.

### To configure deployment to the ColdFusion server

1. Press [Ctrl+Alt+S](#) or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Languages & Frameworks | ColdFusion .
2. On the [ColdFusion page](#) that opens, specify mappings between local folders with the application sources and the paths on the server.
  - To add a new mapping, click [+](#) ( [Alt+Insert](#) ) and specify the local folder with the application sources in the Directory Path field. Type the path manually or click  and choose the folder in the dialog that opens.  
In the Logical Path field, type the URL address of the server to which you want to deploy the contents of the specified local folder.
  - To remove a mapping from the list, select the mapping and click [-](#) ( [Alt+Delete](#) ).

- Copyright
  - Prerequisite
  - Basics
- [Associating a Copyright Profile with a Scope](#)
- [Generating and Updating Copyright Notice](#)

## Prerequisite

Before using copyright profiles and generating copyright notices, make sure that the **Copyright** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Basics

Your project can contain files to be protected by copyright. Instead of generating and editing copyright notices in each file separately, IntelliJ IDEA suggests that you use **copyright profiles**. Each copyright profile is associated with a certain **scope** and defines the text and formatting of the copyright notice to be inserted in the files within this scope.

You may need several different copyright notices for files within the same project. In this case, IntelliJ IDEA enables you to define several profiles and associate them with relevant scopes.

You can also declare one of the available profiles as **default project copyright profile**. The settings of this profile will be applied to any project file that is not included in any scope or belongs to a scope, which has no **associated copyright profile**.

A copyright profile can contain an explicit plain text of the copyright notice or its definition through a **Velocity** template. You can type the desired text or a Velocity template manually or import a copyright notice definition from an existing profile.

Note the following:

- If a file does not belong to any scope with a copyright profile assigned, the **default copyright profile** is used.
- If the No copyright option has been set as the Default Copyright Profile in the **Copyright** settings dialog box, no copyright notice will be created or updated and IntelliJ IDEA will prompt you to configure a profile to apply.

On this page:

- [Associating a profile with a scope](#)
- [Setting the default Copyright profile for a project](#)

## Associating a profile with a scope

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Copyright under Editor . The [Copyright](#) page that opens displays mappings between the available copyright profiles and scopes.  
Note that unless you have at least one [copyright profile](#) and [scope](#) , the controls of the [Scope-profile combinations area](#) are disabled.
2. Click `+` (`Alt+Insert` ). A row to define a new mapping is created.
3. From the Scope drop-down list, select the desired scope.  
To define a new scope, open the [Scopes page](#) or click the link in the lower part of the [Copyright](#) page.
4. From the Copyright drop-down list, select the profile to apply to the selected scope.
5. Continue composing the list of scope-profile mappings. Use `+` (`Alt+Insert` ) or `-` (`Alt+Delete` ) to add or remove the items. To reorder the mappings, use `↑` (`Alt+Up` ) and `↓` (`Alt+Down` ).

## Setting the default Copyright profile for a project

The settings of the default profile will be applied to any project file that is not included in any scope or belongs to a scope that has no associated copyright profile.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Copyright under Editor .
2. On the [Copyright](#) page that opens, select the desired copyright profile from the Default project copyright drop-down list.  
Note that is you select No copyright , any attempt to [generate a copyright notice](#) will fail and IntelliJ IDEA will prompt you to create a profile to apply.

In this section:

- [Prerequisite](#)
- [Creating a Copyright profile from scratch](#)
- [Creating a Copyright profile based on the settings of an existing profile](#)
- [Importing an existing Copyright notice text](#)
- [Discarding a Copyright profile](#)
- [Adding a Copyright notice](#)
- [Updating a Copyright notice](#)

## Prerequisite

Before using copyright profiles and generating copyright notices, make sure that the **Copyright** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Creating a Copyright profile from scratch

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click Copyright Profiles under Copyright. The [Copyright Profiles](#) page opens.
2. Click the Add button  on the toolbar in the Create new copyright profile dialog box that opens specify the name of the new profile and click OK. You return to the Copyright Profiles page where the new profile is added to the list of available copyright profiles.
3. Specify the copyright notice to be generated. Do one of the following:
  - Type the desired plain text.
  - Define a [Velocity template](#), then click the Validate button to check that the template has been specified correctly. Find the list of supported Velocity variables in the [Copyright Profiles](#) dialog box reference.
4. In the Regexp to detect copyright in comments text box, type a character string to distinguish copyright notices from other comments during copyright update.

 Make sure that this regular expression matches the above specified copyright notice. Otherwise instead of [updating](#) copyright notices, IntelliJ IDEA will insert new ones.

## Creating a Copyright profile based on the settings of an existing profile

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click Copyright Profiles under Copyright. The [Copyright Profiles](#) page opens.
2. Select the desired profile to inherit the settings from and click the Copy button  on the toolbar.
3. In the Create new copyright profile dialog box that opens specify the name of the new profile and click OK. You return to the Copyright Profiles page where the new profile is added to the list of available copyright profiles.
4. View and edit the profile settings. Proceed as during creation of a [profile from scratch](#).

## Importing an existing Copyright notice text

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click Copyright Profiles under Copyright. The [Copyright Profiles](#) page opens.
2. Click the Import button  on the toolbar.
3. In the [dialog that opens](#), choose the location of the `%.ipr%` file that refers to the copyright profile with the desired notice definition.
4. From the Choose profile to import list, that appears, select the desired copyright profile.
5. In the Create new copyright profile dialog box that opens specify the name of the new profile and click OK. You return to the Copyright Profiles page where the new profile is added to the list of available copyright profiles.
6. Proceed as during creation of a [profile from scratch](#).

## Discarding a Copyright profile

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click Copyright Profiles under Copyright. The [Copyright Profiles](#) page opens.
2. Select the profile you want to discard and click the Delete button  on the toolbar.

## Adding a Copyright notice

1. Open the desired file in the editor.
2. Press `Alt+Insert`.
3. From the list that is displayed in the editor, choose Copyright.
4. The following steps depend on the belonging of a file to a certain scope and the value of the Default project copyright field in the [Copyright](#) page.
  - If the file where you want to generate a copyright notice belongs to a certain scope, the copyright notice is generated according to the [copyright profile](#) settings.

- If the field Default project copyright has the value No copyright and the file where you want to generate a copyright notice does not belong to any scope, IntelliJ IDEA prompts you to configure copyright settings:

Click OK to open the [Copyright](#) page and configure the desired settings.

Note that if a file belongs to several scopes, these scopes are checked upside down. So doing, the first scope with this file is declared the proper one, and its copyright profile is used.

## Updating a Copyright notice

1. In the Project tool window, select files or directories where you want the copyright notice to be updated or just open the desired file in the editor.
2. Right-click the selection, and choose Update Copyright on the context menu.  
To have copyright notices updated correctly, make sure that the keyword specified in the copyright profile is a part of the notice definition. Otherwise, IntelliJ IDEA will not detect copyright notices and, instead of updating existing notices, will insert new ones.

**Tip** You can also update copyright notices when [committing changes](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Context and Dependency Injection Plugin is installed and enabled!

- [Basics](#)
- [Making sure that the CDI Support plugin is enabled](#)
- [Enabling CDI support when creating a project or module](#)
- [Adding CDI support for an existing module](#)
- [Changing the CDI version](#)

## Basics

The [Context and Dependency Injection](#) (CDI) support in IntelliJ IDEA is based on the Java EE: Context and Dependency Injection [plugin](#). This plugin is bundled with the IDE and enabled by default.

You can enable CDI support when creating a [project](#) or [module](#). You can as well add CDI support for an existing module.

CDI in a module is represented by the corresponding CDI [library](#) in the [module dependencies](#). You can download all the necessary library files right from within the IDE. You can also change the CDI version being used if and when needed.

## Making sure that the CDI Support plugin is enabled

### To make sure that the CDI Support plugin is enabled, follow these steps:

Even though the CDI Support plugin is enabled by default, it's always worth making sure that this plugin is still enabled before you start using CDI.

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S`).
2. In the left-hand part of the dialog, select [Plugins](#).
3. In the right-hand part of the dialog, on the [Plugins page](#), type `cd` in the search box. As a result, only the plugins whose names and descriptions contain `cd` are shown in the list of plugins.
4. If the checkbox to the right of Java EE: Context and Dependency Injection is not selected, select it.
5. Click OK in the Settings dialog.
6. If suggested, restart IntelliJ IDEA.

## Enabling CDI support when creating a project or module

### To enable CDI support, follow these steps:

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project.  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module.  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java Enterprise. In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.
3. Under Additional Libraries and Frameworks, select the CDI: Context and Dependency Injection checkbox.
4. You'll need a [library](#) that implements CDI. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#). (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#).)
  - Download. Select this option to download the library files that implement CDI. (The downloaded files will be arranged in a [library](#).)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .

5. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

## Adding CDI support for an existing module

### To add CDI support for an existing module

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the module of interest and select Add Framework Support .
3. In the left-hand pane of the [Add Frameworks Support dialog](#) that opens, select the CDI: Context and Dependency Injection checkbox.
4. You'll need a [library](#) that implements CDI. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).

Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the library files that implement CDI. (The downloaded files will be arranged in a [library](#) .)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.
5. Click OK in the Add Frameworks Support dialog.

As a result, the CDI library you have specified is added to the list of module dependencies.

## Changing the CDI version

### To change the CDI version

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Select the CDI library whose version you want to change.
3. Click Change Version . (If you are on the Dependencies tab, select to edit the library first.)
4. In the Downloading Options dialog that opens, select the necessary CDI version, specify other settings as needed and click OK .

**Note** For the database and SQL features to be available, the Database Tools and SQL plugin must be enabled. This plugin is bundled with the IDE and enabled by default. See [Enabling and Disabling Plugins](#).

This feature is only supported in the Ultimate edition.

IntelliJ IDEA features for working with databases and SQL include:

- Integration with the most popular database management systems such as [Oracle](#), [PostgreSQL](#), [MySQL](#), [SQL Server](#) and others. To be able to work with your databases, you should define them as data sources. See [Connecting to a database](#).
- Database tool window for managing data structures in your databases ( View | Tool Windows | Database ). See [Working with the Database tool window](#).
- Database consoles that let you compose and execute SQL statements as well as analyze and modify retrieved data ( `Ctrl+Shift+F10` in the Database tool window). See [Working with database consoles](#).
- Data editor that provides a GUI for working with table data ( `F4` in the Database tool window). See [Working with the data editor](#).
- SQL code generation and editing features in the database consoles and the editor, e.g.
  - Predefined code snippets (a.k.a. live templates) such as for `CREATE TABLE`, `SELECT`, `INSERT`, `UPDATE` and other statements ( `Ctrl+J` ).
  - Auto-completion and highlighting of SQL keywords, and table and column names.
  - Data type prompts for columns ( `Ctrl+P` ).

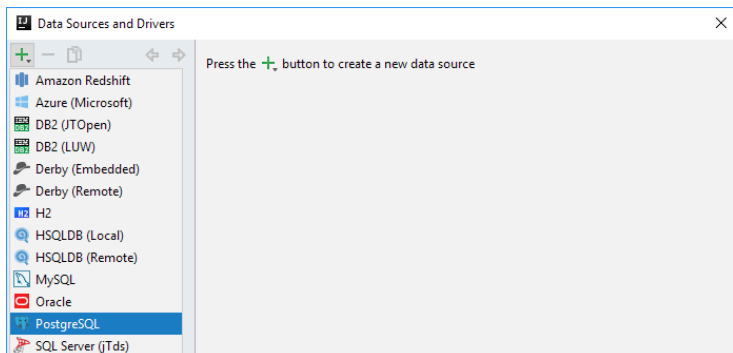

Standardized and DBMS-specific SQL dialects are supported.

- Structure view for tables in the data editor and Database Console tool window as well as for open database consoles and SQL files ( `Ctrl+F12` ). See e.g. [Using the Structure view to sort data, and hide and show columns](#).
- Quick documentation view for database objects and table cells ( `Ctrl+Q` ). See e.g. [Using the quick documentation view](#).
- Navigation capabilities, e.g.
  - From a table or column reference to its definition: `Ctrl+B`.
  - To the view of a table or column in the Database tool window: `Alt+F1` | Database View.
  - By means of the navigation bar: `Alt+Home`.
  - By means of the Switcher: `Ctrl+Tab`.
- Database diagrams ( `Ctrl+Alt+U` or `Ctrl+Shift+Alt+U` in the Database tool window).

To be able to work with your database, define it as a data source. This page provides how tos for popular database management systems and typical situations.

## PostgreSQL

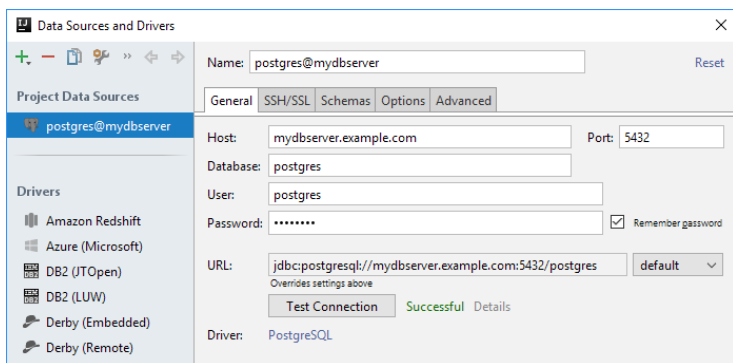

1. Open the Database tool window (e.g. View | Tool Windows | Database ) and click  to open the Data Sources and Drivers dialog.
2. Click  and select PostgreSQL .

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

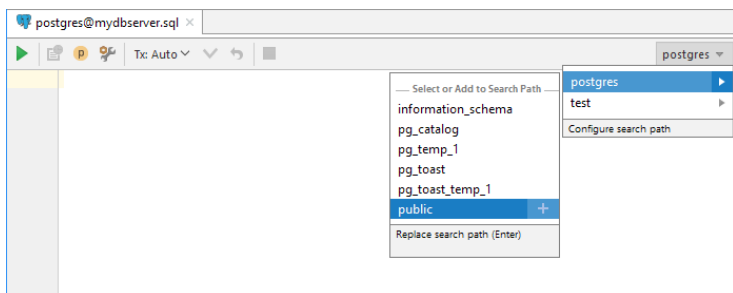

4. Specify the database connection settings and your user account info:
  - Host. If you database server is on a different computer, replace `localhost` with the [FQDN](#) or [IP address](#) of the server host, e.g. `mydbserver.example.com` or `172.20.240.163` .
  - Port. The default PostgreSQL server port is `5432` . If your server uses a different port, specify that port.
  - Database. The name of the database that you are going to work with.
  - User and Password. These are your database user name and password.
5. If necessary, edit the data source name.
6. To connect via SSH, [specify the SSH proxy settings](#) .
7. To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

8. If necessary, form the schema search path using the popup in the upper-right part of the console. For instructions, see [Controlling the schema search path for PostgreSQL and Redshift](#) .

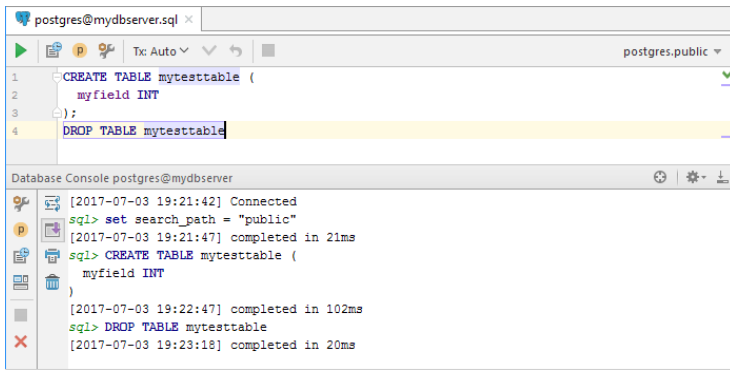

9. Type your query, e.g.

```
CREATE TABLE mytesttable (  
  myfield INT  
);
```

0. Execute the query:  or `Ctrl+Enter` .
1. If necessary, execute another query, e.g.

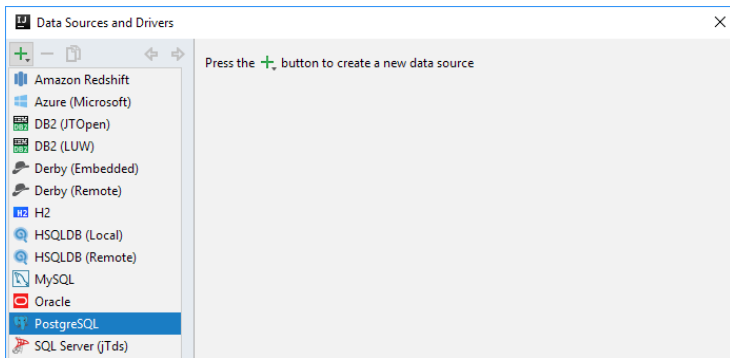

```
DROP TABLE mytesttable
```

## PostgreSQL on Heroku

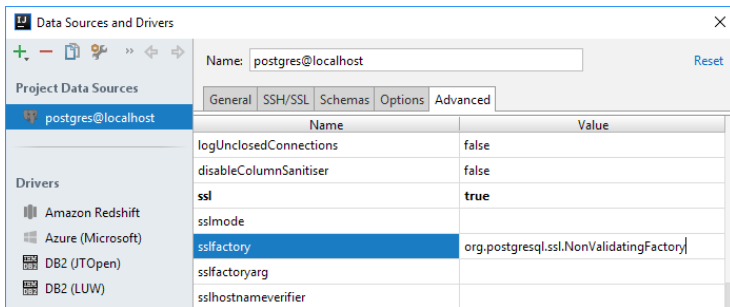

1. Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.
2. Click and select PostgreSQL .

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

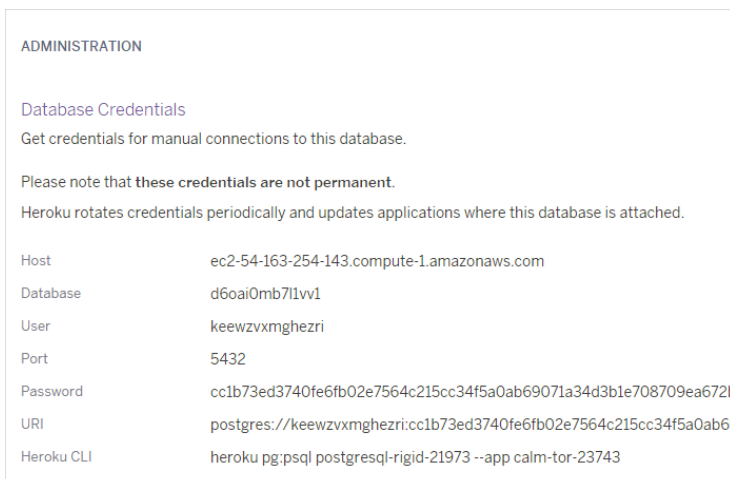

4. Select the Advanced tab and specify the following properties:
  - ssl: true
  - sslfactory: org.postgresql.ssl.NonValidatingFactory

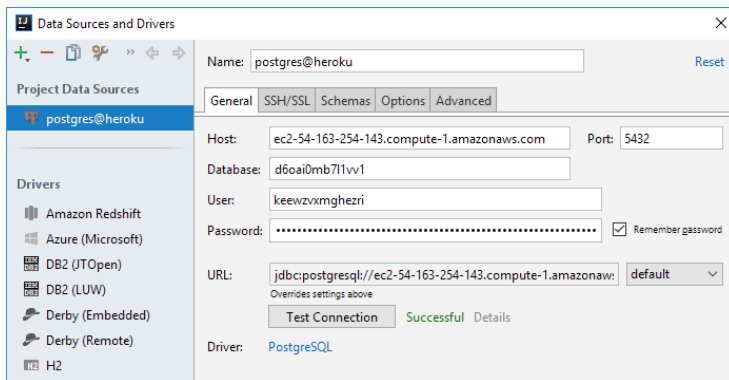

These will turn SSL on and the certificate validation off.

5. Click Apply and select the General tab.
6. Go to your Heroku dashboard and display your database settings: e.g. click your app, under Installed add-ons , click Heroku Postgres , and then, in the ADMINISTRATION section, click View Credentials .

7. Copy the settings from the dashboard onto the General tab.

- If necessary, edit the data source name.
- To make sure that the settings are OK, click Test Connection .

Click OK .

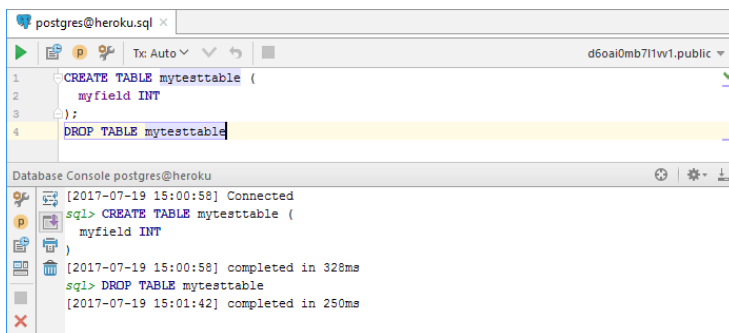

Now, as a final check, execute a couple of queries.

- If necessary, form the schema search path using the popup in the upper-right part of the console. For instructions, see [Controlling the schema search path for PostgreSQL and Redshift](#) .
- Type your query, e.g.

```
CREATE TABLE mytesttable (
  myfield INT
);
```

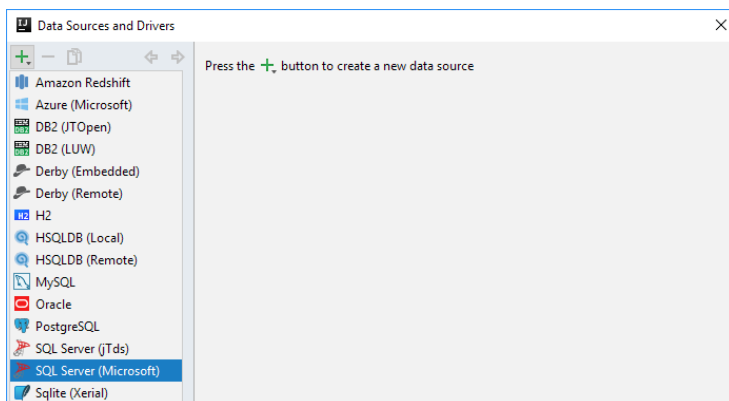

- Execute the query: or `Ctrl+Enter` .
- If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

## Microsoft SQL Server

- Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.
- Click and select SQL Server (JTDs) or SQL Server (Microsoft) . These options differ only in the database driver that is used: [JTDs](#) or [Microsoft](#) .

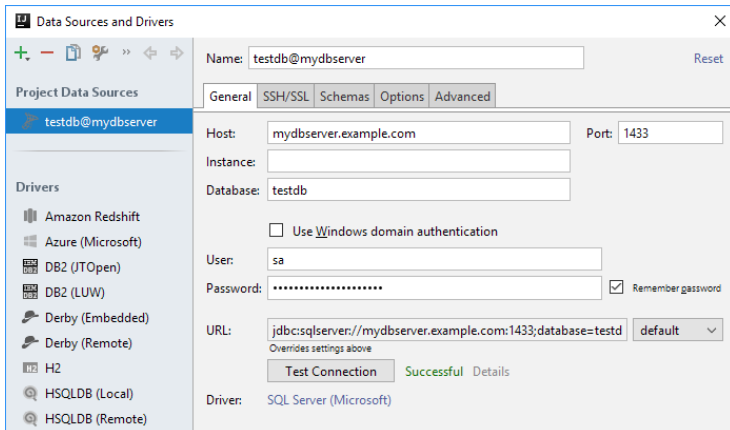

- In the lower part of the dialog, within Download missing driver files , click the Download link.

- Specify the database connection settings and authentication options:
  - Host. If you database server is on a different computer, replace `localhost` with the [FQDN](#) or [IP address](#) of the server host, e.g. `mydbserver.example.com` or `172.20.240.163` .
  - Port. Specify the server port; the default port for SQL Server is `1433` .
  - Instance. If you are connecting to a default [server instance](#) , don't specify anything. Otherwise, specify the instance

name.

- Database. Specify the name of the database that you are going to work with.
  - Use Windows domain authentication. To use [Windows Authentication](#) , leave the checkbox selected. To use SQL Server Authentication, clear the checkbox, and specify your user name and password.
5. If necessary, edit the data source name.
  6. To connect via SSH, [specify the SSH proxy settings](#) .
  7. To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

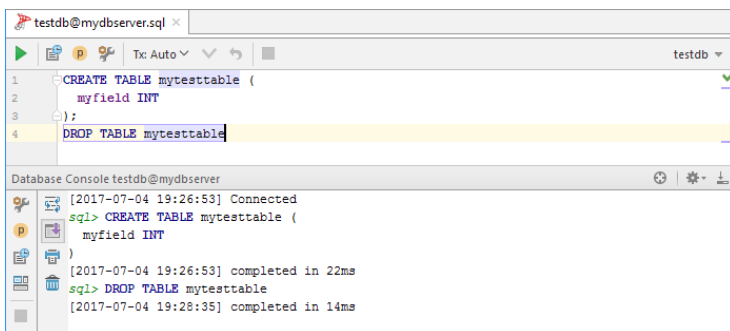

8. Type your query, e.g.

```
CREATE TABLE mytesttable (  
  myfield INT  
);
```

9. Execute the query:  or `Ctrl+Enter` .

0. If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

## Microsoft Azure

1. Open the Database tool window (e.g. View | Tool Windows | Database ) and click  to open the Data Sources and Drivers dialog.
2. Click  and select Azure (Microsoft) .

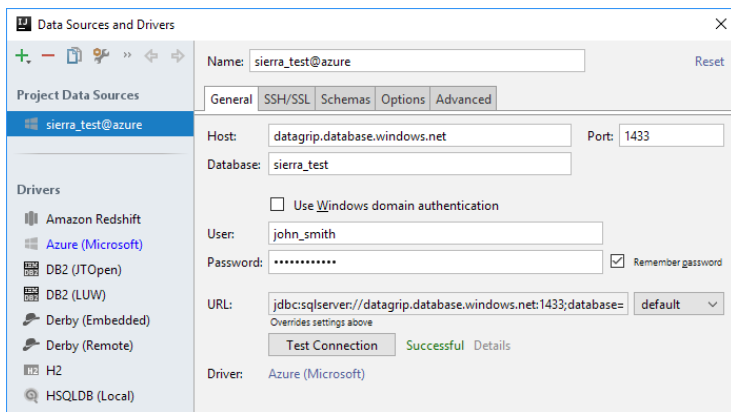

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

4. Specify the database connection settings and authentication options:
  - Host. This is the [FQDN](#) of your server. Within the default `server.database.windows.net` you, most likely, only need to replace the `server` part with the name of your server.
  - Port. The default Azure server port is `1433` .
  - Database. The name of the database that you are going to work with.
  - Use Windows domain authentication. To use [Azure Active Directory Authentication](#) , leave the checkbox selected. To use SQL Authentication, clear the checkbox, and specify your user name and password.
5. If necessary, edit the data source name.

- To connect via SSH, [specify the SSH proxy settings](#) .
- To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

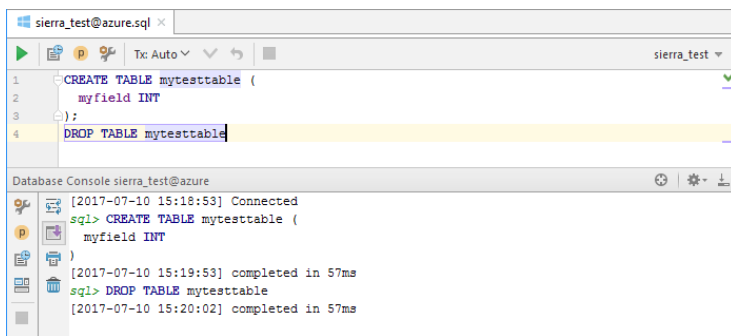

- Type your query, e.g.

```
CREATE TABLE mytesttable (
  myfield INT
);
```

- Execute the query: or `Ctrl+Enter` .

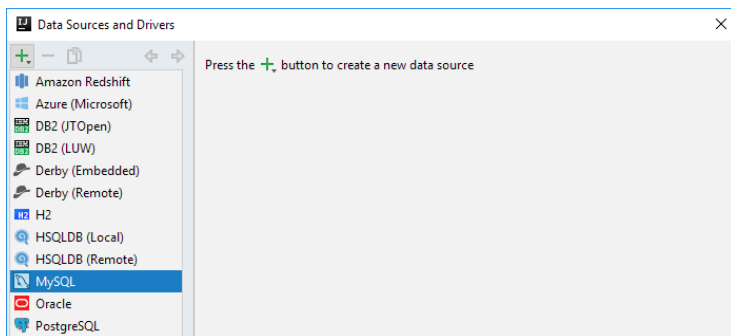

- If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

## MySQL

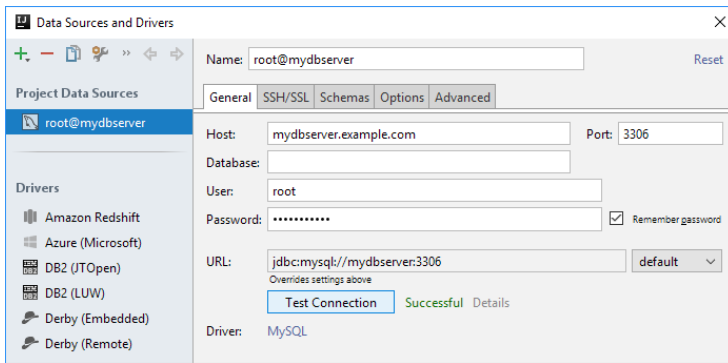

- Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.
- Click and select MySQL .

- In the lower part of the dialog, within Download missing driver files , click the Download link.

- Specify the database connection settings and your user account info:
  - Host. If you database server is on a different computer, replace `localhost` with the [FQDN](#) or [IP address](#) of the server host, e.g. `mydbserver.example.com` or `172.20.240.163` .
  - Port. The default MySQL server port is `3306` . If your server uses a different port, specify that port.
  - User and Password. These are your database user name and password.
- If necessary, edit the data source name.
- To connect via SSH, [specify the SSH proxy settings](#) .
- To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

8. Select your default schema from the list in the upper-right part of the console.

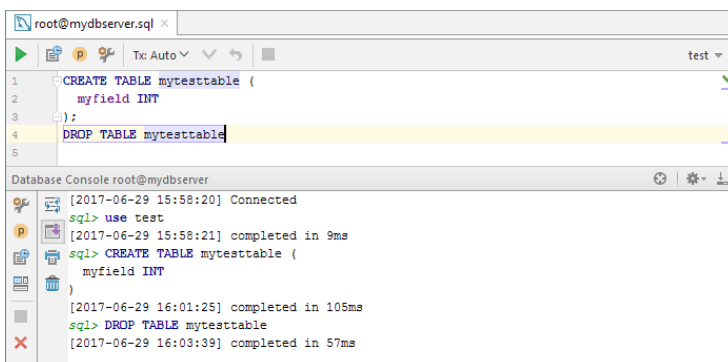

9. Type your query, e.g.

```
CREATE TABLE mytesttable (
  myfield INT
);
```

10. Execute the query: or `Ctrl+Enter` .

11. If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

## Oracle

1. Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.
2. Click and select Oracle .

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

4. Specify the database connection settings and your user account info:

From the list to the right of URL , select **SID or Service Name** , or **TNS** .

– If SID or Service Name is selected, the settings are:

- Host. If you database server is on a different computer, replace `localhost` with the [FQDN](#) or [IP address](#) of the server host, e.g. `mydbserver.example.com` or `172.20.240.163` .

- Port. The default Oracle server port is `1521` . If your server uses a different port, specify that port.
- SID or Service. The Oracle system ID or service name for your database. The typical values are `XE` or `ORCL` .  
To find out what the value should be, check the environment variable `ORACLE_SID` on the server host, or contact your database administrator.
- If TNS is selected, the connection settings are read from a [tnsnames.ora](#) configuration file. So you should specify:
  - TNSADMIN. The path to the directory in which your `tnsnames.ora` file is located.
  - TNS name. If in your `tnsnames.ora` file, there is more than one `net_service_name` , specify the one that should be used.

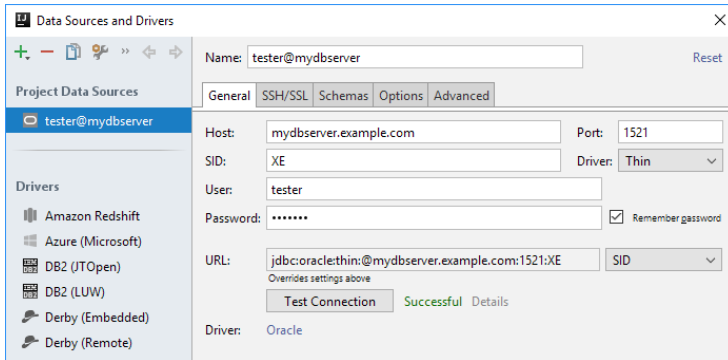

The rest of the settings are:

- Driver. The default Thin driver will do in most of the cases. For more info, see [Oracle JDBC FAQ](#) .
- User and Password. These are your database user name and password.

5. If necessary, edit the data source name.

6. To connect via SSH, [specify the SSH proxy settings](#) .

7. To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

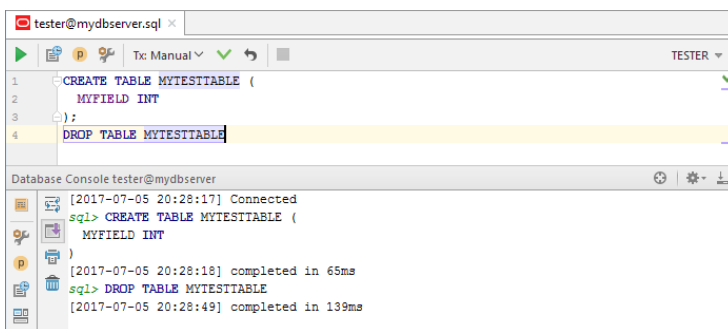

8. Type your query, e.g.

```
CREATE TABLE MYTESTTABLE (
  MYFIELD INT
);
```

9. Execute the query: or `Ctrl+Enter` .

10. If necessary, execute another query, e.g.

```
DROP TABLE MYTESTTABLE
```

## Amazon Redshift

1. Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.

2. Click and select Amazon Redshift .

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

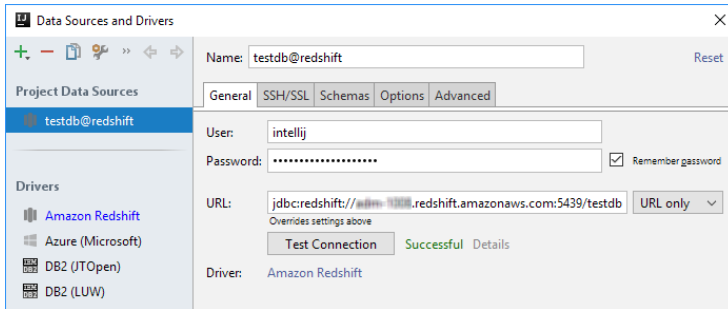

4. To the right of the URL field, select URL only .

5. Go to your Redshift Dashboard, select Clusters , select the cluster you want to connect to, and copy the JDBC URL listed under Cluster Database Properties onto the clipboard.

6. Paste the URL into the URL field.

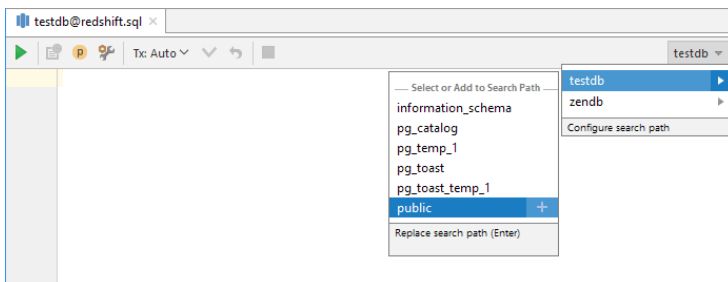

- Specify your user name and password.
- If necessary, edit the data source name.
- To connect via SSH, [specify the SSH proxy settings](#) .
- To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

- If necessary, form the schema search path using the popup in the upper-right part of the console. For instructions, see [Controlling the schema search path for PostgreSQL and Redshift](#) .

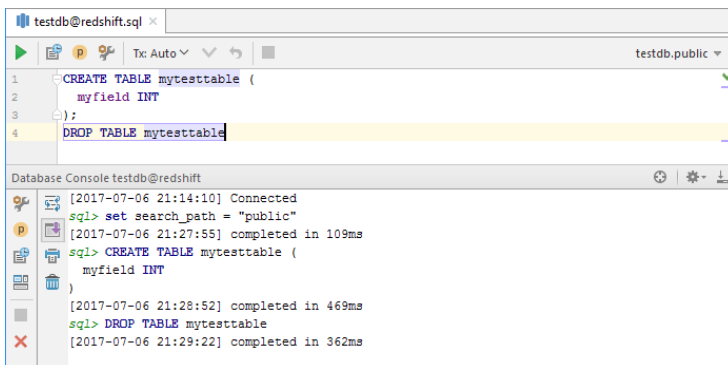

- Type your query, e.g.

```
CREATE TABLE mytesttable (
  myfield INT
);
```

- Execute the query: or `Ctrl+Enter` .

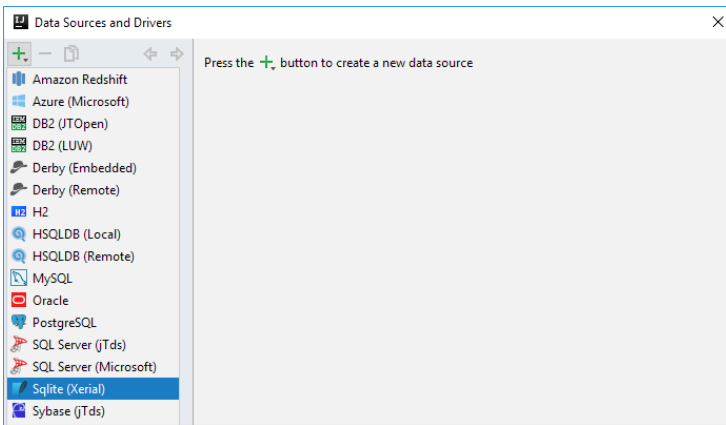

- If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

## SQLite

- Open the Database tool window (e.g. View | Tool Windows | Database ) and click to open the Data Sources and Drivers dialog.
- Click and select SQLite .

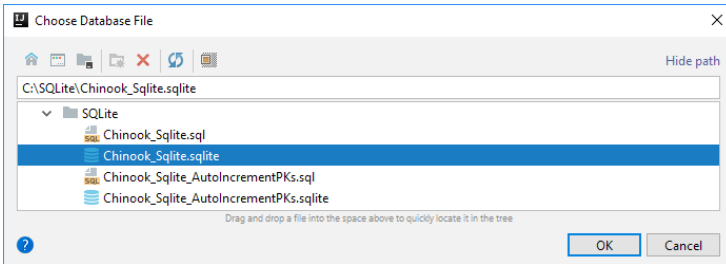

3. In the lower part of the dialog, within Download missing driver files , click the Download link.

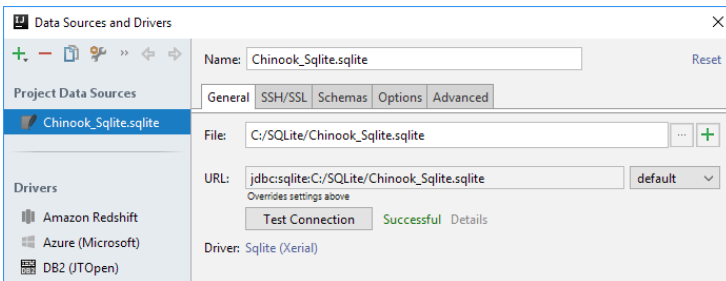

4. To create a new database, specify its name in the File field (e.g. mynewdb.sqlite ) and click + .

To use an existing database, click  and select the database file in the dialog that opens.

5. To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

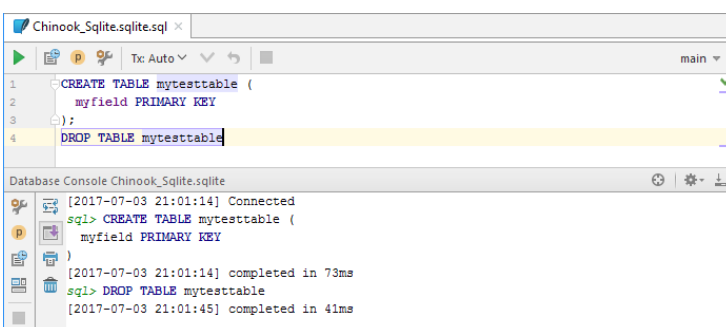

6. Type your query, e.g.

```
CREATE TABLE mytesttable (
  myfield PRIMARY KEY
);
```

7. Execute the query:  or **Ctrl+Enter** .

8. If necessary, execute another query, e.g.

```
DROP TABLE mytesttable
```

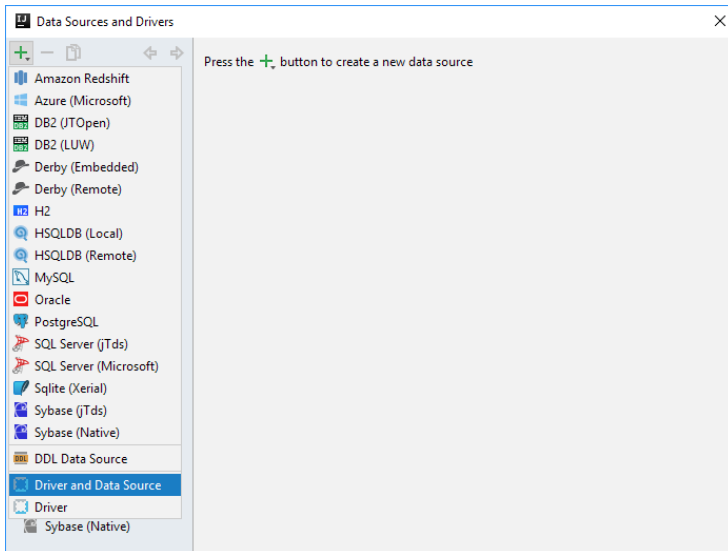

## Vertica as an example of 'unsupported' DBMS

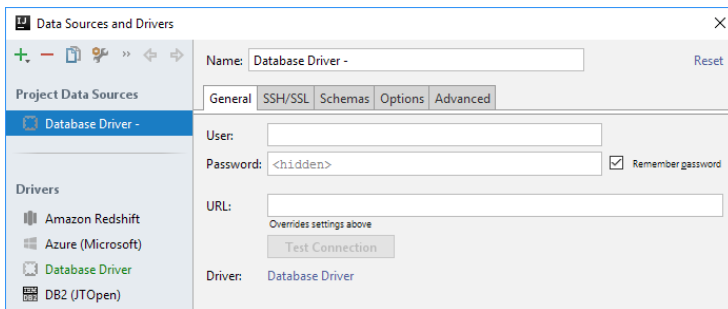

An "unsupported" DBMS is one that is not present in the list of database management systems, when you click **+** in the Data Sources and Drivers dialog. You can still connect to such a database if there is a JDBC driver for it.

In this section, we provide corresponding how-to instructions using [Vertica](#) as an example.

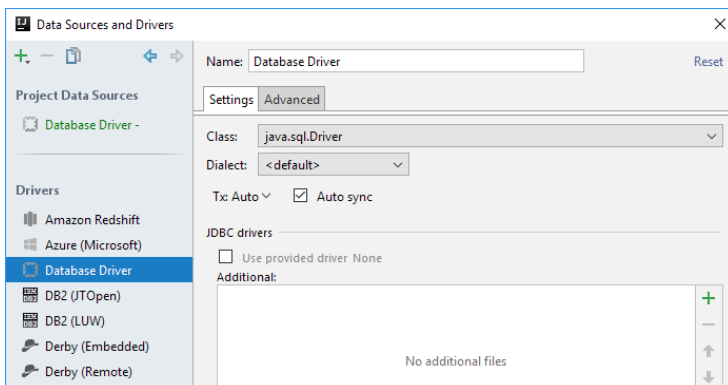

1. Download a JDBC driver for the DBMS that you are going to connect to. A driver, usually, is one or more `.jar` files.
2. Open the Database tool window (e.g. View | Tool Windows | Database ) and click **+** to open the Data Sources and Drivers dialog.
3. Click **+** and select Driver and Data Source .

Your data source settings, initially, look something like this:

4. To the right of Driver , click the Database Driver link.  
Now we are going to specify the driver.

5. In the JDBC drivers section, click **+** and select your driver file or files in the dialog that opens.

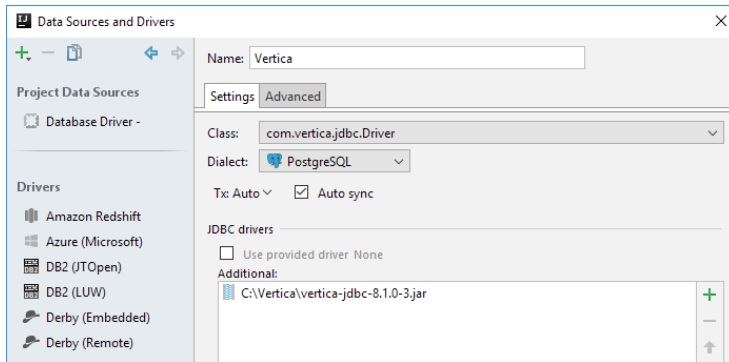

6. Specify:
  - Name. Change the default name, for example, to the name of your DBMS.
  - Class. Usually, this is something like

`com.<company_name>.jdbc.Driver` e.g.

`com.vertica.jdbc.Driver`

– Dialect. Select the dialect which is the closest to your DBMS SQL dialect.

7. Click Apply, and select your data source under Project Data Sources .

8. Specify:

– URL. Your database connection URL. For corresponding info, refer to your DBMS documentation. Usually, this is something like

`jdbc:<dbms_name>://<host>:<port>/<db_name>` e.g.

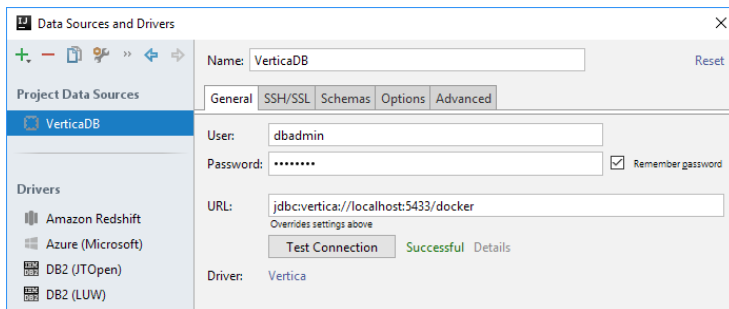

`jdbc:vertica://localhost:5433/docker`

– User and Password . These are your database user name and password.

If necessary, edit the data source name.

9. To connect via SSH, [specify the SSH proxy settings](#) .

0. To make sure that the settings are OK, click Test Connection .

Click OK .

Now, as a final check, execute a couple of queries.

1. Type your query, e.g.

```
CREATE SCHEMA myschema;
```

2. Execute the query:  or `Ctrl+Enter` .

3. If necessary, execute another query, e.g.

```
DROP SCHEMA myschema
```

## Connecting via SSH

To access your database via [SSH](#) , specify the settings for your SSH proxy server on the SSH/SSL tab.

1. Select the Use SSH tunnel checkbox.

2. Specify the settings:

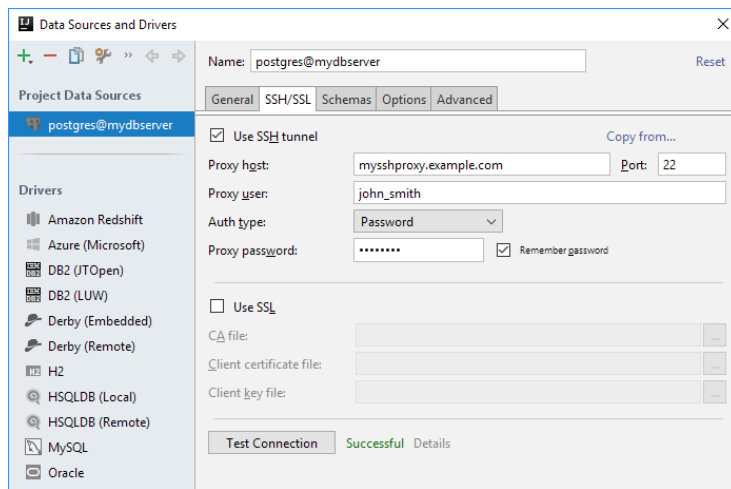

– Proxy host. `localhost` if the server is on the same computer. Otherwise, the [FQDN](#) or [IP address](#) of the server host, e.g. `mysshproxy.example.com` or `172.20.241.34` . The server host must be accessible by the specified name or IP address from your local computer.

– Port. The SSH port; the default port is `22` .

– Proxy user. Your SSH server user name.

- Auth type. The authentication type used by your server:
  - Password. Password-based authentication. If this authentication type is used, you should specify your password.
  - Key pair (OpenSSH). Key-based authentication. If this authentication type is used, you should specify:
    - The location of your private key file.
    - The passphrase for the private key - if the key is locked with the passphrase.

3. To make sure that the settings - ones for the database and the proxy server - are all OK, click Test Connection .

This feature is only supported in the Ultimate edition.

## About data sources

To be able to work with your databases in IntelliJ IDEA, you should define them as data sources. See [Connecting to a database](#).

In addition to data sources that correspond to real databases (DB data sources), IntelliJ IDEA also supports DDL data sources. These are represented by one or more SQL files containing data definition language statements (SQL DDL statements).

Metaphorically, DDL data sources function as databases without data.

Data sources provide the basis for SQL coding assistance and code validation.

## Creating a DB data source for H2 or SQLite by means of drag and drop

If you have H2 or SQLite database files available locally, you can create DB data sources for them by dragging the files to the Database tool window. The files can be dragged from the Project tool window, or from your file manager (e.g. Explorer or Finder).

1. If the database files are in your project folder, open the Project tool window. Otherwise, open your file manager.
2. [Open the Database tool window](#).
3. Select the file or files of interest in the Project tool window, or in your file manager.
4. Drag the selected file or files into the Database tool window. (For each of the files a separate data source will be created.)

5. If you don't have the necessary database driver files yet, you can download them now. Click  on the toolbar of the Database tool window. (Alternatively, select Properties from the context menu.)
6. In the Data Sources and Drivers dialog that opens, within the line Download missing driver files, click the Download link.
7. Click Test Connection to make sure that IntelliJ IDEA can properly communicate with the database.
8. Click OK in the Data Sources and Drivers dialog.

## Creating DB data sources by importing connection settings

XML files that contain database connection settings can be used for creating DB data sources. These may be Spring, Hibernate, JPA and Tomcat `context.xml` configuration files.

1. If the files that you want to import the settings from are not in your project yet, copy them there.
2. [Open the Database tool window](#).
3. Do one of the following:
  - Click  on the toolbar and select Import from sources.
  - Right-click the area under the toolbar or any of the existing data sources, point to New and click Import from sources.

The Data Sources and Drivers dialog opens. The names of candidate data sources are shown in the left-hand pane in green.

4. Specify the driver files if they are missing.  
Do one of the following:
  - To download the necessary driver, click the Download link.
  - To specify the driver files that you already have available on your computer, click the `<DriverName>` link to the right of Driver.  
On the page where the driver settings are shown, under JDBC drivers / Additional, click  and select the files in the dialog that opens.

Go back to the page with the data source settings.

5. Click Test Connection to make sure that IntelliJ IDEA can properly communicate with the database.
6. Click OK in the Data Sources and Drivers dialog.

## Creating a DDL data source

1. [Open the Database tool window](#) and click  on the toolbar.
2. In the Data Sources and Drivers dialog that opens, click  and select DDL Data Source.
3. In the Name field, if necessary, edit the name of the data source.
4. Under DDL Files, click  and select the necessary SQL file or files in the dialog that opens.
5. From the Extend list, if necessary, select another data source as a parent. As a result, the data source whose properties you are editing will "inherit" all the DDL definitions from its parent.
6. Click OK to save the settings and close the dialog.

## Creating a DDL data source by means of drag and drop

You can create DDL data sources by dragging DDL SQL files to the Database tool window. The files can be dragged from the Project tool window, or from your file manager (e.g. Explorer or Finder).

1. If the necessary DDL SQL files are in your project folder, open the Project tool window. Otherwise, open your file manager.
2. [Open the Database tool window](#) .
3. Select the file or files of interest in the Project tool window, or in your file manager.
4. Drag the selected file or files into the Database tool window. For a new data source to be created, the red border, when dropping the file or files, should surround most of the window area (rather than one of the existing data sources).

## Changing data source settings

1. [Open the Database tool window](#) and select the data source of interest.
2. Do one of the following:
  - Click  on the toolbar.
  - Select Properties from the context menu.
  - Press `Alt+Enter` .
3. In the Data Sources and Drivers dialog that opens, edit the settings as necessary. See:
  - [DB data source settings](#)
  - [DDL data source settings](#)

## Making a DB data source available in all your projects

When a DB data source is created, it's assigned to a project. That is, by default, it's available only in the project in which it was defined.

If you want to make a data source available in all your projects, you should make it global:

1. Open the Data Sources and Drivers dialog (e.g. `Alt+Enter` ) and select the data source of interest.
2. Click  on the toolbar or select Make Global from the context menu.
3. Click Apply or OK .

In a similar way, you can move a global data source to the project level - to make it available only in the current project: use  or Move to Project from the context menu.

Note that the DDL data sources exist only on the project level.

## Grouping data sources

If you have many different databases, you can group data sources in the [Database tool window](#) . For this, select the necessary data source and press `F6` or select Move to Group from the context menu.

From this menu, you can move the data source to an existing group, create a new group for it, or remove it from a group (move it into the root list).

## Removing data sources

To remove unnecessary data sources, you can use the Database tool window or the Data Sources and Drivers dialog.

Using the Database tool window. Select the data sources to be removed and do one of the following:

Press `Alt+Enter`

\_ Press **Delete** .

- Select Delete from the context menu.

- Select Edit | Delete .

Using the Data Sources and Drivers dialog. Select the data sources to be removed and do one of the following:

- Click  on the toolbar.

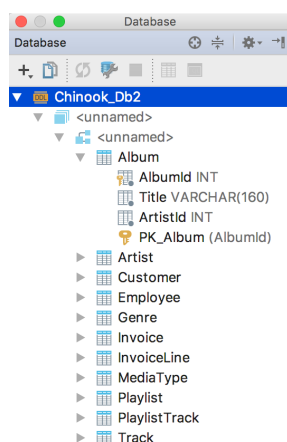

- Press **Delete** .

- Select Remove from the context menu.

This feature is only supported in the Ultimate edition.

## Overview

The Database tool window provides access to functions for working with databases and DDL data sources. It lets you view and modify data structures in your databases, and perform other associated tasks.

## Opening the Database tool window

Do one of the following:

- Select View | Tool Windows | Database .
- Point to  or  in lower-left corner of the workspace, and then click Database .
- Click Database on the right-hand [tool window bar](#) (if the tool window bars are currently shown).

## Creating a data source

To start creating a [data source](#) , you can use the New command when the Database tool window is active, e.g.:

- File | New
-  on the toolbar
- New in the context menu
- 

The DDL Data Source option is for creating a DDL data source. Other data source options correspond to different scenarios of creating a DB data source:

- Data Source. A "usual way" of creating a data source. In this scenario, you start by selecting your DBMS.
- Data Source from URL. In this scenario, you start by specifying your database URL.
- Data Source from Path. In this scenario, you start by specifying your database location (a local file or folder). This option is appropriate only for Derby, H2, HSQLDB and SQLite.
- Import from sources. If you have files that contain database connection settings, you can create data sources by importing those settings. See [Creating DB data sources by importing connection settings](#) .

You can also start creating a data source in the [Data Sources and Drivers dialog](#) . Open the dialog (e.g. ) and use the Add command there: Add from the context menu,  on the toolbar, or  .

For more information, see [Managing data sources](#) .

## Synchronizing the view of a DB data source

If the [Auto sync option](#) for a DB data source is off, the only way to synchronize its view in the Database tool window with the actual state of the database is by using the Synchronize command.

1. Select the item whose view you want to synchronize. This may be a DB data source, schema or table.
2. Do one of the following:
  - Press  .
  - Click  on the toolbar.
  - Select Synchronize from the context menu.

## Resolving visualization problems

If what you see in the Database tool window is somewhat problematic (e.g. no data structures are shown, the objects below the schema level are missing, etc.), try the following to resolve the problem:

1. [Synchronize the view of your data source](#) ().
2. Make sure that at least one of the available schemas is selected for viewing: check the Schemas popup. See [Showing and hiding schemas](#) .
3. Switch to using the JDBC-based introspector:  | Options , select the [Introspect using JDBC metadata](#) checkbox. Then synchronize the view.
4. Clear the IntelliJ IDEA schema cache ([Database Tools](#) | [Forget Cached Schema](#) from the context menu for the data source) and then synchronize the view.

## Adjusting the view by means of view options

You can adjust the view in the tool window by turning the corresponding view options on and off. To access those options, click  on the title bar.

For more information, see [View options](#).

## Adjusting the view by means of object filters

You can limit the set of tables and other database objects shown in the Database tool window by specifying object filters. The object filter is set for each DB data source individually, in the Data Sources and Drivers dialog () , on the Options tab. The object filter syntax is described underneath the Object filter field.

Filter examples

`f.*` Only the objects whose names start with `f` will be shown.

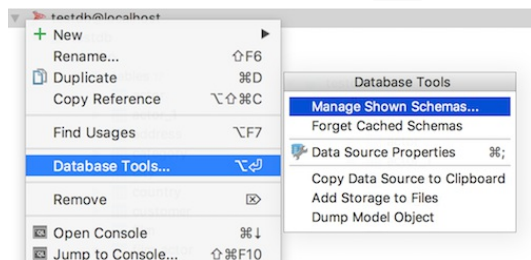

`table:[gh].*` The tables whose names start with `g` or `h` and all the objects in other categories will be shown.

`view:new_.*||routine:-[ps].*` The views whose names start with `new_`, the routines whose names start with the letters other than `p` or `s`, and all the objects in the categories other than views and routines will be shown.

## Showing and hiding schemas

To show or hide schemas:

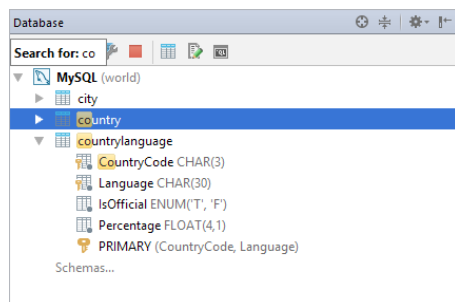

1. Right-click any element within the corresponding data source, point to Database Tools and select Manage Shown Schemas.)
2. Select the schemas you want to show and press `Enter`.

To hide schemas, use the Schemas popup or the Database Tools | Hide Schemas context menu command.

## Finding items

To find an item of interest, simply start typing its name. The specified text within item names is highlighted, and the first of the items that contains the specified text is selected.

## Finding usages of database objects

You can search for usages of database objects in your files and consoles, and also in the source code of other objects (if loaded, see [Load sources for](#)). For example, you can look for references to a table or view in the code of other views, stored procedures and functions.

1. Select the item of interest.
2. Do one of the following:
  - Press `Alt+F7`.
  - Select Find Usages from the context menu.
  - Select Edit | Find | Find Usages in the main menu.

## Creating a copy of a data source

1. Select the data source of interest.
2. Do one of the following:
  - Click  on the toolbar.
  - Select Duplicate from the context menu.
  - Press `Ctrl+D`.

## Creating a database or schema

1. Select any element within the DB data source of interest.
2. Do one of the following:
  - Select File | New | Schema or File | New | Database .
  - Click  and select Schema or Database .
  - In the context menu, select New | Schema or New | Database .
  - Press  and select Schema or Database .
3. In the dialog that opens, specify the name of the schema or database. If necessary, under SQL Script , edit the statement to be executed. Click Execute .
4. If you have created a PostgreSQL database and want to see it in the Database tool window, [create a data source](#) for that database.

See also, [Track creation and deletion of databases/schemas](#) .

## Creating a table, a column, an index, or a primary or foreign key

1. Depending on what you are going to create:
  - To create a table, select a schema, table or column within the target DB data source.
  - To create a column, select the target table or a column within that table.
  - To create an index, or a primary or foreign key, select the column or columns for which you want to create an index, or a primary or foreign key constraint.
2. Carry out the New command and select the item to be created. E.g. for a table, do one of the following:
  - Select File | New | Table .
  - Click  and select Table .
  - In the context menu, select New | Table .
  - Press  and select Table .
3. In the [dialog that opens](#) , specify the item definition.

## Modifying templates for generated index and key names

When you [create indexes, and primary and foreign key constraints](#) , their default names are generated according to corresponding templates. For a primary key, for example, the template is `{table}_{columns}_pk` .

You can view and modify these templates in the Settings / Preferences dialog:  | Editor | Code Style | SQL | Code Generation .

The templates can contain variables (e.g. `{table}` ) and text. When generating a name, the specified text is reproduced literally.

To get the info about the variables and how you should use them, place the cursor into the field of interest and press  .

`{columns}` and `{ref_columns}` , depending on the situation, are the name of the column, or a list where the column names are separated with the underscore (`_`).

`{unique?u:}` checks if the index is unique ( `unique?` ), and, if it is, inserts the sequence of characters specified between `?` and `:` (in this example, it's `u` ). If the index is not unique, the sequence between `:` and `}` is inserted (in this example, it's nothing).

Example. Using the template `{table}_{columns}_{unique?u:}index` , you are creating an index on the columns `FirstName` and `LastName` in the table `persons` . If the index is unique, its name, by default, will be `persons_FirstName_LastName_uindex` . If the index is not unique, its name will be `persons_FirstName_LastName_index` .

## Viewing basic info about an item

You can view basic info about an item in the quick documentation view. For a table, for example, the first ten rows and the table definition (the `CREATE TABLE` statement) are shown.

To open the quick documentation view, select the item of interest and do one of the following:

- Select View | Quick Documentation .
- Press  .

See also, [Show first rows](#) .

## Renaming items

1. Select the item to be renamed.
2. Do one of the following:
  - Select Refactor | Rename .
  - Select Rename from the context menu.
  - Press  .
3. Use the [dialog that opens](#) to specify a new name and associated options.

## Previewing changes

Changes to database objects sometimes assume associated changes to SQL script files and statements in database consoles. For example, you may be changing the name of a table, and this name may be used in your files and consoles.

In such cases, you can look at potential changes, and decide where those changes are desirable and where aren't.

Potentially affected code fragments are shown in the [Find tool window](#) when you click Preview in the corresponding dialogs. Here is an overview of some of the available controls:

- Exclude ([Delete](#)) and Remove ([Alt+Delete](#)). Use these context menu commands for the items that shouldn't be changed.
- Execute SQL Script. If this option is on, and you click Do Refactor, the corresponding SQL statements are run to modify the corresponding database objects.
- Open in Console. Use this button to open the corresponding SQL statements in a [database console](#).
- Do Refactor. Click this button to change the corresponding code fragments and, if the Execute SQL Script option is on, to run the corresponding SQL statements.

## Modifying the definition of a table, column, index, or a primary or foreign key

1. Select the item whose definition you want to change. This may be a table, a column, an index, or a primary or foreign key.
2. Do one of the following:
  - Select Modify <item\_type> from the context menu (e.g. Modify Table).
  - Press [Ctrl+F6](#).
3. Use the [dialog that opens](#) to change the item definition.

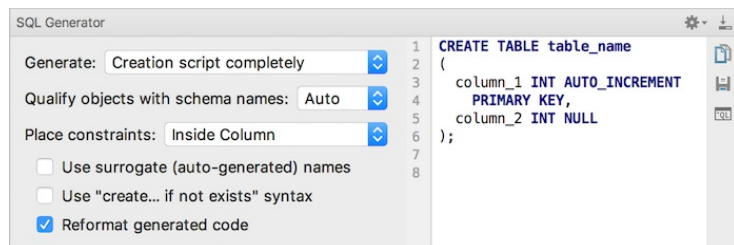

## Opening DDL definitions of database objects in the editor

1. Select the object whose definition you want to view or edit.
2. Do one of the following:
  - Click [DDL](#) on the toolbar.
  - Press [Ctrl+B](#).
  - Select Source Editor under SQL Scripts in the context menu.

## Generating DDL definitions

You can generate DDL for any object or several objects (table, schema, procedure, and so on). To open the SQL Generator tool window, select the object or objects in the Database tree, open the context menu and select SQL Generator under SQL Scripts.

In the SQL Generator window you can configure the output, copy it to clipboard, save it to file, or open it in a database console.

## Opening DDL definitions in a database console

You can open DDL definitions of tables and views in [database consoles](#).

1. In a DB data source, select the table or view of interest.
2. Do one of the following:
  - Select Generate DDL to Console under SQL Scripts in the context menu.
  - Press [Shift+F4](#).

## Generating DDL definitions on the clipboard

1. Select the item or items of interest. These may be data sources, schemas, tables, views, stored procedures or functions, etc.
2. Do one of the following:
  - Select Generate DDL to Clipboard under SQL Scripts in the context menu.
  - Press [Ctrl+Shift+C](#).

Now you can paste the definitions into a [database console](#) or an SQL file.

## Comparing table structures

1. Select two data sources, schemas or tables.
2. Do one of the following:
  - Select Compare from the context menu.

- Press **Ctrl+D** .

The comparison results are shown in the differences viewer.

## Viewing diagrams

To open a diagram for a data source, schema or table, select the item of interest and do one of the following:

- Press **Ctrl+Shift+Alt+U** or **Ctrl+Alt+U** .
- In the context menu, select **Diagrams** , and then select **Show Visualisation** or **Show Visualisation Popup** .

## Copying a table to another database or schema

You can copy (export) a table along with all its data to another schema or database. This is possible even when the source and target databases belong to different DBMSs, e.g. PostgreSQL and MySQL.

To copy a table:

1. Drag the table to the destination schema or database.
2. In the [dialog that opens](#) , specify the settings for your new table.

## Importing delimiter-separated values into a database

To import a text file containing delimiter-separated values (CSV, TSV, etc.) into your database, use drag-and-drop or the **Import from File** context menu command.

If you drag a file into a schema (or carry out the **Import from File** command for a schema), IntelliJ IDEA will create a new table for the data that you are importing. If you drag a file into an existing table (or perform the command for a table), IntelliJ IDEA will try to add the data to that table.

1. Do one of the following:
  - Drag a file from the Project tool window (the file may be a .zip archive) onto a schema or table in the Database tool window.
  - Right-click the target schema or table in the Database tool window, select **Import from File** and then select the file to import the data from (this file may be a .zip archive).
2. In the [dialog that opens](#) , specify the data conversion settings, and, if a new table is to be created, the table name and structure.

## Opening the data editor

1. Select the table of interest.
2. Do one of the following:
  - Click  on the toolbar.
  - Select **Open Editor** from the context menu.
  - Press **F4** .

For more information, see [Working with the data editor](#) .

## Copying data from one table to another one

1. Drag the source table to the destination table.
2. In the [dialog that opens](#) , specify the data mapping info and other settings for the destination table.

## Saving data in files in various forms and formats

You can save database data in files as SQL **INSERT** and **UPDATE** statements, [TSV and CSV](#) , HTML tables and [JSON](#) data. A separate file is created for each individual table or view.

1. Select the data source or the schemas, tables and views of interest.
2. In the context menu, point to **Dump Data to File(s)** and select the output format (e.g. **Comma Separated Values (CSV)** ).
3. In the dialog that opens, specify the destination directory and, if a single file is going to be created, the file name.

## Configuring data output formats and options

To configure the output formats for the **Dump Data to File(s)** command (see [Saving data in files in various forms and formats](#) ), select one of the following from the menu associated with the command:

- **Configure CSV Formats**. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- **Go to Scripts Directory**. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

For SQL INSERTs and UPDATEs, there are additional options: **Add Table Definition** and **Skip Generated Columns**. Those can be set in a data editor or the result pane of a database console. See e.g. [Specifying data output format and options](#) .

## Creating database backups with mysqldump or pg\_dump

You can create backups for database objects by running [mysqldump](#) for MySQL or [pg\\_dump](#) for PostgreSQL.

1. Within a MySQL or PostgreSQL data source, select the items of interest (e.g. schemas, tables and views).

2. From the context menu, select Dump with "mysqldump" or Dump with "pg\_dump" .
3. In the dialog that opens, specify the location of `mysqldump` or `pg_dump` executable, and the settings for performing the dump. If necessary, edit the command-line options in the lower part of the dialog (autocompletion is available).

## Restoring data dumps with mysql, pg\_restore or psql

You can restore [data dumps](#) by means of the `mysql` client utility for MySQL, or `pg_restore` or `psql` for PostgreSQL.

1. Select the target MySQL or PostgreSQL data source, database or schema. For PostgreSQL, you can also select a table.
2. From the context menu, select Restore with "mysql" , Restore with "psql" or Restore .
3. In the dialog that opens, specify the location of the utility executable, the options for restoring the data, and the path to the dump file. If necessary, edit the command-line options in the lower part of the dialog (autocompletion is available).

## Opening a default database console

1. Select the DB data source of interest or any node within it.
2. Do one of the following:
  - Click  on the toolbar.
  - Select Open Console from the context menu.
  - Press `Ctrl+Shift+F10` .

For more information, see [Working with database consoles](#) .

## Creating and opening a new database console

1. Select the DB data source of interest or any node within it.
2. Do one of the following:
  - Select Open New Console from the context menu.
  - Click  and select Console File .

For more information, see [Working with database consoles](#) .

## Generating Java entity classes for tables and views

1. Select the tables and views of interest.
2. In the context menu, point to Scripted Extensions and click Generate POJOs.cj or Generate POJOs.groovy .
3. In the dialog that opens, specify the directory in which you want to create your `.java` class files.

## Closing database connections

IntelliJ IDEA connects to databases automatically, when needed. (The names of the data sources with open database connections are shown in the Database tool window in bold.)

To close unnecessary database connections, select the corresponding data sources and do one of the following:

- Click  on the toolbar.
- Select Disconnect from the context menu.
- Press `Ctrl+F2` .

## Removing items

Depending on what you are going to remove:

- Data source. Use the Remove command ( `Edit | Remove` , Remove from the context menu, or `Delete` on the keyboard).
- Schema, table, column, index, a primary or foreign key constraint, stored procedure or function, etc. Use the Drop command ( `Edit | Drop` , Drop from the context menu, or `Delete` on the keyboard).
- Primary or foreign key constraint. For removing primary and foreign key constraints, in addition to Drop , there are the following context menu commands: Database Tools | Drop Primary Key and Database Tools | Drop Foreign Key . Note that the Drop Foreign Key command is available only when a column with the corresponding foreign key constraint is selected ().
- All rows in a table. Use the Database Tools | Truncate context menu command for the corresponding table.

See also, [Confirm Drop dialog](#) .

This feature is only supported in the Ultimate edition.

Database consoles let you compose and execute SQL statements for databases defined in IntelliJ IDEA as data sources. They also let you analyze and modify the retrieved data.

The following standardized and DBMS vendor-specific SQL dialects are supported: DB2, Derby, H2, HSQLDB, MySQL, Oracle, Oracle SQL\*Plus, PostgreSQL, SQL Server, SQL92, SQLite, and Sybase.

One database console is created for a data source automatically when a data source is created. If necessary, you can create additional consoles.

Database consoles are persistent: they are stored as SQL files.

A database console created in one of your projects can then be accessed from any other project.

## Creating a database console

When you create a DB data source, one database console for that data source is created automatically. If necessary, you can create additional consoles.

To create a database console, you can use the [Database tool window](#) or the [Scratches view](#) of the [Project tool window](#). The procedure is the same in both cases:

Select the data source of interest or any node within it, and do one of the following:

- Select File | New | Console File from the main menu.
- Select New | Console File from the context menu
- Press **Alt+Insert** and select Console File .

In the Database tool window, you can also use **+ | Console File** and the Open New Console context menu command.

## Opening a database console

You can jump to the default console or any custom console that you created from the [Database tool window](#). Select a data source in the list and do one of the following:

- Click  on the title bar if the toolbar is hidden.
- Click  on the toolbar if the toolbar is shown.
- Select Open Console from the context menu to open the default console for this source. Or press **F4** .
- Select Jump to Console from the context menu to choose any console for this source. Or press **Ctrl+Shift+F10** .

You can also open any console in [Scratches view](#) of the [Project tool window](#). Select the console and do one of the following:

- Double-click the console.
- Select View | Jump to Source from the main menu.
- Select Jump to Source from the context menu.
- Press **F4** .

## Viewing and modifying console settings

Before actually starting to use a console, you may want to take a look at the console settings and adjust them to your needs.

- To access these settings, click  on the toolbar of the input pane or on the toolbar of the Database Console tool window. (Alternatively, **Ctrl+Alt+S** | Tools | Database .)

As a result, the [Database page](#) of the Settings / Preferences dialog will open.

## Changing the SQL dialect

By default, the SQL dialect used in a console is defined by the DBMS of an associated data source. If for some reason you want to use a different dialect:

- Right-click the editing area of the input pane, select Change Dialect (<CurrentDialect>), and select the necessary dialect. In addition to particular dialects, also the following option is available:
  - <Generic SQL>. Basic SQL92-based support is provided including completion and highlighting for SQL keywords, and table and column names. Syntax error highlighting is not available. So all the statements in the input pane are always shown as syntactically correct.

## Closing a console

1. Click  (**Ctrl+Shift+F4**) to close the Database Console tool window.
2. Click  on the editor tab (**Ctrl+F4**) to close the input pane.

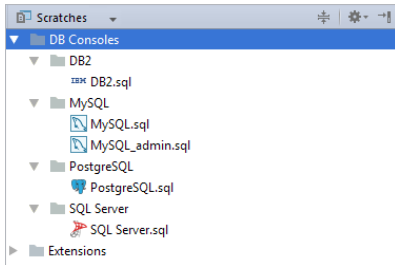

## Managing database consoles

To manage your database consoles, use the [Scratches view](#) of the [Project tool window](#).

To open this view, select Scratches from the list in the left-hand part of the title bar.

The view shows the existing database consoles (represented by SQL files) grouped by your data sources (shown as folders). The default consoles (the ones that were created by IntelliJ IDEA automatically) have the same names as the corresponding data sources.

You can:

- Create new consoles. Select the target data source or a node within it, and do one of the following:
  - Select File | New | Console File from the main menu.
  - Select New | Console File from the context menu
  - Press **Alt+Insert** and select Console File .
- Rename your consoles. When a new console is created, it has the name of the data source with a number at the end, e.g. `MySQL_1` . If you want to give a console a more descriptive name, select the console and do one of the following:
  - Select Refactor | Rename from the main or the context menu.
  - Press **Shift+F6** .

Then, specify a new name in the dialog that opens.

- Save your console files in arbitrary directories. Select the console and then choose Refactor | Copy (**F5**) . Specify the file name and location in the dialog that opens.
- Group your consoles. This is done by creating folders and then dragging your consoles into those folders.
- Open your consoles. Select the consoles of interest and do one of the following:
  - Select View | Jump to Source from the main menu.
  - Select Jump to Source from the context menu.
  - Press **F4** .
- View the history of changes for your consoles. Select File | Local History | Show History from the main menu or Local History | Show History from the context menu.
- Delete individual consoles and groups of consoles. Use Edit | Delete , Delete from the context menu or **Delete** on the keyboard.

## Selecting the default schema or database

You can select the default schema or database by using the list in the right-hand part of the toolbar. If you do so, you'll be able to omit the name of that schema or database in your statements.

See also, [Controlling the schema search path for PostgreSQL and Redshift](#).

## Controlling the schema search path for PostgreSQL and Redshift

When working with a PostgreSQL or Redshift data source, the default search path (one set in a database) is used unless you specify a different search path.

To control the search path, use the popup in the right-hand part of the toolbar. The popup also lets you switch your databases.

To select a database or set the default search path for it, click the database or press `Enter`.

To change the search path for the current database, open the schema list.

If the search path should include only one schema, click the necessary schema. In the same way you can replace a schema with another one in a single-schema search path.

To form a search path that includes two or more schemas, use:

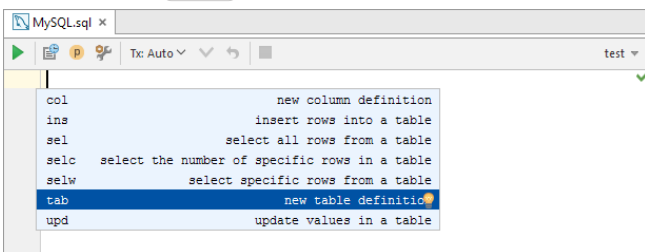

- `Space` to add a highlighted schema to the search path and also to remove a schema from the search path.
- `Alt+Up` and `Alt+Down` to reorder the schemas within the search path.
- OK to apply the changes.

More instructions and usage hints are available right in the popup.

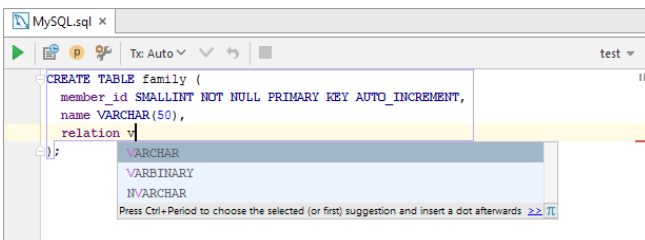

## Composing SQL statements

When composing your SQL statements, use:

- Predefined patterns (`Ctrl+J` or Code | Insert Live Template).

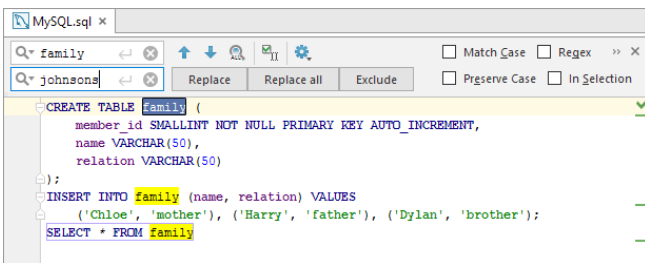

- Auto-completion and highlighting of SQL keywords, and table and column names.

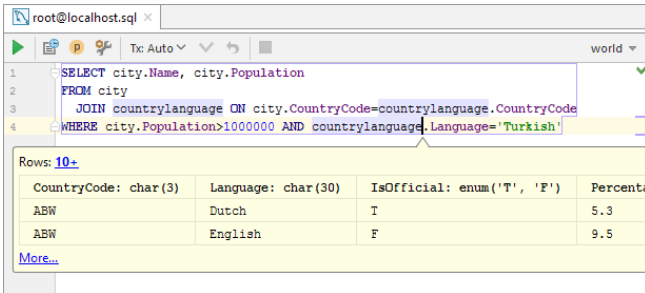

- Data type prompts for columns (`Ctrl+P` or View | Parameter Info).

- Advanced find and replace capabilities (`Ctrl+F` or Edit | Find | Find, and `Ctrl+R` or Edit | Find | Replace).

- Quick evaluations (`Ctrl+Alt+F8`). They are available for table and column names, and SQL keywords, and give you hints about the data and potential result when you compose your statements.

- The console history (`Ctrl+Alt+E`). See [Executing auto-memorized statements](#).

See also, [Navigating to a table or column view in the Database tool window](#).

## Editing data for INSERT statements in table format

1. Select the `INSERT` statement of interest.
2. Select Edit as Table from the context menu.

3. Use context menu commands and associated shortcuts for working with the data.

## Navigating to a table or column view in the Database tool window

When composing a statement, it's sometimes useful to take a look at the structure of a table, or to see the info about a column (field) in the context of the table to which it belongs. For such purposes, IntelliJ IDEA provides the ability to switch from the name of a table or column in the input pane to its view in the Database tool window.

The following ways are available for using this feature:

- Place the cursor within the name of the table or column of interest. Then use `Ctrl+B`. (Alternatively, you can use `Navigate | Declaration` from the main menu or `Go To | Declaration` from the context menu.)
- Press and hold the `Ctrl` key, and point to the name of interest. When the text turns into a hyperlink, click the hyperlink.

## Configuring the Execute command

The Execute command (`Ctrl+Enter` or Execute from the context menu) is used to run your statements.

IntelliJ IDEA provides many options for the Execute command depending on the cursor position and on whether there is a selection.

The options are specified on the `Tools | Database` page in the Settings / Preferences dialog (`File | Settings | Tools | Database on Windows and Linux; IntelliJ IDEA | Preferences | Tools | Database on macOS`). For more information, see [Execute in Console](#).

## Executing an SQL statement

1. Place the cursor within the statement.
2. Do one of the following:
  - Click  on the toolbar.
  - Press `Ctrl+Enter`.
  - Select Execute from the context menu.
3. Select the statement or statements to be run. (The suggestion list always contains an item for running all the statements.)

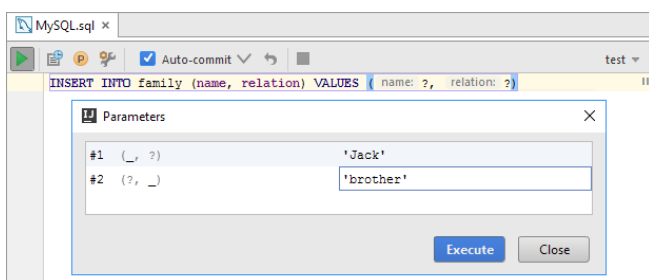

See also, [Execute in Console](#).

## Executing parameterized statements

Your statements can contain parameters, however, by the time you execute such statements the values of the parameters must be specified. There are the following ways of specifying the parameter values:

- Click  on the toolbar or press `Ctrl+Enter` to execute the statement. In the dialog that opens, specify the parameter values and click OK.

( To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press `Enter` or switch to a different cell. To quit the editing mode and restore an initial value, press `Escape` . )

- Alternatively, you can open the Parameters pane in the Database Console tool window ( on the toolbar) and specify the corresponding values there. (The values are edited in the same way as in the corresponding dialog.) Then execute the statement ( on the toolbar or `Ctrl+Enter` ).

For more information, see [Parameters pane](#).

See also, [User Parameters](#) and [Always review parameters before execution](#).

## Executing a group of statements

To execute a group of statements that follow one another in the console, select (highlight) the statements (to select all the statements, use `Ctrl+A`) and do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Enter`.
- Select Execute from the context menu.

See also, [Using the error notification bar](#) and [Execute in Console](#).

## Executing all statements

To execute all the statements contained in a console, as an alternative to the Execute command, you can use the Run console.sql command.

This command is available in the context menu, and its keyboard equivalent is `Ctrl+Shift+F10`.

The Run console.sql command, generally, runs faster but:

- The statements with parameters don't run.
- Retrieved data for the `SELECT` statements are not shown.

## Executing a part of a statement (e.g. a subquery)

To execute a part of a statement (e.g. a subquery), select (highlight) the fragment that you want to execute and do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Enter`.

- Select Execute from the context menu.

See also, [Execute in Console](#) .

## Executing auto-memorized statements

As you run SQL statements in the consoles, IntelliJ IDEA memorizes them. So, at a later time, you can view the statements you have already run and, if necessary, run them again.

To open the dialog where the auto-memorized statements are shown (the History dialog), do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Alt+E` .

There are two panes in the History dialog. The left-hand pane shows the list of the statements that you have run. For "long" statements, only their beginnings are shown. When you select a statement in this pane, the overall statement is shown in the pane to the right.

You can filter the information: just start typing. As a result, only the statements that contain the typed text will be shown.

You can copy the statements from the History dialog into the input pane of the console. To copy a statement, do one of the following:

- Double-click the statement to be copied.
- Select the statement of interest and press `Enter` .
- Select the statement and click OK .

(Once the statement is in the input pane, you can run it straight away.)

You can delete unnecessary memorized statements. To delete a statement, select the statement in the History dialog and press `Delete` .

## Outputting the result of a SELECT statement into a file

Instead of the Result pane of the Database Console tool window, you can output the result of a `SELECT` statement into a file.

1. Right-click the `SELECT` statement of interest.
2. Point to Execute to File and select the output format.
3. Specify the output file location and name.

## Using the error notification bar

If when running a statement an error occurs, an error notification bar appears in the lower part of the input pane.

This bar may be particularly useful when executing a sequence of statements (see [Executing a group of statements](#) ) because in such a case it lets you select how to react.

The options are:

- Retry. Execute the sequence of statements starting from the one that caused the error.
- Ignore. Skip the erroneous statement and execute the sequence starting from the next statement. If another error occurs, the error notification bar will appear again.
- Ignore All. Skip the erroneous statement and execute the sequence starting from the next statement. If other errors occur, all the erroneous statements will be skipped and the error notification bar won't appear for these statements.
- Stop. Stop the execution of the sequence.

Showing the error notification bar in the input pane is enabled or disabled in the Settings dialog (the [Show error notifications in editor](#) checkbox on the [Database page](#) ).

## Canceling running statements

To terminate execution of the current statement or statements, do one of the following:

- Click  on the toolbar of the input pane, or on the toolbar of the Database Console tool window.
- Press `Ctrl+F2` .

## Managing database transactions

You can select to commit transactions automatically or manually. To change the commit mode, use the Tx switch `Tx: Auto` on the toolbar.

If the commit mode is set to Auto , each SQL statement is executed in its own transaction that is implicitly committed. Consequently, the SQL statements executed in this mode cannot be rolled back.

If the commit mode is set to Manual , transactions are committed or rolled back explicitly by means of  or  on the toolbar.

The Tx switch can also be used for selecting the [isolation level](#) for the transactions.

## Showing execution plans

The following context menu commands let you show an [execution plan](#) (a.k.a. explain plan) for a statement:

- Explain Plan. The result is shown in a mixed tree/table format on a dedicated Plan tab.
- Explain Plan (Raw). The result is shown in table format. (Technically, `EXPLAIN <CURRENT_STATEMENT>` or similar statement is executed.)

## Showing DBMS\_OUTPUT for Oracle

For Oracle, you can enable or disable showing the contents of the DBMS\_OUTPUT buffer in the output pane. To do that, use  on the toolbar of the Database Console tool window ( `Ctrl+F8` ).

This feature is only supported in the Ultimate edition.

## Introduction

When you run a query (a `SELECT` statement) in the console, the data retrieved from the database are shown in table format in the Result pane of the Database Console tool window. Depending on the settings, a new Result tab opens for each query, or one and the same tab is used. In the latter case, the results on the tab are updated for each next query.

Use the Result pane to sort, add, edit and remove the data as well as to perform other, associated tasks.

## Hiding or showing the toolbar

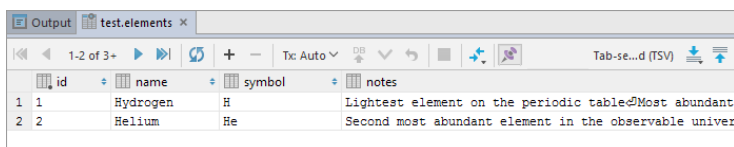

To hide or show the toolbar of the Result pane and also that of the Database Console tool window:

- Click  on the title bar of the Database Console tool window and click Show Toolbar .

## Pinning the Result tab

If one and the same tab is used to show your query results, and you get the result that you want to keep, you can pin the tab to the tool window. Do one of the following:

- Right-click the tab and select Pin Tab .
- Click  on the toolbar.

id	name	symbol	notes
1	Hydrogen	H	Lightest element on the periodic table. Most abundant
2	Helium	He	Second most abundant element in the observable universe

See also, [Show query results in new tab](#) .

## Switching between subsets of rows

If only a subset of the rows that satisfy the query is currently shown, to switch between the subsets, use:

-  First Page
-  Previous Page ( `Ctrl+Alt+Up` )
-  Next Page ( `Ctrl+Alt+Down` )
-  Last Page

See also, [Making all rows visible simultaneously](#) .

## Making all rows visible simultaneously

If you want all the rows that satisfy the query to be shown simultaneously:

1. Click  on the toolbar of the Database Console tool window.
2. Switch to the Database | Data Views page, specify `0` in the Result set page size field, and click OK .
3. Click  or press `Ctrl+F5` to refresh the table view.

See also, [Updating the table view](#) and [Result set page size](#) .

## Navigating to a specified row

To switch to a row with a specified number:

1. Do one of the following:
  - Press `Ctrl+G` .
  - Right-click the table and select Go To | Row from the context menu.
  - Select Navigate | Row from the main menu.
2. In the dialog that opens, specify the row number and click OK .

## Navigating to related records

If a row references a record in a different table or is referenced in a different table, you can switch to the corresponding table to see the related record or records.

To switch to a referenced row:

1. Do one of the following:
  - Press `Ctrl+B` .
  - Select Go To | Referenced Data from the context menu.
2. If more than one record is referenced, select the target record in the pop-up that appears.

To switch to a row that references the current one, or to see all the rows that reference the current one:

1. Do one of the following:
  - Press `Alt+F7` .
  - Select Go To | Referencing Data from the context menu.
2. Select the target in one of the following categories:
  - First Referencing Row. All the rows in the corresponding table will be shown and the first of the rows that references the

current row will be selected.

- All Referencing Rows. Only the rows that reference the current row will be shown.

The options described above can also be accessed by using one of the following:

- **F4** .
- Go To | Related Data in the context menu.
- Navigate | Related Data in the main menu.

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

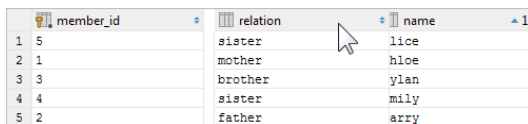

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  .

Finally, when you click the cell for the third time, the initial state is restored. That is, sorting by the corresponding column is canceled:  .

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#) .

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row.

	member_id	relation	name
1	5	sister	lice
2	1	mother	hloe
3	3	brother	ylan
4	4	sister	mily
5	2	father	arry

See also, [Restoring the initial table view](#) .

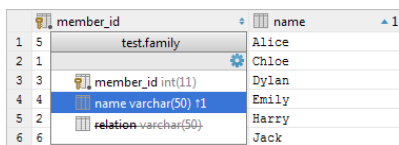

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

To show a hidden column:

1. Do one of the following:
  - Right-click any of the cells in the header row and select Column List .
  - Press **Ctrl+F12** .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name	relation
1	5	Alice	
2	1	Chloe	
3	3	Dylan	
4	4	Emily	
5	2	Harry	
6	6	Jack	

2. Select (highlight) the column name of interest and press **Space** .
3. Press **Enter** or **Escape** to close the list.

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#) .

## Restoring the initial table view

Click  on the toolbar and select Reset View to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the corresponding query, and all the columns are shown.

## Using the Structure view to sort data, and hide and show columns

When working with the Result pane, the table structure view is available as the corresponding popup.

The structure view shows the list of all the columns and lets you sort the data as well as hide and show the columns.

To open the structure popup, do one of the following:

- Right-click a cell in the table header row and select Column List .
- Press **Ctrl+F12** .

In the popup, select the column of interest and do one of the following:

- To sort the data by this column in the ascending order, press **Shift+Alt+Up** .
- To sort the data in the descending order, press **Shift+Alt+Down** .

- To cancel sorting by this column, press `Ctrl+Shift+Alt+Backspace` .
- To hide the column (or show a hidden column), press `Space` . (The names of hidden columns are shown struck through.)

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

The shortcuts for sorting table data (`Shift+Alt+Up` , `Shift+Alt+Down` and `Ctrl+Shift+Alt+Backspace` ) can be used in the Result pane without opening the structure view.

See also, [You can sort table data by any of the columns by clicking the cells in the header row](#) , [Hiding and showing columns](#) and [Restoring the initial table view](#) .

## Using the quick documentation view

The quick documentation view provides details about the values in the selected cell or cells. For example, if a cell contains long text, normally, you can see only its beginning. The whole text is shown in the quick documentation view.

Most abundant pure element on Earth	Most abundant pure element on Earth
Highly reactive nonmetallic element	Highly reactive nonmetallic element
Lightest halogen	Lightest halogen
Colorless, odorless, inert monatomic gas	Third most abundant element in the universe
Soft, silver-white, highly reactive metal	Colorless gas or pale blue liquid
Alkaline earth metal	Extremely reactive
Silvery white soft metal	Highly toxic pale yellow diatomic gas
Crystalline, reflective with bluish-tint	

If a cell contains an image, you can see that image in the quick documentation view.

relation	picture
brother	120x120 PNG image 24.95K
brother	120x120 PNG image 22.32K
cat	120x120 PNG image 25.95K
father	120x120 PNG image 17.65K
mother	120x120 PNG image 27.38K
sister	120x120 PNG image 27.78K

You can also see the records referenced in the current record as well as the records that reference the current one.

first_name	last_name	address_id	email
MARY	SMITH	5	MARY.SMITH@sakilacustomer.org
PATRICIA	JOHNSON	6	PATRICIA.JOHNSON@sakilacustomer.org

Documentation for [1x2]

Transposed View

first_name	last_name
MARY	SMITH

Referenced address:

5	1913 Hanoi Way		Nagasaki	463	35200	2830338429	

If necessary, you can switch to the transposed view. This is when the rows and columns are interchanged. Thus, for a row, the cells are shown one beneath the other.

first_name	last_name	address_id	email
MARY	SMITH	5	MARY.SMITH@sakilacustomer.org
PATRICIA	JOHNSON	6	PATRICIA.JOHNSON@sakilacustomer.org

Documentation for [1x2]

Regular View

Column	1
first_name	MARY
last_name	SMITH
address_id	5
email	MARY.SMITH@sakilacustomer.org

To open the quick documentation view, press `Ctrl+Q` or select Quick Documentation from the View or the context menu.

To switch to the transposed view, click Transposed View . See also, [Transposing the table](#) .

To close the quick documentation view, press `Escape` .

## Transposing the table

The transposed table view is available. In this view, the rows and columns are interchanged.

To turn this view on or off, click  on the toolbar and select Transpose . Alternatively, use the Transpose context menu command.

## Enabling coding assistance for a column

You can assign a column one of the supported languages (e.g. SQL, HTML or XML): right-click the corresponding header cell, select Edit As and select the language. As a result, you get coding assistance for the selected language in all the cells of the corresponding column.

You can also assign a language to an [individual cell](#) .

## Selecting cells and ranges: using unobvious techniques

Adding cells with the same contents. Select a cell. Now, to add the nearest cell with the same contents to the selection, press `Alt+J` . (When looking for the corresponding cell, IntelliJ IDEA moves down.) Each next press of `Alt+J` will add another cell to the selection.

To remove the cells from the selection one by one - starting from the last selected cell - use `Shift+Alt+J` .

If a number of cells in the same row are initially selected, `Alt+J` and `Shift+Alt+J` work the same way.

Expanding a selection: cell - column - row - table. Select a cell. Now, to select all the cells in the current column, press `Ctrl+W` . The second press of `Ctrl+W` cancels the selection of the column and selects all the cells in the current row. Finally, the third press of `Ctrl+W` selects the whole table.

`Ctrl+W` works similarly if a number of cells or a range is initially selected.

## Modifying cell contents

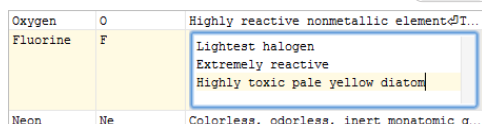

You can modify values in the table cells and, if appropriate, upload files.

1. To start editing a value or uploading a file, do one of the following:

- Double-click the corresponding table cell.
- Right-click the cell and select Edit or Edit Maximized from the context menu.
- Select the cell and press `F2` or `Shift+Enter` . In the latter case, the cell will be maximized.
- Select the cell and start typing. Note that in this case the initial cell contents are deleted right away and is replaced with the typed value.

2. When in the editing mode, you can:

- Modify the value right in the cell. To start a new line, use `Ctrl+Enter` . To enter the value, press `Enter` . To restore an initial value and quit the editing mode, press `Escape` .

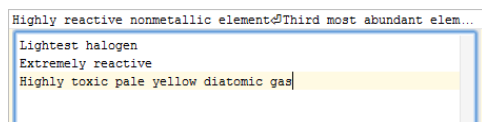

Oxygen	O	Highly reactive nonmetallic element of T...
Fluorine	F	Lightest halogen Extremely reactive Highly toxic pale yellow diatom
Neon	Ne	Colorless, odorless, inert monatomic g...

- Use value completion. Press `Ctrl+Space` to open the suggestion list. The list contains the values from the current column that match your input.

- Maximize the cell if you need more room for editing. To do that, press `Ctrl+Shift+Alt+M` , or right-click the cell and select Maximize .

When working in a maximized cell, use `Enter` to start a new line and `Ctrl+Enter` to enter the value. To restore an initial value and quit the editing mode, press `Escape` .

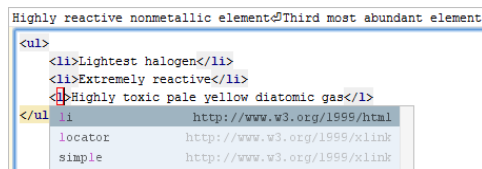

Highly reactive nonmetallic element of Third most abundant elem...
Lightest halogen Extremely reactive Highly toxic pale yellow diatomic gas

- Upload a file into the field (e.g. to replace an existing file with a new one). To do that, right-click the cell and select Load File . Then select the necessary file in the dialog that opens.

If a field can contain text, this function can be used to insert the contents of a text file into the field.

- Replace the current value with the default one or `null` (if appropriate). To do that, right-click the cell and select Set DEFAULT or Set NULL .
- Edit a value in the cell as a fragment in one of the supported languages (e.g. SQL, HTML or XML). To do that, right-click the cell, select Edit As and select the language. As a result, you get coding assistance for the language you have selected.

Highly reactive nonmetallic element of Third most abundant element
<ul> <li>Lightest halogen</li> <li>Extremely reactive</li> <li>Highly toxic pale yellow diatomic gas</li> </ul>
locator http://www.w3.org/1999/xhtml simple http://www.w3.org/1999/xhtml

3. To complete the task, you may want to submit the changes. See [Submitting and reverting changes](#) .

## Modifying values in a number of cells at once

You can modify a value in a number of cells at once:

1. Select the range or ranges of interest.
2. Start editing the value: select Edit from the context menu, press `F2` or simply start typing. The changes are applied to all the selected cells only if those cells can contain the same value.
3. To enter the value, press `Enter` . To cancel editing, press `Escape` .

4. To complete the task, you may want to submit the changes. See [Submitting and reverting changes](#) .

## Adding a row

If  on the toolbar is enabled, you can add rows to the table.

1. To start adding a row, do one of the following:

- Click  on the toolbar.
- Right-click the table and select Add New Row from the context menu.
- Press `Alt+Insert` .

Note that the context menu Clone Row command ( `Ctrl+D` ) can be used as an alternative.

2. Enter the values into the cells. For instructions, see [Modifying cell contents](#) .

3. To save the new row, select Submit from the context menu or press `Ctrl+Enter` .

See also, [Submitting and reverting changes](#) .

## Deleting rows

If  on the toolbar is enabled, you can delete rows. To do that:

1. Select the row or rows that you want to delete.

Rows are selected by clicking the cells in the column where the row numbers are shown. To select more than one row, use mouse clicks in combination with the `Ctrl` key.

2. Do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Y` or `Delete` .

3. Submit the changes to the server or confirm you intention to delete the selected row or rows.

See also, [Submitting and reverting changes](#) .

## Submitting and reverting changes

IntelliJ IDEA lets you specify how the changes that you make to data in a table are submitted to the database server. There is the [Submit changes immediately option](#) for that.

By default, this option is off. So the changes are accumulated in IntelliJ IDEA unless you carry out the Submit command (  ) on the toolbar, Submit in the context menu or `Ctrl+Enter` . Before you submit the changes, you can revert them ( Revert in the context menu or `Ctrl+Z` ).

The changes for a table are submitted all at once.

The scope of the Revert command is defined by the current selection in a table: the command is applied only to the changes within the selection. So you can revert an individual change, a group of changes or all the changes.

If nothing is currently selected, the Revert command is applied to the whole table.

To revert the changes, if the [manual commit mode](#) is selected, you can also use  or the Rollback command.

Unsubmitted changes are highlighted. New rows are green, cells with changed values are blue, and the rows that are going to be deleted are gray.

If the Submit changes immediately option is on, the changes are submitted right-away, and, generally, you don't need to use the Submit command.

## Managing database transactions

You can select to commit transactions automatically or manually. To change the commit mode, use the Tx switch `Tx: Auto` on the toolbar.

If the commit mode is set to Auto , each change of a value, or adding or deleting a row - [when submitted to the database server](#) - is implicitly committed and cannot be rolled back.

If the commit mode is set to Manual , the changes you have submitted to the server can be explicitly committed or rolled back by means of  or  on the toolbar, or the Commit or the Rollback context menu command.

The Tx switch can also be used for selecting the [isolation level](#) for the transactions.

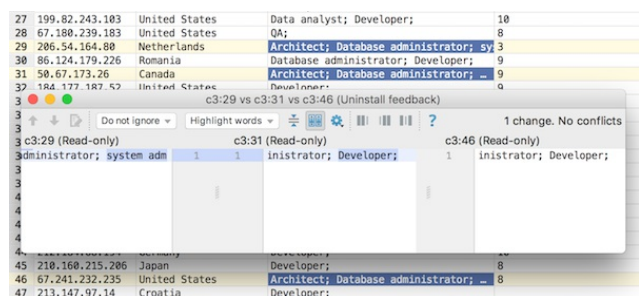

## Comparing tables

You can compare the current table with any other table which is open in a data editor or shown in the Database Console tool window. To do that, click  on the toolbar and select the table of interest.

The comparison results are shown in the [differences viewer](#) .

To compare contents of two or three cells within one table, select them and press `Ctrl+Shift+D` or select Compare Cells from the context menu.

## Copying table data to the clipboard or saving them in a file

When copying table data to the clipboard or saving them in a file, the data are converted into one of the available output formats. This can be SQL `INSERT` or `UPDATE` statements, [TSV or CSV](#) , an HTML table or [JSON](#) data. See [Specifying data output format and options](#) .

To copy or save the data, use:

- Copy (available in the Edit and the context menu, the keyboard equivalent is `Ctrl+C` ). This command copies the data for the selected cells onto the clipboard.
- Dump Data | To Clipboard (available in the context menu and can also be accessed by means of  on the toolbar). This command copies the data for the whole table onto the clipboard.
- Dump Data | To File (available in the context menu and can also be accessed by means of  on the toolbar). This command saves the data for the whole table in a file. Before actually saving the data, the dialog is shown which lets you select the output format and see how your data will look in a file.

## Copying and pasting data: data types are converted if necessary

You can copy (`Ctrl+C` ) and paste (`Ctrl+V` ) selected cells and ranges of cells - within the same table or from one table to another one. When pasting, IntelliJ IDEA converts data types automatically if and as necessary.

## Specifying data output format and options

To specify the output format and options for the Copy and Dump Data commands (see [Copying table data to the clipboard or saving them in a file](#) ), do one of the following:

- Click `Tab-se...d (TSV)` on the toolbar.
- Right-click the table and point to Data Extractor: <current\_format> .

In the menu that opens, the output formats are in the upper part: SQL Inserts , SQL Updates , etc. (The options that look like file names are also the output formats or, to be more exact, the scripts that implement corresponding data converters.)

The output option are:

- Allow Transposition. This option affects only delimiter-separated values formats (TSV, CSV). If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. `Ctrl+C` ), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). This is the option for SQL INSERTs and UPDATEs. When on, auto-increment fields are not included.
- Add Table Definition (SQL). This is also the option for SQL INSERTs and UPDATEs. When on, the table definition (CREATE TABLE) is added.

Additionally:

- Configure CSV Formats. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

## Exporting the data to another table, schema or database

You can export the data to another table, schema or database:

1. Do one of the following:
  - Click  on the toolbar.
  - Select Export to Database from the context menu.
2. Select the target schema (a new table will be created) or table (the data will be added to the selected table).
3. In the [dialog that opens](#) , specify the data mapping info and the settings for the target table.

## Saving a LOB in a file

If a cell contains a [binary large object](#) (a.k.a. BLOB or LOB), you can save such a LOB in a file.

Right-click the cell that contains the LOB of interest and select Save LOB To File.

1. Right-click the cell that contains the LOB of interest and select **Save LOB To File**.
2. In the dialog that opens, specify the name and location of the destination file and click **OK**.

## Updating the table view

To refresh the table view, do one of the following:

- Click  on the toolbar.
- Right-click the table and select **Reload Page** from the context menu.
- Press `Ctrl+F5`.

Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

## Viewing the query

To see the query that was used to generate the table:

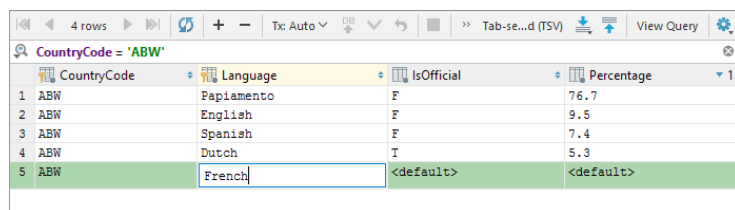

- Click **View Query** on the toolbar.
- If necessary, you can select the query text and copy it to the clipboard (`Ctrl+C`).

To close the pane where the query is shown, press `Escape`.

This feature is only supported in the Ultimate edition.

## Overview

The data editor provides a GUI for working with table data. You can sort, filter, add, edit and remove the data as well as perform other, associated tasks.

	CountryCode	Language	IsOfficial	Percentage
1	ABW	Papiamentu	F	76.7
2	ABW	English	F	9.5
3	ABW	Spanish	F	7.4
4	ABW	Dutch	T	5.3
5	ABW	<input type="text" value="French"/>	<input type="text" value="&lt;default&gt;"/>	<input type="text" value="&lt;default&gt;"/>

## Opening a table in the data editor

In the [Database tool window](#), do one of the following:

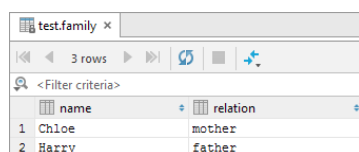

- Double-click the table of interest.
- Click the table and click  on the toolbar (if the toolbar is not currently hidden).
- Select the table and press **F4**.
- Right-click the table and select Open Editor from the context menu.

## Protecting a table from accidental modifications

To protect a table from accidental modifications in the data editor, you can make it read-only. To do that, click the padlock icon in the lower-right corner of IntelliJ IDEA workspace.

As a result, the icon appearance will change to , a padlock will appear on the corresponding editor tab, and you won't be able to make changes to the table.

	name	relation
1	Chloe	mother
2	Harry	father

To turn off the table's read-only status, click the padlock icon again.

Note that the tables with the read-only status in the data editor can still be modified when using the database consoles or in the Database tool window.

## Switching between subsets of rows

If only a subset of all the rows is currently shown, to switch between the subsets, use:

-  First Page
-  Previous Page (**Ctrl+Alt+Up**)
-  Next Page (**Ctrl+Alt+Down**)
-  Last Page

See also, [Making all rows visible simultaneously](#).

## Making all rows visible simultaneously

If you want all the rows to be shown simultaneously:

1. Click  on the toolbar and select Settings.
2. Switch to the Database | Data Views page, specify  in the Result set page size field, and click OK.
3. Click  or press **Ctrl+F5** to refresh the table view.

See also, [Updating the table view](#) and [Result set page size](#).

## Navigating to a specified row

To switch to a row with a specified number:

1. Do one of the following:
  - Press **Ctrl+G**.
  - Right-click the table and select Go To | Row from the context menu.
  - Select Navigate | Row from the main menu.
2. In the dialog that opens, specify the row number and click OK.

## Navigating to related records

If a row references a record in a different table or is referenced in a different table, you can switch to the corresponding table

to see the related record or records.

To switch to a referenced row:

1. Do one of the following:
  - Press **Ctrl+B**.
  - Select **Go To | Referenced Data** from the context menu.
2. If more than one record is referenced, select the target record in the pop-up that appears.

To switch to a row that references the current one, or to see all the rows that reference the current one:

1. Do one of the following:
  - Press **Alt+F7**.
  - Select **Go To | Referencing Data** from the context menu.
2. Select the target in one of the following categories:
  - **First Referencing Row**. All the rows in the corresponding table will be shown and the first of the rows that references the current row will be selected.
  - **All Referencing Rows**. Only the rows that reference the current row will be shown.

The options described above can also be accessed by using one of the following:

- **F4**.
- **Go To | Related Data** in the context menu.
- **Navigate | Related Data** in the main menu.

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this: . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance: . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order: .

Finally, when you click the cell for the third time, the initial state is resorted. That is, sorting by the corresponding column is canceled: .

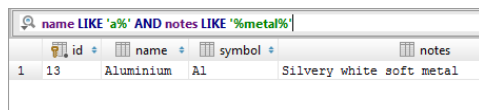

You can turn on the **Sort via ORDER BY** option, to enable sorting the data by the corresponding DBMS.

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#).

## Filtering data

1. If the filter box is not currently shown, click  on the toolbar and select **Row Filter**.
2. In the filter box, specify filtering conditions.

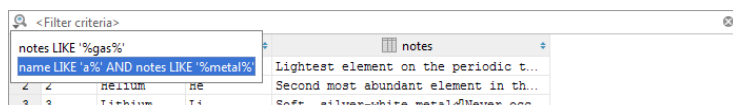

The filtering conditions are specified as in a **WHERE** clause but without the word **WHERE**, e.g. `name LIKE 'a%' AND notes LIKE '%metal%'`. Within the **LIKE** expressions, the SQL wildcards can be used: the percent sign (`%`) for zero or more characters and underscore (`_`) for a single character.

	id	name	symbol	notes
1	13	Aluminium	Al	Silvery white soft metal

To apply the conditions currently specified in the box, press **Enter**. To cancel filtering, click , or delete the contents of the filter box and press **Enter**.

To reapply a memorized filter, click  and select the filter in the list. See also, [Filter history size](#).

<Filter criteria>		notes
notes LIKE '%gas%'		
name LIKE 'a%' AND notes LIKE '%metal%'		Lightest element on the periodic t...
2 2 Helium He		Second most abundant element in th...
3 3 Lithium Li		Soft, silver-white metal; Never occ...

## Using quick filtering options

In addition to specifying filtering conditions manually (see [Filtering data](#)), you can use quick filtering options.

Available as context menu commands, these options are a set of filtering conditions for the current column name. The conditions themselves depend on the value in the current cell.

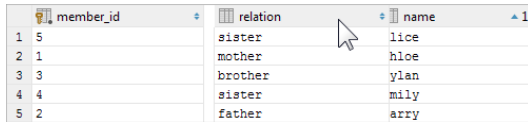

To use a quick filtering option:

1. Right-click a cell of interest and point to **Filter by**.

2. Select the necessary condition from the list.

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row.

	member_id	relation	name
1	5	sister	lice
2	1	mother	hloe
3	3	brother	ylan
4	4	sister	mily
5	2	father	arry

See also, [Restoring the initial table view](#) .

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

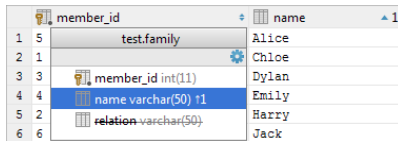

To show a hidden column:

1. Do one of the following:

– Right-click any of the cells in the header row and select Column List .

– Press `Ctrl+F12` .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name	relation
1	5	Alice	
2	1	Chloe	
3	3	Dylan	
4	4	Emily	
5	2	Harry	
6	6	Jack	

2. Select (highlight) the column name of interest and press `Space` .

3. Press `Enter` or `Escape` to close the list.

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#) .

## Restoring the initial table view

Click  on the toolbar and select Reset View to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the database, and all the columns are shown.

## Using the Structure view to sort data, and hide and show columns

When working with a data editor, the table structure view is available in the Structure tool window or as the corresponding popup.

The structure view shows the list of all the columns and lets you sort the data as well as hide and show the columns.

To open the Structure tool window, do one of the following:

– Select View | Tool Windows | Structure in the main menu.

– Click Structure on the left-hand [tool window bar](#) .

– Press `Alt+7` .

To open the structure popup, do one of the following:

– Right-click a cell in the table header row and select Column List .

– Press `Ctrl+F12` .

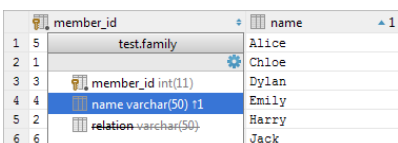

In the tool window or the popup, select the column of interest and do one of the following:

– To sort the data by this column in the ascending order, press `Shift+Alt+Up` . (In the tool window, you can, alternatively, select Sort | Ascending from the context menu.)

– To sort the data in the descending order, press `Shift+Alt+Down` . (In the tool window, alternatively, Sort | Descending .)

– To cancel sorting by this column, press `Ctrl+Shift+Alt+Backspace` . (In the tool window, alternatively, Sort | Unsorted .)

– To hide the column (or show a hidden column), press `Space` . (The names of hidden columns are shown struck through. In the tool window, alternatively, the Hide Column or Show Column context menu command can be used.)

	member_id	name	relation
1	5	Alice	
2	1	Chloe	
3	3	Dylan	
4	4	Emily	
5	2	Harry	
6	6	Jack	

The shortcuts for sorting table data (`Shift+Alt+Up` , `Shift+Alt+Down` and `Ctrl+Shift+Alt+Backspace` ) can be used in the data editor without opening the structure view.

See also, [Sorting data](#) , [Hiding and showing columns](#) and [Restoring the initial table view](#) .

## Using the quick documentation view

The quick documentation view provides details about the values in the selected cell or cells. For example, if a cell contains long text, normally, you can see only its beginning. The whole text is shown in the quick documentation view.

Most abundant pure element on Earth	Most abundant pure element on Earth
Highly reactive nonmetallic element	Highly reactive nonmetallic element
Lightest halogen	Lightest halogen
Colorless, odorless, inert monatomic gas	Third most abundant element in the universe
Soft, silver-white, highly reactive metal	Colorless gas or pale blue liquid
Alkaline earth metal	Extremely reactive
Silvery white soft metal	Highly toxic pale yellow diatomic gas
Crystalline, reflective with bluish-tint	

If a cell contains an image, you can see that image in the quick documentation view.

relation	picture
brother	120x120 PNG image 24.95K
brother	120x120 PNG image 22.32K
cat	120x120 PNG image 25.95K
father	120x120 PNG image 17.65K
mother	120x120 PNG image 27.38K
sister	120x120 PNG image 27.78K

You can also see the records referenced in the current record as well as the records that reference the current one.

first_name	last_name	address_id	email
MARY	SMITH	5	MARY.SMITH@sakilacustomer.org
PATRICIA	JOHNSON	6	PATRICIA.JOHNSON@sakilacustomer.org

Documentation for [1x2]

first_name	last_name
MARY	SMITH

Referenced address:

fk_customer_address(address_id)						
address_id	address	address2	district	city_id	postal_code	phone
5	1913 Hanoi Way		Nagasaki	463	35200	2830338429

If necessary, you can switch to the transposed view. This is when the rows and columns are interchanged. Thus, for a row, the cells are shown one beneath the other.

first_name	last_name	address_id	email
MARY	SMITH	5	MARY.SMITH@sakilacustomer.org
PATRICIA	JOHNSON	6	PATRICIA.JOHNSON@sakilacustomer.org

Documentation for [1x2]

Column	1
first_name	MARY
last_name	SMITH
address_id	5
email	MARY.SMITH@sakilacustomer.org

To open the quick documentation view, press `Ctrl+Q` or select Quick Documentation from the View or the context menu.

To switch to the transposed view, click Transposed View. See also, [Transposing the table](#).

To close the quick documentation view, press `Escape`.

## Transposing the table

The transposed table view is available. In this view, the rows and columns are interchanged.

To turn this view on or off, click  on the toolbar and select Transpose. Alternatively, use the Transpose context menu command.

## Enabling coding assistance for a column

You can assign a column one of the supported languages (e.g. SQL, HTML or XML): right-click the corresponding header cell, select Edit As and select the language. As a result, you get coding assistance for the selected language in all the cells of the corresponding column.

You can also assign a language to an [individual cell](#).

## Selecting cells and ranges: using unobvious techniques

Adding cells with the same contents. Select a cell. Now, to add the nearest cell with the same contents to the selection, press `Alt+J`. (When looking for the corresponding cell, IntelliJ IDEA moves down.) Each next press of `Alt+J` will add another cell to the selection.

To remove the cells from the selection one by one - starting from the last selected cell - use `Shift+Alt+J`.

If a number of cells in the same row are initially selected, `Alt+J` and `Shift+Alt+J` work the same way.

Expanding a selection: cell - column - row - table. Select a cell. Now, to select all the cells in the current column, press

**Ctrl+W** . The second press of **Ctrl+W** cancels the selection of the column and selects all the cells in the current row.

Finally, the third press of **Ctrl+W** selects the whole table.

**Ctrl+W** works similarly if a number of cells or a range is initially selected.

## Modifying cell contents

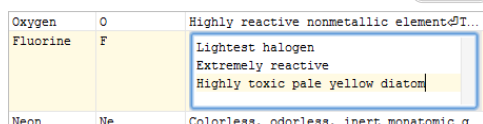

You can modify values in the table cells and, if appropriate, upload files.

1. To start editing a value or uploading a file, do one of the following:

- Double-click the corresponding table cell.
- Right-click the cell and select Edit or Edit Maximized from the context menu.
- Select the cell and press **F2** or **Shift+Enter** . In the latter case, the cell will be maximized.
- Select the cell and start typing. Note that in this case the initial cell contents are deleted right away and is replaced with the typed value.

2. When in the editing mode, you can:

- Modify the value right in the cell. To start a new line, use **Ctrl+Enter** . To enter the value, press **Enter** . To restore an initial value and quit the editing mode, press **Escape** .

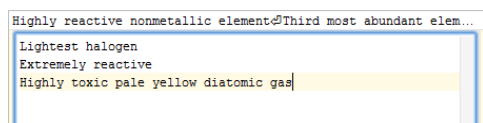

Oxygen	O	Highly reactive nonmetallic element
Fluorine	F	Lightest halogen Extremely reactive Highly toxic pale yellow diatom
Neon	Ne	Colorless, odorless, inert monatomic gas

- Use value completion. Press **Ctrl+Space** to open the suggestion list. The list contains the values from the current column that match your input.

- Maximize the cell if you need more room for editing. To do that, press **Ctrl+Shift+Alt+M** , or right-click the cell and select Maximize .

When working in a maximized cell, use **Enter** to start a new line and **Ctrl+Enter** to enter the value. To restore an initial value and quit the editing mode, press **Escape** .

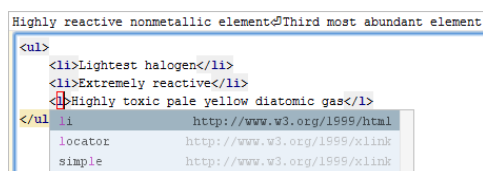

Highly reactive nonmetallic element	Third most abundant element
Lightest halogen	
Extremely reactive	
Highly toxic pale yellow diatomic gas	

- Upload a file into the field (e.g. to replace an existing file with a new one). To do that, right-click the cell and select Load File . Then select the necessary file in the dialog that opens.

If a field can contain text, this function can be used to insert the contents of a text file into the field.

- Replace the current value with the default one or `null` (if appropriate). To do that, right-click the cell and select Set DEFAULT or Set NULL .
- Edit a value in the cell as a fragment in one of the supported languages (e.g. SQL, HTML or XML). To do that, right-click the cell, select Edit As and select the language. As a result, you get coding assistance for the language you have selected.

Highly reactive nonmetallic element	Third most abundant element
<ul>	
<li>Lightest halogen</li>	
<li>Extremely reactive</li>	
<li>Highly toxic pale yellow diatomic gas</li>	
</ul>	
locator	http://www.w3.org/1999/xhtml
simple	http://www.w3.org/1999/xhtml

3. To complete the task, you may want to submit the changes. See [Submitting and reverting changes](#) .

## Modifying values in a number of cells at once

You can modify a value in a number of cells at once:

1. Select the range or ranges of interest.
2. Start editing the value: select Edit from the context menu, press **F2** or simply start typing. The changes are applied to all the selected cells only if those cells can contain the same value.
3. To enter the value, press **Enter** . To cancel editing, press **Escape** .
4. To complete the task, you may want to submit the changes. See [Submitting and reverting changes](#) .

## Adding a row

If **+** on the toolbar is enabled, you can add rows to the table.

1. To start adding a row, do one of the following:

- Click **+** on the toolbar.
- Right-click the table and select Add New Row from the context menu.
- Press **Alt+Insert** .

Note that the context menu Clone Row command ( **Ctrl+D** ) can be used as an alternative.

2. Enter the values into the cells. For instructions, see [Modifying cell contents](#) .

3. To save the new row, select Submit from the context menu or press **Ctrl+Enter** .

See also, [Submitting and reverting changes](#) .

## Deleting rows

If  on the toolbar is enabled, you can delete rows. To do that:

1. Select the row or rows that you want to delete.

Rows are selected by clicking the cells in the column where the row numbers are shown. To select more than one row, use mouse clicks in combination with the  key.

2. Do one of the following:

- Click  on the toolbar.
- Press  or .

3. Submit the changes to the server or confirm you intention to delete the selected row or rows.

See also, [Submitting and reverting changes](#).

## Submitting and reverting changes

IntelliJ IDEA lets you specify how the changes that you make to data in a table are submitted to the database server. There is the [Submit changes immediately option](#) for that.

By default, this option is off. So the changes are accumulated in IntelliJ IDEA unless you carry out the Submit command  on the toolbar, Submit in the context menu or . Before you submit the changes, you can revert them ( Revert in the context menu or ).

The changes for a table are submitted all at once.

The scope of the Revert command is defined by the current selection in a table: the command is applied only to the changes within the selection. So you can revert an individual change, a group of changes or all the changes.

If nothing is currently selected, the Revert command is applied to the whole table.

To revert the changes, if the [manual commit mode](#) is selected, you can also use  or the Rollback command.

Unsubmitted changes are highlighted. New rows are green, cells with changed values are blue, and the rows that are going to be deleted are gray.

If the Submit changes immediately option is on, the changes are submitted right-away, and, generally, you don't need to use the Submit command.

## Managing database transactions

You can select to commit transactions automatically or manually. To change the commit mode, use the Tx switch  on the toolbar.

If the commit mode is set to Auto, each change of a value, or adding or deleting a row - [when submitted to the database server](#) - is implicitly committed and cannot be rolled back.

If the commit mode is set to Manual, the changes you have submitted to the server can be explicitly committed or rolled back by means of  or  on the toolbar, or the Commit or the Rollback context menu command.

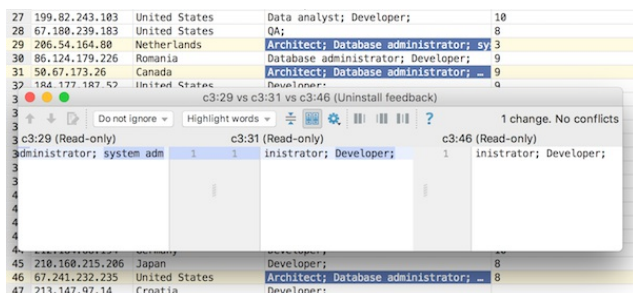

The Tx switch can also be used for selecting the [isolation level](#) for the transactions.

## Comparing tables

You can compare the current table with any other table which is open in a data editor or shown in the Database Console tool window. To do that, click  on the toolbar and select the table of interest.

The comparison results are shown in the [differences viewer](#).

To compare contents of two or three cells within one table, select them and press  or select Compare Cells from the context menu.

## Copying table data to the clipboard or saving them in a file

When copying table data to the clipboard or saving them in a file, the data are converted into one of the available output formats. This can be SQL `INSERT` or `UPDATE` statements, [TSV or CSV](#), an HTML table or [JSON](#) data. See [Specifying data output format and options](#).

To copy or save the data, use:

- Copy (available in the Edit and the context menu, the keyboard equivalent is `Ctrl+C`). This command copies the data for the selected cells onto the clipboard.
- Dump Data | To Clipboard (available in the context menu and can also be accessed by means of  on the toolbar). This command copies the data for the whole table onto the clipboard.
- Dump Data | To File (available in the context menu and can also be accessed by means of  on the toolbar). This command saves the data for the whole table in a file. Before actually saving the data, the dialog is shown which lets you select the output format and see how your data will look in a file.

## Copying and pasting data: data types are converted if necessary

You can copy (`Ctrl+C`) and paste (`Ctrl+V`) selected cells and ranges of cells - within the same table or from one table to another one. When pasting, IntelliJ IDEA converts data types automatically if and as necessary.

## Specifying data output format and options

To specify the output format and options for the Copy and Dump Data commands (see [Copying table data to the clipboard or saving them in a file](#)), do one of the following:

- Click `Tab-separated (TSV)` on the toolbar.
- Right-click the table and point to Data Extractor: `<current_format>`.

In the menu that opens, the output formats are in the upper part: SQL Inserts, SQL Updates, etc. (The options that look like file names are also the output formats or, to be more exact, the scripts that implement corresponding data converters.)

The output options are:

- Allow Transposition. This option affects only delimiter-separated values formats (TSV, CSV). If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. `Ctrl+C`), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). This is the option for SQL INSERTs and UPDATEs. When on, auto-increment fields are not included.
- Add Table Definition (SQL). This is also the option for SQL INSERTs and UPDATEs. When on, the table definition (CREATE TABLE) is added.

Additionally:

- Configure CSV Formats. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

## Exporting the data to another table, schema or database

You can export the data to another table, schema or database:

1. Do one of the following:
  - Click  on the toolbar.
  - Select Export to Database from the context menu.
2. Select the target schema (a new table will be created) or table (the data will be added to the selected table).
3. In the [dialog that opens](#), specify the data mapping info and the settings for the target table.

## Saving a LOB in a file

If a cell contains a [binary large object](#) (a.k.a. BLOB or LOB), you can save such a LOB in a file.

1. Right-click the cell that contains the LOB of interest and select Save LOB To File.
2. In the dialog that opens, specify the name and location of the destination file and click OK.

## Updating the table view

To refresh the table view, do one of the following:

- Click  on the toolbar.
- Right-click the table and select Reload Page from the context menu.
- Press `Ctrl+F5`.

Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

## Viewing the query

To see the query that was used to generate the table:

– Click View Query on the toolbar.

If necessary, you can select the query text and copy it to the clipboard ( `Ctrl+C` ).

To close the pane where the query is shown, press `Escape` .

This feature is only supported in the Ultimate edition.

You can run an SQL file as a whole. You can also execute individual statements contained in an SQL file.

– [Running an SQL file](#)

– [Executing individual statements](#)

## Running an SQL file

When running an SQL script file as a whole:

- You don't need to open the file in the editor. You can select the necessary file in the Project tool window.
- You can run the file for more than one data source at once.

On the other hand:

- The statements with parameters won't run.
- Retrieved data for the `SELECT` statements won't be shown.

To run an SQL file:

1. Select the necessary SQL file in the Project tool window, or open the file in the editor.

2. Do one of the following:

– Select Run "<file\_name>" from the context menu.

– Press `Ctrl+Shift+F10`.

3. In the Choose Data Source pop-up, click the data source to which the script should be applied.

If you want to run the script for more than one data source, select the data sources of interest in the pop-up and press

`Enter`.

## Executing individual statements

When running individual statements contained in an SQL file:

- The statements can contain parameters. Prior to running such statements IntelliJ IDEA will ask you to specify the parameter values.

On the other hand:

- The statements are run for only one data source at a time.

To run a statement or statements:

1. Open the SQL file of interest in the editor.

2. Place the cursor within the statement you want to execute.

If you want to run more than one statement, select (highlight) the necessary statements.

3. Do one of the following:

– Press `Ctrl+Enter` or select Execute from the context menu.

– Press `Alt+Enter` or click , and select Run query in console.

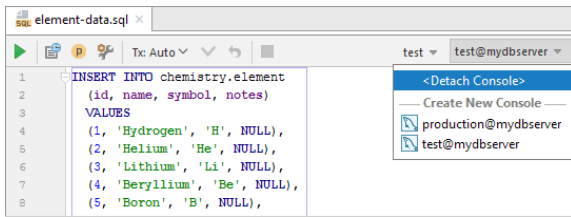

4. Select the database console to be used.

The statement or statements are executed using the selected console. The corresponding console is associated with the file. The name of the associated console is shown in the right-hand part of the toolbar.

The console menu, lets you associate a different console with the file, or remove the association between the file and the console ( `<Detach Console>` ).

The screenshot shows a code editor window titled "element-data.sql". The editor contains the following SQL code:

```
1 INSERT INTO chemistry.element
2 (id, name, symbol, notes)
3 VALUES
4 (1, 'Hydrogen', 'H', NULL),
5 (2, 'Helium', 'He', NULL),
6 (3, 'Lithium', 'Li', NULL),
7 (4, 'Beryllium', 'Be', NULL),
8 (5, 'Boron', 'B', NULL),
```

A context menu is open over the code, with the following options:

- <Detach Console>
- Create New Console —
- production@mydbserver
- test@mydbserver

The IDE interface includes a toolbar with icons for running, saving, and undo/redo, and a status bar at the bottom showing "test" and "test@mydbserver".

**Tip** You can associate a console with a file by using the Attach Console context menu command in the editor or in the Project tool window.

This feature is only supported in the Ultimate edition.

You can [inject](#) an SQL statement into a string literal and then run that statement:

1. In the editor, place the cursor within the corresponding string literal.
2. Do one of the following:
  - Press `Ctrl+Enter` .
  - Press `Alt+Enter` and select Run query in console .
  - Click  and select Run query in console .
3. If asked, select the [database console](#) to be used.
4. If the statement contains parameters, specify the parameter values.

**Warning!** The following is only valid when IntelliJLang, Database Tools and SQL plugins are installed and enabled!

This feature is only supported in the Ultimate edition.

For language injections in SQL, IntelliJ IDEA provides the following additional features (for general info, see [Using Language Injections](#)):

- Auto-injection for XML and JSON data types, see [Using auto-injection for XML and JSON](#).
- Data type patterns, see [Using pattern-based injections for user-defined data types](#).

## Using auto-injection for XML and JSON

For values defined as XML and JSON types, the corresponding languages are injected automatically.

Example

1. Create an SQL file and open it in the editor.
2. Specify PostgreSQL as an SQL dialect for that file.
3. Copy the following into your SQL file:

```
CREATE TABLE test (  
  my_xml XML DEFAULT ''  
);
```

4. Place the cursor between the quotation marks.
5. Check the light bulb menu ([Alt+Enter](#)): there is the Edit XML Fragment command there which means that XML has been auto-injected.

## Using pattern-based injections for user-defined data types

You can create patterns - e.g. for user-defined data types - and associate those patterns with languages. As a result, IntelliJ IDEA, when it comes across a data type that matches the pattern, will inject the language specified for that pattern.

In the following example, we'll create a pattern for a data type ending in `DATA` and associate that pattern with XML.

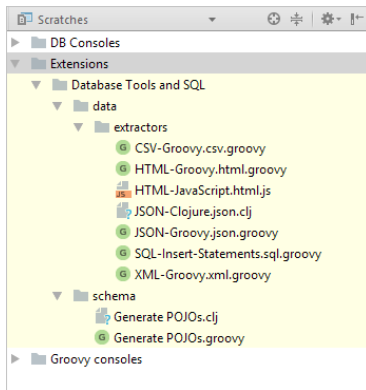

Example

1. In your SQL file, replace `XML` with `MYDATA`.
2. Place the cursor between the quotation marks.
3. Press [Alt+Enter](#). Note that there is no more Edit XML Fragment command in the menu. Select Inject by Type, and then select XML (XML files).
4. In the dialog that opens, in the Type pattern field, specify `(?i).*DATA`. (The type patterns are specified using regular expressions. In this example, `(?i)` turns the case-insensitive mode on; `.*` stands for any number of any characters.)
5. Check the light bulb menu again ([Alt+Enter](#)). The Edit XML Fragment command has become available which means that XML has been injected for the value of the `MYDATA` type.
6. To remove the pattern you have just created (if you don't need it), open the Settings / Preferences dialog (e.g. [Ctrl+Alt+S](#)), go to the Editor | Language Injections page, find and delete the pattern.

You can extend the functionality of your database tools by writing scripts in Groovy, Clojure and JavaScript.

## Example scripts

The IntelliJ IDEA distribution includes example extension scripts which you can access using the Scratches view of the Project tool window.

The `Extensions/Database Tools and SQL/data/extractors` folder contains the scripts that convert table data into CSV, HTML, JSON, SQL INSERTs and XML formats (see e.g. [Specifying data output format and options](#) ).

The `Extensions/Database Tools and SQL/schema` folder contains the scripts that generate a Java entity class for a table (see [Generating Java entity classes for tables and views](#) ).

IntelliJ IDEA supports developing, running, and debugging [Dart](#) web and command-line applications providing code completion, error and syntax highlighting, code inspections and quick-fixes, search and navigation, refactoring, and much more. IntelliJ IDEA also integrates with the [pub tool](#) and the [Dart Analysis Server](#) .

**Warning:** Before you start, install and activate the Dart repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Downloading the Dart tools

**Tip** Dart SDK contains all the tools for developing both command-line and web Dart applications.

1. Download and install the [Dart SDK](#) .

The Dart SDK incorporates the [Dart Virtual Machine](#) , the [Dart Libraries](#) , as well as all the command line tools, including compilers ([dart2js](#) and [dartdevc](#) ) and the [pub](#) tool.

2. For web development, optionally download the [Dartium browser](#) .

This browser provides native Dart support so you can run and debug Dart code without previously compiling it into JavaScript.

Learn more about the Dart development tools from [Dart Official website](#) .

## Creating a new Dart application

If you have no application yet, you can generate a IntelliJ IDEA project with Dart-specific structure from a [Stagehand template](#) . Alternatively, create an empty IntelliJ IDEA project and configure Dart support in it as described in [Starting with an existing Dart application](#) below.

**Tip** Dart SDK is configured for each project separately. This means that you can have several Dart SDKs in IntelliJ IDEA and switch between them from one project to another.

– Dartium is configured globally, see [Web Browsers](#) .

### To create a Dart project from a Stagehand template

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Dart in the left-hand pane.
3. In the right-hand pane, specify the paths to the Dart SDK and optionally to the Dartium executable file (Windows and Linux)/Dartium application (macOS). IntelliJ IDEA detects and displays the **Dart version** .  
To have a sample application created in the project, select the Generate sample content checkbox and choose the relevant Stagehand template from the list below. If you clear the checkbox, IntelliJ IDEA creates an empty project.  
  
Click Next .
4. On the second page of the wizard, specify the project name and the path to the folder where the project-related files will be stored. When you click Finish , IntelliJ IDEA sets up the project structure and generates some sources based on the selected Stagehand template.

### To create an empty IntelliJ IDEA project

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, again choose Static Web and click Next .
4. On the second page of the wizard, specify the project folder and name and click Finish .

## Starting with an existing Dart application

If you are going to continue developing an existing Dart application, open it in IntelliJ IDEA, configure Dart in it, and download the required dependencies as described in [Managing Dart dependencies](#) below.

### If the application sources are already on your machine

Click Open on the Welcome screen or choose File | Open on the main menu. In the dialog that opens, select the folder where your sources are stored.

### If the application sources are under version control

1. Click Check out from Version Control on the Welcome screen or choose VCS | Check out from Version Control on the main menu.
2. Select your version control system from the list.
3. In the VCS-specific dialog that opens, type your credentials and the repository to check out the application sources from.

To configure Dart support in an existing project

1. In Settings/Preferences dialog ( `Ctrl+Alt+S` ), choose Dart under Languages and Frameworks . The [Dart page](#) opens.
2. Select the Enable Dart support for the project <project name> checkbox.
3. In the Dart SDK Path text box, specify the location of the downloaded **Dart SDK** . Type the path manually or click `...` and choose the path in the dialog box that opens. If IntelliJ IDEA recognizes the Dart SDK correctly, its revision number is displayed in the Version read-only field.
4. For Dart web development: optionally specify the location of the Dartium executable (Windows and Linux)/Dartium application (macOS). Type the path manually or click `...` and choose the path in the dialog box that opens. Learn more about Dart web tools from the [Dart Official website](#) .
5. In the Enable Dart support for the following modules area, select the checkboxes next to the names of the modules where you need Dart support.

## Working with several Dart projects (packages) in one IntelliJ IDEA project

To attach a Dart project (package) to an existing IntelliJ IDEA project you need to add its root folder as a content root or as a new module.

To add a Dart project (package) to an existing IntelliJ IDEA project, do one of the following:

- Add a content root on the [Modules page](#) ( File | Project Structure | Modules ) as described in [Adding a content root](#) .
- Add a module to your project: choose File | New | Module from Existing Sources and select the relevant module in the dialog that opens.

## Using Pub

IntelliJ IDEA integrates with the [pub tool](#) and provides a Pub actions pane for running its actions such as installing dependencies or building the project from the editor.

IntelliJ IDEA logs execution of pub commands in the [Messages Tool Window](#) where you can also re-run the last executed command by clicking  on the toolbar.

**Tip** You can also use the tool in the command line mode from the [embedded local terminal](#) .

## Managing Dart dependencies

**Tip** Alternatively open `pubspec.yaml` in the editor or select it in the Project tool window and invoke **pub** actions from the context menu of the selection.

As soon as you open a `pubspec.yaml` file in the editor, IntelliJ IDEA displays a Pub actions pane at the top of the `pubspec.yaml` editor tab. Use the links on this pane to invoke [pub get](#) , [pub upgrade](#) , and [pub cache repair](#) actions.

The **pub** tool saves the downloaded packages in the cache and creates a `.packages` file and a `pubspec.lock` file next to the `pubspec.yaml` file.

## Building a Dart application

**Tip** The term **minification** or **compression** in the context of JavaScript means removing all unnecessary characters, such as **spaces** , **new lines** , **comments** without changing the functionality of the source code.

You can also run the [pub build](#) action from the Pub actions pane in the editor.

To build a Dart application

1. Open the `pubspec.yaml` file in the editor or switch to the tab where it is opened.
2. On the Pub actions pane at the top of the tab, click Build .
3. In the dialog box that opens, choose the build mode which determines the behaviour of the compiler:
  - Release: choose this option to minify the generated JavaScript code. In the **Release** mode, the source `.dart` files are not included in the build output. This mode is applicable when you are going to publish your application.
  - Debug: choose this option if you do not want to compress the generated JavaScript. In this mode, the generated JavaScript files are included in the build output without compression, as well as the source `.dart` files.
  - Other: choose this option if you want to use a custom build mode.

## Running and debugging Dart command-line applications

With IntelliJ IDEA, you can run and debug Dart command line applications. IntelliJ IDEA supports two debugging modes:

- **Local debugging** : in this mode, your application is started from IntelliJ IDEA and is running locally on your computer. To run or debug it, use a Dart Command Line App configuration.
- **Debugging a remote application** : in this mode, your application is running in a remote environment, for example, in a Docker container. To debug it, use a Dart Remote Debug configuration.

## Running a Dart command-line application

1. Open the the Dart file to start the application from or select it in the [Project view](#) . This file must contain a `main()` method.
2. On the context menu of the selection, choose Run '<dart\_file\_name>' . IntelliJ IDEA generates a run/debug configuration of the type [Dart Command Line App](#) and launches your application with it.

## Debugging a Dart command-line application locally

1. [Configure and set breakpoints](#) in the Dart code.
2. Open the the Dart file to start the application from or select it in the [Project view](#) . This file must contain a `main()` method.
3. On the context menu of the selection, choose Debug '<dart\_file\_name>' . IntelliJ IDEA generates a run/debug configuration of the type [Dart Command Line App](#) and starts a debugging session with it.
4. In the [Debug Tool Window](#) that opens, [step through the program](#) , [stop and resume](#) program execution, [examine it when suspended](#) , etc.

## Debugging a remote Dart command-line application

If your application is running in a remote environment, for example, in a Docker container, you can debug it using a Dart Remote Debug configuration.

### To create a Dart Remote Debug run/debug configuration

1. On the main menu, choose Run | Edit Configurations , click **+** and choose Dart Remote Debug from the list. The [Run/Debug Configuration: Dart Remote Debug](#) opens.
2. In the Host field, specify the address of the computer where the Dart Virtual Machine is running, the default value is `localhost` .
3. Specify the port through which the debugger will connect to the remote application, the default value is `5858` . The specified port is shown in the Use the command line arguments when starting the remote VM read-only field. Note that a remote application must be started exactly with these arguments.
4. From the Search Sources in drop-down list, choose the Dart project to debug if your IntelliJ IDEA project contains [several Dart projects](#) configured as content roots.

### To launch a remote debugging session

1. Start a remote Dart application with the VM options from the Command line arguments for the remote Dart VM field in the [Dart Remote Debug](#) run configuration, for example, `--enable-vm-service:5858 --pause_isolates_on_start` . The application starts, immediately suspends thanks to the `--pause_isolates_on_start` argument, and waits for the debugger to connect.
2. Choose the newly created [Dart Remote Debug](#) configuration in the Select run/debug configuration drop-down list and click  .
3. In the [Debug Tool Window](#) that opens, [step through the program](#) , [stop and resume](#) program execution, [examine it when suspended](#) , etc.

## Running and debugging Dart web applications

You can run a Dart web application in any browser, while debugging is supported only in [Dartium](#) and Chrome. To run a Dart web application, open the main HTML file of your application in a browser. Debugging a Dart web application is initiated through a run configuration of the type [JavaScript Debug](#) .

IntelliJ IDEA integrates with the [pub serve](#) tool to compile Dart code into JavaScript if necessary. When you open a Dart web application in a browser, it normally starts with a built-in server URL like `http://localhost:63342/project-name/web/index.html` . However, the built-in server is not used to serve the application. Instead, IntelliJ IDEA automatically starts pub serve (on a random free port, e.g. `54321` ) and the browser page is redirected to the pub serve URL (like `http://localhost:54321/index.html` ).

The work of pub serve is logged in the dedicated Pub Serve tool window. The tool window opens when you start running or debugging a Dart web application for the first time during the current IntelliJ IDEA session. You can stop the tool by clicking  on the toolbar. When you start running or debugging again, pub serve restarts automatically.

## Running a Dart web application

**Tip** Alternatively, open the HTML file in the editor, press `Alt+F2` , and select a browser from the pop-up menu.

Open the HTML file with a Dart reference or select it in the [Project view](#) . On the context menu of the editor or selection, click Open in Browser and choose the required browser in the list.

## Debugging a Dart web application

This feature is only supported in the Ultimate edition.

**Tip** Make sure the port in this URL address is the same as the Built-in server port on the [Debugger](#) page and the port from the Chrome extension settings .

Debugging of Dart web applications is supported only in Dartium and Chrome. A debugging session is initiated via a run configuration of the type [JavaScript Debug](#) .

Before you start, configure the built-in debugger as described in [Configuring JavaScript Debugger](#) . To use the **Live Edit** functionality that shows the changes in your HTML and CSS in the browser on the fly, install the [JetBrains IDE Support](#) Chrome extension. Find more about that in [Live Edit in HTML, CSS, and JavaScript](#) .

#### To create a JavaScript Debug run/debug configuration

1. Open the HTML file that references Dart or select the file in the [Project view](#) .
2. On the context menu, choose **Create '<HTML\_file\_name>'** . The **Run/Debug Configuration: JavaScript Debug dialog** opens.
3. Choose the browser to debug the application in. If you choose Dartium which has a built-in Dart virtual machine, the Dart code is executed natively. If you choose Chrome, the Dart code is compiled into JavaScript through the [dart2js](#) or [dartdevc](#) tool.
4. The **URL** field already shows the URL address of the application in the format `http://localhost:<built-in server port>/<project-name>/<relative path to the HTML file>` . During a debugging session, the browser will be redirected from this URL to the pub serve URL.

#### To start debugging

1. [Configure and set breakpoints](#) in the Dart code.
2. Initiate a debugging session: choose the created run configuration from the Edit configurations drop-down list on the toolbar and click  . IntelliJ IDEA opens the specified URL in the chosen browser.
3. In the **Debug Tool Window** that opens, [step through the program](#) , [stop and resume](#) program execution, [examine it when suspended](#) , etc.

## Testing Dart applications

IntelliJ IDEA supports running and debugging Dart tests that are written using the [dart test package](#) . You can run tests on any [target platform](#) , debugging is supported only for VM tests.

You can run and debug single tests, test groups, as well as tests from entire files and folders. IntelliJ IDEA creates a run/debug configuration with the default settings and a launches the tests. You can later save this configuration for further re-use.

#### To run or debug a single test

Open the test file in the editor, right-click the call of the [test\(\) method](#) , and choose **Run '<test\_name>'** or **Debug '<test\_name>'** on the context menu.

#### To run or debug a group

Open the test file in the editor, right-click the call of the [group\(\) method](#) , and choose **Run '<group\_name>'** or **Debug '<group\_name>'** on the context menu.

**TIP** If a folder is selected, the test runner looks for tests only in the files with the names in the format `*_test.dart` .

#### To run or debug Dart tests from a file

In the [Project view](#) , select the file with the tests to run and choose **Run '<file\_name>'** or **Debug '<file\_name>'** on the context menu.

#### To run or debug Dart tests from a folder

In the [Project view](#) , select the folder with the tests to run and choose **Run '<folder\_name>'** or **Debug '<folder\_name>'** on the context menu.

#### To save an automatically generated default configuration

After a test session is over, choose **Save <default\_test\_configuration\_name>** on the context menu of the test, test group, test file, or folder.

#### To run or debug tests through a previously saved run/debug configuration

Choose the required **Dart Test** configuration from the list on the tool bar and click  or  .

## Preparing to use Docker

### 1. Download, install and start Docker

To download [Docker](#) and find out how to install and start it, see [Install Docker](#) .

### 2. Specify Docker connection settings

**Warning!** To be able to use Docker, you need the Docker integration [plugin](#) .

This plugin is not bundled with IntelliJ IDEA, and should be installed separately, from the JetBrains plugin repository. See [Downloading and installing repository plugins](#) .

**Tip** The default setting `docker-machine` is fine if:

- The actual name of the executable file is `docker-machine` .
- The path to the directory where the file is located is included in the environment variable `Path` .

To specify an actual path to the executable file, click `...` and select the file in the dialog that opens.

1. Open the Settings / Preferences dialog (e.g. `Ctrl+Alt+S` ) and go to the Docker page ( Build, Execution, Deployment | Docker ).

2. Click `+` .

3. The connection settings depend on your Docker version and operating system:

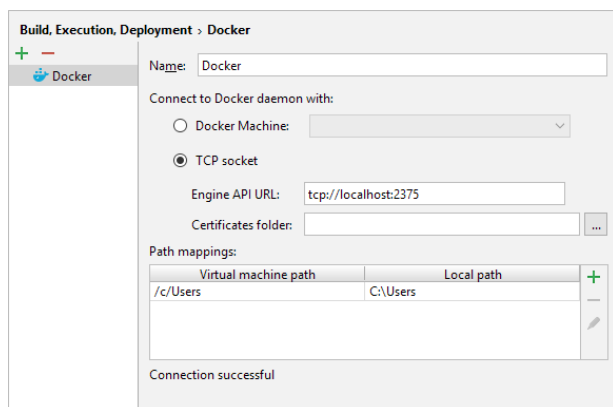

Docker for macOS:

- *Connect to Docker daemon with:* Docker for Mac

Docker for Windows:

- *Connect to Docker daemon with:* TCP socket
- *Engine API URL:* `tcp://localhost:2375`
- *Certificates folder:* This field must be empty.

**IMPORTANT!** In the General section of your Docker settings, turn on the Expose daemon on `tcp://localhost:2375` without TLS option.

Docker for Linux:

- *Connect to Docker daemon with:* Unix socket

Docker Toolbox for Windows or macOS:

- *Connect to Docker daemon with:* Docker Machine

The *Connection successful* message should appear right away. If it doesn't, check your Docker Machine executable setting on the Docker | Tools page.

For more info, see [Docker connection settings](#) .

4. If you are going to map container [volumes](#) onto local host folders, note that on Windows and macOS only the local folders specified in the Path mappings section will be available for corresponding bindings. For more info, see [Working with volume bindings](#) .

5. If you are going to use [Docker Compose](#) , go to the Tools page in the Docker section ( Build, Execution, Deployment | Docker | Tools ) and specify the location of your Docker Compose executable. The default setting `docker-compose` is fine if:

- The actual name of the executable file is `docker-compose` .
- The path to the directory where the file is located is included in the environment variable `Path` .

To specify an actual path to the executable file, click `...` and select the file in the dialog that opens.

6. Click OK in the Settings / Preferences dialog.

### 3. Connect to Docker

**Tip** For the Docker nodes, `D` on the toolbar and the Edit Configuration context menu command provide quick access to your Docker connection settings.

In the Docker tool window ( View | Tool Windows | Docker ), select a Docker node , and then click  or select Connect from the context menu.

## Managing images

### Pulling an image

**Note** If pulling an image assumes user authentication, click New in the Pull Image dialog to create a Docker Registry configuration and [specify your Docker image repository user account info](#).

1. In the Docker tool window, select a Docker node  or the Images node, and then click  or select Pull image from the context menu.

2. In the dialog that opens, specify:

- Registry. The URL of the image repository service (by default, `registry.hub.docker.com` for [Docker Hub](#)) or a Docker Registry configuration.
- Repository. The image name.
- Tag. The image tag, e.g. `latest`.

You can also pull and run an image using a [Dockerfile](#), see [Running an image from a Dockerfile](#).

### Finding out the image ID

In the Docker tool window, select the image of interest. The image ID is shown on the Properties tab.

You can copy the image ID onto the clipboard by using the Copy image ID context menu command or  on the Properties tab.

### Hiding untagged images

Images with no tags ( `<none>: <none>` ) can be one of the following:

- *Intermediate images* serve as layers for other images and do not take up any space.
- *Dangling images* remain when you rebuild an image based on a newer version of another image.

Dangling images should be pruned, because they take up space.

To hide untagged images, click the Filter menu on the Docker toolbar, and then click Show Untagged Images to remove the check mark.

### Finding local images by name or ID

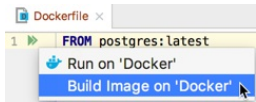

In the Docker tool window, you can search for images:

When in the leftmost pane, simply start typing. As a result, the text you have typed is highlighted in the names and IDs of the images and containers, if present.

## Building an image

Docker can build images by reading instructions from a [Dockerfile](#) . When the Dockerfile is open in the editor, click in the gutter and select to build the image on a specific Docker node.

You can also build the image using `docker build` in the Terminal tool window ( View | Tool Windows | Terminal ).

For information about running images, see [Running an image from a Dockerfile](#)

## Pushing an image

1. In the Docker tool window, select the image that you want to upload to an image repository, and then click or select Push image from the context menu.

2. If you haven't pushed to the corresponding repository yet, click New in the dialog that opens to create a Docker Registry configuration and [specify your image repository user account info](#) .
3. Specify the settings for the image that you are pushing:
  - Registry. The Docker Registry configuration to be used.
  - Repository. The name for the image that you are pushing.
  - Tag. The tag for the image that you are pushing.

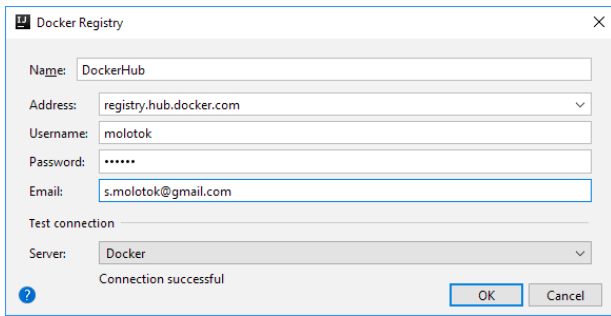

## Specifying your image repository user account info

**TIP** You can manage your Docker Registry configurations in the Settings / Preferences dialog: `Ctrl+Alt+S` | Build, Execution, Deployment | Docker Registry .

Pushing an image to an image repository and, for certain image repositories, also pulling an image from the repository requires your logging on to the corresponding server. Your image repository user account info that you have to provide in such cases is stored in what is called a Docker Registry configuration.

You can start creating a Docker Registry configuration when pulling or pushing an image by clicking New in the Pull image or the Push image dialog. Here are the Docker Registry configuration settings:

- Address. The image repository service URL (by default, `registry.hub.docker.com` for [Docker Hub](#) or `quay.io` for [Quay](#) ).
- Username and Password. The user name and password for your user account.
- Email. The email address that you specified when creating your user account.
- Server. The name for the associated [Docker connection settings](#) (usually, Docker ). They are used to connect to the service to check that your user account info is correct.

## Running images

IntelliJ IDEA uses [run configurations](#) ( Run | Edit Configurations | ) to run Docker images. There are three types of Docker run configurations:

- Docker Image : Created automatically when you [run an image from the Docker tool window](#) . It must be a locally existing Docker image that you either [pulled](#) or [built](#) previously.
- Dockerfile : Created automatically when you [run an image from a Dockerfile](#) .
- Docker-compose : Created manually if you want to [run a multi-container Docker application](#) using [Docker Compose](#) .

## Running an image from the Docker tool window

**Tip** If you already have a [Docker run configuration](#) for your image, the Create container popup, in addition to Create , will also have the name of that run configuration as an option. By selecting the run configuration name, you can run your image according to that run configuration.

1. In the Docker tool window, select the image of interest, and then click or select Create container from the context menu.

2. In the Create container popup, click Create .
3. In the Create Docker Configuration dialog that opens:
  - Image ID. Initially, this is the ID of the image for which you called the Create container command.
  - Container name. You can specify the name for the container that will be created or, otherwise, Docker will itself give your container a name.

4. Click Run .

## Running an image from a Dockerfile

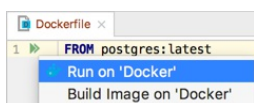

**Tip** In the Project tool window, for Dockerfiles, there are context menu commands that you may find useful:

Run 'Docker ...' runs the Dockerfile, creates a run configuration for it, and makes it current.

Save 'Docker ...' saves the run configuration.

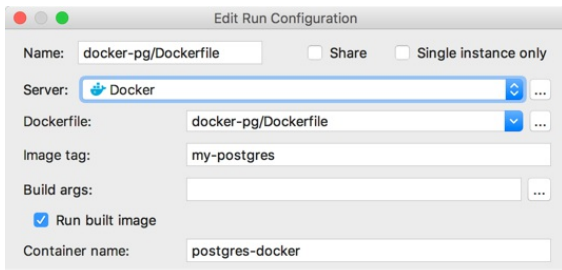

Select 'Docker ...' makes the run configuration for the Dockerfile current, so you can run it straight away by clicking .

1. Open your [Dockerfile](#) in the editor.
2. Click in the gutter and select to run the image on a specific Docker server. If there is an existing configuration for the image, you can run this configuration or edit it.

The main settings of a run configuration associated with a `Dockerfile` are:

- Image Tag. Custom name and optional tag for the image that will be built, for example `my-image:latest` .
- Container Name. The name of the container that will be created. If omitted, Docker will itself give your container a name.

## Viewing logs

After an image is built and the corresponding container is started, select the container in the Docker tool window and open one of the following tabs in the right-hand pane:

- Deploy log shows log messages from the run configuration

- Log shows log messages from the running container

## Adding command-line options for the container

When running a container on the command line, the following syntax is used:

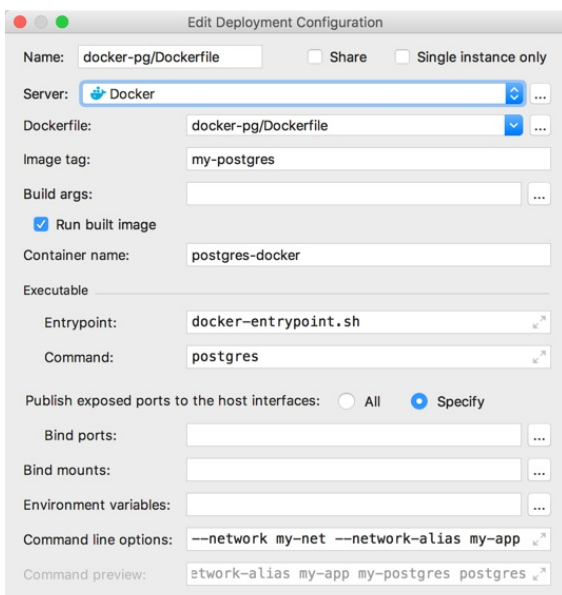

```
docker run [OPTIONS] IMAGE [COMMAND] [ARG...]
```

All optional parameters can be specified in the corresponding [Docker run configuration](#) fields.

- Options are specified in the Command line options field. In the previous screenshot, the container is connected to the `my-net` network and is assigned an alias `my-app`.

**Note** Not all `docker run` options are supported. If you would like to request support for some option, leave a comment in [IDEA-181088](#).

- Commands and arguments to be executed when starting the container are specified in the Entrypoint and Command fields. These fields override the corresponding `ENTRYPOINT` and `CMD` instructions in the Dockerfile. In the previous screenshot, when the container starts, it executes the `docker-entrypoint.sh` script with `postgres` as an argument.

The Command preview field shows the actual Docker command used for this run configuration.

You can also use the run configuration to bind [volumes](#) and [ports](#) , set [environment variables](#) and [build-time arguments](#) .

## Working with containers

### Running commands in a container

**Tip** As you run the commands, IntelliJ IDEA memorizes them. So you can rerun the commands by selecting them in the Run command in container popup.

You can run [docker exec](#) commands:

1. In the Docker tool window, right-click the container of interest and select Exec .
2. In the Run command in container popup, click Create .
3. In the dialog that opens, type the command and click OK . For

```
docker exec [OPTIONS] CONTAINER COMMAND [ARG...]
```

you need to specify only the

```
COMMAND [ARG...] part. For example:
```

```
ls /tmp or mkdir /tmp/my-new-dir .
```

### Starting a Shell or Bash session in a container

Use Exec as [described earlier](#) , i.e:

1. In the Docker tool window, right-click the container and select Exec | Create .
2. Type:

```
/bin/sh or /bin/bash
```

3. Press **Enter** or click OK .

**Tip** For Bash, instead of `/bin/bash` , try just `bash` .

### Finding out the container and image IDs

In the Docker tool window, select the container of interest. Its ID and the ID of its parent image are shown on the Properties tab.

You can copy the image ID, and the container ID and name onto the clipboard: select the corresponding row in the table and click  . As an alternative, you can use the Copy image ID and Copy container ID context menu commands.

### Renaming a container

**Note** As a result, the container is stopped and removed, and then re-created from scratch. The previous state of the container is effectively lost. The new container, most probably, will have a different ID.

1. In the Docker tool window, select the container of interest.
2. Select the Properties tab.
3. In the Container name field, specify a new name for your container, and click Save .

### Inspecting a container

**Tip** Use **Ctrl+F** to find the necessary information in the inspection result.

You can get detailed low-level information about a container in JSON format by running [docker inspect](#) :

In the Docker tool window, right-click the container of interest and select Inspect . The result is shown on the Inspection tab.

```

"NetworkSettings": {
  "Bridge": "",
  "SandboxID": "dbacd106e93c0f4ff76b32ba07bfb987e36af6de17d2787669262a172d909",
  "HairpinMode": false,
  "LinkLocalIPv6Address": "",
  "LinkLocalIPv6PrefixLen": 0,
  "Ports": {
    "8080/tcp": [ {
      "HostIp": "0.0.0.0",
      "HostPort": "8888"
    } ]
  }
},

```

## Showing container processes

To show the list of processes running in a container, right-click the container of interest in the Docker tool window and select Show processes . The result is shown on the Processes tab.

## Opening a console for an ENTRYPOINT process

To see the output of the [ENTRYPOINT](#) process running inside a container, you can attach to its `stdin/out` :

In the Docker tool window, right-click the container and select Attach . The console will open on the Attached console tab.

## Viewing the container log

**Tip** There is also the Show log context menu command that you may find useful.

When you select a container in the Docker tool window, the container log is shown on the Log tab.

## Stopping a container

In the Docker tool window, select the container, and then click or select Stop container from the context menu.

## Restarting a container

In the Docker tool window, select the container, and then click or select Redeploy from the context menu.

## Rerunning an image with different settings

1. In the Docker tool window, select the container in which the image of interest runs.
2. Click or select Edit Configuration from the context menu.
3. In the associated [Docker run configuration](#) that opens, edit the settings as necessary.
4. Click or select Redeploy from the context menu.

## Hiding stopped containers

By default, the Docker tool window displays all containers, including those that are not running. To hide stopped containers from the list, click the Filter menu on the Docker toolbar, and then click Show Stopped Containers to remove the check mark.

## Working with volume bindings

### Preparing for volume bindings on Windows and macOS

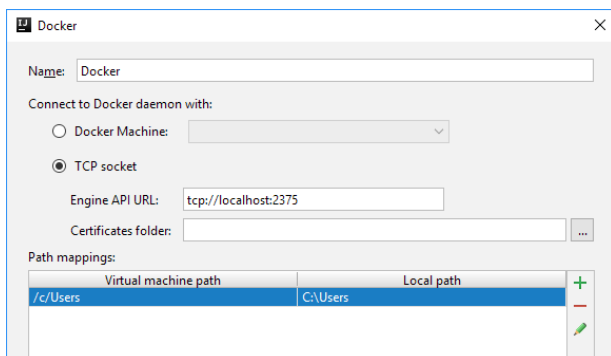

To be able to map host folders to container [volumes](#) on Windows or macOS, you should first specify corresponding path mappings:

**Warning!** If you are using Docker for Windows, you should start by enabling drive sharing:

Open your Docker settings, select the Shared Drives section and then select the drive (e.g. C ) that you want to make available to your containers.

Once you've done that, restart Docker.

1. Open your Docker connection settings: in the Docker tool window, select the Docker node and click . Alternatively, `Ctrl+Alt+S` | Build, Execution, Deployment | Docker .
2. In the Path mappings section, select an existing mapping and click to edit it, or click to create a new mapping.

3. In the dialog that opens, specify the mapping:
  - Local path. The path to a local folder that you want to make available for volume bindings.

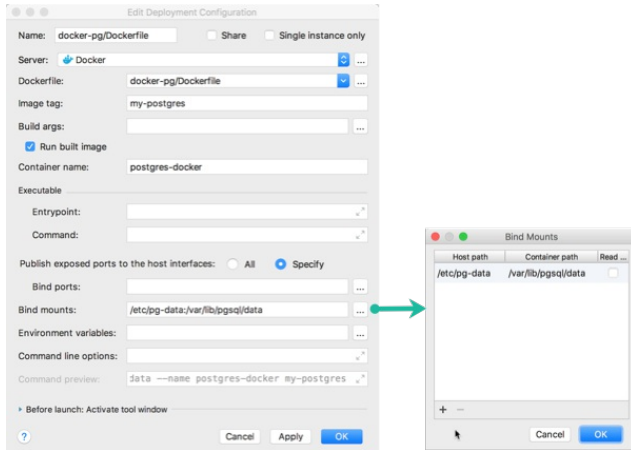

– Virtual machine path. This is the corresponding directory path in the Docker virtual machine's file system.

## Specifying volume bindings in a run configuration

Docker can mount a file or directory from the host machine to the container using the `-v` or `--volume` option. You can configure this in the [Docker run configuration](#) using the Bind mounts field.

In the Bind Mounts dialog, you can create a list of bindings by specifying the host directory and the corresponding path in the container where it should be mounted. Select Read only if you want to disable writing to the container volume.

The Bind mounts field shows the configured volume bindings. For example, if you want to mount some local PostgreSQL data directory ( `/etc/pg-data` ) to the PostgreSQL data directory inside the container ( `/var/lib/pgsql/data` ), this can be configured as illustrated on the previous screenshot.

If you expand the Command preview field, you will see that the following line was added:

```
-v /etc/pg-data:/var/lib/pgsql/data
```

This can be used in the Command line options field instead of creating the list of volume bindings using the Bind Mounts dialog.

## Viewing and editing volume bindings for a running container

1. In the Docker tool window, select the container and then select the Volume Bindings tab.
2. To create a new binding, click `+`. To edit an existing one, select the binding and click `✎`.
3. Specify the settings as necessary.
4. To apply the changes, click `Save`.

**Note** As a result, the container is stopped and removed, and then re-created from scratch. The previous state of the container is effectively lost.  
Also note that the changes are not saved in the [corresponding run configuration](#). So, if you restart the container, e.g. `+`, the corresponding run configuration will be rerun, and the settings specified in that run configuration will be reapplied.

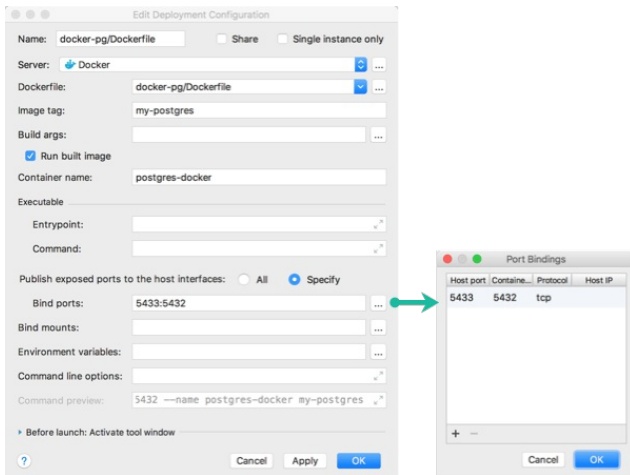

## Working with port bindings

You can specify the [port binding](#) settings in a [Docker run configuration](#). Then, when your container is running, you can [view and change these settings](#), and apply the changes.

## Specifying the port binding settings in a run configuration

Docker can map specific ports on the host machine to ports in the container using the `-p` or `--publish` option. This can be used to make the container accessible from outside. In the [Docker run configuration](#), you can select to expose all container ports to the host or use the Bind ports field to specify port mapping.

In the Port Bindings dialog, you can create a list of bindings by specifying which ports on the host should be mapped to which ports in the container. You can also provide a specific host IP from which the port should be accessible (for example, you can set it to `127.0.0.1` to make it accessible only locally, or set it to `0.0.0.0` to open it for all computers in your network).

The Bind ports field shows the configured port bindings. For example, if you already have PostgreSQL running on the Docker host port 5432, you can map port 5433 on the host to 5432 inside the container as illustrated on the previous screenshot. This will make PostgreSQL running inside the container accessible via port 5433 on the host.

If you expand the Command preview field, you will see that the following line was added:

```
-p 5433:5432
```

This can be used in the Command line options field instead of creating the list of port bindings using the Port Bindings dialog.

### Viewing and editing the port binding settings for a running container

1. In the Docker tool window, select the container and then select the Port Bindings tab.
2. If the container was started with the Publish all ports option on, to see the port mappings, run the Inspect command from the container's context menu, and then search the result (`Ctrl+F`) for "Ports" .
3. To create a new binding, click `+`. To edit an existing one, select the binding and click `✎`. If the Publish all ports option is currently on, turn it off to be able to specify individual port mappings.
4. For each particular binding, specify the settings as necessary.
5. To apply the changes, click Save .

**Note** As a result, the container is stopped and removed, and then re-created from scratch. The previous state of the container is effectively lost. Also note that the changes are not saved in the corresponding run configuration . So, if you restart the container, e.g. `↺`, the corresponding run configuration will be rerun, and the settings specified in that run configuration will be reapplied.

### Working with environment variables

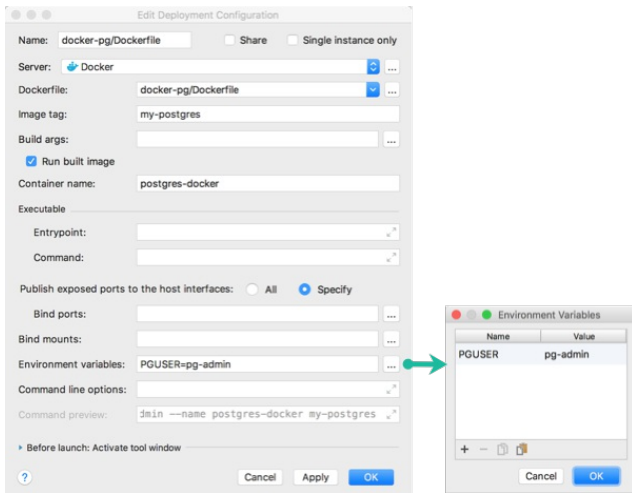

The environment variables are usually set in the [Dockerfile](#) associated with the base image that you are using. There are also the [environment variables that Docker sets automatically](#) for each new container.

In a [Docker run configuration](#) , you can specify additional variables and redefine the ones that Docker sets. At a later time, when your container is running, you can [view and edit](#) the existing variables, and create and set new ones.

### Specifying the environment variables in a run configuration

Docker can define environment variables for the container using the `-e` or `--env` option. You can configure this in the [Docker run configuration](#) using the Environment variables field.

In the Environment Variables dialog, you can create a list of names and values for variables.

The Environment variables field shows the configured variables. For example, if you want to connect to PostgreSQL with a specific user name by default (instead of the operating system name of the user running the application), you can define the `PGUSER` variable as illustrated on the previous screenshot.

If you expand the Command preview field, you will see that the following line was added:

```
--env PGUSER=pg-admin
```

This can be used in the Command line options field instead of creating the list of names and values using the Environment Variables dialog. If you need to pass sensitive information (passwords, secrets, etc.) as environment variables, you can use the `--env-file` option to specify a file with this information.

### Viewing and editing the environment variables for a running container

**Tip** To manage your container's environment variables, you can use your Bash shell. To open the shell: Exec from the context menu, then Create | bash.

1. In the Docker tool window, select the container and then select the Environment variables tab.
2. To create a new variable, click `+`. To edit an existing one, select the variable and click `✎`.
3. To apply the changes, click Save.

**Note** As a result, the container is stopped and removed, and then re-created from scratch. The previous state of the container is effectively lost.

### Specifying build-time variables

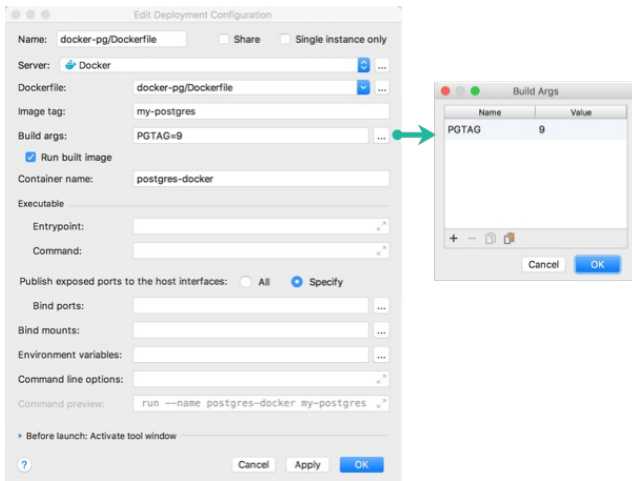

Docker can define build-time values for certain environment variables that do not persist in the intermediate or final images using the `--build-arg` option for `docker build`. These must be specified in the `ARG` instruction of the Dockerfile with a default value. You can configure build-time variables in the [Docker run configuration](#) using the Build args field.

For example, you can use build-time variables to build the image with a specific version of PostgreSQL. To do this, add the `ARG` instruction to the beginning of your Dockerfile:

```
ARG PGTAG=latest

FROM postgres:$PGTAG
```

The `PGTAG` variable in this case will default to `latest` if you do not redefine it as a build-time variable. So by default, this Dockerfile will produce an image with the latest available PostgreSQL version. However, you can use the Build Args dialog to redefine the `PGTAG` variable.

In the previous screenshot, `PGTAG` is set to `9`, which will instruct Docker to pull `postgres:9`. When you build and run the image now, it will start the container with latest PostgreSQL 9 version. To check this, execute `postgres --version` inside the container and see the output; it should be `postgres (PostgreSQL) 9.6.6` or some later version.

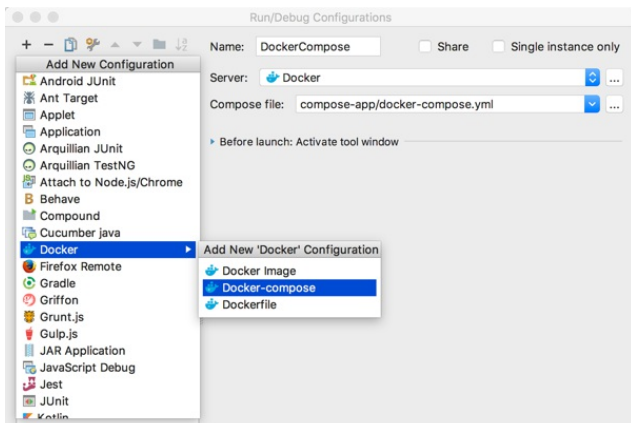

If you expand the Command preview field, you will see that the following option was added to the `docker build` command:

```
--build-arg PGTAG=9
```

## Using Docker Compose

### Running services via a Docker run configuration

1. Create a [Docker Compose docker-compose.yml file](#) and specify your services.
2. Create a *Docker-compose* run configuration: Run | Edit Configurations | + | Docker .

3. Specify your `docker-compose.yml` file in the Compose file field.
4. Execute the run configuration.

## Scaling a service

**Note** Scaling means changing the number of containers within a service.

1. In the Docker tool window, select the service you want to scale.
2. Click  or select Scale from the context menu.

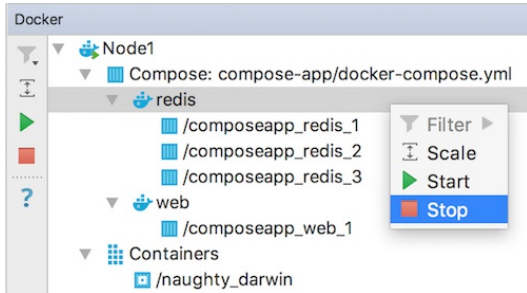

3. Specify how many containers you want in the service.

## Stopping and starting a service

In the Docker tool window, select the service.

- To stop the service, click  or select Stop from the context menu.
- To start the service, click  or select Start from the context menu.

## Interacting with containers

Most of the functions that IntelliJ IDEA provides for working with "independent" containers are also available for the containers within Docker Compose services. To access these functions, use the containers' context menus and the toolbar icons in the Docker tool window. For more info, see [Working with containers](#).

## Troubleshooting

### Unable to connect to Docker

Make sure that:

- Docker is running.
- Your [Docker connection settings](#) are correct.
- If you are using Docker for Windows:

In the General section of your Docker settings, the Expose daemon on top://localhost:2375 without TLS option is on.

- If you are using Docker Toolbox:
  - Your Docker Machine is running.
  - The [Docker Machine executable setting](#) on the Docker | Tools page is correct.

### Unable to use Docker Compose

Make sure that the Docker Compose executable setting in your [Docker settings](#) is correct.

### Unable to use port bindings

Make sure that the corresponding container ports are exposed. Use the [EXPOSE Dockerfile](#) command.

### My deployment log is empty

If you have another project open at the moment, you may find your deployment log in that project.

## Limitations

Our Docker integration has limitations but we are working on its improvement. [See the list of Docker issues](#) in our tracking system and vote for the ones that you think should be resolved first of all.

You can run a DBMS image from a Dockerfile, [from the Docker tool window](#) or [using a Compose file](#) . When the DBMS image is running, you can [connect to the database](#) .

## 1a. Run an image from a Dockerfile

1. Create a Dockerfile and open it in the editor.
2. Type `FROM <DBMS_image_name>:<tag>` e.g. `FROM postgres:latest` . If necessary, add other instructions.
3. Click  and select Run on 'Docker' .
4. When the container starts, find out which port the database server is listening on:

In the Docker tool window, right-click your database container and select Inspect . Search the inspection result ( `Ctrl+F` ) for `ExposedPorts` . For a postgres container you are likely to find something like `5432/tcp` .

5. Make the container database port available on the host:

Select the Port Bindings tab. You can choose to specify the host port yourself or let Docker decide which port should be used. So, do one of the following:

- Click  and specify the mapping. To make the port accessible only from your localhost, for Host IP , specify `localhost` or `127.0.0.1` . To make the port accessible from other computers on your network as well, specify `0.0.0.0` . To apply the changes, click Save .
- Select the Publish all ports checkbox and click Save . Run the Inspect command for the container. Search the inspection result ( `Ctrl+F` ) for `NetworkSettings` . The `"Ports"` subsection will include the info about the database host port you should be using.

6. [Connect to your database](#) .

## 1b. Pull and then run an image from the Docker tool window

1. In the Docker tool window ( `View | Tool Windows | Docker` ), right-click the Docker node and select Pull image .
2. To pull an image from [Docker Hub](#) ( `registry.hub.docker.com` ), specify the image name in the Repository field, e.g. `postgres` , and the image tag, e.g. `latest` .  
If pulling an image assumes user authentication, click New to create a Docker Registry configuration and [specify your Docker image repository user account info](#) .
3. When the image is downloaded, select it, and then click  or select Create container from the context menu.
4. In the Create container popup, click Create .
5. In the dialog that opens, if necessary, specify the name for the container that will be created.
6. To make the database port in the container available from the host, either select All for Publish exposed ports to the host interfaces or specify necessary port bindings.
7. Click Run .
8. When the container starts, run the Inspect command for the container and search the inspection results ( `Ctrl+F` ) for `NetworkSettings` . In the `"Ports"` subsection, note the values for the host IP and port number for connecting to the database.

9. Connect to your database .

### 1c. Run an image using a Compose file

1. Create a `docker-compose.yml` file. A minimal Compose file for a DBMS image should contain something like this:

```

version: '3'
services:
  db:
    image: postgres:latest

```

Specify the name and tag of the image that you are going to use in place of `postgres` and `latest` .

2. Create a Docker run configuration ( Run | Edit Configurations | + | Docker | Docker-compose ) and select your `docker-compose.yml` file.

3. To execute the run configuration, right-click the `docker-compose.yml` file in the Project view and click Run (▶).

4. When the container starts, find out which port the database server is listening on:

In the Docker tool window, right-click your database container and select Inspect . Search the inspection results ( `Ctrl+F` ) for `ExposedPorts` . For a postgres container you are likely to find something like `5432/tcp` .

5. Make the container database port available on the host:

Select the Port Bindings tab. You can choose to specify the host port yourself or let Docker decide which port should be used. So, do one of the following:

- Click + and specify the mapping. To make the port accessible only from your localhost, for Host IP , specify `localhost` or `127.0.0.1` . To make the port accessible from other computers on your network as well, specify `0.0.0.0` . To apply the changes, click Save .
- Select the Publish all ports checkbox and click Save . Run the Inspect command for the container. Search the inspection result ( `Ctrl+F` ) for `NetworkSettings` . The "Ports" subsection will include the info about the database host port you should be using.

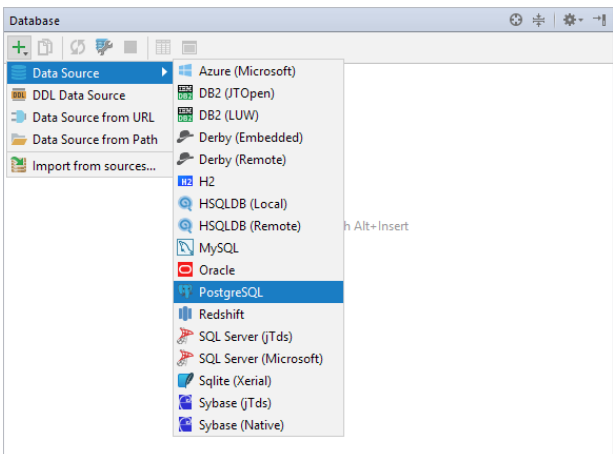

6. Connect to your database .

## 2. Connect to your database

1. Open the Database tool window, e.g. View | Tool Windows | Database .

2. Click + , point to Data Source , and select your DBMS, e.g. PostgreSQL .

3. If there is the message Download missing driver files in the lower part of the Data Sources and Drivers dialog that opens, click the Download link.

- Specify the database settings. In the Port field, specify the host port mapped to the container database port. For the `postgres:latest` image, the database and user, by default, are both `postgres`, and the password is empty. For other images, refer to corresponding documentation to find out what your database settings should be.
- To make sure that the settings are all correct and IntelliJ IDEA can properly interact with your database, click Test Connection.

The screenshot shows the 'Database Configuration' dialog in IntelliJ IDEA. The 'Name' field is set to 'postgres@localhost'. The 'General' tab is selected, showing the following settings:

- Host: localhost
- Port: 32769
- Database: postgres
- User: postgres
- Password: <hidden> (with a checked 'Remember password' checkbox)
- URL: jdbc:postgresql://localhost:32769/postgres (with a 'default' dropdown menu)
- Driver: PostgreSQL
- Options:  Read-only,  Auto commit,  Auto sync

A 'Test Connection' button is present, which has been clicked, resulting in a green 'Successful' status and a 'Details' link. At the bottom, there are 'OK', 'Cancel', and 'Apply' buttons.

For more info on working with databases and SQL, see [Databases and SQL](#).

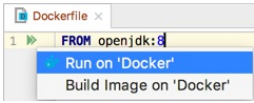

## 1. Run a JDK image

To be able to deploy and run Java apps in containers, you need a JDK image. You can choose to run that image from your [Dockerfile](#) , or you can pull and then run the image from the Docker tool window.

### 1a. Run the image from a Dockerfile

1. Create a `Dockerfile` and open it in the editor.
2. Type `FROM <jdk_image_name>:<tag>` e.g. `FROM openjdk:8` .
3. Click  and select Run on 'Docker' .

As a result, a Docker run configuration is created, your image runs, and the corresponding container appears in the Docker tool window.

At a later time, you may want to make adjustments to your run configuration. In such a case, click  and select Edit '<Configuration Name>' .

### 1b. Pull and then run the image from the Docker tool window

1. In the Docker tool window ( View | Tool Windows | Docker ), right-click the Docker node and select Pull image .

2. To pull an image from [Docker Hub](#) ( `registry.hub.docker.com` ), specify the image name in the Repository field, e.g. `openjdk` , and the image tag, e.g. `8` .

If pulling an image assumes user authentication, click New to create a Docker Registry configuration and [specify your Docker image repository user account info](#) .

3. When the image is downloaded, select it, and then click  or select Create container from the context menu.

4. In the Create container popup, click Create .
5. In the dialog that opens, specify the name for the container that will be created.

6. Click Run .

## 2. Make the app available for the container and run it

You can expose your Java app by mapping the compilation output folder to a container folder or copy the compilation output directly to the container.

### 2a. Run the app inside the container by mapping the app compilation output folder to a container folder

1. Build the project: e.g. Build | Build Project .
2. Make adjustments to the run configuration associated with the JDK container:

In the Docker tool window, select your JDK container, and then click  or select the Edit Configuration from the context menu.

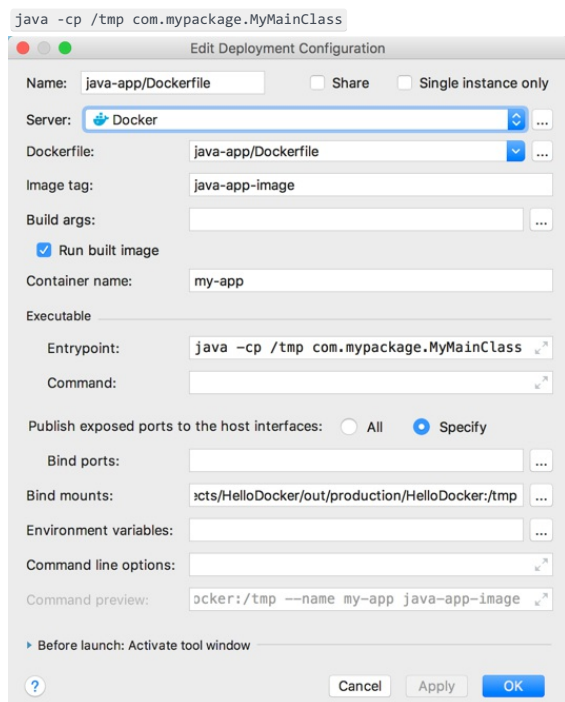

3. Open the Bind mounts dialog and add a new binding:

- Container path : Specify the path to a container folder that you want to map, e.g. `/tmp` .
- Host path: Specify the path to the compilation output folder. If you didn't change the default output paths, select the `<ProjectName>/out/production/<ModuleName>` folder.

4. Specify the command for running the app, for example, as the container's `ENTRYPOINT` . In the Entrypoint field, type:

```
java -cp <pathToMappedContainerFolder> <qualifiedMainClassName> , e.g.
```

**Note** For the image that you are using, just java may not work, and you'll need to specify the full path.

**Note** Make sure that the host path is available for mapping ( Settings / Preferences | Build, Execution, Deployment | Docker | Path mappings ).

5. Rerun the run configuration for your JDK container, e.g. by clicking  or selecting Deploy from the container's context menu in the Docker tool window.

## 2b. Run the app inside the container by copying the compilation output folder to a working container folder

1. Your compilation output must be in the same folder as your `Dockerfile` . So, you should start by changing your module compilation output path(s):

Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ), select Modules , select your module, and select the Paths tab.

2. Under Compiler output , select Use module compile output path . In the Output path field, specify the path to the folder in which your `Dockerfile` is located. E.g. if your `Dockerfile` is in the `docker-dir` folder, specify the path to `docker-dir` . You may also want to turn off the Exclude output paths option in order not to make the folder with your `Dockerfile` excluded .

3. Build the project: e.g. Build | Build Project .

4. In your `Dockerfile` , on the lines that follow `FROM <jdk_image_name>:<tag>` e.g. `FROM openjdk:8` , type:

```
COPY . /tmp
WORKDIR /tmp
ENTRYPOINT ["java", "com.mypackage.MyMainClass"]
```

Use your app's qualified main class name in place of `com.mypackage.MyMainClass` . You can as well use a container

folder other than `/tmp` for copying your app to.

**Note** For the image that you are using, just `java` may not work, and you'll need to specify the full path.

**Note** Make sure that the host path is available for mapping ( Settings / Preferences | Build, Execution, Deployment | Docker | Path mappings ).

5. Rerun your `Dockerfile` : click  and select Run '<ConfigurationName>'

### 3. Package your app in a JAR and build an image for it

When happy with your app, you may want to package it in a [JAR](#) , build an image that contains that JAR, and then push the image to the image repository. Here is how you do that:

1. Create a `Dockerfile` for the image you are going to build. A "minimal" file for a JAR app may look something like this (in your situation, the file contents may be different):

```
FROM openjdk:8
RUN mkdir /var/my-app
COPY my-app.jar /var/my-app
WORKDIR /var/my-app
ENTRYPOINT ["java", "-jar", "my-app.jar"]
```

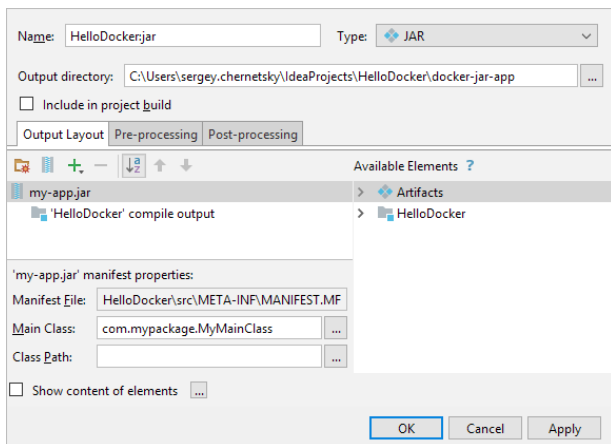

2. Create an artifact configuration for packaging the app in a JAR:

Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ), select Artifacts , click  , select JAR , and select From modules with dependencies .

3. In the dialog that opens, specify your main application class. Specify other options as needed. (The defaults will do.)

4. Specify the following artifact settings:

- Output directory. Specify the path to the directory in which your `Dockerfile` is located.
- The JAR file name (shown on the Output Layout tab underneath the toolbar). Right-click the file name and select Rename . Change the name to `my-app` or whatever you think is appropriate.

5. Build the artifact: Build | Build Artifacts | <ArtifactName> | Build . (Alternatively, you can include the Build artifact task in the Before launch task list in the corresponding Docker run configuration.)

6. Build the image from your Dockerfile:  | Build on 'Docker' .

7. Push the image to the image repository:

Select the image in the Docker tool window, and click  or select Push image from the context menu.

8. In the dialog that opens:

If you already have the corresponding Docker Registry configuration, select it from the list next to Registry . Otherwise, click New and [specify your Docker image repository user account info](#) . Then, specify the name for your image (the Repository field) and its tag.

## 1. Build a web app artifact

**Note** If you already have your web app in deployable format - as a WAR or a directory structure - you can skip this section and go to [Running an app server image](#) .

**Note** Some servers are unable to deploy exploded WAR artifacts.

For web apps, IntelliJ IDEA provides deployment-ready [WAR](#) and Exploded (unzipped) WAR [artifact](#) formats. To build such artifacts:

1. Enable web app development support:

– When creating a project:

File | New | Project | Java Enterprise | Web Application , etc.

– For an existing project:

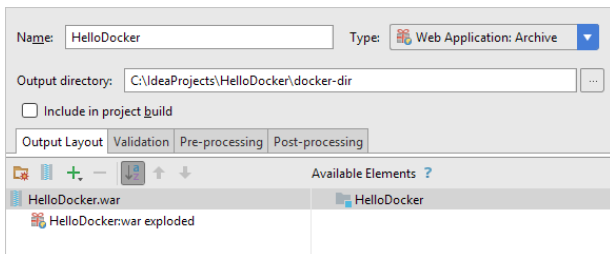

In the Project tool window ( View | Tool Windows | Project ), right-click the corresponding module folder and select Add Framework Support . Then select the Web Application checkbox in the dialog that opens.

2. Create artifact configurations for your app: File | Project Structure | Artifacts .

– Web Application: Exploded artifact configuration was created automatically when you enabled web app development support.

– Web Application: Archive (WAR) artifact configuration. To create such an artifact configuration:

+ | Web Application: Archive | For '...' exploded' . Then click Create Manifest and accept the default location `.../web` for `META-INF/MANIFEST.MF` .

3. Build the artifact: Build | Build Artifacts | <ArtifactName> | Build . Alternatively, you can include the Build artifact task in the Before launch task list in your Docker run configuration.

For more info on web application development and related artifacts, see the [Developing a Java EE Application tutorial](#) .

## 2. Run an app server image

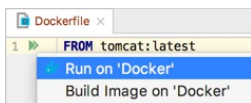

You can choose to run the app server image from your `Dockerfile` , or you can pull and then run the image from the Docker tool window.

### 2a. Run the image from a Dockerfile

1. Create a `Dockerfile` and open it in the editor.

2. Type `FROM <app_server_image_name>:<tag>` e.g. `FROM tomcat:latest` .

3. Click  and select Run on 'Docker' .

As a result, a Docker run configuration is created, your image runs, and the corresponding container appears in the Docker tool window.

At a later time, you may want to make adjustments to your run configuration. In such a case, click  and select Edit '<Configuration Name>' .

### 2b. Pull and then run the image from the Docker tool window

1. In the Docker tool window ( View | Tool Windows | Docker ), right-click the Docker node and select Pull image .

2. To pull an image from [Docker Hub](#) ( `registry.hub.docker.com` ), specify the image name in the Repository field, e.g.

`tomcat` , and the image tag, e.g. `latest` .

If pulling an image assumes user authentication, click New to create a Docker Registry configuration and [specify your Docker image repository user account info](#) .

3. When the image is downloaded, select it, and then click  or select Create container from the context menu.

4. In the Create container popup, click Create .

- In the dialog that opens, if necessary, specify the name for the container that will be created.
- Click Run .

### 3. Deploy the app

You can deploy your web app by mapping the artifact folder to the app server deployment folder. You can as well deploy your app by copying the artifact to the deployment folder.

#### 3a. Deploy the app by mapping the artifact output folder to the deployment folder

**Tip** Alternatively, you can specify the necessary mapping in your Docker run configuration.

To start editing the run configuration, select the container, and then click  or select Edit Configuration from the context menu.

Then, to restart the container, click  or select Redeploy from the context menu.

- In the Docker tool window, select your app server container, and then select the Volume Bindings tab.
- Click  to create a new binding.
- In the dialog that opens, specify:
  - Container path. The path to server deployment folder, e.g. `/usr/local/tomcat/webapps` for Tomcat.
  - Host path. For a WAR artifact, the path to the artifact output directory, for an exploded WAR artifact, the path to the directory that contains the artifact output directory.
- To apply the changes, click Save .
- To check the mapping, run the Inspect command for the container and search the inspection result ( `Ctrl+F` ) for `HostConfig` . You'll find the mapping of interest next to `"Binds"` .

#### 3b. Deploy the app by copying the artifact to the server deployment folder

- Make sure that your artifact is in the same directory as your `Dockerfile` .
- In your `Dockerfile` , on the line that follows `FROM <app_server_image_name>:<tag>` , e.g. `FROM tomcat:latest` , add:
  - For an exploded artifact:

```
COPY . </server/deployment/path> , e.g. COPY . /usr/local/tomcat/webapps for Tomcat.
```

- For a WAR artifact:

```
COPY <artifactname>.war </server/deployment/path>
```

- Click  and select Run '<ConfigurationName>' .

### 4. Map the container http port onto a host port

**Tip** Alternatively, you can specify this mapping in your Docker run configuration.

Use:

 to start editing the run configuration.

 to restart the container after specifying the mapping.

- Though the http server port is usually 8080, make sure that this is the case:

In the Docker tool window, right-click your app server container and select Inspect . Search the inspection result ( `Ctrl+F` ) for `ExposedPorts` to see which port is being used.

- Make the container http port available on the host:

Select the Port Bindings tab. You can choose to specify the host port yourself, or let Docker decide which port should be used. So, do one of the following:

- Click  and specify the mapping. To make the port accessible only from your localhost, for Host IP , specify `localhost` or `127.0.0.1` . To make the port accessible from other computers on your network as well, specify `0.0.0.0` . To apply the changes, click Save .
- Select the Publish all ports checkbox and click Save .

Now, you need to find out which host port is mapped to the container http port. To do that, run the Inspect command for the container. Then search the inspection result ( `Ctrl+F` ) for `NetworkSettings` . The `"Ports"` subsection will include the info about your http host port.

## 5. Check the application output in a web browser

To see the application output, open a web browser and go to:

- `http://localhost:<host-port>/<artifact-name>/` if you are using Docker for Windows, macOS or Linux.
- `http://192.168.99.100:<host-port>/<artifact-name>/` if you are using Docker Toolbox for Windows or macOS (deprecated).

`<host-port>` is the host port mapped onto the container's http port.

`<artifact-name>`, by default, is the name of the `.war` file if you deployed your app as a WAR, or the name of the app root directory if you deployed your app as a directory structure.

**Tip** You can also add the corresponding Build artifact task to the Before launch task list. Then, your WAR artifact will be built automatically each time you execute the run configuration.

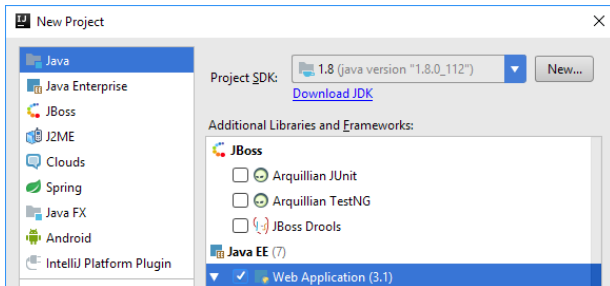

**Tip** This Dockerfile sets `jboss/wildfly` as the base image and copies the local file `<artifact-name>.war` located in the same as the Dockerfile directory to the server deployment directory

```
/opt/jboss/wildfly/standalone/  
deployments/
```

In this example, a one-page JSP application is deployed into a [Wildfly app server image](#) -based container.

## 1. Develop the app

1. Create a project for developing a Java web application: File | New | Project | Java Enterprise | Web Application , etc.

2. When the project is created, add text (e.g. `Hello World!` ) to `index.jsp` , see e.g. [Developing source code](#) .

## 2. Specify deployment info in a Dockerfile

1. In the project root directory, create a new directory (e.g. `docker-dir` ): File | New | Directory .  
We'll use this directory to store our `Dockerfile` and a `.war` application artifact.
2. In the `docker-dir` directory, create a `Dockerfile` .
3. Add the following to your `Dockerfile` :

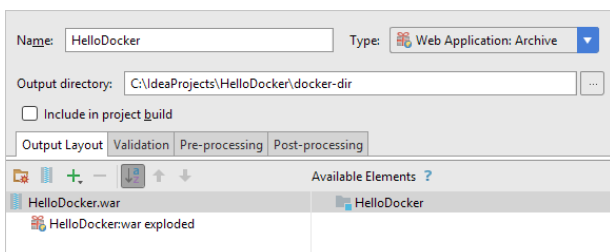

```
FROM jboss/wildfly  
COPY <artifact-name>.war /opt/jboss/wildfly/standalone/deployments/
```

Use the actual artifact name in place of `<artifact-name>` . On the following picture, the name of the artifact is `HelloDocker` .

## 3. Configure a WAR artifact

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ) and select Artifacts .
2. Click `+` , select Web Application: Archive and select For '`<project-name>.war exploded`' .
3. Change the artifact name. The name should be the same as in your `Dockerfile` ( `<artifact-name>` ) but without `.war` at the end.
4. Select the `docker-dir` directory as the artifact output directory.

5. Click OK in the Project Structure dialog.

## 4. Build the artifact

- Select Build | Build Artifacts | `<WarArtifactName>` | Build .

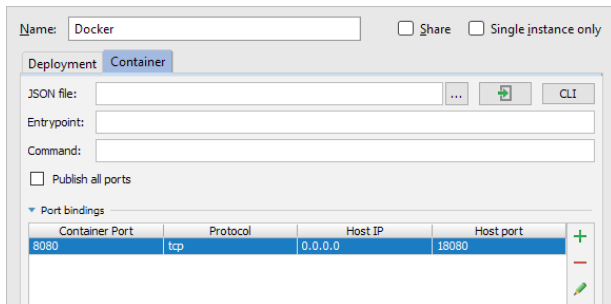

## 5. Run your Dockerfile

- In your `Dockerfile`, click  and select Run on 'Docker'.

## 6. Map the container http port 8080 onto a host port

1. Open the run configuration associated with your `Dockerfile` for editing:  | Edit '<ConfigurationName>'
2. Select the Container tab, expand the Port bindings section, and click  to create a new port mapping.
3. In the dialog that opens, specify:

- Container port: `8080`
- Protocol: `tcp`
- Host IP: `0.0.0.0`
- Host port: `18080`

4. Click Run.

## 7. Check the application output in a browser

When the container is started, open a web browser and go to:

- If you are using Docker for Windows, macOS or Linux: `http://localhost:18080/<artifact-name>/`
- If you are using the Docker Toolbox for Windows or macOS (deprecated): `http://192.168.99.100:18080/<artifact-name>/`

This feature is only supported in the Ultimate edition.

In this section:

- EJB
  - [General EJB features](#)
  - [EJB 3.0-specific features](#)
- [Enabling EJB Support](#)
- [Creating EJB](#)
- [Configuring Primary Key](#)
- [Configuring Service Endpoint](#)
- [Creating and Editing Assembly Descriptors](#)
- [Creating CMP Bean Fields](#)
- [Creating Local and Remote Interfaces](#)
- [Creating Message Listeners](#)
- [Creating Transfer Objects](#)
- [Defining Bean Class and Package](#)
- [Editing Module with EJB Facet](#)
- [Migrating to EJB 3.0](#)
- [Using EJB ER Diagram](#)

## General EJB features

IntelliJ IDEA features the complete EJB support. It understands EJB specifications from 1.x to 3.0, and leverages them through all of its productivity-boosting features - from coding assistance to refactoring, creating the environment ideally suited for developing EJB applications.

- [File](#) and [live](#) templates for entity, session, message and other beans.
- Auto-generating code for CMP beans, fields and relationships.
- Dedicated context editors for all supported beans.
- Automatic building of standard EJB deployment packages.
- Automatic generation of appropriate EJB XML descriptors.
- Complete EJB-aware coding assistance:
  - [Code completion](#) for both EJB code and descriptor files.
  - EJB error highlighting.
  - EJB-aware [intention actions](#) and [quick fixes](#).
  - Powerful EJB-aware [refactorings](#).

IntelliJ IDEA unifies all EJB-related application parts in the dedicated [facet](#), which includes EJB descriptors, build, and library settings.

Multiple EJB facets are allowed per module.

## EJB 3.0-specific features

- Annotation mechanism for creating EJB, and Interceptors.
- Automatic code generation, completion and dedicated binding editor.
- Full EJB persistence support, powered with generating of persistence mapping from entity beans, [Hibernate](#) or JDBC source.
- Visual Persistence diagram builder.
- Migration of your existing EJB projects (versions 1.x and 2.x) to EJB 3.0 with:
  - Converting EJB environment access.
  - Rebuilding EJB deployment descriptors.
  - Transforming EJB interfaces.
  - Turning Entity Beans into Container Managed Persistence.

This feature is only supported in the Ultimate edition.

You can enable EJB support when creating a new project or module. You can also add the EJB support for an existing module.

- [Enabling EJB support when creating a project or module](#)
- [Enabling EJB support for an existing module](#)

## Enabling EJB support when creating a project or module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.

2. On the first page of the wizard, in the left-hand pane, select Java Enterprise . In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.

3. Under Additional Libraries and Frameworks , select the EJB: Enterprise Java Beans checkbox.

4. Select the EJB version to be supported from the Versions list.  
If you want an EJB deployment descriptor file `ejb-jar.xml` to be created, select the Create ejb-jar.xml checkbox.

Select the required library option and, if necessary, specify the associated settings. You can choose to:

- Download and use an EJB library.  
To do that, under Libraries , select Download .

Now, to view or modify the associated options, click [Configure](#) , and in the Downloading Options dialog that opens:

- Specify the library name.
- Select the [library level](#) (global, project, or module).
- Under Files to download , select which of the files you want to download.
- Under Copy downloaded files to , specify the path to the destination folder. If you want to change the default path, click  and specify the folder location in the [dialog that opens](#) .
- Use an EJB library IntelliJ IDEA is already aware of.  
To do that, click Use library and select the required library from the list.

If necessary, configure the library settings (for example, change its name). This is done in the Edit Library dialog which you can open by clicking [Configure](#) .

- Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click [Create](#) . Select the required JAR files in the [dialog that opens](#) . (For multiple selection, keep the `Ctrl` key pressed.)

If necessary, configure the new library (for example, change its name or [level](#) ). To do that, click [Configure](#) and specify the required settings in the Create Library dialog.

- Postpone setting up the library until a later time. In this case, select Set up library later .

Click [Next](#) .

5. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click [Finish](#) .

## Enabling EJB support for an existing module

1. [Open the Project tool window](#) (e.g. View | Tool Windows | Project ).
2. Right-click the module and select Add Framework Support .
3. In the left-hand pane of the Add Frameworks Support dialog, select the EJB: Enterprise Java Beans checkbox.  
Select the EJB version to be supported from the Versions list.

If you want an EJB deployment descriptor file `ejb-jar.xml` to be created, select the Create ejb-jar.xml checkbox.

Select the required library option and, if necessary, specify the associated settings. You can choose to:

- Download and use an EJB library.  
To do that, under Libraries , select Download .

Now, to view or modify the associated options, click [Configure](#) , and in the Downloading Options dialog that opens:

- Specify the library name.

- Select the [library level](#) (global, project, or module).
- Under Files to download , select which of the files you want to download.
- Under Copy downloaded files to , specify the path to the destination folder. If you want to change the default path, click  and specify the folder location in the [dialog that opens](#) .
- Use an EJB library IntelliJ IDEA is already aware of.  
To do that, click Use library and select the required library from the list.

If necessary, configure the library settings (for example, change its name). This is done in the Edit Library dialog which you can open by clicking Configure .

- Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click Create . Select the required JAR files in the [dialog that opens](#) .  
(For multiple selection, keep the  key pressed.)

If necessary, configure the new library (for example, change its name or [level](#) ). To do that, click Configure and specify the required settings in the Create Library dialog.

- Postpone setting up the library until a later time. In this case, select Set up library later .

4. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides the following ways to create beans:

- Manually, by means of direct [editing](#) the `ejb-jar.xml` file, using the extensive coding assistance provided by IntelliJ IDEA.
- Using the [context menu](#) commands.

## To create an Enterprise Java bean using the editor

1. Open the deployment descriptor file `ejb-jar.xml` for editing.
2. Create the `<enterprise-beans>` section.
3. In this section, create tags for the desired bean types: `<session>` , `<entity>` , or `<message-driven >`
4. Specify the bean name and class by adding tags `<ejb-name>` . and `<ejb-class>` . Note that you can specify the target package in this tag, for example, `samples.ejb.ManuallyCreatedEntity` , using code completion after each dot.
5. If the declared class does not yet exist, IntelliJ IDEA suggests a quick fix:

Choose Create Class `<class name>` from the suggestion list. If the target package was not defined in the `<ejb-class>` tag, select the desired package in the Choose Destination Directory dialog box. The stub class is created in the specified location.

6. Proceed with defining the other bean components.

## To create an Enterprise Java bean, follow these general steps

1. Open the [EJB tool window](#) .
2. Right-click the desired module, choose New on the context menu, and then select the bean type on the submenu.  
The New `<bean type>` Bean dialog box opens.

**Tip** Alternatively, choose Jump to Source on the context menu of a module, to open the dedicated editor, in the General tab click New , or right-click the diagram background in the EJB Relationships tab, and select the desired bean type.

3. Specify the [bean name](#), [class](#) and [package](#) .
4. Define the bean-specific settings:
  - For Entity beans (1.x and 2.x) and Session beans (1.x and 2.x), [configure local and remote interfaces](#) .
  - For Entity beans (1.x and 2.x), [configure primary keys](#) and [CMP bean fields](#) .
  - For Message beans, [configure message listener](#) .
  - For Session beans, [configure service endpoint](#) .

This feature is only supported in the Ultimate edition.

Primary keys are defined for CMP Entity beans and BMP Entity beans , versions 1.x and 2.x.

Same as the other bean properties, the primary keys can be defined by editing the source code, or using the tools provided by IntelliJ IDEA.

## To configure a primary key

1. [Create a new entity bean](#) .  
Alternatively, [open the desired bean for editing](#) , and click the Change EJB Classes button.
2. In the Primary key class field specify the class that will be used to access the primary key of a datasource the bean is associated with.
3. From the CMP version list select EJB specification version for the bean. This setting is disabled for BMP entity beans.

This feature is only supported in the Ultimate edition.

Service endpoint is defined for Session beans , versions 1.x, 2.x and 3.0.

Same as the other bean properties, the service endpoint can be defined by editing the source code, or using the tools provided by IntelliJ IDEA.

## To configure a service endpoint

1. Open a session bean for [editing](#) , and click Change EJB Classes .
2. In the Change EJB Classes dialog box, select the Service Endpoint checkbox and specify the to be used as an endpoint for calling services.

**Note** For bean specification prior to 3.0 you also need to [configure interfaces](#) .

This feature is only supported in the Ultimate edition.

Assembly Descriptors define how a bean is deployed and configured at the application server.

Same as the other bean properties, the application descriptors can be defined by editing the source code, or using the tools provided by IntelliJ IDEA.

### To add an assembly descriptor to a bean

1. [Open the desired bean for editing](#) , and select the [Assembly Descriptor](#) tab.
2. Click **+** on the toolbar.
3. From the drop-down list, select the desired assembly descriptor type.
4. In the dialog box that opens, specify the assembly descriptor properties. Refer to the [EJB Editor - Assembly Descriptor](#) page for the detailed description of options.

This feature is only supported in the Ultimate edition.

CMP fields are used to provide persistence of the entity beans. Being created, a CMP field appears in the deployment descriptor, and its accessor methods are added to the entity bean classes. So doing, IntelliJ IDEA provides gutter icons in the editor that help you jump from a CMP field declaration in the deployment descriptor to the accessor methods in the bean class, and vice versa:

IntelliJ IDEA enables you to create CMP fields in several ways:

- By means of direct [editing the source code](#) . In this case, IntelliJ IDEA provides coding assistance, and the corresponding nodes are created in the [EJB](#) tool window.
- Using the [context menu of an entity bean](#) .
- Using the [bean editor](#) .

## To create a CMP field by editing the source code

1. Open the deployment descriptor file `ejb-jar.xml` for editing.
2. In the `entity` section for the corresponding entity bean, type the tags for CMP fields, and specify their names.
3. Open the source code of the desired entity bean class for editing. The code inspection detects missing accessor methods:

4. Press `Alt+Enter` to reveal the list of suggested quick fixes:

5. Create getter and setter methods in the bean implementation class.
6. If you want to make the new CMP field a primary key , add the `<primkey-field>` entry to the deployment descriptor.

## To create a CMP field

1. In the [EJB](#) tool window, right-click the desired entity bean.
2. On the context menu, click `New` , and then choose `CMP field` on the submenu.

**Tip** Alternatively, [open the desired bean for editing](#) , and in the `CMP Fields` section click `+` .

3. In the `Create CMP Field` dialog box, specify the following parameters:
  - Field name, optional description and type. You can choose the desired type from the drop-down list, or click the ellipsis button and select type from the `Choose CMP Field Class` dialog box.
  - Whether the new CMP field will be a primary key. Select the `Primary key` checkbox, if you want to make this field a primary key.
  - Whether the accessor methods will be generated in the local and remote interfaces. If you select the corresponding checkboxes, the getter and setter methods will be created in the local and remote interfaces, in addition to the bean class.
4. Click `OK` .

This feature is only supported in the Ultimate edition.

Local and remote interfaces are used to provide access to the bean from the calling clients, and are defined for the following types of beans:

- Entity Beans, both CMP and BMP versions 1.x and 2.x
- Session Beans versions prior to 3.0

IntelliJ IDEA provides the following ways to create local and remote interfaces:

- Manually, by means of direct [editing](#) the `ejb-jar.xml` file, using the extensive coding assistance provided by IntelliJ IDEA.
- Using the [context menu](#) commands.

## To define local and remote interfaces of an enterprise bean using the editor

1. Open the deployment descriptor file `ejb-jar.xml` for editing.
2. In the `<entity>` section, create tag `<local>`, or `<remote>` and type the name of the desired interface. Note that you can specify the target package in this tag, for example, `samples.ejb.ManuallyCreatedEntityLocalInterface`, using code completion after each dot.
3. If the declared class does not yet exist, IntelliJ IDEA suggests a quick fix. Choose Create Class `<class name>` from the suggestion list. If the target package was not defined in the `<ejb-class>` tag, select the desired package in the Choose Destination Directory dialog box. The stub class is created in the specified location.

## To configure local and remote interfaces

1. [Open the New Bean dialog box](#).
2. If you need to configure remote client view of a bean, select the Remote Interface checkbox.
  - In the Home field specify the name for the bean remote home interface .
  - In the Remote field specify the name for the bean remote interface .
3. If you need to configure local client view of a bean, select the Local Interface checkbox.
  - In the Home field specify the name for the bean local home interface .
  - In the Remote field specify the name for the bean local interface .

This feature is only supported in the Ultimate edition.

Message listener is defined for a Message bean , versions 1.x, 2.x or 3.0.

Same as the other bean properties, the message listener can be defined by editing the source code, or using the tools provided by IntelliJ IDEA.

### **To configure a message listener**

1. [Open the New Bean dialog box](#) .  
Alternatively, [open the message desired bean for editing](#) , and click the Change EJB Classes button.
2. In the Message Listener field specify class that will be used to handle the Java Messaging Service messages.

This feature is only supported in the Ultimate edition.

Transfer Object is used as a proxy between an entity bean and its client. Entity beans use transfer objects to send data to the clients thus reducing the exchange traffic, because all required data are transferred at once, packed in a single object.

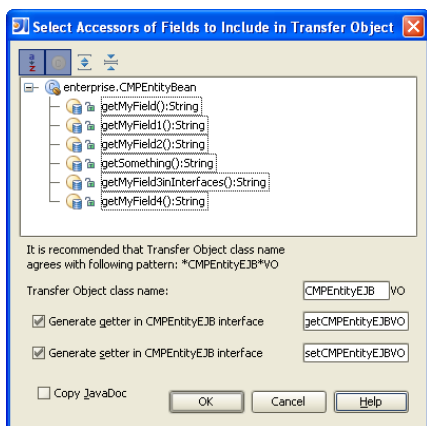

Though you can create a transfer object manually, as a class that implements the `Serializable` interface and provides accessor methods to certain fields of an entity bean, IntelliJ IDEA helps automatically generate stub source code.

## To create a transfer object

1. In the EJB tool window, right-click the desired entity bean.
2. On the context menu, click New , and then choose Transfer Object on the submenu.

3. In the dialog box Select Accessors of Fields to Include in Transfer Object , select the methods to be included in the new transfer object.

**Tip** Use **Ctrl** and **Shift** keys in combination with the mouse click to select multiple adjacent or non-adjacent methods.

4. Specify the following parameters:
  - Name of the transfer object class. Note that IntelliJ IDEA suggests a pattern for generating the class name, so you can only change the initial part of it.
  - Whether the accessor methods will be generated in the bean interface.
5. Click OK .

This feature is only supported in the Ultimate edition.

You can define the bean class and package by means of editing the source code, or use the tools provided by IntelliJ IDEA.

## To define bean class and package

1. [Open the New Bean dialog box](#) .

Alternatively, [open the desired bean for editing](#) , and click the Change EJB Classes button.

2. In the <ejb-name > field, specify the bean name that will be complemented with a prefix and suffix configured in the [Java EE Names](#) tab of the [Global Code Style](#) dialog box.
3. In the Package field, specify the name of the package where the bean will reside. In the EJB class field, specify class name for this bean.

This feature is only supported in the Ultimate edition.

Though you can directly edit the source code of the deployment descriptor of a module with EJB facet, it is also possible to use a dedicated [editor](#) , where you can manage the contained beans, their relationships and security permissions.

**Note** You can only edit the modules that contain `ejb-jar.xml` descriptor. For annotations-only modules, edit the annotations manually to adjust the module settings. If both annotations and `ejb-jar.xml` descriptor are present in a module, the descriptor settings override annotations.

## To edit a module with EJB facet

1. Open the [EJB tool window](#) .
2. Right-click the desired module, and do one of the following:
  - Choose Jump to Source on the context menu.
  - Press `F4` .
  - Double-click the EJB module node.

**Tip** Same way you can also open for editing the `ejb-jar.xml` file. In this case, in addition to the General , Method Permissions , and Transaction Attributes tabs, the editor provides the Text tab, with the EJB-aware XML editor.

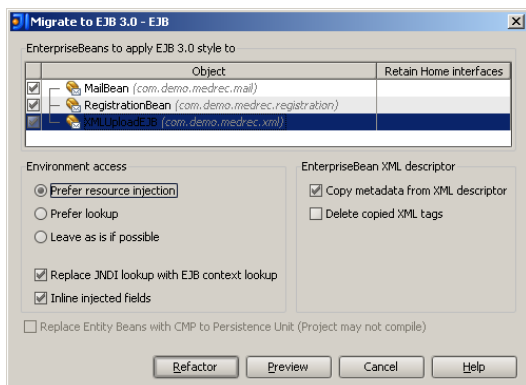

3. On the [General tab](#) of the editor, [add new beans](#) , [edit existing beans](#) , or delete them.
4. On the [Method Permissions tab](#) , configure security roles.
5. On the [Transaction Attributes tab](#) , specify transaction attributes for the bean methods.

This feature is only supported in the Ultimate edition.

If you want to use the advantages of EJB 3.0 specification, you can migrate your existing beans of the various types from EJB 1.x or 2.0 to EJB 3.0. IntelliJ IDEA suggests the Apply EJB 3.0 Style refactoring that brings the structure of the beans into compliance with the requirements of EJB 3.0 specification.

## To migrate a bean to EJB 3.0 specification

1. Open the [EJB tool window](#) .
2. Select the desired module, or bean, to be migrated, and choose Apply EJB 3.0 Style on the context menu.
3. In the Apply EJB 3.0 Style dialog box displaying the list of all items within the module, select the ones to be migrated:

If you want to convert home interfaces rather than remove them, select the Retain Home Interfaces checkbox, where applicable.

4. Configure the environment access and XML descriptor options. Refer to the [Apply EJB 3.0 Style dialog](#) for the detailed description of options.
5. Though you can click Refactor and perform migration straight away, it is recommended to click Preview first, and explore the tentative migration results in the [Find Tool Window](#) .
6. In the Find tool window, click Do Refactor .

This feature is only supported in the Ultimate edition.

EJB entity-relationship (ER) diagrams let you view entity beans, and also create and edit relationships between them.

### To select elements in an EJB ER diagram

- To select an element, just click it on the diagram.
- To select multiple adjacent elements, keep the **Shift** key pressed, and click the desired elements, or just drag a *lasso* around the elements to be selected.
- To select multiple non-adjacent elements, keep **Ctrl+Shift** pressed and click the desired elements.

### To manage the diagram layout

- Right-click the diagram background, and choose Layout command in the diagram context menu. Next, select the desired layout from the submenu.
- Use Drag-and-drop technique to lay out entities in the diagram manually.
- Restore the last selected layout by clicking  on the diagram toolbar.

**Warning!** The following is only valid when Erlang Plugin is installed and enabled!

IntelliJ IDEA provides [Erlang](#) support. IntelliJ IDEA recognizes `*.erl` files, and allows you to edit them providing full range of coding assistance. Erlang files are marked with  icon.

In this section:

- [Getting Started with Erlang](#)

[Erlang](#) is a great language that lets you build highly concurrent applications. This tutorial will teach you how to quickly get started with it.

In this section:

- [Preliminary steps](#)
  - [Installing Erlang OTP](#)
    - [Windows](#)
    - [macOS](#)

  - [Learning Erlang](#)
  - [Learning IntelliJ IDEA](#)
  - [Providing Feedback](#)

## Preliminary steps

### Installing Erlang OTP

The first thing for setting up an Erlang environment is installing Erlang OTP, a set of Erlang libraries essential for development.

#### Windows

If you are a Windows user, download the [Erlang OTP package](#) and run the installation wizard. Once the installation is over, add the installation path plus `\bin` to the PATH environment variable.

#### MacOS

If you are an macOS user, to install Erlang OTP, type the following at the Terminal prompt (make sure you have [Homebrew](#) installed on your machine):

```
brew install erlang
```

If you prefer [MacPorts](#) to Homebrew, your command line should be different:

```
port install erlang +ssl
```

#### Linux

The installation process for Linux is similar to macOS, except that instead of `brew` or `port` you have to use `apt-get` (a Linux package management utility):

```
apt-get install erlang
```

**Tip** You can always [download](#) the latest version of Erlang OTP package for any OS.

### Verifying Erlang OTP installation

To verify that Erlang OTP is installed correctly, run the Erlang shell by typing `erl` in a Terminal prompt:

```
unit-496:local jetbrains$ erl
Erlang/OTP 17 [erts-6.3] [source] [64-bit] [smp:4:4] [async-threads:10] [hipe] [kernel-poll:false] [dtrace] 3 shell

Eshell V6.3 (abort with ^C)
1> X = 42.
42
2>
```

To learn more about the Erlang shell, read its [user guide](#).

### Installing Rebar

In addition to Erlang OTP, you'll also need [Rebar](#), a build tool that helps compile and test Erlang applications. The easiest way to install it on your machine is to download its sources and build it locally:

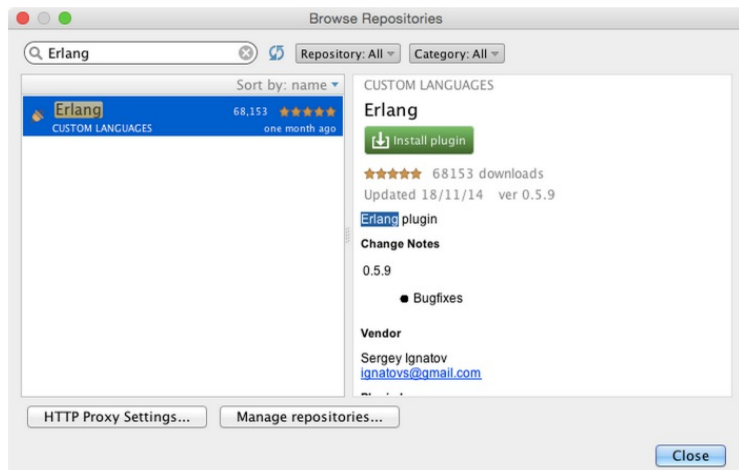

```
git clone git://github.com/rebar/rebar.git
$ cd rebar
$ ./bootstrap
Recompile: src/getopt
...
Recompile: src/rebar_utils
==> rebar (compile)
```

Congratulations! You now have a self-contained script called "rebar" in your current working directory. Place this script anywhere in your path and you can use rebar to build OTP-compliant apps.

## Setting up IntelliJ IDEA

Now when Erlang OTP and Rebar are set up, it's time to [download](#) and [install](#) IntelliJ IDEA. Keep in mind, that for Erlang development you can use IntelliJ IDEA Community Edition (which is free and open-source).

Once the IDE is up and you see its [Welcome screen](#), go to [Configure | Plugins](#), then click [Browse repositories](#), locate the Erlang plugin and install it:

After installing the plugin, restart IntelliJ IDEA.

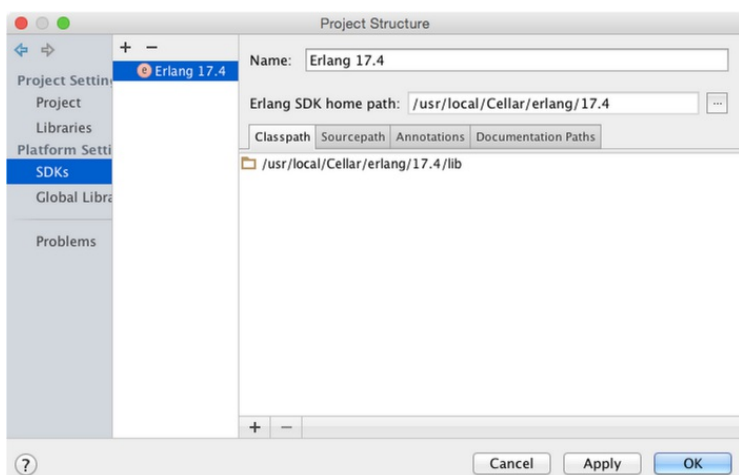

## Configuring an Erlang SDK

One more thing you'll have to do to configure IntelliJ IDEA is to add an Erlang SDK.

To do that, change the structure of the default project. Open the default project structure in one of the two ways:

- On the [Welcome screen](#), go to [Configure | Project Defaults | Project Structure](#)
- On the main menu, choose [File | Other Settings | Default Project Structure](#)

Then, add an Erlang SDK by specifying the path to the Erlang OTP installation directory.

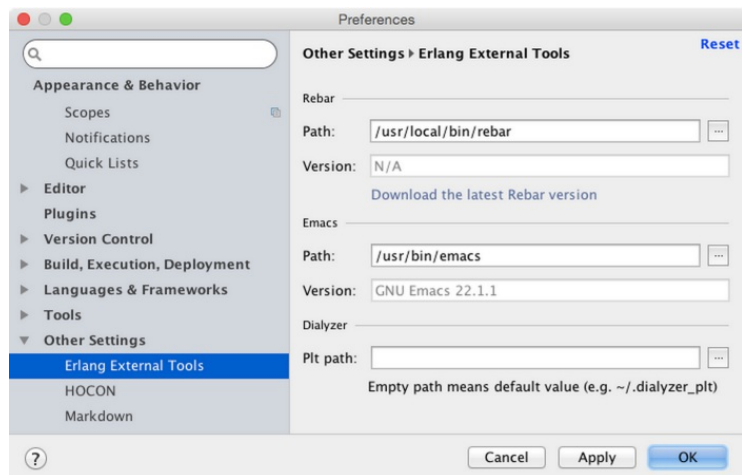

If you don't know where Erlang OTP was installed, check the following directories:

- Windows: `C:\Program Files\erl<version>`
- Linux: `/usr/lib/erlang/<version>`
- MacPorts, macOS: `/opt/local/lib/erlang/<version>`
- Homebrew, macOS: `/usr/local/Cellar/erlang/<version>`

## Configuring Rebar

The final adjustment you have to do is to specify the path to Rebar, so that IntelliJ IDEA can run Rebar commands from the IDE.

You can do it via Configure | Preferences | Other Settings → Erlang External Tools :

## Creating a new project

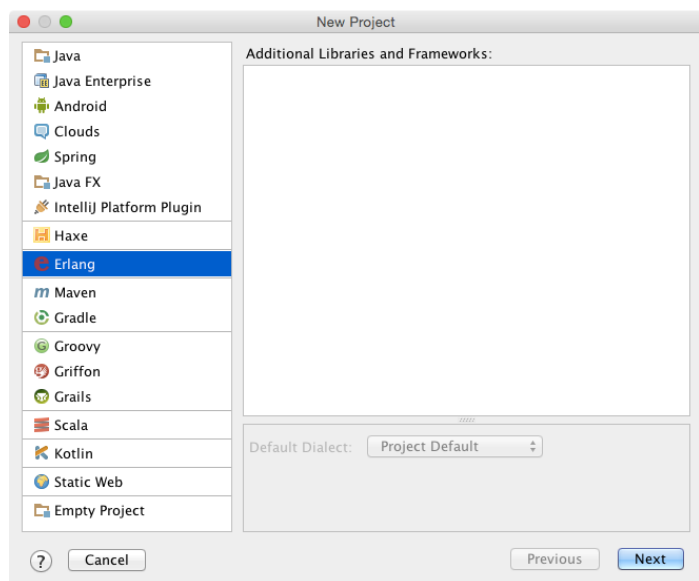

### Creating an Erlang project

There are several ways to [create](#) a new Erlang project. The easiest one is to use the [New Project Wizard](#) from the Welcome screen.

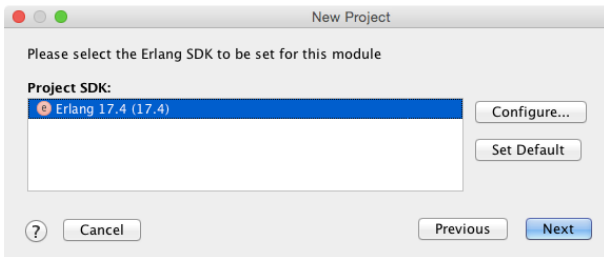

Click Create New Project :

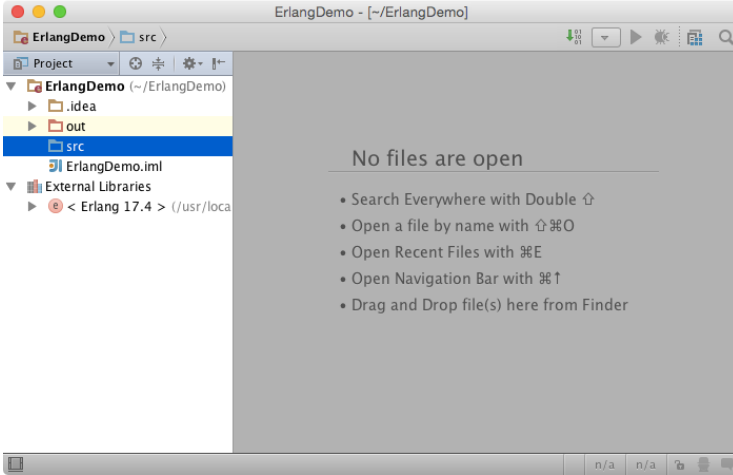

Then choose Erlang in the left pane, and click Next.

IntelliJ IDEA prompts you to choose an Erlang SDK (which you've already configured):

After that you'll be asked to specify the name of your project and its directory. The following image shows the resulting Erlang project with the name `Er1angDemo` :

## Creating a Rebar project

Instead of a pure Erlang project, you might want to create a [Rebar](#) project. To do that, type the following code at the Terminal prompt:

```
rebar create-app appid=<project name>
```

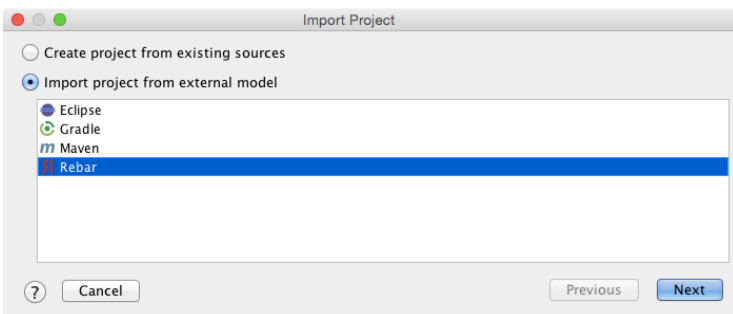

Once the project has been created, [import](#) it into IntelliJ IDEA to make it possible to open this project in the IDE.

## Importing a project into IntelliJ IDEA

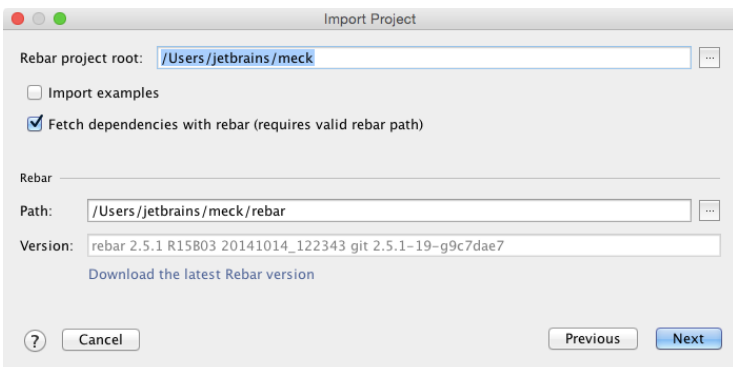

You can [import](#) a project into IntelliJ IDEA in several ways. Let's explore importing from the Welcome screen.

To import an existing project into IntelliJ IDEA, click Import on the Welcome Screen, and choose the project directory. IntelliJ IDEA offers you to either import the project from existing sources, or from an external model (a build file).

If your project uses Rebar, select the corresponding option when asked.

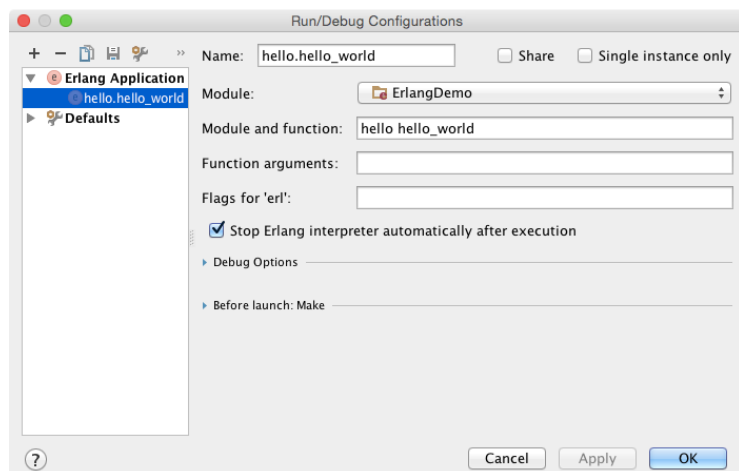

When importing a Rebar project, make sure to enable the option Fetch dependencies with rebar :

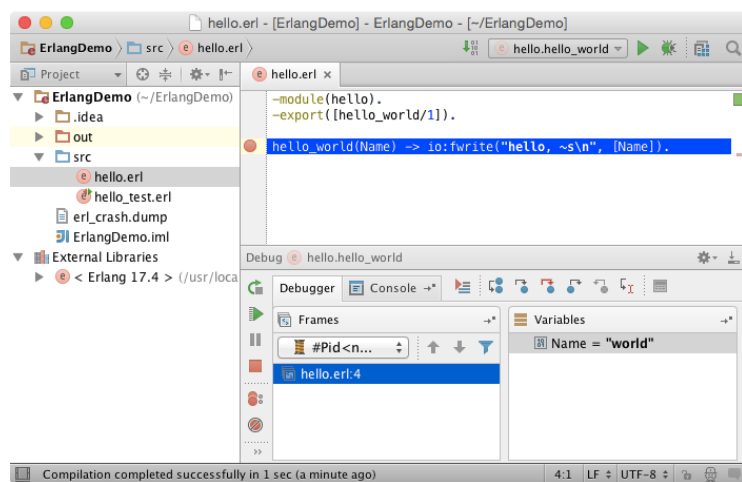

## Running and debugging an application

To run an application, you have to [create a run/debug configuration](#) created against the stub Erlang Application . To do this, on the main menu choose Run | Edit Configurations , select the stub Erlang Application , specify the name (here it is `hello.hello_world` ), and specify the application's module and function:

After that you'll be able to run your application via the main menu ( Run | Run <run configuration name> ), the toolbar (  ), or a even a shortcut ( `Ctrl+Shift+F10` ).

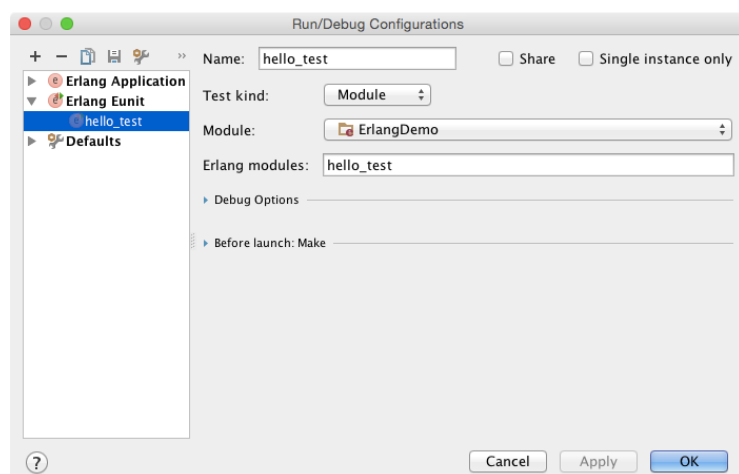

Once you have a run/debug configuration, you can also debug your application via the main menu ( Run | Debug '<run configuration name>' ), the toolbar (  ), or a shortcut ( `Shift+F9` ):

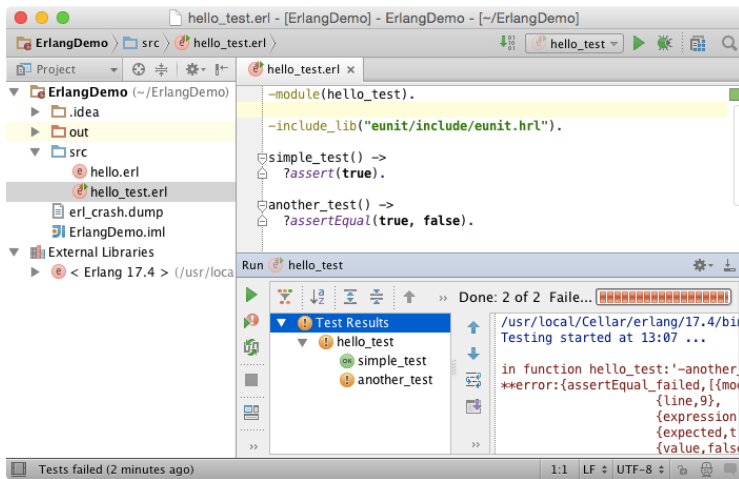

For more information, refer to the [concept of a run/debug configuration](#) and the procedural sections [Running](#) and [Debugging](#)

## Running Eunit tests

Running Eunit tests is similar to running an application, but needs a different run/debug configuration, created against the stub Erlang Eunit :

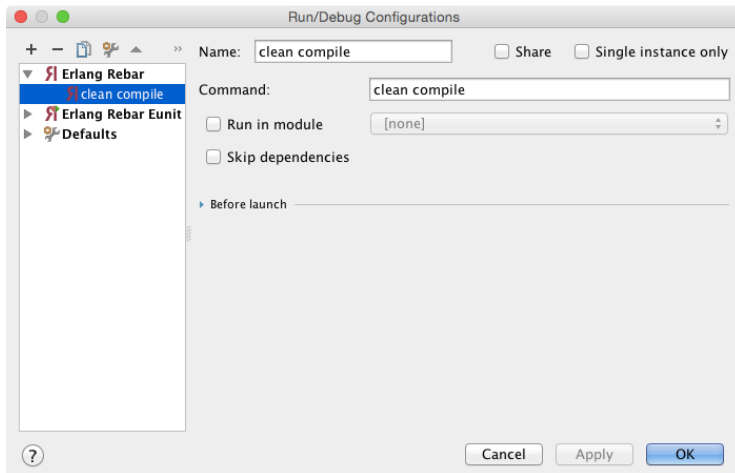

IntelliJ IDEA provides a handy [Test Runner](#) with support for [Eunit](#) . It shows test results, lets you rerun tests of you choice, jump to failed tests, etc.:

## Running Rebar commands

Running Rebar commands is also possible right from the IDE – with the help of the Erlang Rebar run/debug configuration:

Note that if your Rebar commands run tests, you can use a Erlang Rebar Eunit run/debug configuration to see test results in a Test Runner.

## Additional

### Learning Erlang

To learn Erlang, we recommend that you start by reading the [official Erlang user guide](#), and of course the [Learn You Some Erlang for Great Good](#) tutorial by [Fred Hebert](#).

### Learning IntelliJ IDEA

IntelliJ IDEA is a Java IDE in the first place, however it's also a platform and IDE for other languages, such as Erlang, Python, Ruby, PHP, and many other. To learn more about IntelliJ IDEA, it's worth checking out the section [Discover IntelliJ IDEA](#) and watch the [Video Tutorials](#).

If you have a question, you can always ask it on [StackOverflow](#) (probably it's already answered).

### Providing Feedback

In case you'd like to share your feedback about IntelliJ IDEA or its support for Erlang, feel free to submit an issue in [Erlang plugin GitHub repository](#), or to the [IntelliJ IDEA issue tracker](#).

Refer to the section [Reporting Issues and Sharing Your Feedback](#).

This feature is only supported in the Ultimate edition.

IntelliJ IDEA implements [Grails](#) technology and allows creating Grails application with the specific folder structure and all the necessary artifacts.

IntelliJ IDEA supports all features of Grails 3.0.0 and later versions.

In this section:

- Grails
  - [Prerequisites](#)
  - [Grails features in IntelliJ IDEA](#)
- [Getting Started with Grails 3](#)
- [Getting Started with Grails 1/2](#)
- [Creating a Grails Application Module](#)
- [Creating Grails Application from Existing Code](#)
- [Grails Procedures](#)

## Prerequisites

Make sure that the desired SDK is downloaded and installed on your computer, and the libraries are properly configured.

Also, make sure that the Grails plugin is enabled in IntelliJ IDEA. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not enabled, [enable the plugin](#).

## Grails Features in IntelliJ IDEA

Grails support in IntelliJ IDEA includes the following features:

- Automated way of creating Grails Applications that provides generation of the specific structure and artifacts.
- Automatic enabling Groovy support in the Grails Application modules, allowing creation of the Groovy classes, interfaces and scripts.
- Execution of the [targets](#).
- Possibility to [generate scaffolding](#).
- Possibility to [generate tests](#).
- [Code completion](#).
- Querying with [dynamic finders](#).
- Dedicated [run/debug configuration](#).
- Grails 3.1.0 supports the GORM version 5.0.
- Grails [Web Layer](#).
- [Grails Resources plugin](#).
- Grails [Spock](#).
- Grails [Standalone GORM](#)

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports [Grails version 3.0](#) and later.

- [Before you start](#)
- [Creating Grails 3 Project](#)
- [Exploring Grails Application](#)
- [Running Grails 3 Application](#)
- [Debugging Grails 3 Application](#)
- [Grails 3 Coding Assistance](#)
- [Grails 3 Gradle Support](#)

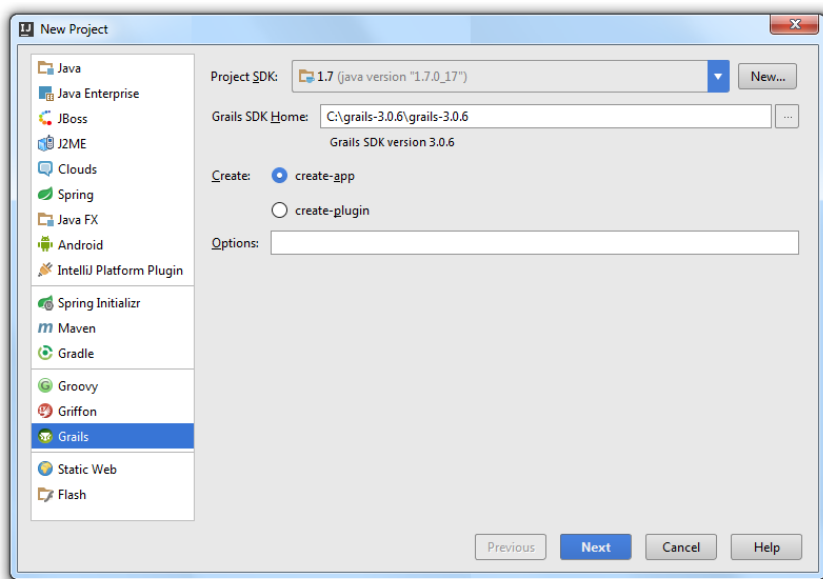

## Before you start

Before you start creating your project with Grails framework, make sure that you have the latest Grails SDK version downloaded on your machine. You can download the latest SDK version from the [Grails page](#) . Also, make sure that you are working with IntelliJ IDEA ultimate edition, version 15 or higher if you want to work with the Grails 3.0 version. See the [latest available version](#) .

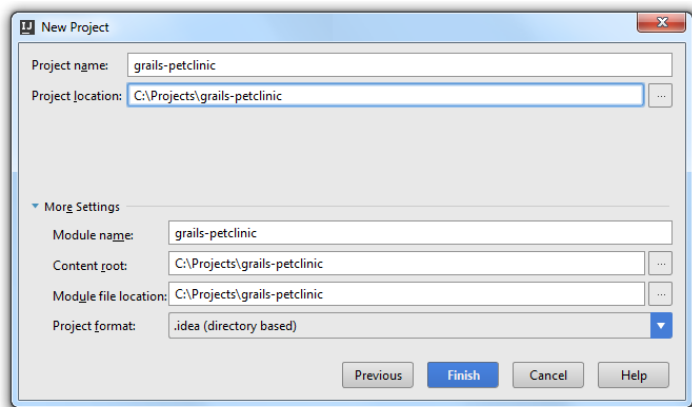

## Creating Grails 3 Project

1. Open [Project Wizard](#) , in the left-hand pane select Grails .
2. In the right-hand part of the page, specify the following information:
  - Project [JDK](#) that you are going to use for your project.
  - Grails SDK Home - your local Grails 3 installation which is represented by a [library](#) .
  - Create create-app or create-plugin - select one of these options depending on what you want to create.
  - Options - use this field for additional options. For example, you can specify a profile such as `--profile=web` for Grails 3.

Click Next .

3. On the next page of the wizard, specify the project's information and click Finish .

IntelliJ IDEA creates the Grails application.

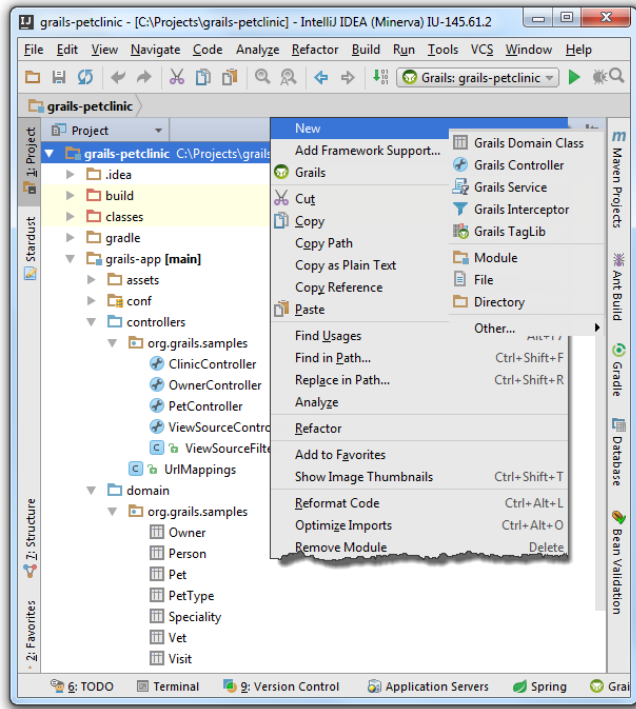

## Exploring Grails Application

IntelliJ IDEA enables you to explore your Grails application. Note that the [Grails view](#) is supported for Grails 3. Also, note that all the [Project view settings](#) are available for the Grails view as well.

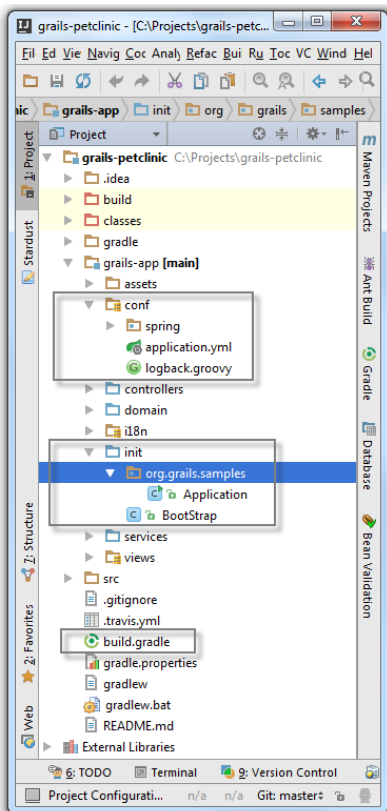

Grails actions are available in the Project view. All artifact icons are changed to Grails icons.

Other notable differences from the previous Grails versions are as follows:

- `build.gradle` - the Grails version 3 uses Gradle for building. When you import Grails 3 project you can import it through the Gradle model.
- `config` directory - the content of the config directory enables you to use either a YAML file or Groovy file for your configuration. The logging configuration is also available.
- `init` directory - this directory contains main application file the lets you run your application with default settings.

For more information on the Grails version 3 changes, please see the [Grails](#) page.

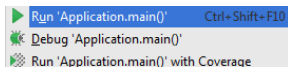

## Running Grails 3 Application

When the Grails application is created it is ready to run.

Click the  icon on the top right corner of your workspace.

If you want to run the application from the editor, perform the following steps:

1. In the Project tool window, click the init folder.
2. From the drop-down list, select Application.groovy to open the file in the editor.
3. In the editor, in the left gutter, click  icon and in the window that opens click Run 'Application.main()' .

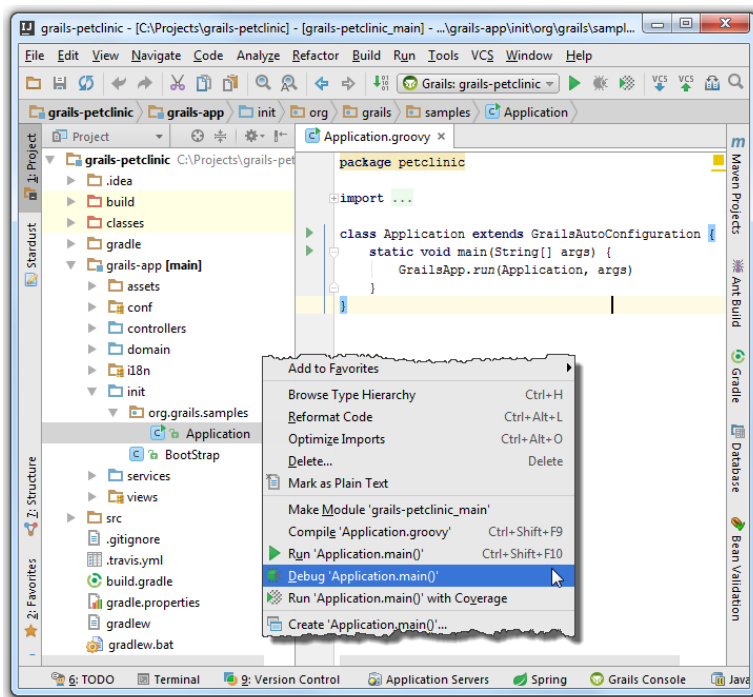

Your application starts in your default browser, with the following URL in the address bar:

`http://localhost:8080/`

## Debugging Grails 3 Application

IntelliJ IDEA lets you debug your Grails 3 application using `Application.groovy` .

1. In the Project tool window, open init directory and right-click the Application.groovy
2. From the drop-down list select Debug Grails:'name'

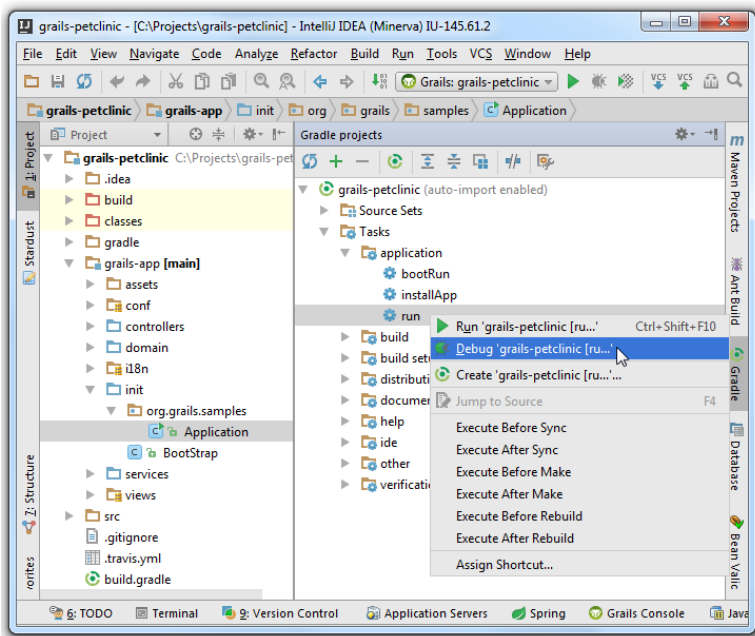

You can also use the editor to start the debugging process.

IntelliJ IDEA lets you also debug your Grails 3 application using Gradle tasks.

1. Open [Gradle tool window](#) .
2. From the list of tasks, click application and in the list that opens, right-click run .
3. From the drop-down list that opens, select Debug Grails:'name'

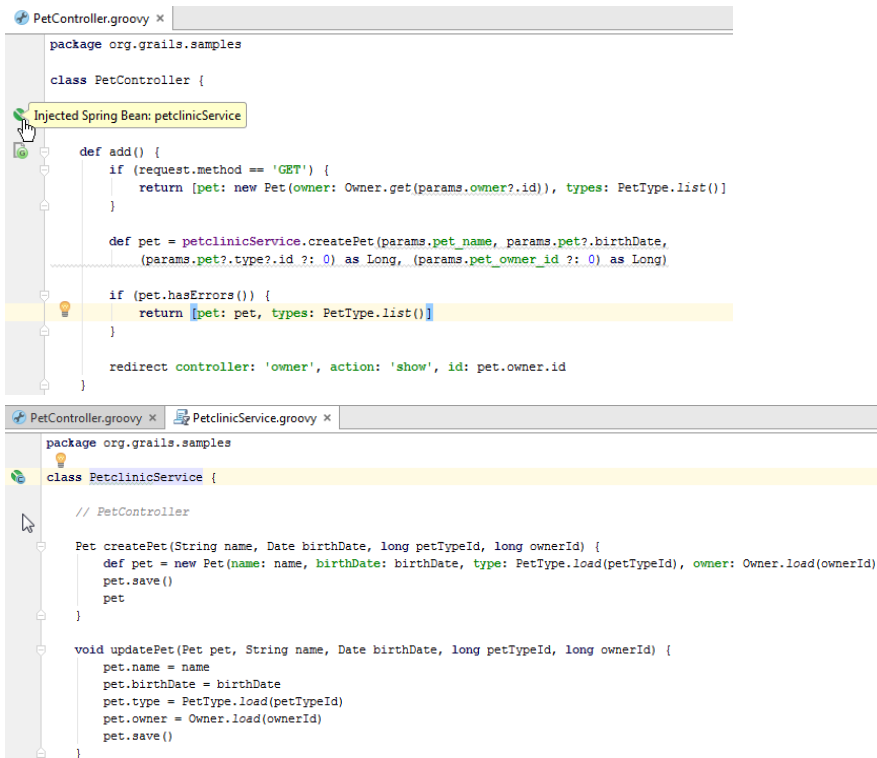

### Grails 3 Coding Assistance

- IntelliJ IDEA provides navigation between all related files such as domain classes, views, services and controllers. Press `Ctrl+Alt+Home` in the editor and choose your target.

- IntelliJ IDEA provides navigation between the injected dependencies.

- IntelliJ IDEA also provides navigation between the methods of the controller and `.gsp` files.

```

package org.grails.samples

class PetController {

    def petclinicService

    def add() {
        if (request.method == 'GET') {
            return [pet: new Pet(owner: Owner.get(params.owner?.id)), types: PetType.list()]
        }

        def pet = petclinicService.createPet(params.pet_name, params.pet?.birthDate,
            (params.pet?.type?.id ?: 0) as Long, (params.pet_owner_id ?: 0) as Long)

        if (pet.hasErrors()) {
            return [pet: pet, types: PetType.list()]
        }

        redirect controller: 'owner', action: 'show', id: pet.owner.id
    }
}

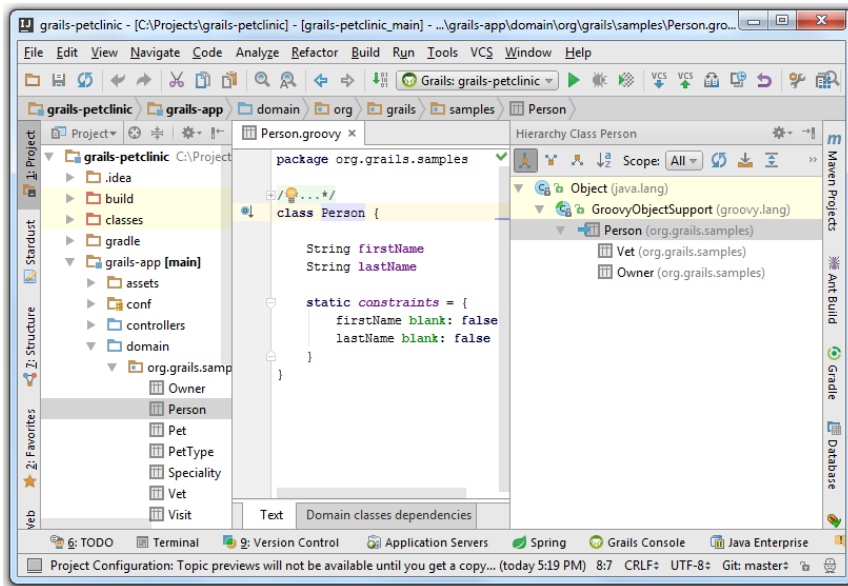

```

```

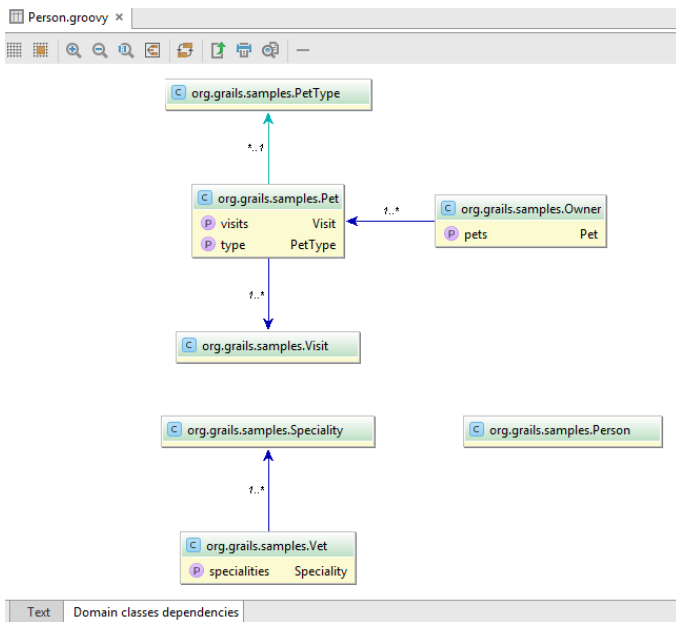

<html>
<head>
<meta name="layout" content="main">
<title>${ pet.id ? 'Update' : 'Add'} Pet</title>
</head>
<body id="add">
<h2><g:if test="${!pet.id}">New </g:if>Pet</h2>
<br><b>Owner:</b> ${pet.owner?.firstName} ${pet.owner?.lastName}
<br>
<g:form action="${pet.id ? 'edit' : 'add'}">
<g:if test="${pet.id}">
<input type="hidden" name="id" value="${pet.id}" />
</g:if>
<input type="hidden" name="pet_owner_id" value="${pet.owner.id}" />
<table>
<tr>
<th>
<g:render template="/common/formField"
model="[name:'pet', bean:pet, field:'name', label:'Name']" />
</th>
</tr>
</table>
</body>
</html>

```

IntelliJ IDEA lets you open and check the hierarchy of the domain classes. Press `Ctrl+H` in the editor to open Hierarchy tool window.

IntelliJ IDEA also lets you check the domain classes dependencies.

### Grails 3 Gradle Support

Grails 3 uses Gradle build system. You can use Gradle for the following actions:

- run Gradle tasks
- rely on the coding assistance when you edit build files
- import Grails 3 project from a Gradle model
- automatically update project dependencies

The screenshot shows an IDE window for a Grails 3 project. The main editor displays a `buildscript` block with the following content:

```

buildscript {
  ext {
    grailsVersion = project.grailsVersion
  }
  repositories {
    mavenLocal()
    maven { url "https://repo.grails.org/grails/core" }
  }
  dependencies {
    classpath "org.grails:grails-gradle-plugin:$grailsVersion"
    classpath 'com.bertramlabs.plugins:asset-pipeline-gradle:2.1.1'
  }
}

```

The right-hand pane shows the 'Gradle projects' view for the `grails-petclinic-master` project, listing tasks such as `bootRun`, `installApp`, `run`, `build`, `build setup`, `distribution`, and `documentation`. The `bootRun` task is currently selected.

The bottom pane shows the 'Run' console output for the `bootRun` task:

```

Run grails-petclinic-master [bootRun]
5:12:21 PM: Executing external task 'bootRun'...
:compileJava UP-TO-DATE
:compileGroovy
:processResources UP-TO-DATE
:classes
:findMainClass
:bootRun
Grails application running at http://localhost:8080 in environment: development

```

This feature is only supported in the Ultimate edition.

IntelliJ IDEA tightly integrates with [Grails](#) , and makes it possible to work with Grails applications from within the IDE, sparing you from the need to use a command line. Grails support in IntelliJ IDEA lets you do the following:

- [Before you start](#)
- [Creating Grails Project](#)
- [Exploring Grails Application](#)
- [Creating Elements in your Grails Project](#)
- [Running the Application](#)

## Before you start

Before you start creating your Grails project, make sure that you have Grails SDK downloaded on your machine. You can download the latest SDK version from the [Grails page](#) . Also, make sure that you are working with IntelliJ IDEA ultimate edition, version 9 or higher. See the [latest available version](#) .

**Warning!** If you plan on using the Grails 3.0 version, please see the [Getting Started with Grails 3](#) .

## Creating Grails Project

Do one of the following:

- If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project . As a result, the [New Project wizard](#) opens.
- If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module . As a result, the [New Module wizard](#) opens.

On the first page of the wizard, in the left-hand pane, select Grails . In the right-hand part of the page, specify the following setting:

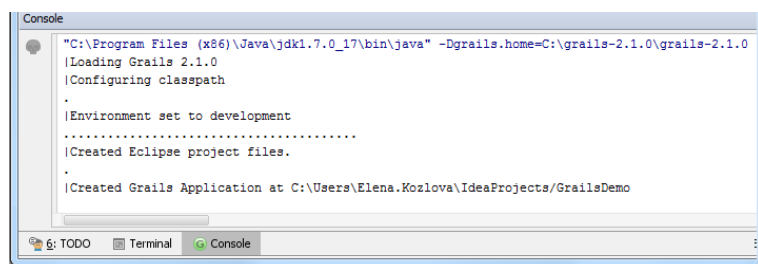

- [Project SDK](#) that you are going to use.
- Grails SDK Home - select a local Grails installation that is represented by a [library](#) .
- Create create-app or create-plugin - select one of these options depending on what you want to create.
- Options - specify additional options.

Click Next .

Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

Since we chose to create an application, IntelliJ IDEA executes the **create-app** target, which generates the directory structure of a Grails application. All output information is displayed in the Console :

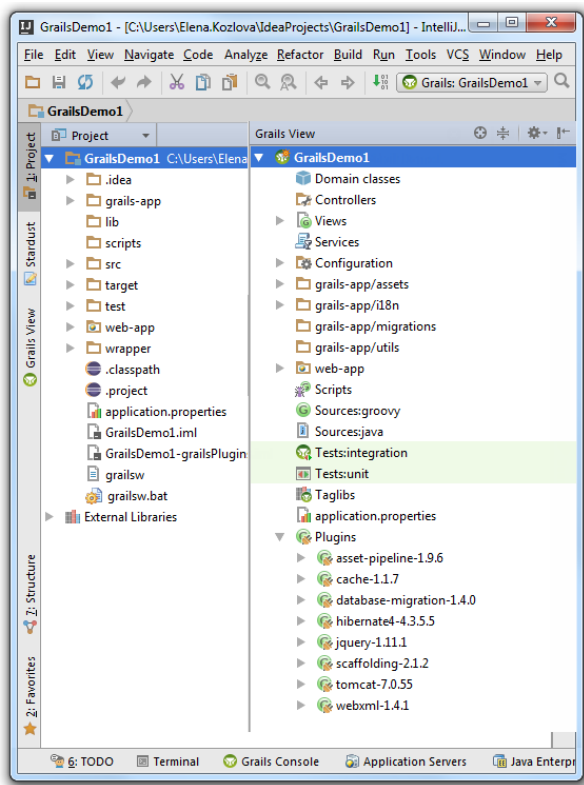

```
Console
"C:\Program Files (x86)\Java\jdk1.7.0_17\bin\java" -Dgrails.home=C:\grails-2.1.0\grails-2.1.0
|Loading Grails 2.1.0
|Configuring classpath
.
|Environment set to development
.....
|Created Eclipse project files.
.
|Created Grails Application at C:\Users\Elena.Kozlova\IdeaProjects\GrailsDemo
```

## Exploring Grails Application

IntelliJ IDEA enables you to explore your Grails application from two different viewpoints:

- The Project tool window shows the typical Grails directory structure.
- The Grails tool window shows the logical set of Grails application elements (Domain classes, Controllers, Views, etc.)

## Creating Elements in your Grails Project

To illustrate IntelliJ IDEA abilities, let's start developing a very basic library management system.

1. Create a domain class for the library system. This class will represent a book within a library.

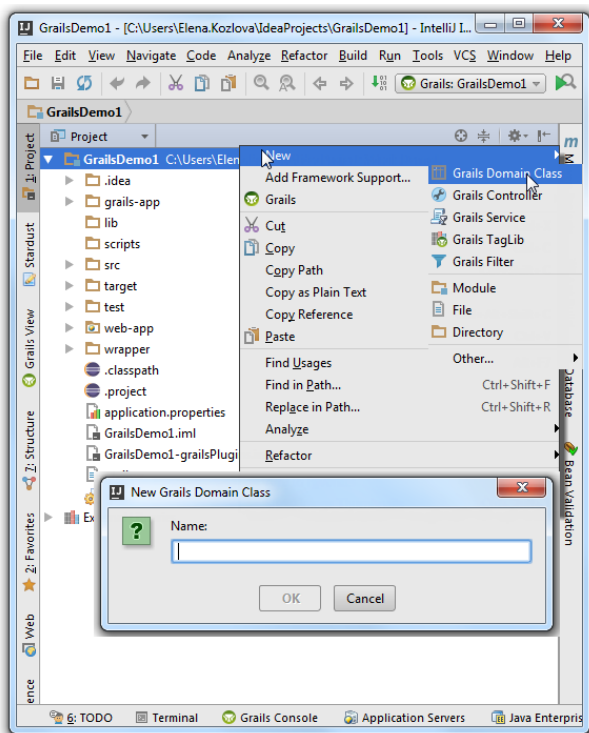

There are two possible ways of doing that in IntelliJ IDEA:

- Execute a Grails target. Press `Ctrl+Alt+G`, and enter Grails target name.

Note that code completion `?` is available in the Run Grails target dialog box:

- Right-click the Grails tool window background, and choose New | Grails Domain class on the context menu:

As a result, two stub classes are created in the project:

- Domain class Book.groovy
- Test class BookTests.groovy

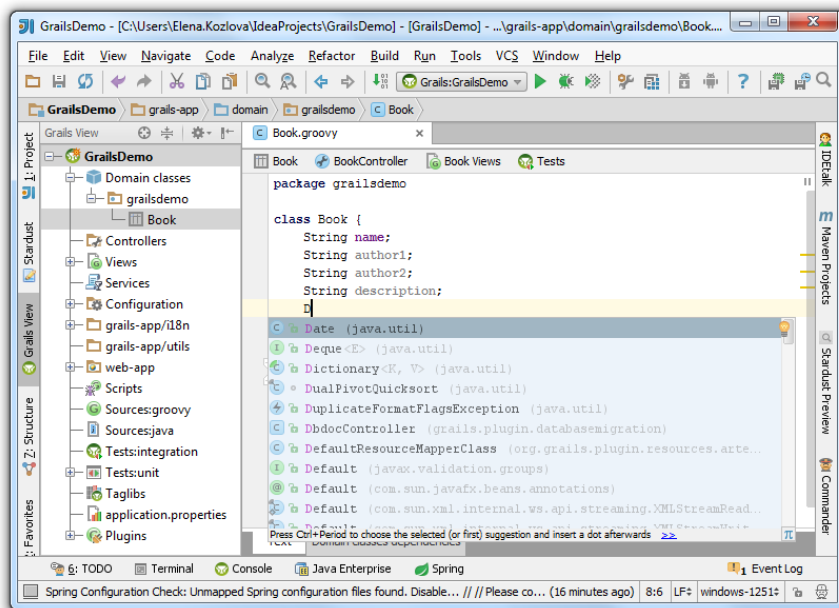

IntelliJ IDEA diligently shows all output messages in the Console .

For the purposes of our tutorial, we will work with the domain class Book.groovy .

Now it is just a stub, and we'll add the following fields:

- Book title
- Author name (maybe two author names?)
- Description
- Publisher
- Date published
- Copyright
- ISBN
- Reader name
- Date taken

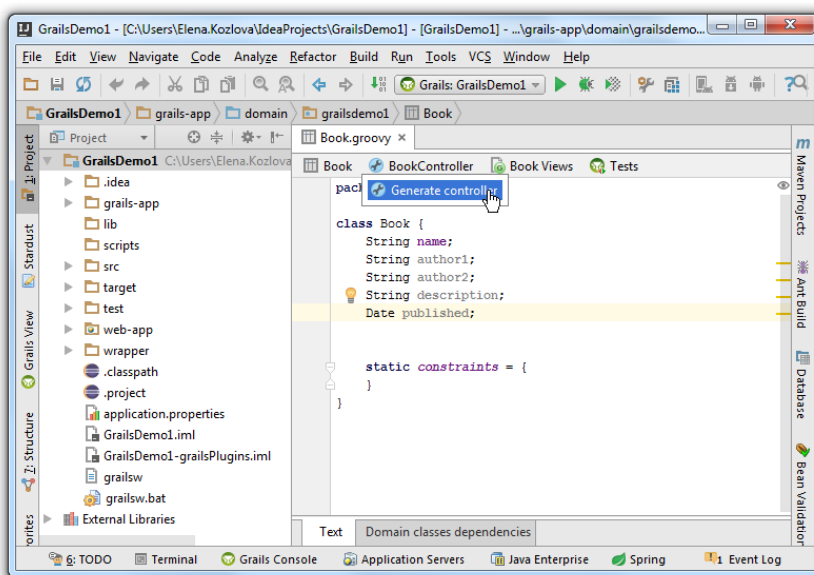

2. Open Book.groovy for editing ( F4 ), and type these fields in your code, using the code completion Ctrl+Space :

3. Provide a controller and views.

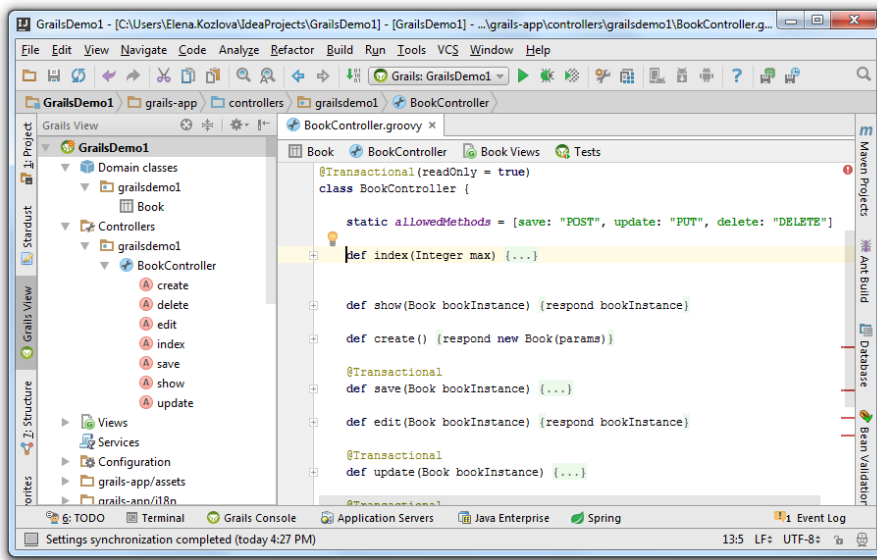

You can do it in two ways:

- run the Grails target generate-all Book
- use Scaffolding - the handy tool that you can find at the top of the domain class editor:

IntelliJ IDEA works hard (you can see that in the console), and produces the BookController.groovy class:

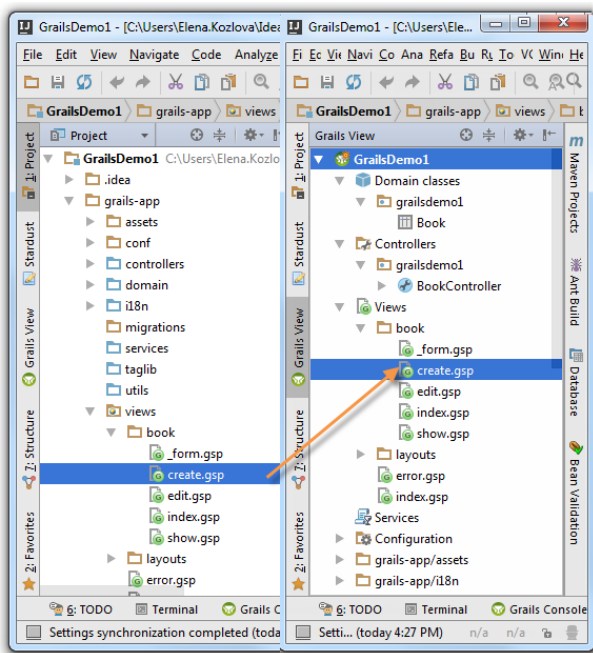

Next, create views the same way:

For each method of the controller, IntelliJ IDEA generates a file with the .gsp extension (create.gsp, edit.gsp, list.gsp, show.gsp).

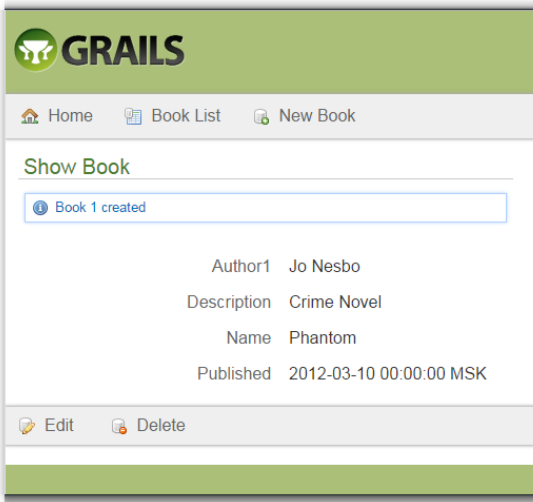

## Running the Application

There are more things you might want to do to make your application useful, but let's try to run it straight away with the default settings. To do that, press `?` and after a turmoil of messages in the Console, your application starts in your default browser, with the following URL in the address bar: `http://localhost:8080/GrailsDemo`.

On that page, you will see something like this:

- [grailsdemo.BookController](#)

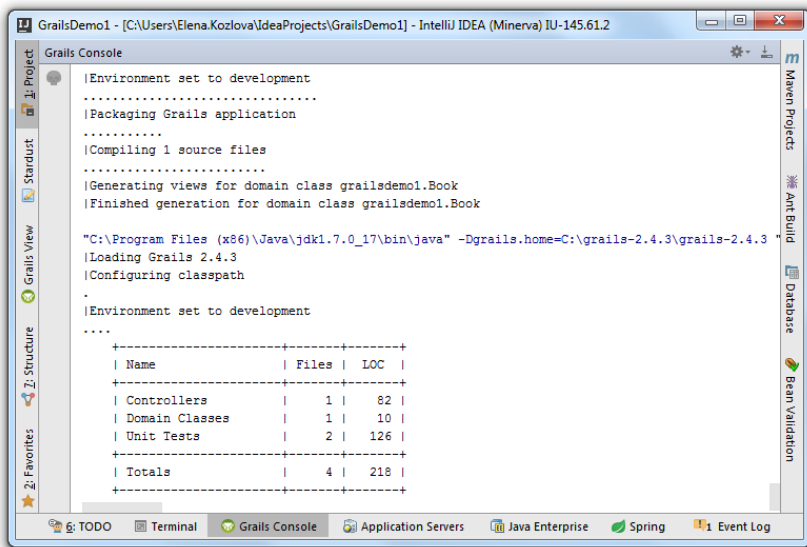

Click the controller link to open the list of books, which is empty by default. Now, you can try to fill out the entries of your library management system, for example, click the New Book button to add a book:

As you see, our basic library management system is ready. If you want to extend its functionality or you are not very happy with the code generated by Grails, you can modify the files in the IntelliJ IDEA editor to fit your particular needs, and rerun the application.

Finally, if you want to evaluate your effort for creating and running your Grails application under IntelliJ IDEA, view the number of files and lines of source code.

Press `Ctrl+Alt+G`, type `stats` in the pop-up window, and see the results in the Console :

This feature is only supported in the Ultimate edition.

You can create a new project with a Grails module or add a new Grails module to an existing project.

## To create a Grails Application module

1. Do one of the following:

- If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
- If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.

2. On the first page of the wizard, in the left-hand pane, select Grails . In the right-hand part of the page, specify the following setting:

- [Project SDK](#) that you are going to use.
- Grails SDK Home - select a local Grails installation that is represented by a [library](#) .
- Create create-app or create-plugin - select one of these options depending on what you want to create.
- Options - specify additional options.

Click Next .

3. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

This feature is only supported in the Ultimate edition.

If you already have a Grails project, you can create a IntelliJ IDEA Grails Application around its source code. IntelliJ IDEA recognizes the structure and creates the Grails project view.

1. Launch the [New Project wizard](#) . If no project is currently opened in IntelliJ IDEA, click Import Project on the Welcome screen. Otherwise, select File | New | Project from Existing Sources from the main menu.
2. In the dialog that opens, select your Grails project and click OK .
3. On the next page of the wizard, select Create project from existing sources and click Next .
4. On the next page of the wizard, specify the name and the location of your Grails project and click Next .
5. On the next page of the wizard, select the source roots that you want to include in your project and click Next .
6. On the next page of the wizard, select the libraries that will be included in your project and click Next .
7. On the next page of the wizard, review the module structure and dependencies that will be added to the project and click Next .
8. On the next page of the wizard, select the project SDK and click Next .
9. On the next page of the wizard, IntelliJ IDEA displays frameworks if they were detected. Click Finish .

IntelliJ IDEA opens a Grails project with its dedicated structure. At this point if IntelliJ IDEA detects a Gradle build tool inside your project, the pop-up message suggesting to import the Gradle project will be displayed.

This feature is only supported in the Ultimate edition.

This section covers Grails- and Griffon-specific procedures:

- [Creating Grails Application Elements](#)
- [Scaffolding](#)
- [Creating and Editing Relationships Between Domain Classes](#)
- [Creating Grails Views and Actions](#)
- [Navigating Between Actions and Views](#)
- [Running Grails Targets](#)
- [Running and Debugging Grails Applications](#)
- [Testing Grails Applications](#)
- [Working with Grails Plugins](#)
- [Dynamic Finders](#)

This feature is only supported in the Ultimate edition.

IntelliJ IDEA enables easy creation of the Grails or Griffon Application elements in the modules of the corresponding type (domain classes, controllers, scripts etc.) You can create new elements using the application-specific Grails or Griffon tool windows, or the Project tool window.

Execution of the target that corresponds to the selected element type, is displayed in the console.

## To add a new Grails or Griffon element

1. Open [Grails](#) or [Griffon](#) tool window, depending on the desired application type, and right-click the package where a new application element should be added.
2. On the context menu of the destination package, choose New , or press `Alt+Insert` , and choose the element type.
3. Type the name of the new element. So doing, you may not care about capitalization: when a new element is generated, its name is capitalized automatically. Click OK . A Groovy class of the selected type is created in the location stipulated by the application structure.
4. Add the necessary source code in the editor, using the Groovy-aware coding assistance, refactorings and intention actions.

IntelliJ IDEA provides the possibility to create Grails filters in one click. Just press `Alt+Insert` , and choose Grails Filter on the pop-up menu. After executing the `CreateFilters.groovy` target, the stub class with the filter definition is created under `grails-app/conf` directory of your Grails application.

Note that IntelliJ IDEA automatically provides the proper name of your filter class ( `*Filters.groovy` ), so you only need to specify the initial characters of the filter class name.

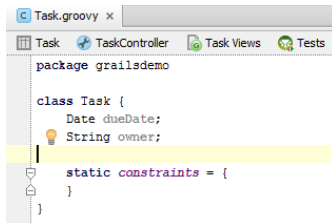

This feature is only supported in the Ultimate edition.

IntelliJ IDEA implements the powerful Grails facility to generate controllers, views, and tests from the Grails elements. For this purpose, the editor for the Grails elements provides a toolbar, which enables you to run the Grails scaffolding generation targets.

When you run a target, the names of the scaffolding elements are generated on the base of the Grails elements' names, and the scaffolding files are placed to the corresponding directories of the module structure.

## To generate scaffolding for a Grails element

1. Open the desired Grails element in the editor:

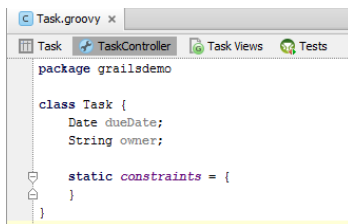

```
Task.groovy x
Task TaskController Task Views Tests
package grailsdemo

class Task {
    Date dueDate;
    String owner;

    static constraints = {
    }
}
```

2. Click the desired scaffolding button, and choose Generate :

```
Task.groovy x
Task TaskController Task Views Tests
package grailsdemo

class Task {
    Date dueDate;
    String owner;

    static constraints = {
    }
}
```

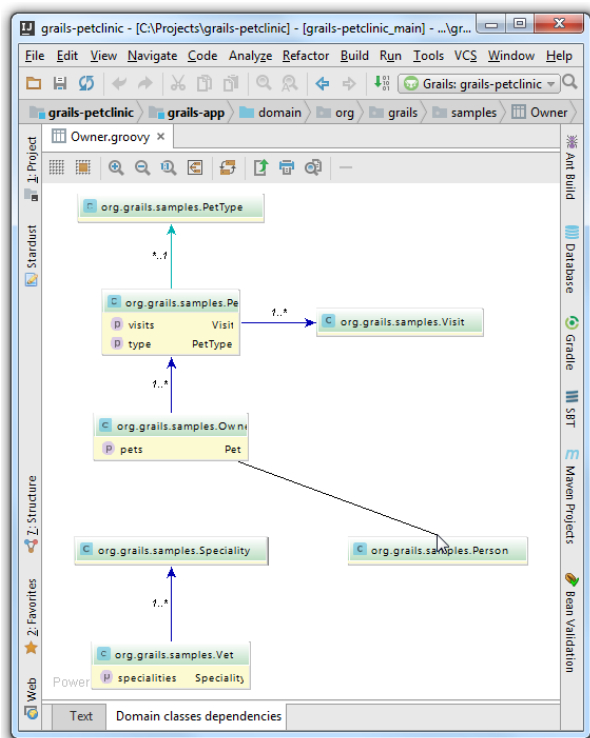

This feature is only supported in the Ultimate edition.

Use the Domain classes dependencies diagram for creating and editing relationships between the domain classes.

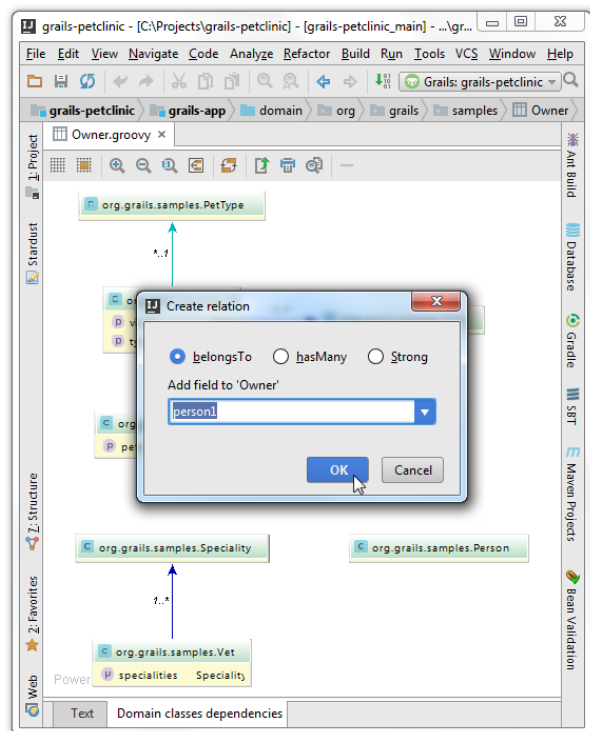

The [diagram](#) is completely synchronized with the source code: the changes in the source code are immediately reflected in the diagram, and vice versa, adding or deleting a link in diagram introduces relevant changes to the source code.

## To create relationship between domain classes

1. Select the desired domain class, and click the Domain classes dependencies tab that is located on the bottom of the editor.
2. Click the source domain class and draw a link to the target domain class:

3. In the dialog box that opens, specify the type of relationship, and the name of the field to be created:

The resulting relationship is displayed in diagram:

This feature is only supported in the Ultimate edition.

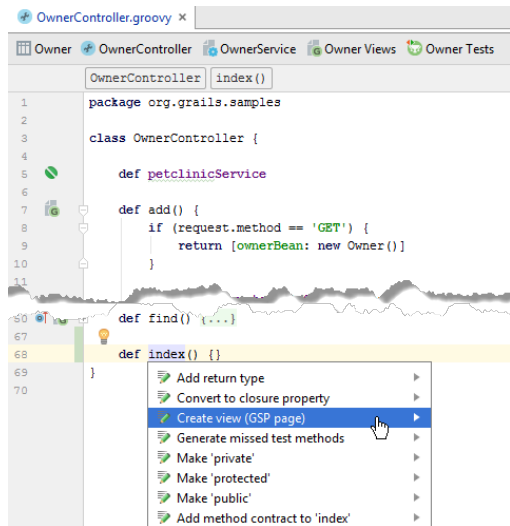

IntelliJ IDEA provides intention actions to create views and actions "from usage".

## To create an action from a view

1. In a Grails `*.gsp` page, place the caret at a view that refers to a non-existent action.
2. Press `Alt+Enter`, and choose Create Action from the suggestion list. The action is created in the controller, with the caret at the insertion point.
3. Type the meaningful action code.

## To create a Grails view from an action

1. In a Grails controller, place the caret at an action that refers to a non-existent view.
2. Press `Alt+Enter`, and choose Create View (GSP page) from the suggestion list.

A `.gsp` file with the corresponding name is created under the `views` directory of the Grails application.

**Tip** Configure code style of `.gsp` pages [here](#).

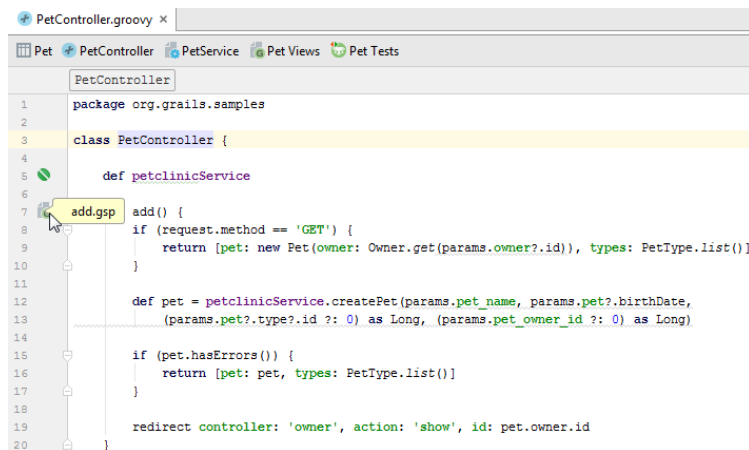

This feature is only supported in the Ultimate edition.

IntelliJ IDEA suggests convenient means of navigation within Grails applications. The following cases are possible:

- Between a [controller action and a view with the same name](#) .
- From `redirect` and `render` [methods to the corresponding controllers and actions](#) .

## To navigate between an action and the corresponding view

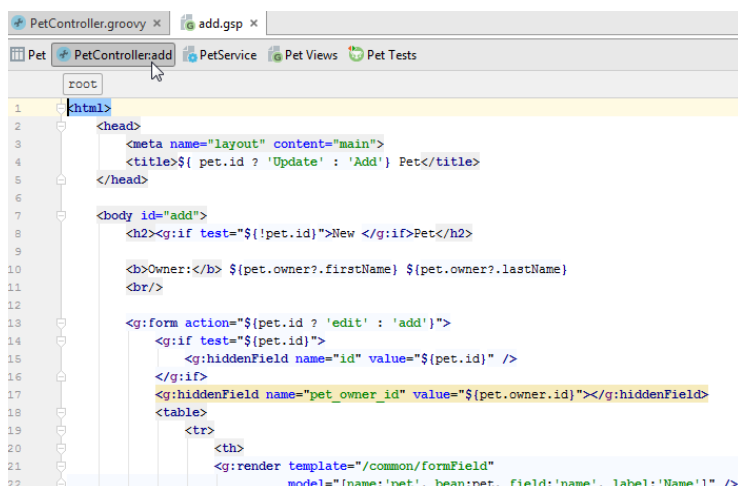

- In a controller, with the caret within an action: Click the icon  in the left gutter:

```
1 package org.grails.samples
2
3 class PetController {
4
5     def petclinicService
6
7     add.gsp add() {
8         if (request.method == 'GET') {
9             return [pet: new Pet(owner: Owner.get(params.owner?.id)), types: PetType.list()]
10        }
11
12        def pet = petclinicService.createPet(params.pet_name, params.pet?.birthDate,
13            (params.pet?.type?.id ?: 0) as Long, (params.pet_owner_id ?: 0) as Long)
14
15        if (pet.hasErrors()) {
16            return [pet: pet, types: PetType.list()]
17        }
18
19        redirect controller: 'owner', action: 'show', id: pet.owner.id
20    }
```

The corresponding `<name>.gsp` file opens in the editor.

- In a view file `<name>.gsp` : click the Controller button on the [scaffolding toolbar](#) :

```
1 <html>
2 <head>
3     <meta name="layout" content="main">
4     <title>${ pet.id ? 'Update' : 'Add'} Pet</title>
5 </head>
6
7 <body id="add">
8     <h2><g:if test="!{pet.id}">New </g:if>Pet</h2>
9
10    <b>Owner:</b> ${pet.owner?.firstName} ${pet.owner?.lastName}
11    <br/>
12
13    <g:form action="{pet.id ? 'edit' : 'add'}">
14        <g:if test="{pet.id}">
15            <g:hiddenField name="id" value="{pet.id}" />
16        </g:if>
17        <g:hiddenField name="pet_owner_id" value="{pet.owner.id}"></g:hiddenField>
18        <table>
19            <tr>
20                <th>
21                    <g:render template="/common/formField"
22                        model=[name:'pet', bean:pet, field:'name', label:'Name'] />
```

The corresponding controller opens in the editor, with the caret resting before the action name.

## To navigate from Grails render or redirect methods, do one of the following

- With the caret at the template name, press `Ctrl+B`
- Keeping `Ctrl` pressed, click the template name:

```
PetController.groovy x Pet.groovy x add.gsp x
Pet PetController PetService Pet Views Pet Tests

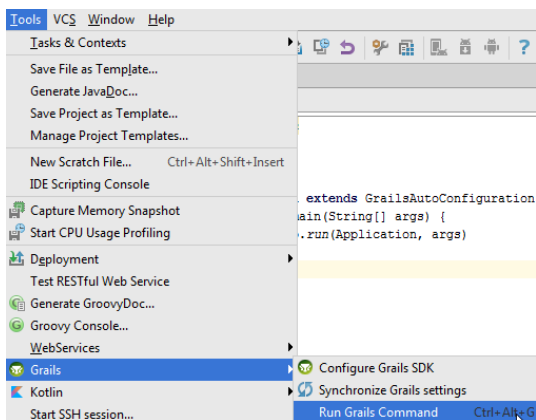

1 package org.grails.samples
2
3 class PetController {
4
5     def petclinicService
6
7     def add() {
8         if (params.owner) {
9             private def petclinicService
10             [inferred type] PetclinicService
11             owner: Owner.get(params.owner?.id), types: PetType.list()
12
13             def pet = petclinicService.createPet(params.pet_name, params.pet?.birthDate,
14                 (params.pet?.type?.id ?: 0) as Long, (params.pet_owner_id ?: 0) as Long)
15
16             if (pet.hasErrors()) {
17                 return [pet: pet, types: PetType.list()]
18             }
19
20             redirect controller: 'owner', action: 'show', id: pet.owner.id
21         }
22     def edit() {
```

This feature is only supported in the Ultimate edition.

IntelliJ IDEA enables launching targets in the Grails or Griffon applications. When Grails or Griffon application is selected, the respective Run target command appears in the Grails or Griffon nodes of the main Tools menu.

## To run a Grails or Griffon target

1. Select Grails or Griffon application module. You can do this in a number of ways:
  - In the Project tool window, select module of the corresponding type.
  - Bring forward [Grails View](#) or [Griffon View](#) tool window.
  - Open in the editor the desired file that pertains to a Grails or Griffon application.
2. On the Tools menu, choose Grails | Run Grails Command or Griffon | Run Griffon Command :

Alternatively, just press `Ctrl+Alt+G` .

3. In the dialog box that opens, start typing the target name, and press `Ctrl+Space` to show the list of matching targets:

4. Click OK , and view the output messages in the console.

Please note the following:

- The history drop-down list is available in the RunTarget dialog box. Use the arrow keys to browse through the recently executed targets.
- You can run or debug any target immediately from the Run/Debug configuration, if you enter an arbitrary command in the Command line field of the Run/Debug Configuration dialog.

This feature is only supported in the Ultimate edition.

In IntelliJ IDEA, you can launch Grails or Griffon applications using the regular procedures, with the dedicated [Grails Application](#) or [Griffon Application](#) run/debug configuration:

- [Running](#)
- [Debugging](#)

**Note** Note that IntelliJ IDEA enables you to debug `*.gsp` files: you can set breakpoints at the lines of the views, examine variables, and evaluate expressions.

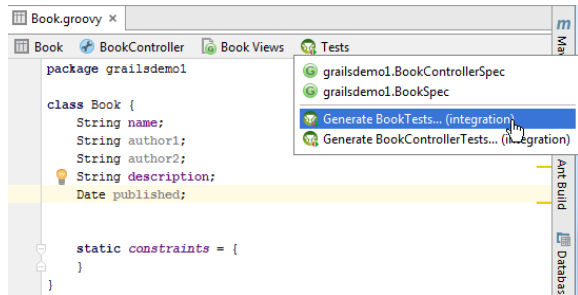

Besides that, you can [execute Groovy scripts](#) that exist in Grails or Griffon applications. Observe results in the [Run](#) and [Debug](#) tool windows.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA enables creating and running unit and integration Grails tests, and provides run configurations for each test type.

### To create Grails test, do one of the following:

- Use **scaffolding** of a domain class you want to create a test for:

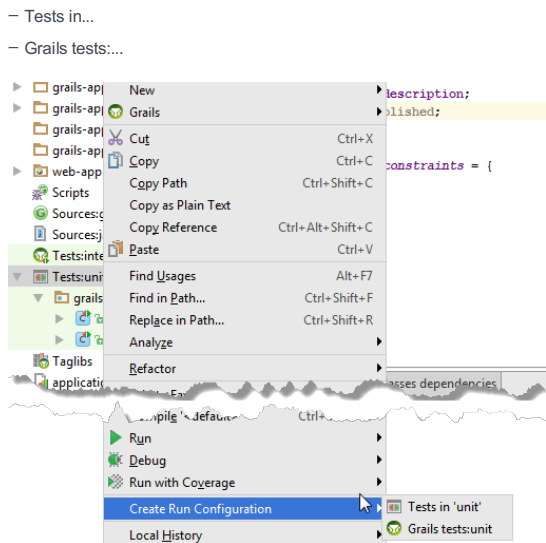

- **Run Grails target**: press **Ctrl+Alt+G**, and type the target name in the text field. Use code completion to narrow down the list of matching targets:

### To create a Grails test run/debug configuration

1. In the **Grails view**, right-click one of the test directories, point to **Create Run Configuration** on the context menu, and then choose one of the suggested options:

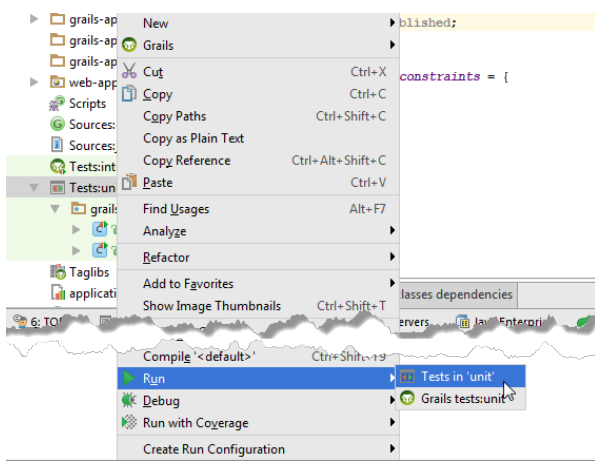

2. In the Run/Debug Configuration dialog that opens, specify the run/debug configuration settings: test type, Grails scripts etc.

**Note** You can specify several test names separated with spaces, all these tests will run in a single run configuration.

### To run a Grails test

1. In the **Grails view**, select the desired test class.
2. In the menu that opens, select **Run** and the desired configuration type:

The selected run/debug configuration is executed in the Run tool window.

This feature is only supported in the Ultimate edition.

You can extend the functionality of your Grails application with the Grails plugins downloaded from the Grails repository. Once downloaded, the plugins reside under the `plugins` directory of your Grails application. Each plugin has the same directory structure as the entire Grails application. The source directories of the installed plugins are included in the source routes and are marked in the module tree view with the  icon.

For the sake of better communication with the Grails repository, IntelliJ IDEA provides the plugin manager that enables viewing, installing and uninstalling plugins.

**Note** The first communication with the Grails repository from a Grails application can take time.

For Grails versions 2.3.0 and later, refer to the [Grails documentation](#).

## To open the Grails plugin manager, do one of the following

- On the main menu choose Tools | Grails | Plugins .
- On the context menu of the Project view, choose Grails | Plugins .

## To view the available plugins

- Open the Grails plugin manager, click the refresh button  if necessary, and view the list of plugins in the Grails plugins dialog box:

**Tip** You can also view the list of plugins by running the `list-plugins` Grails target. To do that, press `Ctrl+Alt+G`, and type `list-plugins` in the Run Grails Target dialog box.

## To install or uninstall Grails plugins

1. Open the Grails plugin manager. In the Enable column, select the checkboxes of the plugins to be installed, and clear the checkboxes of the plugins to be uninstalled. Then click Apply Changes .
2. In the Install/Uninstall Grails plugins dialog box, review the list of plugins. If necessary, select the plugin version. Click OK .

**Tip** You can also install plugins using the `install-plugin` Grails target. To do that, press `Ctrl+Alt+G`, and in the Run Grails Target dialog box type `install-plugin <plugin name>`.

This feature is only supported in the Ultimate edition.

Grails integration allows performing dynamic queries for the domain class instances. So doing, code completion makes it possible to combine different queries based on the fields of the domain classes.

## To create a dynamic query

1. In a Grails domain class, declare fields to define mappings. For example, in the domain class `Pet.groovy` there are four fields:

```
String name
Date birthDate
PetType type
Owner owner
```

2. In a Grails view, controller, or test class, create a method. For example, in the `PetSpec.groovy`, create method `testSomething()`.

3. In the method body, reference a domain class to be queried, and start typing the query. Press

`Ctrl+Space` :

```
void testSomething() {
    assert true
    Pet.findByVisitsBetween(1>5)
    Pet.
}
@Test
class Pet {
    m countBy... int
    m findAllBy... List<Pet>
    m findBy... Pet
    m findOrCreateBy... Pet
    m findOrSaveBy... Pet
    p all List<Pet>
    p async GormAsyncStaticApi<Pet>
    p constrainedProperties Map<String, Constrained>
    p constraints Closure
    p count Integer
    p ...
}
Press Ctrl+Period to choose the selected (or first) suggestion and insert a dot afterwards >>
```

4. Press `Ctrl+Space` once more, and select the desired condition from the suggestion list:

```
void testSomething() {
    assert true
    Pet.findByVisitsBetween(1>5)
    Pet.countBy
}
@Test
class Pet {
    m countBy... int
    m findAllBy... List<Pet>
    m findBy... Pet
    m findOrCreateBy... Pet
    m findOrSaveBy... Pet
    p all List<Pet>
    p async GormAsyncStaticApi<Pet>
    p constrainedProperties Map<String, Constrained>
    p constraints Closure
    p count Integer
    p ...
}
Pressing Ctrl+Space twice without a class qualifier would show all accessible static methods
```

Repeat code completion to concatenate as many search conditions as required.

IntelliJ IDEA lets you create a project using [Grails Application Forge](#) service. Application Forge generates a template project and automatically sets all required dependencies according to the selected features and profiles instead of configuring them manually. It generates a full project, or a build file with Gradle.

## Creating a project with Grails Application Forge

1. If no project is currently open, click Create New Project on the welcome screen; otherwise select File | New | Project .
2. On the [page that opens](#) , in the left pane, select Application Forge .
3. In the right pane, specify a project SDK (JDK). If the necessary JDK is already defined in IntelliJ IDEA, select it from the list. Otherwise, click New and select JDK from the list. Then, in the [dialog that opens](#) , select the installation folder of the desired JDK (by this time, the corresponding JDK must already be installed on your computer).
4. Specify the Grails SDK, other [Application Forge settings](#) and click Next .
5. On the next page, specify the project information and click Finish .

IntelliJ IDEA will create a fully-functional Grails project with the predefined structure, Gradle build file and a set of libraries.

This feature is only supported in the Ultimate edition.

[Griffon](#) support is available in the Community and in the Ultimate editions of IntelliJ IDEA.

In this section:

- Griffon
- [Prerequisites](#)
- [Griffon features in IntelliJ IDEA](#)
- [Griffon changes in the IntelliJ IDEA UI](#)
- [Creating a Griffon Application Module](#)

## Prerequisites

Make sure that the desired SDK is downloaded and installed on your computer, and the libraries are properly configured.

Also, make sure that the Groovy plugin is enabled in IntelliJ IDEA. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not enabled, [enable the plugin](#).

## Griffon Features in IntelliJ IDEA

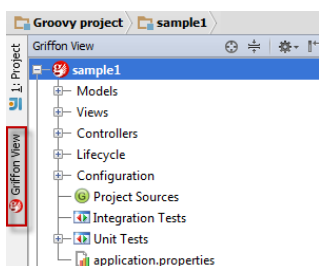

[Griffon](#) support in IntelliJ IDEA includes the following features:

- Automated way of creating Griffon Applications that provides generation of the specific structure and artifacts.
- Automatic enabling Groovy support in the Griffon Application modules, allowing creation of the Groovy classes, interfaces and scripts.
- Execution of the [targets](#).
- ability to [generate tests](#).
- [Code completion](#).
- Dedicated [run/debug configuration](#).

## Griffon Changes in the IntelliJ IDEA UI

Once IntelliJ IDEA recognizes the project or module as a Griffon application, it introduces the following changes to the UI:

- [Griffon View](#) tool window is added, and the tool window button appears in the left tool windows bar:

- Griffon node is added to the context menu of the Griffon modules in the Griffon view:

- Griffon node is added to the Tools menu:

This feature is only supported in the Ultimate edition.

You can create Griffon Application modules. IntelliJ IDEA generates the necessary infrastructure. You can view module structure in the [Griffon](#) tool window, and use framework-specific commands.

## To create a Griffon Application module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Griffon . In the right-hand part of the page, specify the [JDK](#) that you are going to use and your local Griffon installation. (Griffon in IntelliJ IDEA is represented by a [library](#) .) If you need, specify additional libraries and frameworks.  
Click Next .
3. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click Finish .

In this section:

- Groovy
  - [Prerequisites](#)
  - [Groovy support](#)
- [Getting Started with Groovy](#)
- [Coding Assistance in Groovy](#)
- [Groovy Procedures](#)
- [Groovy-Specific Refactorings](#)
- [Launching Groovy Interactive Console](#)

## Prerequisites

Make sure that the desired SDK is downloaded and installed on your computer, and the libraries are properly configured.

Also, make sure that the Groovy plugin is enabled in IntelliJ IDEA. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not enabled, [enable the plugin](#).

## Groovy support

IntelliJ IDEA enables you to use [Groovy language](#) and Groovy-based frameworks.

IntelliJ IDEA supports Groovy versions up to 2.4.

Groovy files are marked with  icon.

Groovy support includes:

- Ability to add Groovy framework to the Java module dependency.
- Ability to create an extension module to support custom extension methods.
- [Coding assistance](#).
- [Common](#) and [specific](#) refactorings.
- Numerous ways to [navigate](#) through the source code, among them:
  - [Navigating with Structure View](#).
  - Navigate | Declaration ([Ctrl+B](#)).
  - Navigate | Implementation ([Ctrl+Alt+B](#)) from overridden method / subclassed class.
- Advanced facilities to [search through the source code](#).
- [Viewing reference](#) information.
- Possibility to [generate](#) documentation, created according to GroovyDoc syntax.
- Possibility to [compile](#) mixed Groovy and Java code.
- [Running and debugging](#).
- Possibility to [create](#), and [perform](#) tests.

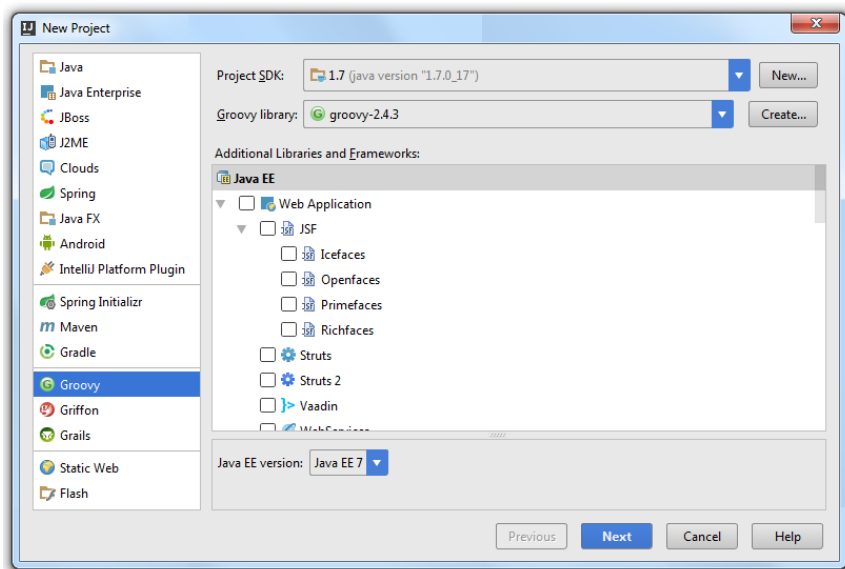

IntelliJ IDEA lets you create and run Groovy applications.

Before you start working with Groovy, make sure that the Groovy plugin is [enabled](#) in IntelliJ IDEA.

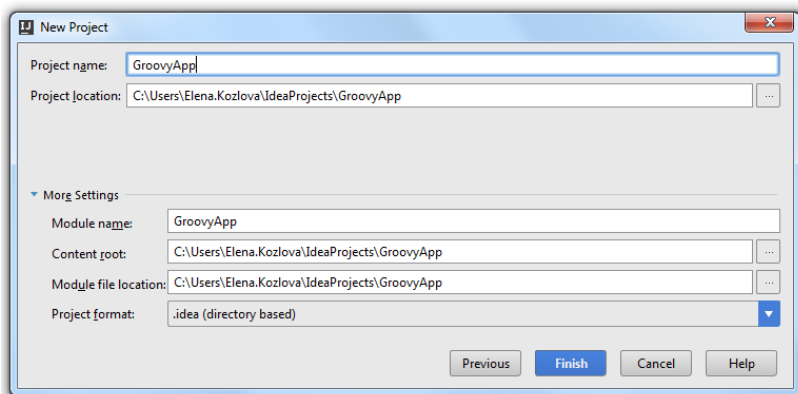

- [Creating a Groovy Project](#)
- [Adding Frameworks to Existing Groovy Project](#)
- [Creating Groovy Class](#)
- [Creating Groovy Script](#)
- [Running Groovy Application](#)

## Creating a Groovy Project

1. Open [Project Wizard](#) , in the left-hand pane select Groovy .
2. In the right-hand pane, specify the following settings:
  - Project SDK - specify your project SDK.
  - Groovy library - specify your Groovy SDK or click Create to choose one from the list that opens.
  - Additional libraries and frameworks - specify additional libraries and frameworks that Groovy supports.
  - Java EE version - select the appropriate Java EE version.

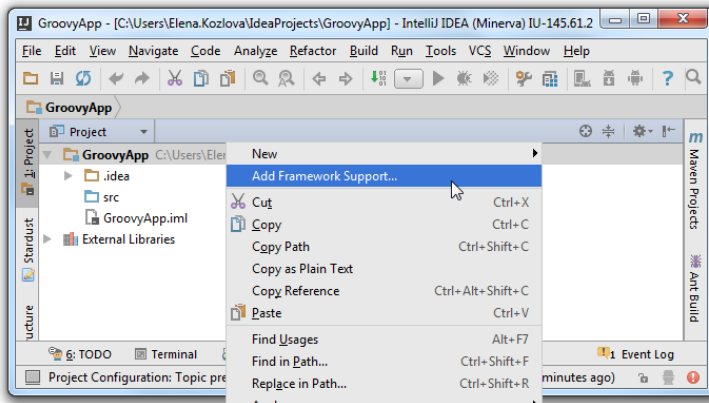

3. Click Next .
4. Specify your project information and click Finish .

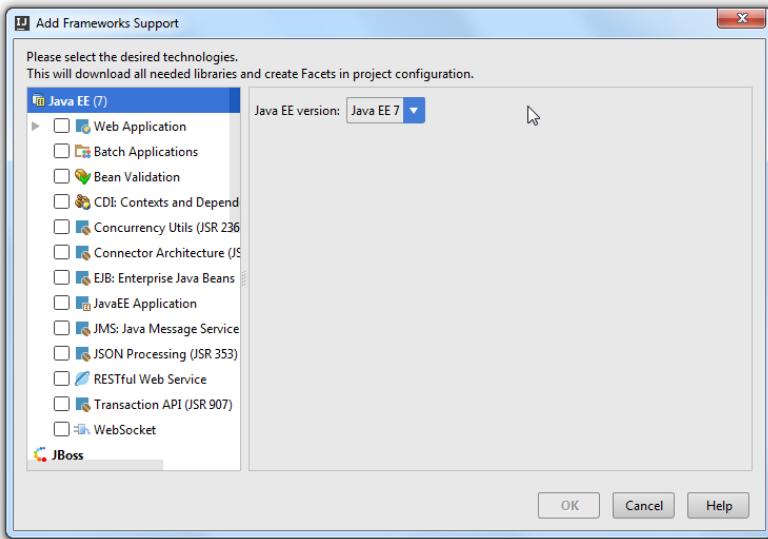

## Adding Frameworks to Existing Groovy Project

1. In the [Project](#) tool window, right-click the project directory and from the drop-down list select Add Framework Support .

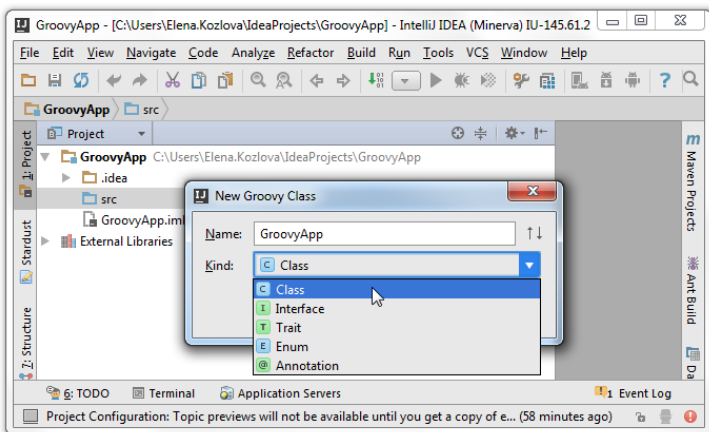

2. In the **Add Frameworks Support** dialog, select a framework and click **OK** .

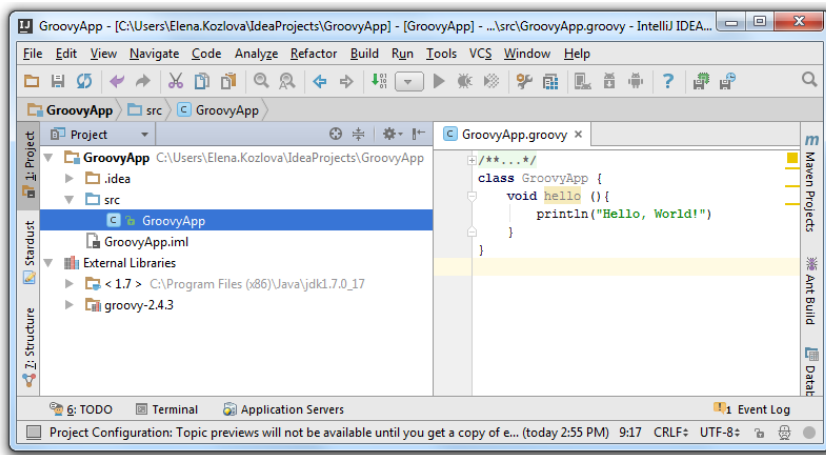

## Creating Groovy Class

1. Press **Ctrl+N** or in the **Project** tool window right-click on the directory and select **New | Groovy Class**
2. In the **New Groovy Class** dialog, in the **Name** field, specify a name of the class. In the **Kind** field, choose between class, interface, trait, enum or annotation.

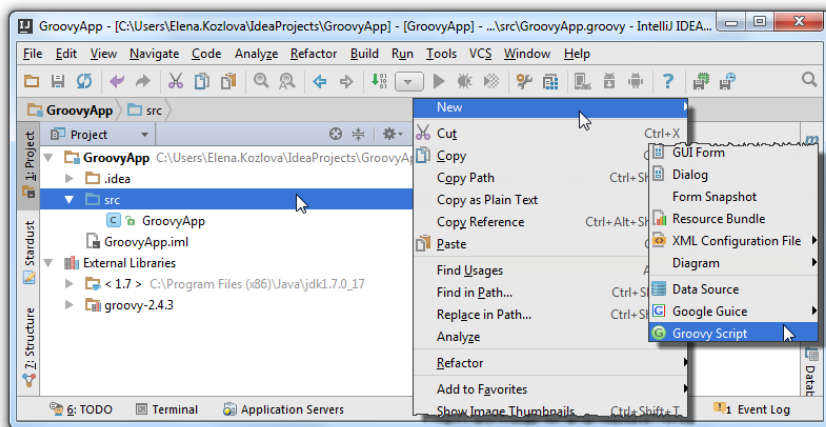

3. Now you can enter your code.

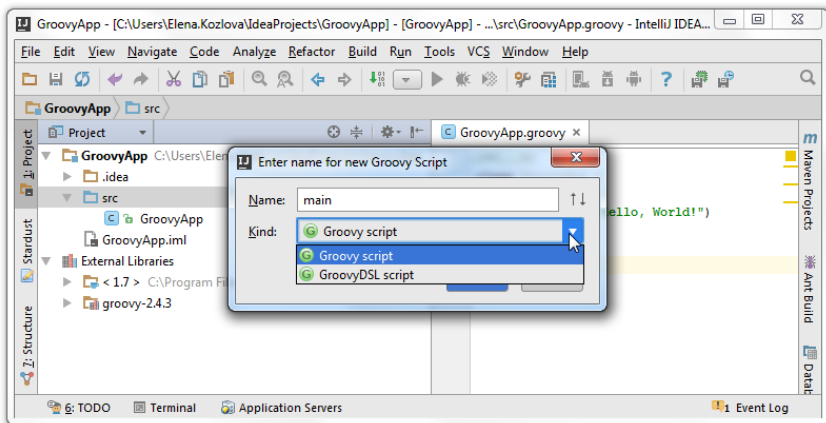

## Creating Groovy Script

1. Press `Ctrl+N` or in the **Project** tool window right-click on the directory and select **New | Groovy Script**.

2. In the dialog that opens, in the **Name** field, enter the name of your Groovy script. In the **Kind** field, choose between Groovy script and GroovyDSL script.

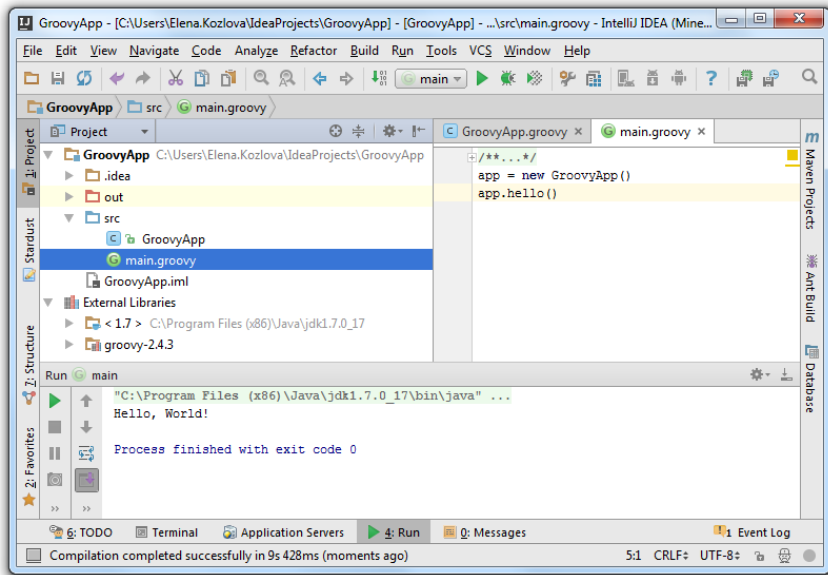

3. IntelliJ IDEA creates a file with the specified name and `groovy` extension, and adds a node to the module tree view.

## Running Groovy Application

1. Create a Run configuration using **Run | Edit Configurations** or run the active script automatically by pressing

`Ctrl+Shift+F10`.

2. View the result in the Run tool window.

IntelliJ IDEA supports the following coding assistance for Groovy:

- [Code completion](#) for keywords, labels, variables, parameters and functions.
- [Chained expression completion](#).
- Error and syntax highlighting.
- Code [formatting](#) and [folding](#).

For example, all closures that have their parameters described in the separate line are formatted the following way:

```
def c1 = {  
    param1, param2 ->  
    body()  
}
```

- Numerous code [inspections](#) and [quick-fixes](#).
- Ability to check what generics to specify for a method call or for a type variable using Parameter info (Ctrl+P).
- [Code generation](#)
  - Inserting, expanding, and generating code blocks using [live templates](#).
  - Creating various applications elements via [intention actions](#).
  - Possibility to create [line and block comments](#) (`Ctrl+Slash` / `Ctrl+Shift+Slash`).
- Ability to add [annotations](#). For example, `@Builder` annotation. IntelliJ IDEA supports all Strategies from the standard library as well as code completion and navigation.

```
import groovy.transform.builder.Builder  
@Builder  
class GroovyApp {  
    //You can enter fields for the class  
}
```

- Expression Type action for Groovy expressions. Use `Ctrl+Shift+P` to see the expression type without clicking the mouse.

This section covers Groovy-specific procedures:

- [Creating Groovy Tests and Navigating to Tests](#)
- [Generating Groovy Documentation](#)
- [Running and Debugging Groovy Scripts](#)
- [Working with Lists and Maps](#)

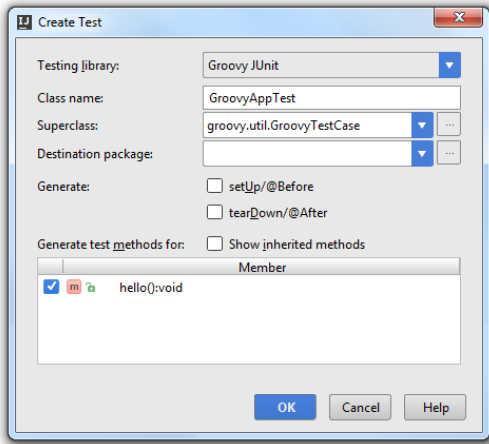

## To create a test for a Groovy class

1. Do one of the following:

- Use [intention action Create test](#).
- Press `Ctrl+Shift+T`, and choose Create New Test.

2. In the Create Test dialog box, specify the required information, as described in the section [Creating Tests](#).

3. In the editor of the created test file, in the left gutter, click on the  icon to execute run/debug configuration.

You can also use a context menu to run or debug your test.

**Note** You can navigate between Groovy tests and test subjects ( `Navigate | Test / Test Subject` ). If a test class doesn't yet exist, IntelliJ IDEA suggests to create one.

IntelliJ IDEA provides a front-end to the standard GroovyDoc utility for generating GroovyDoc reference for your Groovy-enabled project. This feature is available when the editor has the focus.

## To generate Groovy project documentation

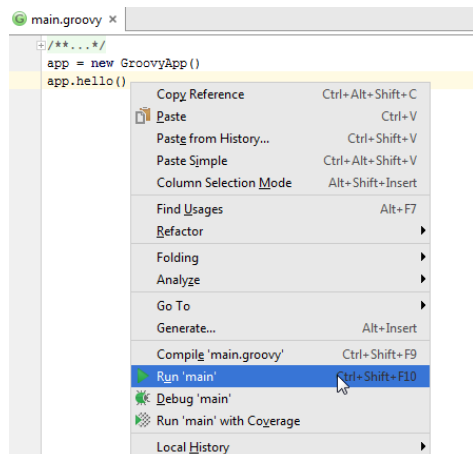

1. On the main menu, choose Tools | Generate GroovyDoc. [Generate Groovy Documentation](#) dialog box opens.
2. In the Generate GroovyDoc dialog, specify the input and output directories, and the visibility level. Refer to [Generate Groovy Documentation](#) for description of controls.
3. Click Start .

## Running Groovy scripts

In IntelliJ IDEA, you can run and debug Groovy scripts using the regular procedures:

- [Running](#)
- [Debugging](#)

Besides executing a Groovy script with the permanent run/debug configuration, you can use a temporary one, which is available at the context menu of a script:

Observe results in the [Run](#) and [Debug](#) tool windows. Note that in Groovy-enabled modules, the debugger is aware of the Groovy syntax, and enables handy evaluation of expressions.

## Validating Groovy scripts located in resource directories

Starting with the IntelliJ IDEA version 2016.3 you can validate Groovy scripts that are located in resource roots.

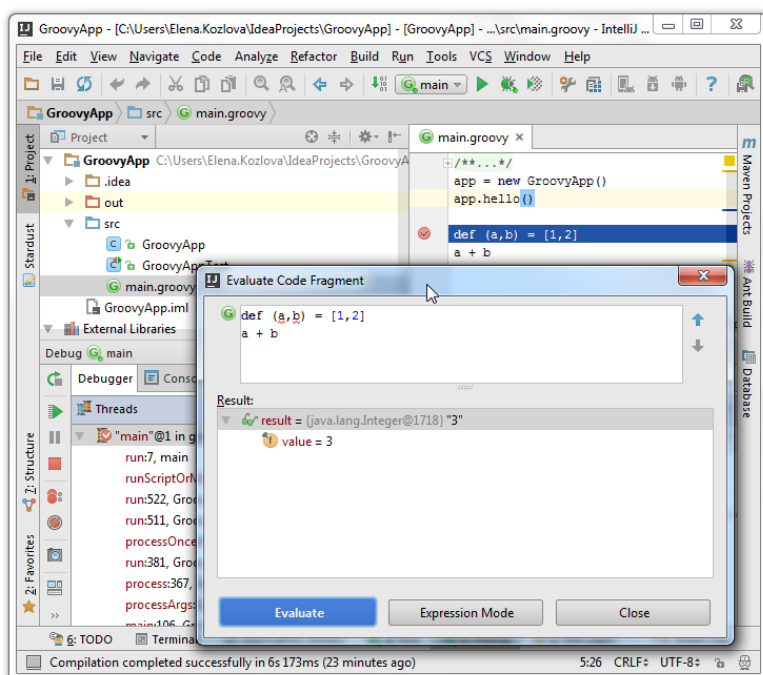

1. Select directories for which you want to start the build.
2. On the main menu, select Build | Groovy Resources .
3. In the drop-down list select Build Resources .

IntelliJ IDEA starts the incremental build for the files located in the resource directories.

Use Rebuild Resources for re-compiling. Note that all files in the project are compiled or recompiled excluding the ones that are specifically excluded from the [Validation](#) .

## Evaluating Groovy expression

1. Launch the debugger session, as described in the section [Debugging](#) .
2. When you reach a breakpoint, where you want to evaluate expression, press `Alt+F8` .
3. In the [Code Fragment Evaluation](#) dialog box, select Groovy from the Language drop-down list, type the desired expression, and click Evaluate :

In this section you can find some examples of working with lists and maps in IntelliJ IDEA:

- [To convert a parameter of a function to a map entry](#)
- [To convert Groovy map to a class instance](#)
- [To produce a list or a map](#)
- [To inline a list or a map](#)

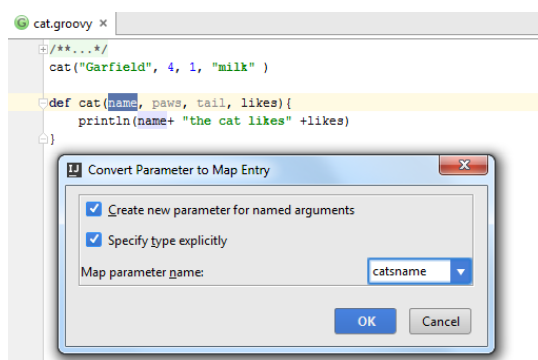

## To convert a parameter of a function to a map entry

If a function has a lengthy list of named arguments, you can reduce it by representing parameters as map entries. For this purpose, IntelliJ IDEA suggests the Convert parameter to map entry intention action.

1. Place the caret at a parameter you want to convert, and press `Alt+Enter` :

2. On the context menu, choose Convert parameter to map entry , and specify conversion parameters:

3. Repeat the procedure until all the required named arguments are represented as map entries. Note that all the subsequent conversions are done silently.

## To convert Groovy map to a class instance

1. In a Groovy method, place the caret at a map to be converted, and press `Alt+Enter` :

2. On the context menu, choose Convert to class , and specify new class name and the package where the new class will be created. If such package doesn't yet exist, click  to create one.
3. If necessary, choose to change return type of the method.
4. Click OK to apply changes and perform conversion.  
As a result, a class is created, with the fields corresponding to the keys of the original map.

## To produce a list or a map

1. Type contents of a list or a map in the editor:

```
[55, 127, -9, -100, 568]
```

or

```
[fname:"John", lname:"Smith", age:31]
```

2. Place the caret somewhere inside the square brackets, and press `Ctrl+Alt+V`. The expression in brackets is converted to a list or map respectively.

## To inline a list or a map

1. Place the caret on the list or map declaration, and press `Ctrl+Alt+N`. IntelliJ IDEA highlights the encountered usages:

2. Confirm inlining:

```
println [fname:"John", lname:"Smith", age:31]
```

This section covers Groovy-specific refactoring procedures:

- [Extracting Parameter in Groovy](#)
- [Extracting Method in Groovy](#)

This section discusses the [Extract Parameter](#) refactoring for Groovy. This refactoring lets you perform the following actions:

- Creating a new method parameter from the selected expression within a method. All the usages of the method will be auto-updated.
- Adding a parameter to a closure. If there is a variable, associated with the closure, the calls to this variable are replaced with the corresponding expressions.

In this section:

- [Examples](#)
- [To extract a parameter in Groovy](#)

## Examples

### Before/After

<pre>class Cat {     Cat cat = new Cat()     def makePestOfItself(){         print ("miaou!!!!!!!!!!")     }     def makeTroubles(){         if (makePest){             makePestOfItself()         }     } }</pre>	<pre>class Cat {     Cat cat = new Cat()     def makePestOfItself(String warning){         print (warning)     }     def makeTroubles(){         if (makePest){             makePestOfItself("miaou!!!!!!!!!!")         }     } }</pre>
<pre>class Bar {     def foo = {         print 'Hccaret here&gt;ello, world!'     } }  new Bar().foo() new Bar().foo.call()</pre>	<pre>class Bar {     def foo = { String s -&gt;         print s     } }  new Bar().foo('Hello, world!') new Bar().foo.call('Hello, world!')</pre>

## To extract a parameter in Groovy

1. In the editor, place the cursor within the expression to be replaced by a parameter.
2. Do one of the following:
  - Press `Ctrl+Alt+P`.
  - Choose Refactor | Extract | Parameter on the main menu.
  - Choose Refactor | Extract | Parameter from the context menu.
3. In the [Extract Parameter](#) dialog:
  1. Specify the parameter name in the Name field.
  2. Choose parameter type, and specify whether you want to declare the new parameter final, and create the overloading method.
  3. Click OK.

This section discusses Extract Method refactoring in Groovy.

This refactoring lets you perform the following actions:

- Extract method for a variable.
- Extract method for a list of variables.
- Extract method for one or several statements.

In this section:

- [Examples](#)
- [To extract a method in Groovy](#)

## Examples

### Before/After

<pre>iii = 6 int kkk = 5 def vv = 6 def gg = 7  println(kkk + iii + (vv + gg))</pre>	<pre>iii = 6 int kkk = 5 def vv = 6 def gg = 7  println(kkk + iii + testMethod(vv, gg))  private int testMethod(int vv, int gg) {     return vv + gg }</pre>
<pre>def a = 5</pre>	<pre>def a = 5  thod(a)  stMethod(int a) {</pre>
<pre>static def foo(int i, int j, int k){     def v     println(i + j - k)     v = 42      if (i &gt; 42) {         println("hello!")     } else {         return v + j     }     return 239 }</pre>	<pre>static def foo(int i, int j, int k) {     def v     println(i + j - k)     v = 42     return testMethod(i, v, j) }  private static int testMethod(int i, int v, int j) {     if (i &gt; 42) {         println("hello!")     } else {         return v + j     } } return 239 }</pre>

## To extract a method in Groovy

1. In the editor, select a block of code to be transformed into a method or a function.

**Tip** The code fragment to form the method does not necessarily have to be a set of statements. It may also be an expression used somewhere in the code.

2. On the main menu or on the context menu of the selection, choose Refactor | Extract | Method or press

`Ctrl+Alt+M` .

3. In the [Extract Method](#) dialog box that opens, specify the name of the new method.
4. To return the value of a data type explicitly, select the Specify return type explicitly checkbox.
5. To return a keyword, select the Use explicit return statement checkbox.
6. In the Parameters area, do the following:
  - Specify the variables to be passed as method parameters, by selecting/clearing the corresponding checkboxes; if a parameter is disabled, a local variable of the corresponding type, with the initial value ... will be created in the extracted method, so that you will have to enter the initializer with an appropriate value manually.
  - Rename the desired parameters, by double-clicking the corresponding parameter lines and entering new names.
7. Check the result in the Signature Preview pane and click OK to create the method. The selected code fragment will be replaced with a method call. Additionally, IntelliJ IDEA will propose to replace any similar code fragments found within the current class.

IntelliJ IDEA lets you launch an interactive Groovy console in any project. You can use the console as a temporary file to write and evaluate your code. If dependencies in your project contain a Groovy library then the specified Groovy library is used to launch the Groovy console. If the dependencies do not contain a Groovy library then the bundled Groovy library of the Groovy version 2.3.9 will be used.

**Note** You can access the Groovy console in any Java project ( [Tools | Groovy Console](#) ).

In this section:

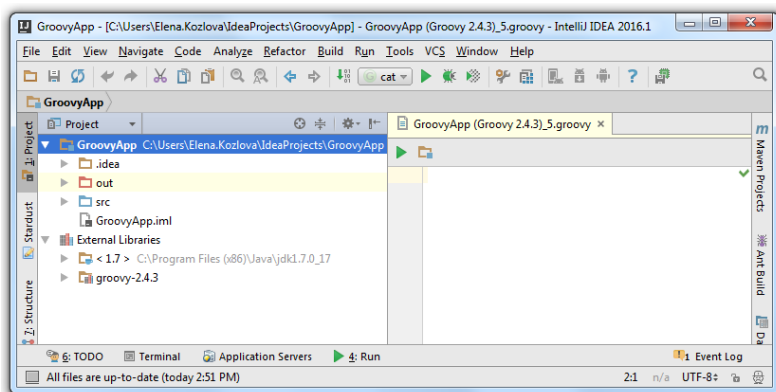

- [Launching the Groovy interactive console](#)
- [Working in Groovy interactive console](#)

## To launch Groovy console

1. On the main menu, choose [Tools | Groovy Console](#) .
2. If your project consists of two modules or more, choose the module to use the classpath of:

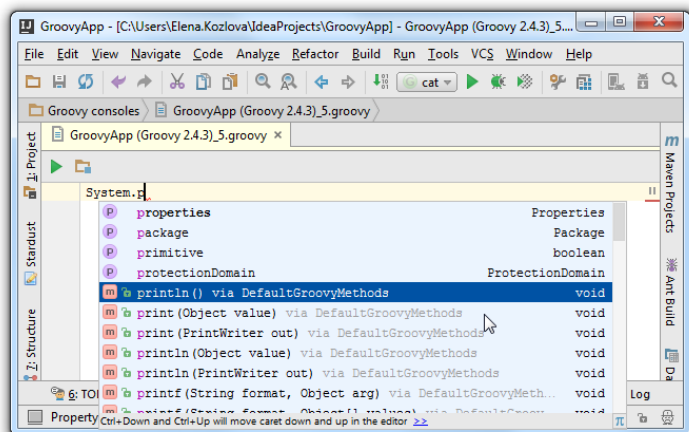

The Groovy console starts in a separate tab in the editor:

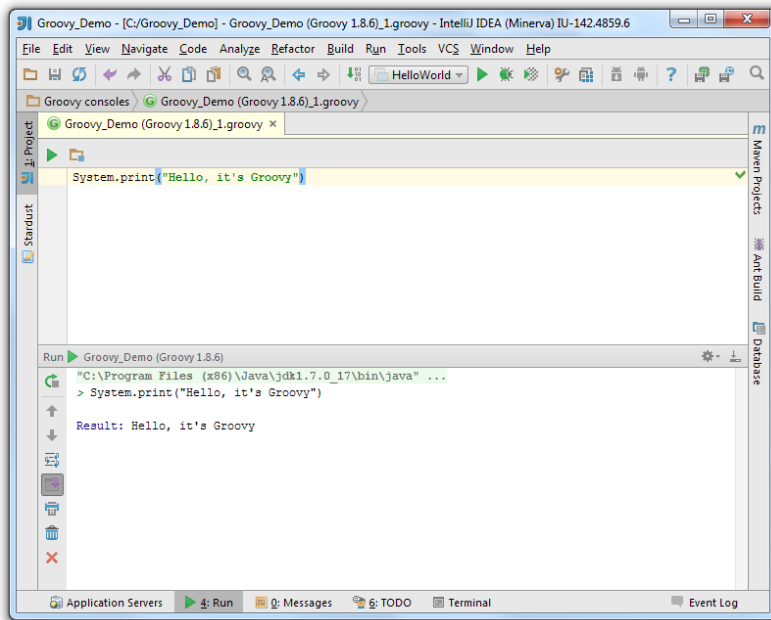

## To use Groovy interactive console

1. Type code in the console after the prompt character, or just paste from a different file.

Note that coding assistance is available, as you type (code completion and error highlighting):

2. Click , or press  to execute the entered code.

3. View the results in the **Run Tool Window for Groovy Console** .
4. Use up and down arrow keys to navigate through the results' history. Depth of the history is defined by the Console commands history size in the **Editor** settings.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA comes bundled with the GWT Support plugin that provides native support for developing Web applications based on the [Google Web Toolkit](#) (GWT).

IntelliJ IDEA GWT support, that extends to the version 2.7, includes the following features:

- GWT-aware coding assistance, such as [refactoring](#), code completion, [code inspections](#) with quick-fixes in the following areas:
  - client-side Java code
  - [remote services](#)
  - [JavaScript methods in Java code](#)
  - [enhanced syntax in \\*.css files](#)
  - [UiBinder \\*.ui.xml files](#)
- [Navigation to implementation](#),  .
- [Intention Actions](#) that let create various application elements.
- Code blocks, [live templates](#), and [file templates](#) .
- Integration with GWT compiler.
- GWT-ready [internationalization](#) (i18n).
- Automatic [creation of GWT components](#) : modules, entry points, remote services and serializable classes.
- Support of GWT specific [run configurations](#) for running and debugging GWT applications directly from IntelliJ IDEA.
- Basic [Vaadin](#) support, implemented by the Vaadin Support plugin that comes bundled with IntelliJ IDEA.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports the use of Google Web Toolkit through the dedicated GWT [facet](#) . Before you enable GWT support, make sure [GWT SDK](#) is downloaded and installed on your computer.

When you have downloaded and installed GWT SDK, there are several ways to enable the GWT support, depending on your context:

- [Create a module](#) with a dedicated GWT facet.
- [Attach a GWT facet](#) to an existing module.

To have IntelliJ IDEA pick the path to the GWT installation folder every time you enable GWT support for a module, specify this path in the default GWT facet settings.

### Configuring default path to GWT

1. Open the Project Structure dialog ( `Ctrl+Shift+Alt+S` ).
2. Go to Facets , and select GWT .
3. In the Defaults tab, specify the path to the GWT installation folder. Click OK .

This feature is only supported in the Ultimate edition.

When you create a module with a dedicated GWT [facet](#), IntelliJ IDEA configures the module and adds all the necessary libraries automatically.

## To create a module with a GWT facet

Depending on the situation, you can choose to create a new project or to add a module to an existing project.

1. Do one of the following:

- If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .

As a result, the [New Project wizard](#) opens.

- If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .

As a result, the [New Module wizard](#) opens.

2. On the first page of the wizard, in the left-hand pane, select Java Enterprise . In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.

3. Under Additional Libraries and Frameworks , select the Google Web Toolkit checkbox.

In the GWT SDK field, specify the GWT SDK location. (To download the latest version of the GWT SDK, use the [Download GWT link](#).)

If you want a [sample GWT application](#) to be created, select the Create sample application checkbox and specify the application name in the field underneath.

Click Next .

4. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

This feature is only supported in the Ultimate edition.

When you add a dedicated GWT [facet](#) to a module, IntelliJ IDEA re-configures the module and adds all the necessary libraries automatically.

### Adding a GWT facet to an existing module

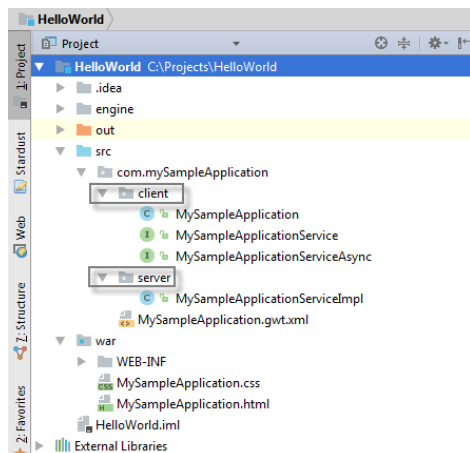

1. [Open the Project tool window](#) (e.g. View | Tool Windows | Project ).
2. Right-click the module and select Add Framework Support .
3. In the left-hand pane of the Add Frameworks Support dialog, select the Google Web Toolkit checkbox.
4. In the GWT SDK field, specify the GWT SDK location. (To download the latest version of the GWT SDK, use the [Download GWT link](#).)
5. If you want a [sample GWT application](#) to be created, select the Create sample application checkbox and specify the application name in the field underneath.
6. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

When the GWT support is [enabled](#), you can start developing GWT application components.

### GWT Package Structure

The standard GWT package layout facilitates differentiating the client-side code from the server-side code. The image below illustrates the structure of a standard GWT package.

- Client - this directory contains the client-side source files and subpackages.
- Public - this directory contains various static resources that can be served publicly. By default, this directory is not created in the project.
- Server - this directory contains the server-side code and subpackages.
- GWT Module XML descriptor.

### GWT Module

Individual units of a GWT configuration are XML files called modules. A module bundles all the configuration settings that your GWT project needs, namely:

- Inherited modules.
- An entry point application class name; these are optional, although any module referred to in HTML must have at least one entry-point class specified.
- Source path entries.
- Public path entries.
- Deferred binding rules, including property providers and class generators.

The GWT Module XML descriptor (5) should reside in the root package of a standard project layout. IntelliJ IDEA can simply [generate a GWT Module](#) with the corresponding project structure for you.

### Entry Point

A module entry-point is any class that is assignable to `EntryPoint` and that can be constructed without parameters.

When a module is loaded, every entry point class is instantiated and its `EntryPoint.onModuleLoad()` method is called.

**Tip** To get more familiar with the GWT application structure, have IntelliJ IDEA generate a [GWT Sample Application](#) for you.

In this part:

- [Creating a GWT Module](#)
- [Creating an Entry Point](#)
- [Creating a Remote Service](#)
- [Creating a GWT UiBinder](#)
- [Creating GWT UiRenderer and ui.xml file](#)
- [Creating Event and Event Handler Classes](#)

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you do not need to remember the required GWT module structure because a GWT module will be generated along with the standard package layout. IntelliJ IDEA also enables [code completion](#) for you by adding the relevant GWT DOCTYPE to the `.xml` descriptor of a new module automatically.

## To generate a GWT module

1. In the Project view , right-click the package where you want to generate a GWT module. If you already have a GWT module, select any package outside the existing GWT module, to generate a new one.
2. From the context menu, select New | Google Web Toolkit | GWT Module .
3. Specify the name for the module and directory where html and css files should be created, then click OK .  
IntelliJ IDEA creates an `.xml` GWT Module descriptor and generates the correct package layout:
  - The client part with an entry point in it.
  - The server part.
  - A public folder with an `html` page and a `css` .

This feature is only supported in the Ultimate edition.

A GWT module entry point is any class that can be assigned to `EntryPoint` and can be constructed without parameters. When a module is loaded, every entry point class is instantiated and its `EntryPoint.onModuleLoad()` method is called.

## To generate an entry point

1. In the Project view , right-click the client package.
2. From the context menu, select New | Google Web Toolkit | GWT Entry point .
3. Specify the name of the entry point and click OK .

This feature is only supported in the Ultimate edition.

Developing a GWT service requires creating synchronous and asynchronous interfaces as well as server implementation with the correct names and structure. Also they should be registered in the `xml` module descriptor. IntelliJ IDEA can generate all the required parts automatically.

### **To generate a remote service**

1. In the Project view , right-click the client package.
2. From the context menu, select New | Google Web Toolkit | GWT Remote service .
3. Specify the name for the service and click OK .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA can generate a [GWT UiBinder](#) and a `ui.xml` file for you. While defining the declarative layout in the `ui.xml`, various types of coding assistance, such as [code completion](#) and [generation of import statements](#), are at your disposal.

IntelliJ IDEA supports integration between the declarative layout in the `ui.xml` and the corresponding Java class, including [Finding usages](#).

If you are using the `ClientBundle` interface, IntelliJ IDEA marks its methods with the icon  in the left gutter area. Click this icon to navigate to the corresponding resource.

**Warning!** A GWT UiBinder can be created in the client part only.

## To generate a GWT UiBinder

1. In the Project view, right-click the client package.
2. From the context menu, select New | Google Web Toolkit | GWT UiBinder and ui.xml.
3. In the Create GWT UiBinder and ui.xml file dialog box that opens, specify the name of the UiBinder and the ui.xml file.
4. Specify the [type of the root element](#). Select the relevant item from the drop-down list or click the Browse button  and choose the relevant type in the Search dialog box that opens.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA can generate a [GWT UiRenderer](#) and a `ui.xml` file for you. While defining the declarative layout in the `ui.xml`, various types of coding assistance, such as [code completion](#) and [generation of import statements](#), are at your disposal.

IntelliJ IDEA supports integration between the declarative layout in the `ui.xml` and the corresponding Java class, including [Finding usages](#).

If you are using the `ClientBundle` interface, IntelliJ IDEA marks its methods with the icon  in the left gutter area. Click this icon to navigate to the corresponding resource.

**Warning!** A GWT UiRenderer can be created in the client part only.

## Generating GWT UiRenderer

1. In the Project view, right-click the client package.
2. From the context menu, select New | Google Web Toolkit | GWT Renderer and ui.xml file.
3. In the Create New GWT Renderer and ui.xml file dialog box that opens, specify the name of the UiRenderer and the ui.xml file.

Click OK.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA can generate stubs for [GWT Event](#) classes and [GWT Event Handler](#) interfaces.

**Tip** GWT Event classes and Event Handler interfaces can be created in the client part only.

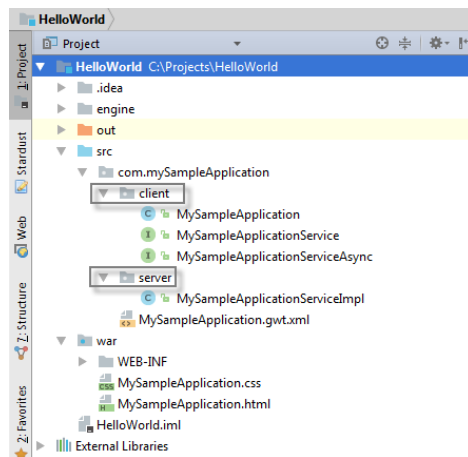

## To create a GWT event and event handler

1. In the Project view , right-click the client package.
2. From the context menu, select New | Google Web Toolkit | GWT Event and Handler classes .
3. In the Create GWT Event and Handler Classes dialog box that opens, specify the names of the event class, the event handler interface, and the abstract "callback" method for callers to override.  
Actually, you do not need to specify all the three names manually. As soon as you type the event class name in the Event class name text box, IntelliJ IDEA automatically completes the names of the handler interface and the "callback" method and displays the suggestions in the Handler class name and Handle method name text boxes respectively. This ensures that the generated stubs will be generated in accordance with [GWT Google API libraries](#).
4. When you click OK , IntelliJ IDEA generates the stubs for the event class and event handler interface and opens them in the editor. Populate the generated stubs as necessary.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA can generate a sample GWT application when you are [creating a module with GWT support](#) . This application helps you familiarize yourself with the GWT application structure. For a detailed description of the GWT fundamentals, please refer to <http://code.google.com/webtoolkit/overview.html> .

IntelliJ IDEA creates a simple HelloWorld application that meets all the GWT requirements.

As you can see, IntelliJ IDEA has generated a [GWT Module](#) ( `MySampleApplication.gwt.xml` ) in the root of the package. The corresponding package layout (client and server parts) is also generated automatically.

- `client` : contains the required entry point ( `MySampleApplication` class) and remote service interfaces.
- `server` : contains the server implementation of the remote service.

When creating a remote GWT service, IntelliJ IDEA automatically generates both synchronous and asynchronous interfaces (in the `client` part), creates the server implementation, and registers them in the GWT Module `.xml` , as required.

The HTML host file, that is used to run the application, is located in a separate Web facet.

IntelliJ IDEA also adds comments to the sample application code to make it clear to the maximum.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA helps you understand the compiled output of your GWT application by providing [GWT Compile Reports](#).  
Generated reports are displayed in the browser.

## To view the GWT compile output report

1. On the main menu, choose Tools | Generate GWT Compile Report .
2. In the [Generate GWT Compile Report](#) dialog box that opens, choose the module to view the output of from the GWT Module drop-down list.
3. Specify whether you want to view an existing report or a new one. Do one of the following:
  - To have a new report created, click the Generate button.
  - To view the previous generated report, click the View Report button.

**Tip** IntelliJ IDEA informs you how long ago the last report was generated.

This feature is only supported in the Ultimate edition.

You can specify whether you need the [application to open in a browser](#) or not. Moreover, you can choose a browser to use. This can be the default IntelliJ IDEA browser or any other browser of your choice.

## To enable or disable opening a GWT application in the browser

1. Open [Run/Debug Configuration for GWT](#) .
2. Select Open in browser checkbox and from the drop-down list select a browser that you want to use for your application. Otherwise, clear the Open in browser checkbox.

Note that even if you decide to run the application in the embedded [GWT development mode](#) without launching the browser, you can still specify the `.html` file from which you can start the application.

## To configure the way to show a GWT application

1. Open [Run/Debug Configuration for GWT](#) .
2. Select the Open in browser checkbox and from the drop-down list, select the browser in which you want to open the application.  
To use the default IntelliJ IDEA browser, choose the Default item from the drop-down list.
3. To specify the starting page of the application, in the Start page field, select the `.html` file that implements this page.

In this section:

- [Introduction](#)
- [Creating an HTML file](#)
- [Generating references in an HTML file](#)
- [Previewing output of an HTML file in a browser](#)
- [Viewing HTML source code of a web page in the editor](#)
- [Viewing embedded images](#)
- [Extracting an include file](#)

## Introduction

IntelliJ IDEA brings powerful support for HTML that includes syntax and error highlighting, formatting according to the code style, structure validation, code completion, and much more .

## Creating an HTML file

On the main menu, choose File | New , and then choose HTML File in the pop-up list. IntelliJ IDEA creates a stub file and opens it in the editor.

**Tip** The stub is generated using the [HTML file template](#) .

## Generating references in an HTML file

IntelliJ IDEA can generate `<script>` , `<link>` , or `<img>` tags inside `<head>` .

To generate a tag, select a JavaScript, CSS, or image file in the Project tool window and drag it into the HTML file.

**Tip** The `width` and `height` attributes are also generated automatically.

## Previewing output of an HTML file in a browser

You can preview a file with Web contents in the [IntelliJ IDEA default browser](#) or in the one of your choice.

**Tip** To preview PHP pages in the browser, you need to [configure synchronization with a server](#) first.

To open the page preview in the default browser

Open the file in the editor and choose View | Open in Browser on the main menu.

To open the page preview in a browser of your choice

Open the file in the editor, choose View | Preview file in on the main menu, and select the desired browser from the pop-up menu. Alternatively, hover your mouse pointer over the code to show the browser icons bar, and click the icon that indicates the desired browser:

**Tip** To hide all the icons or some of them, clear the Active checkboxes for the unnecessary browsers on the [Web Browsers page](#) .

## Viewing HTML source code of a web page in the editor

1. Choose File | Open URL .
2. In the Open URL dialog box that opens, type the URL address of the web page or choose a previously opened URL from the list.

## Viewing embedded images

IntelliJ IDEA offers several ways to view images embedded in an HTML file. You can use [navigation to source](#) , [open an image in an external graphical editor](#) , or [preview images on-the-fly](#) .

**Tip** Check and configure the preview appearance on the [Images page](#) .

To view an image in IntelliJ IDEA, do one of the following

- Select the image file in the Project tool window, and choose Jump to Source on the context menu of the selection or press `F4` .
- In the editor, place the cursor at the reference to the image, and choose Jump to Source on the context menu or press `Ctrl+B` .

To view an image in an external editor

1. Configure the path to the external editor on the [Images page](#) ( File | Settings | Editor | Images for Windows and Linux or IntelliJ IDEA | Preferences | Editor | Images for macOS).
2. Select the image file in the Project tool window, and choose Open in external editor or press `Ctrl+Alt+F4` .

## Extracting an include file

**Tip** Type the file name without an extension.

**Tip** If there are any duplicates of the selected fragment, IntelliJ IDEA will suggest to change them for the corresponding reference as well.

You can extract a fragment of HTML or CSS code into a separate include file. Entire JavaScript code blocks inside a `<script>` tags can also be extracted.

1. In the editor, select the code block to be extracted and choose Refactor | Extract | Extract Include File on the main menu or on the context menu of the selection.
2. In the [Extract Include File](#) dialog box that opens, specify the name of the target include file in the Name for extracted include file text box.
3. In the Extract to directory text box, specify the directory to store the include file in. Leave the predefined directory or choose another one.
4. Click **OK** , when ready. IntelliJ IDEA extracts the selected source code into the specified file in the target directory and generates the corresponding reference in the source file.

The following basic how tos are intended to help you get started using Java in IntelliJ IDEA.

## Moving source files into a subfolder

You shouldn't keep your source (.java) files in the project root directory. If this is, currently, the case, create a subdirectory in the project root directory and move all your source files into that subdirectory.

## Enabling coding assistance for .Java files

Coding assistance for [Java](#) turns on automatically as soon as you mark the folder with your .java files as containing source code. In the Project tool window ( View | Tool Windows | Project ), right-click the folder, point to Mark Directory as and select Sources Root .

## Making the Java API accessible to your code

When writing in Java, you, generally, reuse (i.e. reference) the [Java API](#) classes. These classes are available in a [JDK](#) . So, to make the Java API accessible to your code, you should [download](#) and then specify your JDK:

1. Open your .java file in the editor: select the file in the Project tool window and press `F4` .  
If you haven't specified your JDK yet, there will be a *Project SDK is not defined* message above the editing area.
2. Click Setup SDK .
3. In the dialog that opens, select your JDK and click OK , or click Configure , click `+` , select JDK , and then select the directory where you have the desired JDK installed.

## Creating a folder structure for your package or specifying a package prefix

If you don't have an appropriate folder structure for your [package](#) yet (let's assume that the name of your package is `com.example.mypackage` ), you have two options leading to about the same result:

- *Create the corresponding folder structure* in your source directory (e.g. `<your-source-dir>/com/example/mypackage` ):  
In the editor, within the package statement (e.g. `package com.example.mypackage;` ), place the cursor within the package name, press `Alt+Enter` and select Move to package 'com.example.mypackage' .
- *Assign your source folder a package prefix* without actually creating the folder structure:
  1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ), select Modules and select your module.
  2. In the right-hand part of the Sources tab, next to your source folder, click `⋮` .
  3. In the dialog that opens, specify the prefix (e.g. `com.example.mypackage` ).

## Making classes in a JAR accessible to your app

Say, you have a [JAR](#) with the classes that you want to reuse in your app. In that case, you should add the JAR to the dependencies of your module. As a result, the JAR classes become available for referencing in your code, and they are included in your app when you build it.

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ), select Modules and select your module.
2. Select the Dependencies tab, click `+` and select JARs or directories .
3. In the dialog that opens, select your JAR file.

## Compiling .Java files

If you did everything as discussed earlier on this page, compiling your .java file or files is not going to be a problem. Just select one of the following options: Build | Build Project or Build | Build Module 'module\_name' .

If compilation is problematic, IntelliJ IDEA will inform you about the reason and provide hints for fixing the problem.

## Running your app

If the [compilation is a success](#) , you can run your app:

1. Open the class with a [main\(\) method](#) in the editor.
2. In the left margin, next to the main() method, click the run marker (the green arrow) and select Run '<ClassName>.main()' .

## Packaging your app in a JAR

To package your app in a JAR, you should configure a JAR artifact and then build it:

1. Open the Project Structure dialog (`Ctrl+Shift+Alt+S` ) and select Artifacts .
2. Click `+` , select JAR and select From modules with dependencies .
3. In the dialog that opens, select the class with a main() method (the Main Class field).
4. Save the artifact settings by clicking OK in the Project Structure dialog.
5. Select Build | Build Artifacts , select your artifact and select Build . (If there's only one artifact, you can just press `Enter` when the Build Artifact menu pops up.)

This tutorial illustrates a Java SE application development workflow. The age-old [Hello, World](#) application is used as an example.

- [Creating a project](#)
- [Exploring the project structure](#)
- [Creating a package and a class](#)
- [Writing code for the HelloWorld class](#)
  - [Using a live template for the main\(\) method](#)
  - [Using code auto-completion](#)
  - [Using a live template for println\(\)](#)
- [Building and running the application](#)
- [Remarks: building and running applications](#)
- [Packaging the application in a JAR](#)
  - [Creating an artifact configuration for the JAR](#)
  - [Building the JAR artifact](#)
- [Running the packaged application](#)
  - [Creating a JAR Application run configuration](#)
  - [Executing the run configuration](#)

## Creating a project

Any new development in IntelliJ IDEA starts with creating a [project](#) . So let's create one now.

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the Welcome screen. Otherwise, select File | New | Project .  
As a result, the New Project wizard opens.
2. In the left-hand pane, select Java . (We want a Java-enabled project to be created, or, to be more exact, a project with a Java [module](#) .)
3. Specify the [JDK](#) that you want to use in your project (the Project SDK field). Do one of the following:
  - Select the JDK from the list.
  - If the desired JDK is already available on your computer but is missing from the list, click New and, in the dialog that opens, select the JDK installation directory.
  - Click Download JDK .

Because our application is going to be a "plain old Java application", we don't need any additional technologies to be supported. So, don't select any of the options under Additional Libraries and Frameworks .

Click Next .

4. The options on the next page have to do with creating a Java class with a `main()` method.  
Since we are going to study the very basics of IntelliJ IDEA, and do everything from scratch, we don't need these options at the moment. So, don't select any of the options.

Click Next .

5. On the next page, specify the project name (e.g. `HelloWorld` ). If necessary, change the project location suggested by IntelliJ IDEA.

Click Finish .

Wait while IntelliJ IDEA is creating the project. When this process is complete, the structure of your new project is shown in the Project tool window.

## Exploring the project structure

Let's take a quick look at the project structure.

There are two top-level nodes:

- HelloWorld. This node represents your Java module. The `.idea` folder and the file `HelloWorld.iml` are used to store configuration data for your project and module respectively. The folder `src` is for your source code.
- External Libraries. This is a category that represents all the "external" resources necessary for your development work. Currently in this category are the `.jar` files that make up your JDK.

(For more information, see [Tool Windows](#) and [Project Tool Window](#).)

## Creating a package and a class

Now we are going to create a package and a class. Let the package and the class names be `com.example.helloworld` and `HelloWorld` respectively.

Though a package can be created separately, we will create both the package and the class at once.

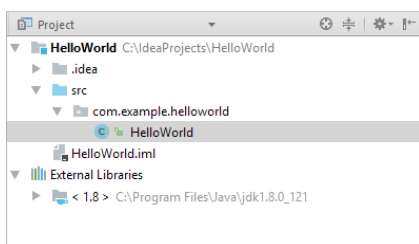

1. In the Project tool window, select the `src` folder and press `Alt+Insert`. (Alternatively, you can select `File | New`, or `New` from the context menu for the folder `src`.)
2. In the New menu, select `Java Class` (e.g. by pressing `Enter`).

3. In the Create New Class dialog that opens, type `com.example.helloworld.HelloWorld` in the Name field. The `Class` option selected in the Kind list is OK for creating a class. Press `Enter` to create the package and the class, and close the dialog.

The package `com.example.helloworld` and the class `HelloWorld` are shown in the Project tool window.

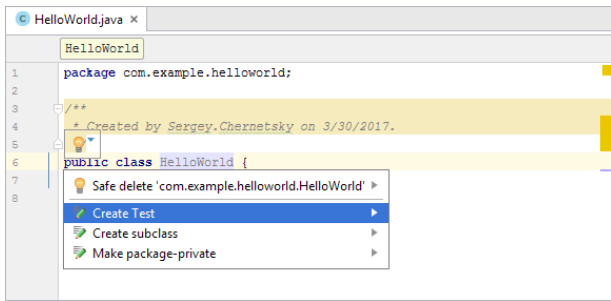

At the same time, the file `HelloWorld.java` (corresponding to the class) opens in the editor.

Note the package statement at the beginning of the file and also the class declaration. When creating the class, IntelliJ IDEA used a file template for a Java class. (IntelliJ IDEA provides a number of predefined file templates for creating various file types. For more information, see [File and Code Templates](#).)

Also note a yellow light bulb . This bulb indicates that IntelliJ IDEA has suggestions for the current context. Click the light bulb, or press `Alt+Enter` to see the suggestion list.

At the moment, we are not going to perform any of the actions suggested by IntelliJ IDEA (such actions are called [intention actions](#) .) Note, however, that this IntelliJ IDEA feature may sometimes be very useful.

Finally, there are code folding markers next to the commented code fragment (☰). Click one of them to collapse that fragment. (For more information, see [Folding Code Elements](#) .)

## Writing code for the HelloWorld class

The code in its final state (as you probably know) will look this way:

```
package com.example.helloworld;

public class HelloWorld {
    public static void main(String[] args) {
        System.out.println("Hello, World!");
    }
}
```

The package statement and the class declaration are already there. Now we are going to add the missing couple of lines.

Press `Shift+Enter` . (In contrast to `Enter` , `Shift+Enter` starts a new line without breaking the current one.)

## Using a live template for the main() method

The line

```
public static void main(String[] args) {}
```

may well be typed. However, we suggest that you use a different method. Type `p` and press `Ctrl+J` .

Select `psvm` - `main()` method declaration . (Use the `Up` and `Down` arrow keys for moving within the suggestion list, `Enter` for selecting a highlighted element.)

Here is the result:

```
1 package com.example.helloworld;
2
3 /**...*/
4
5 public class HelloWorld {
6     public static void main(String[] args) {
7
8     }
9 }
10
11
```

IntelliJ IDEA provides code snippets called live templates. `psvm` is an abbreviation for one of such templates. To insert a live template into your code, you can use Code | Insert Live Template or `Ctrl+J`. For more information, see [Live Templates](#).

### Using code auto-completion

Now, it's time to add the remaining line of code

```
System.out.println("Hello, World!");
```

We'll do that using code auto-completion.

Type `Sy`

The code completion suggestion list is shown.

```
1 package com.example.helloworld;
2
3 /**...*/
4
5 public class HelloWorld {
6     public static void main(String[] args) {
7         Sy
8     }
9 }
10
11
```

Suggestion list:

- System (java.lang)
- SynchronousQueue<E> (java.util.concurrent)
- Sync (com.sun.corba.se.impl.orbutil.concurrent)

Select System (java.lang) by pressing `Enter`.

Type `.o` and press `Ctrl+Period`.

```
1 package com.example.helloworld;
2
3 /**...*/
4
5 public class HelloWorld {
6     public static void main(String[] args) {
7         System.o
8     }
9 }
10
11
```

Suggestion list:

- out (= null) PrintStream
- setOut(PrintStream out) void
- runFinalizersOnExit(boolean value) void

`out` is inserted followed by a dot. (You can select an item in the suggestion list by pressing `Ctrl+Period`. In that case, the selected item is inserted into the editor followed by a dot.)

Type `p` and then find and select `println(String x)`.

```
1 package com.example.helloworld;
2
3 /**...*/
4
5 public class HelloWorld {
6     public static void main(String[] args) {
7         System.out.p
8     }
9 }
10
11
```

Suggestion list:

- println(long x) void
- println(Object x) void
- println(String x) void
- append(char c) PrintStream

IntelliJ IDEA prompts you which parameter types can be used in the current context.

```
1 package com.example.helloworld;
2
3 /**...*/
4
5 public class HelloWorld {
6     public static void main(String[] args) {
7         System.out.println(
8     }
9 }
10
11
```

Suggestion list:

- <no parameters>
- boolean x
- char x
- int x
- long x
- float x
- double x
- @NotNull char[] x
- String x
- @Nullable Object x

Type `"`

The second quotation mark is inserted automatically and the cursor is placed between the quotation marks. Type `Hello, World!`

```
1 package com.example.helloworld;
2
3 /**...*/
4
5
6 public class HelloWorld {
7     public static void main(String[] args) {
8         System.out.println("Hello, World!");
9     }
10 }
11
```

The code at this step is ready.

(For more information, see [Auto-Completing Code](#).)

## Using a live template for println()

As a side note, we could have inserted the call to `println()` by using a live template (`sout`).

If you think that it's enough for live templates, proceed to [running the application](#). Otherwise, try that now as an additional exercise. Delete

```
System.out.println("Hello, World!");
```

Type `s`, press `Ctrl+J` and select `sout` - Prints a string to System.out.

The line

```
System.out.println();
```

is added and the cursor is placed between `(` and `)`.

Type `"` and then type `Hello, World!`

## Building and running the application

Classes with a `main()` method can be run right from the editor. To show that, there are the green arrow markers () in the left margin.

Click one of the markers and select `Run 'HelloWorld.main()'`.

```
1 package com.example.helloworld;
2
3 /**...*/
4
5
6 public class HelloWorld {
7     public static void main(String[] args) {
8         System.out.println("Hello, World!");
9     }
10 }
11
```

Wait while IntelliJ IDEA is compiling the class. When the compilation is complete, the Run tool window opens at the bottom of the screen.

```
Run HelloWorld
"C:\Program Files\Java\jdk1.8.0_121\bin\java" ...
Hello, World!
Process finished with exit code 0
```

On the first line, there is a fragment of the command that IntelliJ IDEA used to run the class. (Click the fragment to see the whole command line including all options and arguments.) The last line shows that the process has exited normally, and no infinite loops occurred. And, finally, you see the program output `Hello, World!` between these lines.

(For more information, see [Run Tool Window](#).)

## Remarks: building and running applications

Some remarks related to building and running applications in IntelliJ IDEA:

– Prior to running the class, IntelliJ IDEA has automatically compiled it. When necessary, you can initiate the compilation yourself. The corresponding options can be found in the Build menu.

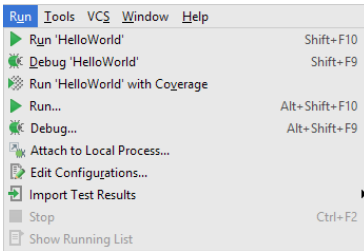

Many of these options are also available as context menu commands in the Project tool window and in the editor.

Finally, there is an icon in the upper-right part of the workspace that corresponds to the Build Project command (🏗).

For more information, see [Build Process](#) and [Compilation Types](#).

- The options for running and debugging applications can be found in the Run menu.

As in the case of the build operations, the run options can also be accessed from the Project tool window and the editor, as well as by means of controls in the upper-right part of the workspace.

- Applications in IntelliJ IDEA are run according to what is called run/debug configurations. Such configurations, generally, should be created prior to running an application.

When you performed the Run 'HelloWorld.main()' command, IntelliJ IDEA, first, created a run configuration and then executed it.

The name of this run configuration (HelloWorld) is now shown in the run/debug configuration selector to the left of ▶.

The HelloWorld configuration now exists as a temporary configuration and, if necessary, you can save it to make it permanent.

- Run/debug configurations can do a lot more than just run applications. They can also build applications and perform other useful tasks.

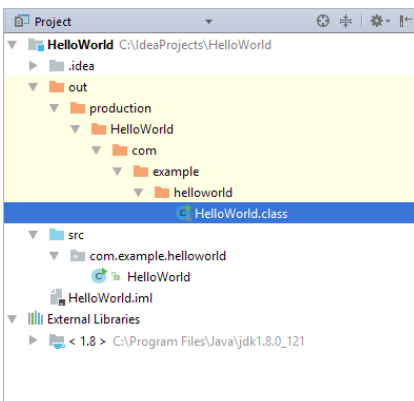

If you look at the settings for the HelloWorld run configuration (Run | Edit Configurations or Edit Configurations from the run configuration selector), you'll see that the Build option is included by default in the Before launch task list. That's why IntelliJ IDEA compiled the class when you performed the Run 'HelloWorld.main()' command.

- If you look at the Project tool window, you'll see that now there is the folder `out` there. This is the project output folder.

Inside it is the module output folder ( `production\HelloWorld` ), the folder structure for the package

`com.example.helloworld` and the compiled class file `HelloWorld.class`.

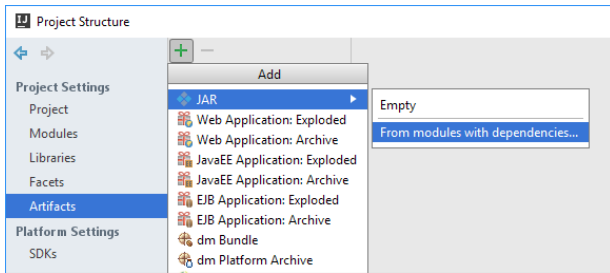

For more information, see [Specifying Compilation Settings](#).

## Packaging the application in a JAR

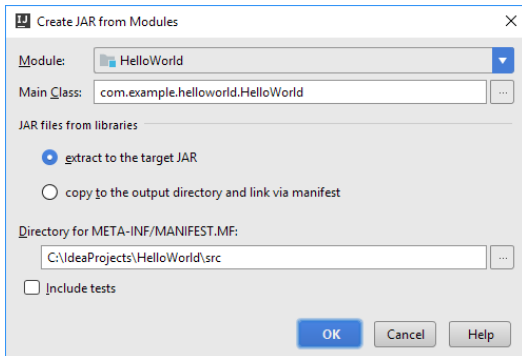

When happy with your application, you may want to package it in a Java archive ([JAR](#)) for distribution. To do that, you should create an [artifact](#) configuration for your JAR and then build the artifact.

## Creating an artifact configuration for the JAR

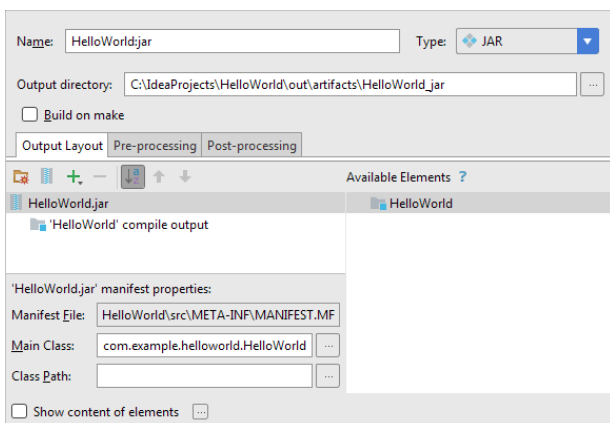

1. Select File | Project Structure to open the Project Structure dialog.
2. Under Project Settings, select Artifacts.
3. Click +, point to JAR and select From modules with dependencies.

4. In the dialog that opens, specify the main application class. (To the right of the Main Class field, click ... and select HelloWorld (com.example.helloworld) in the dialog that opens.)

As a result, the artifact configuration is created and its settings are shown in the right-hand part of the Project Structure dialog.

5. Click OK.

## Building the JAR artifact

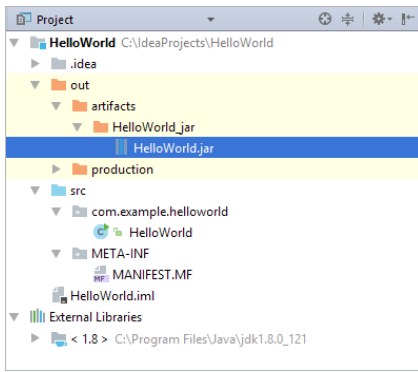

1. Select Build | Build Artifacts.

2. Point to HelloWorld.jar and select Build. (In this particular case, Build is the default action, so you can just press Enter instead.)

If you now look at the `out/artifacts` folder, you'll find your JAR there.

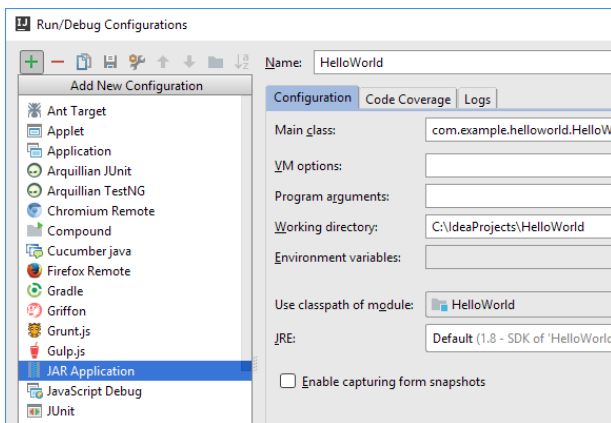

## Running the packaged application

To make sure that everything is fine with the JAR, let's run it. To do that, we'll create a JAR Application run configuration and then execute that run configuration.

### Creating a JAR Application run configuration

To run Java applications packaged in JARs, IntelliJ IDEA provides the JAR Application run configurations. To create such a configuration:

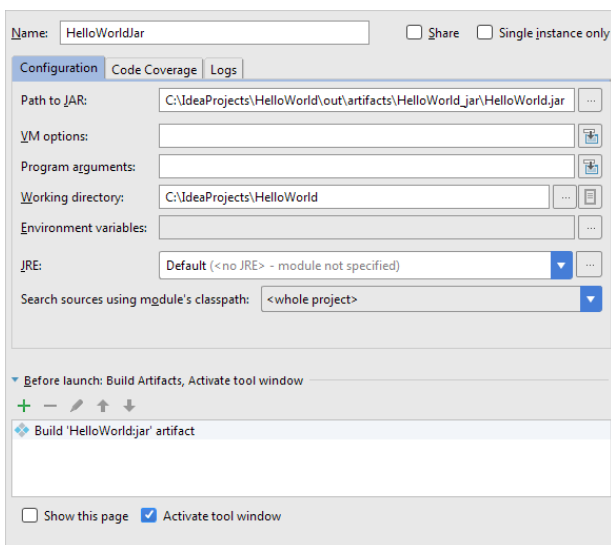

1. Select Run | Edit Configurations .
2. In the Run/Debug Configurations dialog that opens, click **+** and select JAR Application .

3. Specify the path to the JAR file. (To the right of the Path to JAR field, click **...** and select the JAR file in the dialog that opens.)

The rest of the settings in this case don't matter, however, there's one more thing that we'll do - just for convenience.

4. Under Before launch , click **+** , select Build Artifacts and select the HelloWorld.jar artifact in the dialog that opens. The Build 'HelloWorld.jar' artifact task is included in the Before launch task list. So each time you execute this run configuration, the artifact will be built automatically.

### Executing the run configuration

- To the right of the run configuration selector, click **▶** .

As before, the Run tool window opens and the application output is shown there.

On this page:

- [Before you start...](#)
- [Putting breakpoints](#)
- [Starting a debugger session](#)
- [Stepping through the application](#)
  - [Stepping through the statements directly](#)
  - [Stepping through the method calls](#)

## Before you start...

You have already [created and executed your first Java application](#) . Now it's time to [debug it](#).

However, it would be nice to add one more line to the application - let it be

```
System.out.println("it's me, Wombat!");
```

## Putting breakpoints

To start a debugger session, first of all you need to place a [breakpoint](#) at the statement where you want to suspend the execution of your application. The existing source code does not give you much of a choice - the only place, where you can put breakpoints, are the statements

```
System.out.println("Hello World!");  
System.out.println("it's me, Wombat!");
```

So let's do it. Click the left gutter at the line of the statement you want to put a breakpoint on, or just press `Ctrl+F8` :

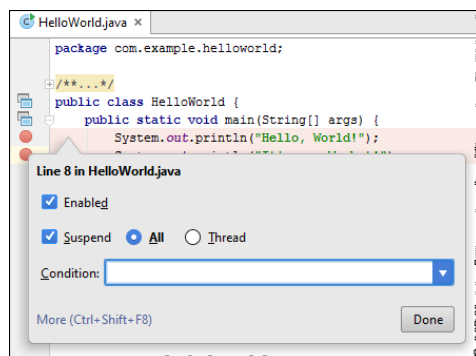

As you see, the new breakpoint is added to the source code. The line where the breakpoint is set changes its color to pink.

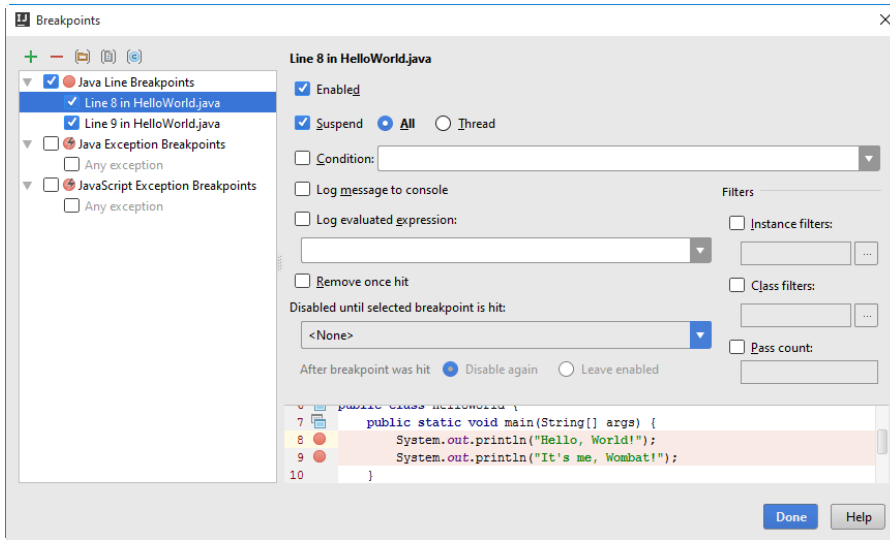

If you just hover your mouse pointer over the breakpoint, you will see its properties in the tooltip:

Suppose you want to change some properties of this breakpoint. Then right-click it and see the following dialog box:

Finally, you would like to explore and change all the available properties of a breakpoint and see its location among the other breakpoints (if any). In this case, press `Ctrl+Shift+F8` :

## Starting a debugger session

Now that the breakpoints are added, you can debug your application. This can be done in numerous ways; however, let's follow the easiest one.

Mind the icon  that marks a class with the `main()` method. Clicking this icon reveals a menu that enables running and debugging such a class:

What does it mean?

IntelliJ IDEA launched the debugger session with the [temporary run/debug configuration](#). This run/debug configuration has the default name "HelloWorld.main()". To view and change the settings of this run/debug configuration, choose `Run | Edit Configurations...` on the main menu:

or click the run/debug configuration selector, and then choose `Edit Configurations...`:

IntelliJ IDEA compiles your application (which takes time!), and then suspends the application at the first breakpoint.

The IntelliJ IDEA window now looks different:

- The first thing that has changed is the color of the first line with the breakpoint. Now this line is rendered blue:

It means that (according to the breakpoint properties) the application has reached this breakpoint, hit it and suspended before the statement `println`.

- Next, in the lower part of the IntelliJ IDEA window, a special tool window has emerged. This is the [Debug tool window](#) that features the stepping toolbar and shows all the necessary information you might need during the debugger session:

## Stepping through the application

### Stepping through the statements directly

Let's step through the application. Click  on the stepping toolbar, or just press **F8**.

The next line now becomes blue. If you look at the Debug tool window, you notice the following changes:

- In the **Frames** pane, the next line number is shown.
- The **Console** tab is marked with the icon , which means that it contains new output.

Click the Console tab. You see the message of the first line with the breakpoint "Hello, World!". The second message is not yet visible:

Click  again on the stepping toolbar, or press **F8**. Now the second message appears in the console. After you click  the next time, the application stops:

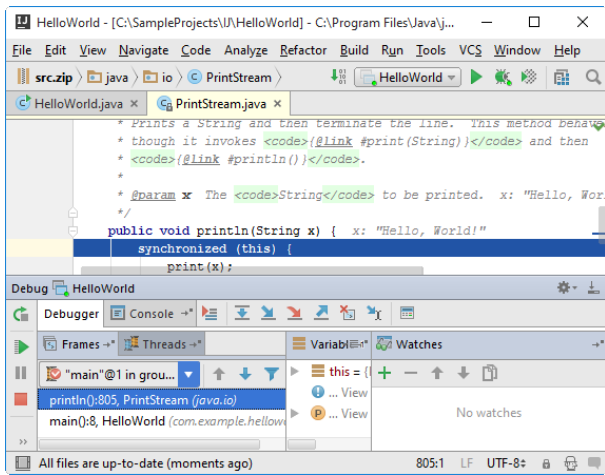

This debugging session is over.

## Stepping through the method calls

Now let's explore a more complicated way and step into the `println()` call.

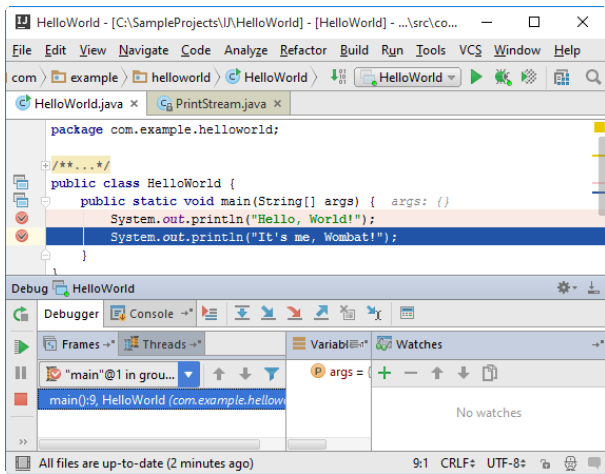

First, restart the debugger session. To do that, just click  on the toolbar of the **Debug tool window**. Thus you'll rerun the latest run/debug configuration, namely, HelloWorld.

The application again pauses at the first breakpoint. This time, click , or press **Shift+Alt+F7**. You see a different picture:

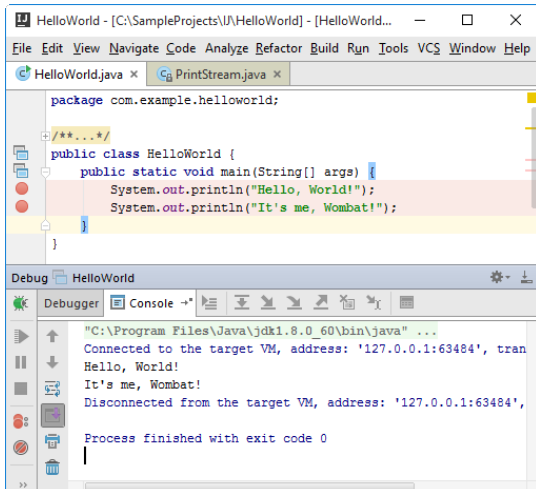

It means that IntelliJ IDEA has stepped into the method `println(String x)` of the library class `PrintStream.java`. Note that a new thread appears in the list of threads.

Click or press `Shift+F8` to return to the next breakpoint:

Note that the Console tab has again got the marker , which means that new output is available. Next, click . You see that the process terminates:

Keeping your code up to date with the latest versions of languages and libraries is a challenging task. Fortunately, IntelliJ IDEA can make this easier, with inspections to guide your efforts, automatic fixes, and the usual refactoring tools.

[Java SE 8](#) brings entire new concepts to the language, like lambda expressions, and adds new methods to classes that developers have been using comfortably for years. In addition, there are new ways of doing things, including the new [Date and Time API](#), and an [Optional](#) type to help with null-safety.

In this tutorial we're going to show how IntelliJ IDEA can help you transition your code from Java 6 (or 7) to Java 8, using code examples to show what help is available and when you may, or may not, choose to use new features.

This tutorial assumes the following prerequisites:

- You already have an IntelliJ IDEA project for an existing codebase.

On this page:

- [Approaching the problem](#)
- [Initial setup](#)
- [Configuring and running language level migration inspections](#)
- [Lambda expressions](#)
- [Impact of applying lambda expressions](#)
- [New Collection Methods](#)
- [Streams API - foreach](#)
- [Streams API - collect](#)
- [Impact of replacing foreach with Streams](#)
- [New Date and Time API](#)
- [Impact of migrating to the new Date and Time API](#)
- [Using Optional](#)
- [Impact of migrating to Optional](#)
- [Summary](#)

## Approaching the problem

The sheer number of options and features that IntelliJ IDEA has available might be overwhelming, especially when tackling a problem as big as trying to migrate a whole codebase (or even just a module or package) to a new version. As with most software development problems, it pays to approach this in an iterative fashion.

1. Pick a small number of changes to implement.
2. Pick a section of the codebase to apply them to.
3. Apply the changes in batches, running your project tests frequently and checking in to your VCS system when the tests are green.

To this end, this tutorial will group changes into sections rather than assume a Big Bang approach.

## Initial setup

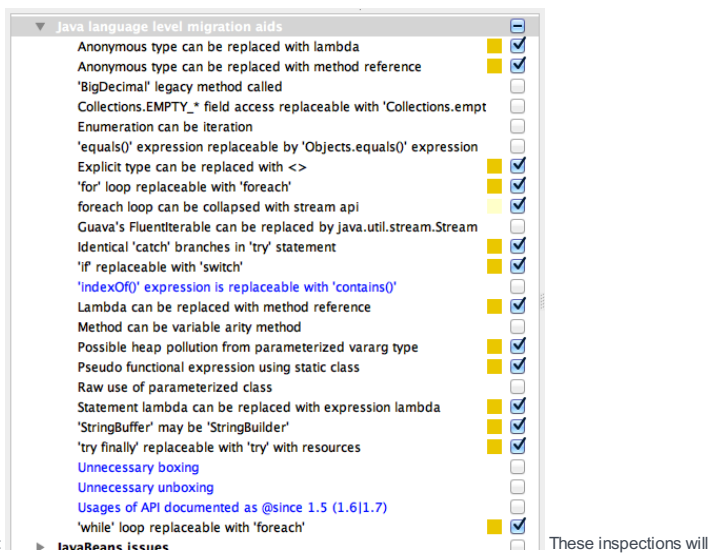

1. Make sure you're compiling with a Java 8 SDK. If you're not, change your SDK to the latest version of Java 8.
2. In the [project settings](#), you should set your language level to "8.0 - Lambdas, type annotations".

If you are compiling the code in a CI environment, you'll need to ensure the new code is compiled using Java 8 there as well. Configuring this is beyond the scope of this tutorial.

## Configuring and running language level migration inspections

Your project may already make use of inspections to encourage a certain level of consistency and quality in the code. To focus purely on just making changes related to upgrading to Java 8, we're going to create a new inspection profile.

1. Navigate to the [inspections settings](#).
2. [Create a new inspection profile](#) called "Java8".
3. As a starting point for this profile, deselect everything using the "reset to empty" button .
4. We're going to select a set of language migration inspections to point out sections of the code we might want

to update: **Java8 inspections** These inspections will

show us areas in your code where you may be able to use the following Java 8 features:

- [Lambda expressions](#)
- [Method references](#)
- New [Collection](#) methods
- [Streams API](#)

5. Click OK to save these settings to the "Java8" profile and close the settings window.
6. [Run the inspections](#) , selecting the "Java8" profile and the scope to run the inspections on. If your project is small, that might be the whole codebase, but more likely you will want to select a module or package to start with.

Once Analyse code has finished running, you'll see a set of results in the [Inspection Results Tool Window](#) .

## Lambda expressions

The inspections will show you places where you can convert code automatically to use lambda expressions. There are a number of places you might typically discover this in your existing code, for example when you create anonymous inner classes for:

- [Runnable](#) , [Callable](#)
- [Comparator](#)
- [FileFilter](#) , [PathMatcher](#)
- [EventHandler](#)
- Third party interfaces like [Guava's Predicate](#)

1. In the [Inspection Results Tool Window](#) , you should see results grouped under "Java language level migration aids". Under this heading, you may see "Anonymous type can be replaced with lambda". Open up this heading to see all the sections of the code where IntelliJ IDEA has detected you can use a lambda. You might see something like this:

2. For example, you may come across a `Runnable` anonymous inner class:

```

executorService.scheduleAtFixedRate(new Runnable() {
    @Override
    public void run() {
        getDs().save(new CappedPic(title));
    }
}, 0, 500, MILLISECONDS);

```

3. Many inspections suggest a fix that can be applied, and "Anonymous type can be replaced with lambda" does have a suggested resolution. To apply the fix, either:
  - Click on the Problem Resolution in the right of the inspection window, in our case this is Replace with lambda .
  - Or press `Alt+Enter` on the grey code in the editor and select Replace with lambda .

4. IntelliJ IDEA will then automatically change the code above to use a lambda expression:

```
executorService.scheduleAtFixedRate(() -> getDs().save(new CappedPic(title)), 0, 500, MILLI
```

You'll notice that lambda expressions can state very little in terms of type information. Here, the fact that this lambda represents an implementation of `Runnable` all but disappears. IntelliJ IDEA will provide you with information about the type of the lambda expression via the lambda icon in the left gutter:

```
Overrides method in java.lang.Runnable  
Click or press ⌘U to navigate  
leAtFixedRate(() -> getDs().save(new CappedPic(title)), 0, 500, MILLISECOND);
```

Hovering over this will tell you the type, and clicking lets you navigate to the declaration.

## Impact of applying lambda expressions

You should be able to automatically apply this fix to all places where anonymous inner classes are found in your codebase without impacting the functionality in your system. Applying the change will generally also improve the readability of your code, removing lines of boilerplate like in the example above.

However, you may want to check each individual change, as:

- Larger anonymous inner classes may not be very readable in a lambda form.
- There may be additional changes and improvements you can make.

Let's address both points with an example.

We might be using a `Runnable` to group a specific set of assertions in our test:

```
Runnable runnable = new Runnable() {  
    @Override  
    public void run() {  
        datastoreProvider.register(database);  
        Assert.assertNull(database.find(User.class, "id", 1).get());  
        Assert.assertNull(database.find(User.class, "id", 3).get());  
  
        User foundUser = database.find(User.class, "id", 2).get();  
        Assert.assertNotNull(foundUser);  
        Assert.assertNotNull(database.find(User.class, "id", 4).get());  
        Assert.assertEquals("Should find 1 friend", 1, foundUser.friends.size());  
        Assert.assertEquals("Should find the right friend", 4, foundUser.friends.get(0).id);  
    }  
};
```

Converting this to a lambda results in:

```
Runnable runnable = () -> {  
    datastoreProvider.register(database);  
    Assert.assertNull(database.find(User.class, "id", 1).get());  
    Assert.assertNull(database.find(User.class, "id", 3).get());  
  
    User foundUser = database.find(User.class, "id", 2).get();  
    Assert.assertNotNull(foundUser);  
    Assert.assertNotNull(database.find(User.class, "id", 4).get());  
    Assert.assertEquals("Should find 1 friend", 1, foundUser.friends.size());  
    Assert.assertEquals("Should find the right friend", 4, foundUser.friends.get(0).id);  
};
```

This is not much shorter, nor does it impact readability much.

In cases like these, you may choose to use IntelliJ IDEA's extract method to pull these lines into a single method instead:

```
Runnable runnable = () -> {  
    assertUserMatchesSpecification(database, datastoreProvider);  
};
```

The second reason to check all your lambda conversions is that some lambdas can be further simplified. This last example is one of them - IntelliJ IDEA will show the curly braces in grey, and pressing `Alt+Enter` with the cursor on the braces will pop up the suggested change Statement lambda can be replaced with expression lambda :

```
final Runnable runnable = () -> {  
    assertUserMatchesSpecification(database, datastoreProvider);  
};  
Statement lambda can be replaced with expression lambda more... (98F1)
```

Accepting this change will result in:

```
Runnable runnable = () -> assertUserMatchesSpecification(database, datastoreProvider);
```

Once you've changed your anonymous inner classes to lambdas and made any manual adjustments you might want to make, like extracting methods or reformatting the code, run all your tests to make sure everything still works. If so, commit these changes to VCS. Once you've done this, you'll be ready to move to the next step.

## New Collection Methods

Java 8 introduced a new way of working with collections of data, through the Streams API. What's less well known is that many of the `Collection` classes we're used to working with have new methods on them that are not via the Streams API. For example, `java.util.Iterable` has a `forEach` method that lets you pass in a lambda that represents an operation to run on every element. IntelliJ IDEA's inspections will highlight areas where you can use this and other new methods.

1. Back in the [Inspection Results Tool Window](#), you should see "foreach can be collapsed with stream api" under "Java language level migration aids". You may not realise when you're going through all the inspections, but not all of these fixes will use the Streams API (more on Streams later). For example:

```
for (Class<? extends Annotation > annotation : INTERESTING_ANNOTATIONS) {
    addAnnotation(annotation);
}
```

IntelliJ IDEA suggests "Can be replaced with foreach call". Applying this inspection gives us:

```
INTERESTING_ANNOTATIONS.forEach(this::addAnnotation);
```

Note that IntelliJ IDEA has applied all simplifications it could, going as far as using a [Method Reference](#) rather than a lambda. Method references are another new features in Java 8, which can generally be used where a lambda expression would usually call a single method.

2. Method references take a while to get used to, so you may prefer to expand this into a lambda to see the

```
INTERESTING_ANNOTATIONS.forEach(this::addAnnotation);
```

```
final List<Class<?>> lifecycleClasses
lifecycleClasses.add(clazz);
```

lambda version:

Press `Alt+Enter` on the method reference and click `Replace method reference with lambda`. This is especially useful as you get used to all the new syntax. In lambda form, it looks like:

```
INTERESTING_ANNOTATIONS.forEach((annotation) -> addAnnotation(annotation));
```

Both of the new forms do exactly the same thing as the original code - for every item in the

`INTERESTING_ANNOTATIONS` list, it calls `addAnnotation` with the item.

## Streams API - foreach

IntelliJ IDEA's inspections will suggest using the `forEach` on `Iterable` where appropriate, but it will also the new Streams API where this is a better choice.

The [Streams API](#) is a powerful tool for querying and manipulating data, and using it could significantly change and simplify the code you write. For this tutorial, we're going to look at some of the simplest use cases to get you started. Once you're more comfortable using this style of coding, you may then want to use its capabilities further.

1. What does the Streams API give us that we can't simply get from using a `forEach` method? Let's look at an example that's a slightly more complicated for loop than the previous one:

```
public void addAllBooksToLibrary(Set<Book> books) {
    for (Book book: books) {
        if (book.isInPrint()) {
            library.add(book);
        }
    }
}
```

Firstly the loop body checks some condition, then does something with the items that pass that condition.

2. Selecting the fix `Replace with forEach` will use the Streams API to do the same thing:

```
public void addAllBooksToLibrary(Set <Book> books) {
    books.stream()
        .filter(book -> book.isInPrint())
        .forEach(library::add);
}
```

In this case, IntelliJ IDEA has selected a method reference for the `forEach` parameter. For filter, IntelliJ IDEA has used a lambda, but will suggest in the editor that this particular example can use a method reference:

```
public void addAllBooksToLibrary(Set<Book> books) {
    books.stream()
        .filter(book -> book.isInPrint())
        .forEach(library::add);
}
```

Can be replaced with method reference [more...](#) (⌘F1)

3. Applying this fix gives:

```
books.stream()
    .filter(Book::isInPrint)
    .forEach(library::add);
```

## Streams API - collect

Instead of "can be replaced with foreach" call you might see "can be replaced with collect call". This is very similar to the above example, but instead of calling a `forEach` method at the end of the stream and performing some operation, this will use the stream's `collect` method to put all the results from the stream operation into a new `Collection`. It's very common to see a `for` loop that iterates over some collection, performs some sort of filtering or manipulating, and outputs the results into a new collection, and that's the sort of code this inspection will identify and migrate to using the Streams API.

1. In the [Inspection Results Tool Window](#), you should see "foreach can be replaced with collect call" under "Java language level migration aids". Selecting one of these inspection results will show you a for loop that might look something like:

```
List<Key> keys = ....

List<Key.Id> objIds = new ArrayList<Key.Id>();
for (Key key : keys) {
    objIds.add(key.getId());
}
```

Here, we're looping over a list of `Key` objects, getting the `Id` from each of these objects, and putting them all into a separate collection of `objIds`.

2. Apply the Replace with collect fix to turn this code into:

```
List<Key.Id> objIds = keys.stream().map(Key::getId).collect(Collectors.toList());
```

3. Reformat this code so that you can see more clearly all the Stream operations:

```
List<Key.Id> objIds = keys.stream()
    .map(Key::getId)
    .collect(Collectors.toList());
```

This does exactly the same thing the original code did - takes a collection of `Key` s, "maps" each `Key` to its `Id`, and collects those into a new list, `objIds`.

Like the `forEach` example, IntelliJ IDEA can work out if a filter needs applying to a collect statement as well as maps, so it can cleverly turn many of your complex loops into a set of Stream operations.

## Impact of replacing foreach with Streams

It may be tempting to run these inspections and simply apply all fixes automatically. When it comes to converting your code to use new methods on Collections or Streams, a little care should be taken. The IDE will ensure that your code works the same way it used to, but you need to check that your code remains readable and understandable after applying the changes. If you and your team are using Java 8 features for the first time, some of the new code will be very unfamiliar and probably unclear. Take the time to look at each change individually and check you're happy you understand the new code before going ahead.

Like with lambdas, a good rule of thumb is to start with small sections of code - short for loops that translate into two or fewer stream operations, preferably with single-line lambdas. As you become more familiar with the methods, then you may want to tackle more complex code.

Let's look at an example:

IntelliJ IDEA suggests that this code:

```
for (Entry<Class<? extends Annotation>, List<Annotation>> e : getAnnotations().entrySet()) {
    if (e.getValue() != null && !e.getValue().isEmpty()) {
        for (Annotation annotation: e.getValue()) {
            destination.addAnnotation(e.getKey(), annotation);
        }
    }
}
```

Can be converted to this code:

```

getAnnotations().entrySet()
    .stream()
    .filter(e -> e.getValue() != null && !e.getValue().isEmpty())
    .forEach(e -> {
        for (Annotation annotation: e.getValue()) {
            destination.addAnnotation(e.getKey(), annotation);
        }
    });

```

Setting aside the fact that the original code is challenging to understand to begin with, you may choose not to apply the changes for a number of reasons:

- Despite refactoring away the outer-loop, there's still a for loop inside the `forEach` method. This suggests that there may be a different way to structure the stream call, perhaps using `flatMap`.
- The `destination.addAnnotation` method suggests that there may be a way to restructure this to use a `collect` call rather than a `forEach`.
- It's arguably not easier to understand than the original code.

However, you may choose to accept this change for the following reasons:

- This is a complex piece of code that is iterating through and manipulating data in a collection, therefore a move towards the Streams API is a move in the right direction. It can be further refactored or improved later when the team's developers are more familiar with the way Streams work.
- In the new code the `if` condition has been moved into a `filter` call, making clearer what purpose this section of the code is.

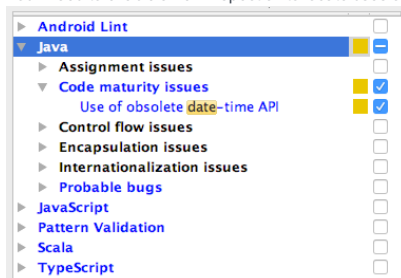

Apart from the options "keep the code" and "apply the changes", there's a third option: refactor the old code to something more readable, even if it doesn't use Java 8. This might be a good piece of code to make a note of to refactor later, rather than trying to tackle all the code's problems while simply trying to adopt more Java 8 conventions.

## New Date and Time API

The inspections we've selected for our "Java8" profile help us to locate places where we can use lambda expressions, new methods on Collections and the Streams API, and will apply fixes automatically to those places. There are plenty of other new features in Java 8, and in the following sections we'll highlight some features of IntelliJ IDEA that may help you use these too.

In this section, we'll look at locating places that may benefit from using the new [Date and Time API](#) instead of `java.util.Date` and `java.util.Calendar`.

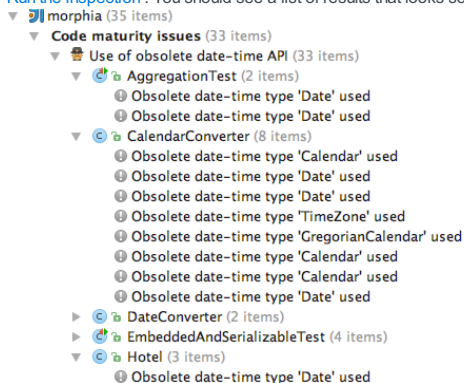

1. You'll need to enable a new inspection to locate uses of the old Date and Time API.

Note that although many methods have been

deprecated on `java.util.Date` for some time, the class itself is not deprecated, so if you use it in your code you will not receive deprecation warnings. That's why this inspection is useful to locate usages.

2. Run the inspection. You should see a list of results that looks something like this:

3. Unlike the earlier inspections, these do not have suggested fixes as they will require you and your team to evaluate the use of the old classes and decide how to migrate them to the new API. If you have a `Date` field that represents a single date without a time, for example:

```
public class HotelBooking {
    private final Hotel hotel;
    private final Date checkInDate;
    private final Date checkOutDate;

    // constructor, getters and setters...
}
```

you may choose to replace this with a `LocalDate`. This can be done via the context menu Refactor | Type Migration... or via `(Ctrl+Shift+F6)`. Type `LocalDate` in the popup and select `java.time.LocalDate`. When you press enter, this will change the type of this field and getters and setters. You may still need to address compilation errors where the field, getters or setters are used.

- For fields that are both date and time, you may choose to migrate these to `java.time.LocalDateTime`. For fields that are only time, `java.time.LocalTime` may be appropriate.
- If you were setting the original values with a new `Date`, knowing that this is the equivalent to the date and time right now:

```
booking.setCheckInDate(new Date());
```

you can instead use the `now()` method:

```
booking.setCheckInDate(LocalDate.now());
```

- A common and readable way to set a value for `java.util.Date` was to use `java.text.SimpleDateFormat`. You might see code that looks something like:

```
SimpleDateFormat format = new SimpleDateFormat("yyyy-MM-dd");
booking.setCheckInDate(format.parse("2017-03-02"));
```

If this check in date has been migrated to a `LocalDate`, you can easily set this to the specific date without the use of a formatter:

```
booking.setCheckInDate(LocalDate.of(2017, 3, 2));
```

These examples barely scratch the surface of the changes you may want or need to do in order to fully utilise the new date and time features in Java 8. Take a look at the [tutorial provided by Oracle](#) for more information on the new API features and how to use them.

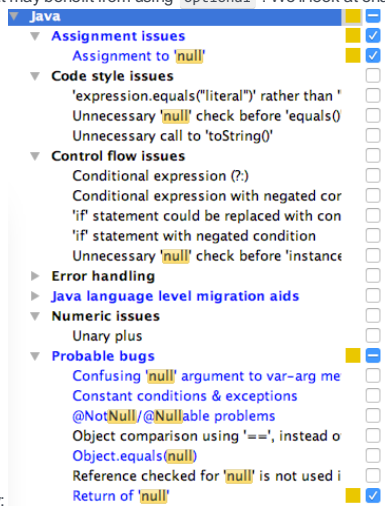

## Impact of migrating to the new Date and Time API

Updating your code to use the new Date and Time API requires much more manual intervention than migrating anonymous inner classes to Lambda Expressions and loops to the Streams API. IntelliJ IDEA will help you see how much and where you use the old `java.util.Date` and `java.util.Calendar` classes, which will help you understand the scope of the migration. IntelliJ IDEA's refactoring tools can help you migrate these types if necessary. However, you will need to have a strategy on how to approach each of the changes, which new types you want to use, and how to use these correctly. This is not a change you can apply automatically.

## Using Optional

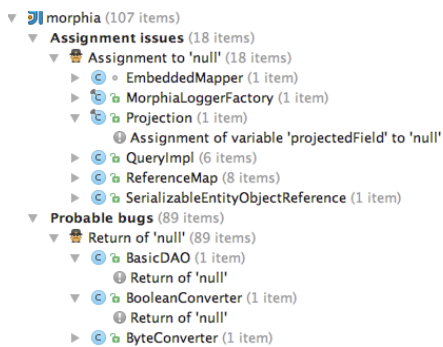

The last Java 8 feature we'll look at is the new `Optional` type. `java.util.Optional` gives you a way to handle null values, and a way to specify if a method call is expected to return a null value or not. Like Date and Time, IntelliJ IDEA's features will help you to identify areas of your code that might benefit from using the `Optional` type.

- There are a number of inspections that look for the use of nulls in Java code, these can be useful for identifying areas that may benefit from using `Optional`. We'll look at enabling just two of these inspections for

simplicity:

- Run the code analysis. You should see a list of results that looks something like this:

3. If you see "Assignment to null" for fields, you may want to consider turning this field into an `Optional`. For example, in the code below, the line where `offset` is assigned will be flagged:

```
private Integer offset;

// code...

public Builder offset(int value) {
    offset = value > 0 ? value : null;
    return this;
}

// more code...
```

That's because in another method, the code checks to see if this value has been set before doing something with it:

```
if (offset != null) {
    cursor.skip(offset);
}
```

In this case, `null` is a valid value for `offset` - it indicates this has not been set, and therefore shouldn't be used. You may wish to change the field into an `Optional` of `Integer` via `Ctrl+Shift+F6`, and alter the way the value is set:

```
private Optional<Integer> offset;

// code...

public Builder offset(int value) {
    offset = value > 0 ? Optional.of(value) : Optional.empty();
    return this;
}

// more code...
```

Then you can use the methods on `Optional` instead of performing null-checks. The simplest solution is:

```
if (offset.isPresent()) {
    cursor.skip(offset);
}
```

But it's much more elegant to use a Lambda Expression to define what to do with the value:

```
offset.ifPresent(() -> cursor.skip(offset));
```

4. The inspections also indicate places where a method returns null. If you have a method that can return a null value, the code that calls this method should check if it returned null and take appropriate action. It's easy to forget to do this though, especially if the developer isn't aware the method can return a null. Changing these methods to return an `Optional` makes it much more explicit this might not return a value. For example, maybe our inspections flagged this method as returning a null value:

```
public Customer findFirst() {
    if (customers.isEmpty()) {
        return null;
    } else {
        return customers.get(0);
    }
}
```

We could alter this method to return an `Optional` of `Customer` :

```

public Optional<Customer> findFirst() {
    if (customers.isEmpty()) {
        return Optional.empty();
    } else {
        return Optional.ofNullable(customers.get(0));
    }
}

```

5. You'll need to change the code that calls these methods to deal with the `Optional` type. This might be the correct place to make a decision about what to do if the value does not exist. In the example above, perhaps the code that calls the `findFirst` method used to look like this:

```

Customer firstCustomer = customerDao.findFirst();
if (firstCustomer == null) {
    throw new CustomerNotFoundException();
} else {
    firstCustomer.setNewOffer(offer);
}

```

But we're now returning an `Optional`, we can eliminate the null check:

```

Optional<Customer> firstCustomer = customerDao.findFirst();
firstCustomer.orElseThrow(() -> new CustomerNotFoundException())
    .setNewOffer(offer);

```

## Impact of migrating to Optional

Changing a field type to `Optional` can have a big impact, and it's not easy to do everything automatically. To start with, try to keep the use of `Optional` inside the class - if you can change the field to an `Optional` try not expose this via getters and setters, this will let you do a more gradual migration.

Changing method return types to `Optional` has an even bigger impact, and you may see these changes ripple through your codebase in an unexpected way. Applying this approach to all values that can be null could result in `Optional` variables and fields all over the code, with multiple places to performing `isPresent` checks or using the `Optional` methods to perform an action or throw an appropriate exception.

Remember that the goal of using the new features in Java 8 is to simplify the code and aid readability, so limit the scope of the changes to small sections of the code and check that using `Optional` is making your code easier to understand, not more difficult to maintain.

IntelliJ IDEA's inspections will identify possible places for change, and the refactoring tools can help apply these changes, but refactoring to `Optional` has a large impact and you and your team should identify a strategy for which areas to change and how to approach these changes. You can even use the suggested fix of "Annotate field [fieldName] as @Nullable" to mark those fields that are candidates for migrating to `Optional`, in order to take a step in that direction with a smaller impact on the code.

## Summary

IntelliJ IDEA's Inspections, in particular those around language migration, can help identify areas in your code that can be refactored to use Java 8 features, and even apply those fixes automatically.

If you have applied the fixes automatically, it's valuable to look at the updated code to check it isn't harder to understand, and to help you become familiar with the new features.

This tutorial gave some pointers on how to migrate your code. We've covered [lambda expressions](#) and [method references](#), some new methods on [Collection](#), introduced the [Streams API](#), shown how IntelliJ IDEA can help you use the new [Date and Time API](#) and looked at how to identify places that might benefit from using the new `Optional` type.

There are plenty of new features in Java 8 designed to make life easier for programmers - to make code more readable, and to make it easier to perform complex operations on data structures. IntelliJ IDEA of course not only supports these features, but helps developers make use of them, including migrating existing code and providing help and suggestions in the editor to guide you as you use them.

The Java platform module system (JSR 376) a.k.a Project Jigsaw is on target to be part of the JDK 9 release. The goals of the system as described by the JSR are:

- *Reliable configuration* , to replace the brittle, error-prone class-path mechanism with a means for program components to declare explicit dependencies upon one another, along with
- *Strong encapsulation* , to allow a component to declare which of its public types are accessible to other components, and which are not.

**Warning!** The features discussed below are based on early access releases of both IntelliJ IDEA and JDK 9 and might change in future

IntelliJ IDEA already has a concept of modules for a project. Every IntelliJ IDEA module builds its own classpath.

With the introduction of the new Java platform module system, IntelliJ IDEA modules had to extend their capability by supporting the Java platform's module-path if it is used instead of the classpath .

In this tutorial we explore where IntelliJ IDEA assists in creating and using Java Platform modules and how these modules work with IntelliJ IDEA modules.

We will use the 'Greetings World' example given in full in the [OpenJDK quick start guide](#) .

## Creating a module

After [creating a module in IntelliJ IDEA](#) we can define it as a Java Platform module by creating a module-info.java file under the module source directory.

Every IntelliJ IDEA module can have at most a single Java platform module.

We can create a new module-info.java for our module by selecting the source directory where we want to create it and using the menu option New | module-info.java

When creating the module-info.java declaration file, IntelliJ IDEA will choose the name of the IntelliJ IDEA module as the default name for the Java Platform module. This can be changed and is not required to match.

## Using a module

As with all java file types, IntelliJ IDEA helps us with auto-completion and validity checks of the module-info.java content.

The dependencies of a module need to be defined in IntelliJ IDEA and Java Platform (Jigsaw) modules.

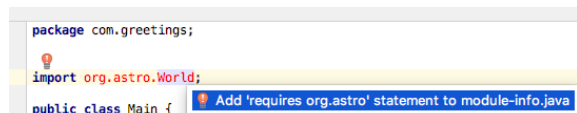

IntelliJ IDEA helps us keeping them in sync.

To define dependencies between our project modules, We can write a `requires` declaration in module-info.java and then IntelliJ IDEA will suggest to us to also add it as a dependency in its module.

This works also with library dependencies but only if the library jar file was already declared as a project dependency.

From the other direction, we can just write our java code. IntelliJ IDEA will suggest to add the other module as a dependency on our current module and then will also suggest to us adding a `requires` declaration as well.

## Running with modules

The information declared in the Java platform modules is used when running a class `Ctrl+Shift+F10` in IntelliJ IDEA.

This means that IntelliJ IDEA will run the JVM using a module-path and not a classpath .

This will enforce the strong encapsulation we get from the module system and any dependency issues we might have will be then reproduced by this run.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides facilities for developing applications using Java EE technologies.

- [Enabling Java EE Application Support](#)
- [Working with Application Servers](#)
- [Working with Cloud Platforms](#)
- [Developing a Java EE Application](#)

This feature is only supported in the Ultimate edition.

This topic discusses the features that become available when you turn on the JavaEE Application option.

- [Prerequisites](#)
- [Overview of the features](#)
- [Turning on the JavaEE Application option](#)
- [Managing deployment descriptors](#)
- [Managing application artifacts](#)

## Prerequisites

For the JavaEE Application option and associated features to be available:

- You should be using the ULTIMATE Edition of IntelliJ IDEA. (The corresponding functionality is not available in the Community Edition.)
- The Java EE: EJB, JPA, Servlets [plugin](#) must be enabled. (This plugin is bundled with the IDE and enabled by default.)

## Overview of the features

When you turn on the JavaEE Application option, IntelliJ IDEA:

- Creates `META-INF/application.xml`, an enterprise application archive [deployment descriptor](#).
- Creates a Java EE Application [facet](#) that lets you specify the locations of your `application.xml` and application server-specific deployment descriptors (e.g. `glassfish-application.xml`, `jboss-app.xml`).
- Creates an Exploded [EAR artifact](#) configuration.
- Makes various quick fixes available in the Project Structure dialog, e.g. for synchronizing `application.xml` with the structure of your EAR artifact.
- Makes the [JavaEE:App tool window](#) available.

If you turn on the JavaEE Application option when creating a project or module and specify an application server, IntelliJ IDEA also creates a [run/debug configuration for that server](#).

## Turning on the JavaEE Application option

You can turn on the JavaEE Application option:

- When creating a project or module ( `File | New | Project` or `File | New | Module` ). On the first page of the New Project or the New Module wizard, select Java Enterprise , and then select the JavaEE Application checkbox under Additional Libraries and Frameworks .
- For an existing module. In the Project tool window ( `View | Tool Windows | Project` ), right-click the module folder and select Add Framework Support . Then select the JavaEE Application checkbox in the dialog that opens.

## Managing deployment descriptors

You can manage your `application.xml` and server-specific deployment descriptor files in the Project Structure dialog:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the leftmost pane, select Modules or Facets .
3. In the pane to the right, select javaEEApplication .
4. On the [page that opens](#) in the right-hand part of the dialog, form the list of deployment descriptors for your application.

## Managing application artifacts

To deploy your application to a server, you need an application [artifact](#) . For Java EE applications, IntelliJ IDEA provides the following artifact formats:

- JavaEE Application: Exploded. This is a decompressed enterprise application archive ([EAR](#) ), a directory structure that is ready for deployment onto an application server.
- JavaEE Application: Archive. This is, obviously, an EAR file.

To manage your artifact configurations, use the Project Structure dialog ( `File | Project Structure | Artifacts` ).

See also, [Working with Artifacts](#) .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA can be integrated with the "most popular" application server systems. You can deploy your application [artifacts](#) onto the corresponding servers and debug the deployed applications right from within the IDE. You can also start and stop the servers installed on your computer.

- [Supported application servers](#)
- [Main tasks related to working with application servers](#)
- [Enabling application server integration plugins](#)
- [Defining Application Servers in IntelliJ IDEA](#)
- [Working with Server Run/Debug Configurations](#)
- [Updating Applications on Application Servers](#)

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides integration with the following application servers:

- [CloudBees](#)
- [Geronimo](#)
- [GlassFish](#) (currently not supported under JDK).
- [Google App Engine Development Server](#)
- [JBoss](#)
- [Jetty](#)
- JSR45-compatible application servers (any server that supports [JSR-45](#) )
- [Resin](#)
- [SpringSource dm Server](#)
- [Tomcat](#)
- [TomEE](#)
- [WebLogic](#)
- [WebSphere](#) (starting from version 6.1)

This feature is only supported in the Ultimate edition.

Here are main tasks related to working with application servers in IntelliJ IDEA.

1. Download and install the server that you are going to use. Even if you are going to use a remote server (i.e. one running on a different computer), the same server version must be installed locally.
2. Make sure that the necessary server integration [plugin](#) or plugins are enabled in IntelliJ IDEA. See [Enabling application server integration plugins](#) .
3. Define the server in IntelliJ IDEA. See [Defining Application Servers in IntelliJ IDEA](#) .
4. Create an [artifact configuration](#) for your application.
5. Create a [run/debug configuration](#) for your server. See [Creating a server run/debug configuration](#) .
6. Start the server run/debug configuration to run or debug your application. See [Starting a server run/debug configuration](#) .

This feature is only supported in the Ultimate edition.

All the available server integration [plugins](#) are enabled by default. However, before you start working with an application server, it's always worth making sure that the necessary plugin or plugins are enabled.

The server integration plugin names, normally, include the name of the server and the word Integration or Support, for example, GlassFish Integration, dmServer Support, Tomcat and TomEE Integration, etc.

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S` ).
2. In the left-hand part of the dialog, select [Plugins](#) .
3. In the right-hand part of the dialog, on the [Plugins page](#) , type the server name of interest (e.g. `tomcat` ) in the search box. As a result, only the plugins whose names and descriptions contain the typed text are shown in the list of plugins.
4. If the checkbox to the right of the plugin name is not selected, select it.
5. Click OK in the Settings dialog.
6. If suggested, restart IntelliJ IDEA.

This feature is only supported in the Ultimate edition.

To define a server in IntelliJ IDEA, in most of the cases, all you have to do is to specify where the corresponding server is installed.

You can define a server:

- Separately, in the Settings dialog: `Ctrl+Alt+S` | Build, Execution, Deployment | Application Servers | `+`, etc.
- When creating a project or module.
- When creating a server [run/debug configuration](#): Run | Edit Configurations | `+` | <Server Name> , etc.

In this section:

- [Defining a server in the Settings dialog](#)
- [Defining a server when creating a project or module](#)
- [Defining a server when creating a run/debug configuration](#)

## Defining a server in the Settings dialog

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S` ).
2. In the left-hand pane, in the Build, Execution, Deployment category, select Application Servers .
3. On the Application Servers page that opens in the right-hand part of the dialog, click `+` . (Alternatively, press `Alt+Insert` .)
4. Select the server that you are going to use.
5. In the dialog that opens, specify the server settings and click OK . For most of the servers, you have to specify just the server home, i.e. the server installation directory. For more information, see [Application Servers](#) .
6. Click OK in the Settings dialog.

## Defining a server when creating a project or module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project . As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module . As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java Enterprise .
3. In the right-hand part of the page, to the right of the Application Server field, click New .
4. Select the server that you are going to use.
5. In the dialog that opens, specify the server settings and click OK . For most of the servers, you have to specify just the server home, i.e. the server installation directory.
6. Specify other settings as necessary and click Next . For more information, see [Project Category and Options](#) or [Module Category and Options](#) .
7. Specify the name and location settings and click Finish . For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

## Defining a server when creating a run/debug configuration

1. Open the Run/Debug Configurations dialog (e.g. Run | Edit Configurations ).
2. Click `+` (`Alt+Insert` ), select the server of interest (e.g. Tomcat Server ) and, if available, select Local or Remote .
3. In the right-hand part of the dialog, on the Server tab, click Configure to the right of the Application server list.
4. In the dialog that opens specify the server settings and click OK .
5. Specify other run/debug configuration settings as necessary and click OK .

This feature is only supported in the Ultimate edition.

To run or debug your Java EE or Web application on an application server, you need an application server [run/debug configuration](#).

One such configuration may be created by IntelliJ IDEA automatically. This happens if you, when creating a project or module, specify an application server that you are going to use (see [Defining a server when creating a project or module](#)).

You can create more server run/debug configurations if and when needed.

- [Local and remote run configurations](#)
- [What happens when a server run configuration is started](#)
- [Creating a server run/debug configuration](#)
- [Starting a server run/debug configuration](#)

## Local and remote run configurations

A server run/debug configuration may be local or remote.

Local configurations are for servers installed on your computer. Such configurations include the settings that define how the corresponding server is to be started. Consequently, when you execute a local configuration, IntelliJ IDEA, among other things, starts the server.

Remote configurations don't start a server. Usually, they are used for servers running on different (remote) computers. They may as well be used for servers installed locally (on your computer) in cases when you don't want the run configuration to start (or stop) the server.

When you execute a remote configuration, IntelliJ IDEA connects to the server to be able to deploy application artifacts or to perform their debugging. At that time, the corresponding server must already be running.

To conclude, what principally distinguishes local and remote configurations is not where the server is physically installed (though this is also important) but whether or not the server is started (or stopped) by means of the corresponding run configuration.

## What happens when a server run configuration is started

When you start a server run/debug configuration, IntelliJ IDEA, usually, does the following:

1. Performs the Before launch tasks. By default, these are Make and Build Artifacts : IntelliJ IDEA compiles the project and builds the application artifacts. The Build Artifacts task is not initially present in a run configuration but added automatically as soon as you specify the artifacts to be deployed onto the server.
2. Starts the server (for a local configuration) or connects to the server (for a remote configuration). (At that moment, the [Run](#) or the [Debug tool window](#) opens so that you can monitor and control the process.)
3. Deploys the specified artifacts (and/or deployable components external to your project) to the server.
4. If so specified, starts a web browser and opens a specified URL (which usually corresponds to a starting page of your application).

## Creating a server run/debug configuration

1. Open the Run/Debug Configurations dialog (e.g. Run | Edit Configurations ).
2. Click  ( [Alt+Insert](#) ), select the server of interest (e.g. Tomcat Server ) and, if available, select Local or Remote . (See [Local and remote run configurations](#) .)
3. In the right-hand part of the dialog, specify the run/debug configuration settings and click OK . (For information on the available settings, see the corresponding server-specific topic in [Run/Debug Configurations Dialog](#) ).

See also, [Creating and Editing Run/Debug Configurations](#) .

## Starting a server run/debug configuration

An application server run/debug configuration can be started in a usual way, as any other run configuration. See [Running Applications](#) and [Starting the Debugger Session](#) .

Alternatively, you can use the [Application Servers tool window](#) :

1. Open the Application Servers tool window (e.g. View | Tool Windows | Application Servers ).
2. Select the server run/debug configuration that you want to use.
3. On the toolbar of the tool window, click:
  -  to start the selected configuration in the run mode.
  -  to start the selected configuration in the debug mode.

As a result, the [Run](#) or the [Debug tool window](#) opens.

This feature is only supported in the Ultimate edition.

When running or debugging a Java EE or Web application, you can modify the source code and, almost immediately, see the result of your changes.

- [Updating an application: Process overview](#)
- [Specifying application update options](#)
- [Updating an application](#)
- [Application update options](#)

## Updating an application: Process overview

1. Specify the necessary application update options in your server run/debug configuration, see [Specifying application update options](#) .
2. Start the run/debug configuration.
3. After making changes to the source code, update your application, see [Updating an application](#) .

## Specifying application update options

In server run/debug configurations, the following settings on the Server tab have to do with updating an application:

- On 'Update' action. The *Update action* refers to clicking  in the Run or the Debug tool window (alternatively, `Ctrl+F10` or Run | Update '<app name>' application ).

Use the list to select the default update option. See [Application update options](#) .

Show dialog. If this checkbox is not selected, the default update option is used. Otherwise, a dialog is shown that displays all the available update options, and you'll be able to select the necessary option prior to actually updating your application.

- On frame deactivation. *Frame deactivation* means switching from IntelliJ IDEA to a different application (e.g. a Web browser). Use the list to specify what IntelliJ IDEA should do in such cases.

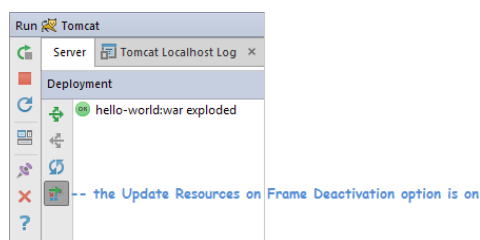

## Updating an application

When the Run or the Debug tool window is active, do one of the following:

- Click  on the toolbar of the tool window.
- Press `Ctrl+F10` .
- Select Run | Update '<app name>' application .

If the necessary update option is associated with [frame deactivation](#) , your application is updated automatically when you switch from IntelliJ IDEA to a different application (e.g. a Web browser).

Note that you can turn the Update Resources on Frame Deactivation option on and off right in the Run or the Debug tool window. To do that, click .

You can also update your application in the [Application Servers tool window](#) by redeploying your application artifact (.

## Application update options

The update options are different depending on:

- the artifact format, i.e. on whether the application artifact is exploded (unpacked) or packed (e.g. WAR, EAR)
- the run/debug configuration type, i.e. on whether the run/debug configuration is local or remote (see [Local and remote run configurations](#) )

### OptionDescriptionAvailable for

Update resources	All changed resources are updated (HTML, JSP, JavaScript, CSS and image files).	Exploded artifacts in local configurations
Update classes and resources	Changed resources are updated; changed Java classes (EJBs, servlets, etc.) are recompiled. In the debug mode, the updated classes are hot-swapped. In the run mode, IntelliJ IDEA just updates the changed classes in the output folder. Whether such classes are actually reloaded in the running application,	Exploded artifacts in local configurations

depends on the capabilities of the runtime being used.

---

Hot swap classes	Changed classes are recompiled and reloaded at runtime. This option works only in the debug mode.	Packed artifacts in local configurations; exploded and packed artifacts in remote configurations
Redeploy	The application artifact is rebuilt and redeployed. The operation may be time-consuming.	Exploded and packed artifacts in local and remote configurations
Restart server	The server is restarted. The application artifact is rebuilt and redeployed. The operation may be very time-consuming.	Exploded and packed artifacts in local configurations

This feature is only supported in the Ultimate edition.

- [Supported cloud platforms](#)
- [Overview of the cloud support](#)
- [Working with a cloud platform: Process overview](#)
- [Cloud integration plugins](#)
- [Cloud run configurations](#)

## Supported cloud platforms

IntelliJ IDEA provides integration with the following cloud platforms:

- [CloudBees](#)
- [Cloud Foundry](#)
- [Google App Engine](#)
- [Heroku](#)
- [OpenShift](#)

## Overview of the cloud support

IntelliJ IDEA lets you:

- Deploy your [application artifacts](#) to the clouds.
- Deploy your code to Heroku and OpenShift.
- Debug applications on Heroku and OpenShift.

For all such purposes, IntelliJ IDEA provides corresponding [cloud run/debug configurations](#).

You can also monitor and control the deployment process, and view your application logs in the [Application Servers tool window](#).

## Working with a cloud platform: Process overview

1. Sign up for a user account at the cloud service provider website.
2. Make sure that the corresponding [cloud integration plugin](#) is enabled.
3. Register your cloud user account in IntelliJ IDEA. You can do that:
  - Separately, in the Settings dialog: `(Ctrl+Alt+S)` | Build, Execution, Deployment | Clouds | [+](#), etc.
  - When creating a project or module for working with a cloud, e.g. File | New | Project | Clouds, etc.
  - When creating a cloud run configuration: Run | Edit Configurations | [+](#) | <Cloud Name> Deployment, etc.

For information on cloud user account settings, see [Clouds](#).

4. Create an [artifact configuration](#) for your application. (For Heroku or OpenShift, this may be unnecessary. You can deploy your source code to the cloud, and the cloud platform will do the rest of the work for you. For CloudBees and Cloud Foundry, IntelliJ IDEA can create the necessary configurations automatically.)
5. Build the artifact. You can do that separately ( Build | Build Artifacts ), or when executing the corresponding run configuration. (In the case of deploying code to Heroku or OpenShift, an artifact is unnecessary.)
6. Create a cloud run configuration for deploying your artifact or code to the cloud. (IntelliJ IDEA can create such a run configuration automatically.)
7. Execute the run configuration to deploy your artifact or code to the cloud.

## Cloud integration plugins

There is a separate cloud integration [plugin](#) for each of the supported cloud platforms. All the cloud integration plugins are bundled with the IDE and enabled by default.

The plugin names, normally, include the cloud name and the word *integration*, e.g. *Heroku integration*.

See also, [Enabling and Disabling Plugins](#).

## Cloud run configurations

There are run configurations for each of the supported clouds:

- [Run/Debug Configuration: CloudBees Deployment](#)
- [Run/Debug Configuration: Cloud Foundry Deployment](#)
- [Run/Debug Configuration: Google App Engine Deployment](#)
- [Run/Debug Configuration: Heroku Deployment](#)
- [Run/Debug Configuration: OpenShift Deployment](#)

This feature is only supported in the Ultimate edition.

This tutorial illustrates main tasks related to working with Heroku.

## Creating a Heroku user account

Go to the [Heroku web site](#) and sign up for a user account.

## Generating and installing SSH keys

To be able to deploy your code to the cloud, you have to upload your public SSH key to Heroku. You can do that, for example, when [registering your Heroku user account in IntelliJ IDEA](#).

If you don't have a private/public SSH key pair, generate one. Search the Internet for corresponding tools and instructions.

Put your keys to the `.ssh` folder in your user home directory.

## Making sure that Heroku and Git Integration plugins are enabled

To be able to work with Heroku and Git on Heroku, the Heroku Integration and the Git Integration [plugins](#) must be [enabled](#).

To make sure that these plugins are enabled, use the [Plugins page](#) of the Settings/Preferences dialog (`Ctrl+Alt+S` | Plugins).

## Registering your Heroku user account in IntelliJ IDEA

1. Open the Settings/Preferences dialog (e.g. `Ctrl+Alt+S`) and select Build, Execution, Deployment | Clouds.
2. Click `+` and select Heroku.
3. Specify your user name and password.

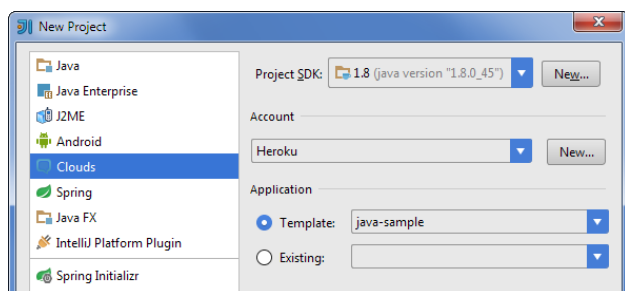

4. If you haven't uploaded your public SSH key to Heroku yet, you can do that now. Click Upload Public SSH Key and select the key file in the dialog that opens.

The key file should have the `.pub` extension and may be called `id_rsa.pub`, `id_dsa.pub` or something similar.

5. Click OK.

## Creating a project

1. Click Create New Project on the Welcome screen, or select File | New | Project on the main menu. The New Project wizard opens.
2. In the left-hand pane, select Clouds. The rest of the settings should be similar to this:

Click Next.

3. Specify the name for your new project (e.g. `MyFirstAppForHeroku`).

Click Finish.

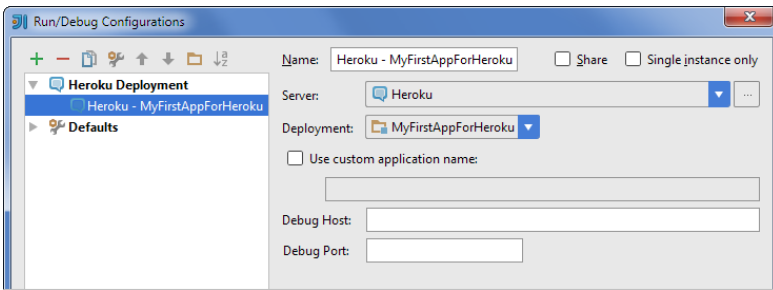

## Exploring a run configuration

To deploy and debug your applications on Heroku, IntelliJ IDEA provides [Heroku Deployment run/debug configuration](#).

There is already one such configuration in your project.

Let's take a quick look at its settings.

1. Select Run | Edit Configurations.

The run/debug configuration specifies that your module source code should be deployed to Heroku. (MyFirstAppForHeroku is the name of a module.)

The application will be deployed under its default name, in this case, myfirstappforheroku. (The application name defines its URL, https://<app-name>.herokuapp.com/.) If you want to use a different name, select the Use custom application name checkbox and specify the name.

If you wanted to use the run configuration also for debugging your app, you'd specify the debug host and port.

To create another run configuration for Heroku, you should click + and select Heroku Deployment. For more information, see Working with Run/Debug Configurations and Run/Debug Configuration: Heroku Deployment.

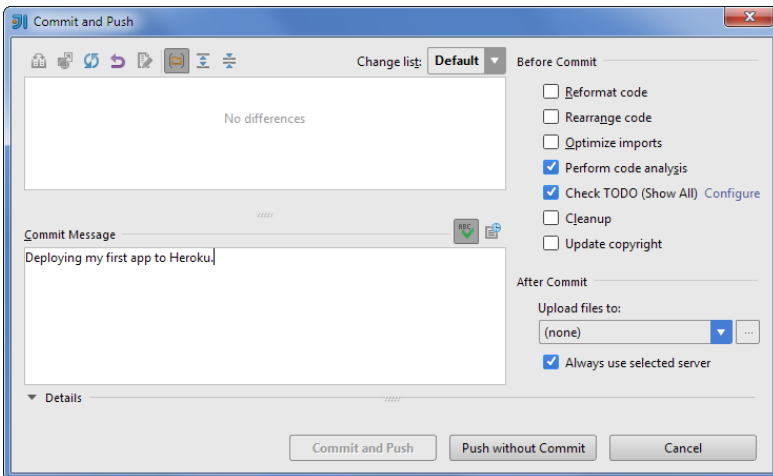

2. Click OK.

## Deploying your app

1. Start the run configuration: click ▶ to the right of the run configuration selector or press Shift+F10.

The Commit and Push dialog opens. This dialog is used to commit changes to your local Git repository and to push them to a remote Git repository, in this case, the one on Heroku.

2. Write the commit message and click Push without Commit.

As a result (all the following takes place on Heroku; you can monitor the process in the Application Servers tool window):

- A Git repository for your app source code is created.
- The app dependencies specified in pom.xml are installed.
- Your app is built and started.

Finally, when your app is deployed, the link to it is shown within the line Application is available at ...

3. Click the link.

Your web browser opens and your application output is shown.

## Modifying the source code

1. Open the file index.jsp for editing: select the file in the Project tool window and press F4.

2. Change the text, say, to `Hello from IntelliJ IDEA!`

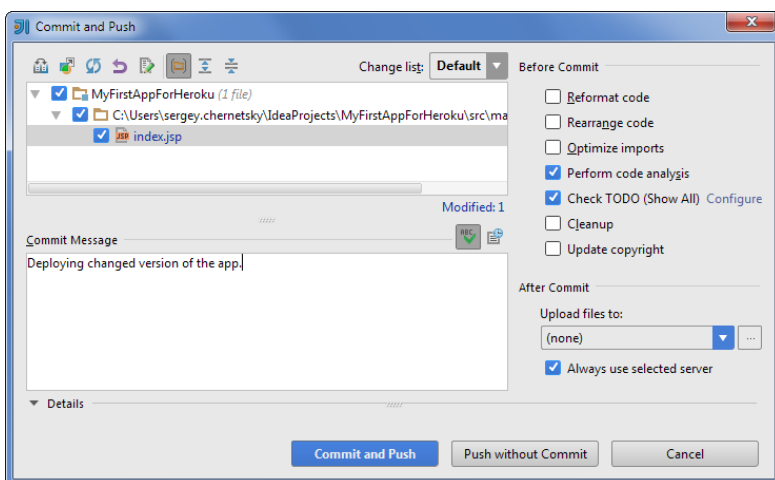

## Redeploying the app

To publish the changed version of your app, you should redeploy the app.

1. In the Application Servers tool window, right-click your app and select Redeploy .

2. In the Commit and Push dialog, write the commit message and click Commit and Push .

3. When the message `'<app-name>' has been deployed successfully` is output, switch to the web browser and reload the page to see the changes.

## Undeploying the app

When your app is no longer needed, you should undeploy it (i.e. remove it from Heroku along with its source code).

1. In the Application Servers tool window, right-click your app and select Undeploy .

2. Provide your Heroku password to confirm your intention to delete the app.

3. Switch to the web browser and reload the page to see that you app has become unavailable.

## Disconnecting from Heroku

- In the Application Servers tool window, right-click Heroku and select Disconnect .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA lets you create Google App Engine projects and upload your applications to Google infrastructure.

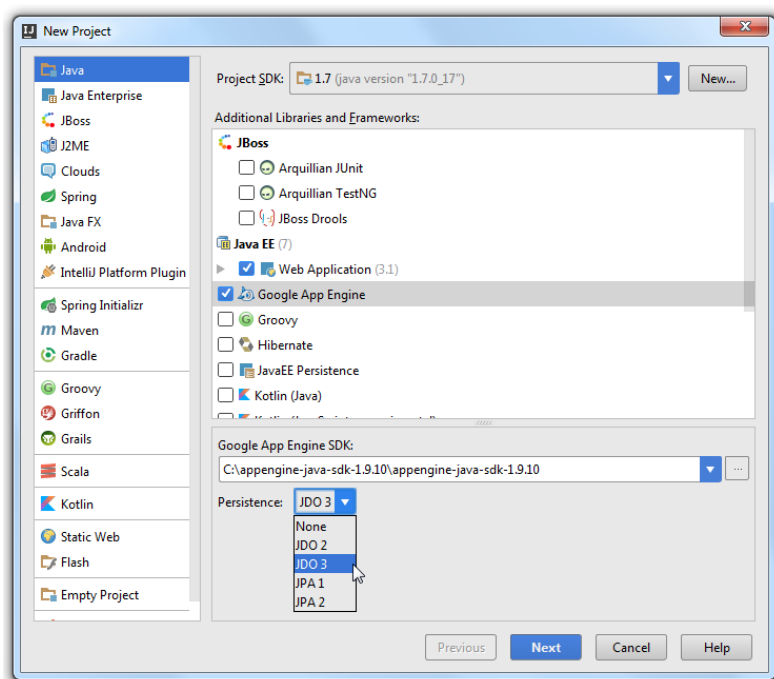

- [Before you start](#)
- [Creating Google App Engine Project](#)
- [Checking Project Structure](#)
- [Running the Application](#)
- [Debugging the Application](#)
- [Configuring Google App Account](#)
- [Deploying Google App Engine Application](#)
- [Using Google App Engine Deployment](#)

## Before you start

Before you start creating your Google App Engine project, make sure that the Google App Engine plugin is [downloaded and enabled](#) in IntelliJ IDEA.

## Creating Google App Engine Project

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the Welcome screen. Otherwise, select File | New | Project .  
As a result, the New Project wizard opens.
2. In the left-hand pane, select Java .
3. In the right-hand pane, select your project SDK.
4. Under Additional Libraries and Frameworks select Google App Engine .

Note that the Web Application option will be selected automatically.

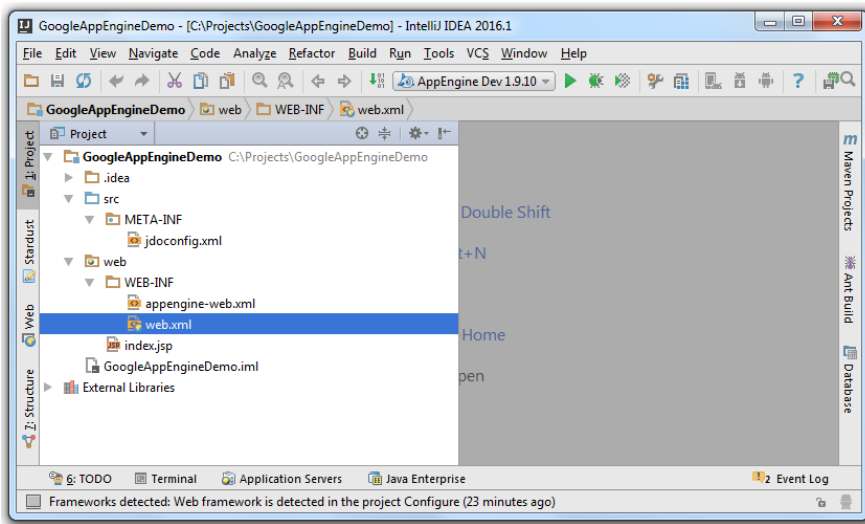

5. In the Google App Engine SDK field, select the SDK you want to use. If the list is empty click [Download](#) link to download the latest Google App Engine SDK. If the field doesn't contain the SDK that you want, click  and select the installation folder of the required Google App Engine SDK in the [dialog that opens](#) .
6. Click Next .
7. On the next page of the wizard, specify the name and location settings.

For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

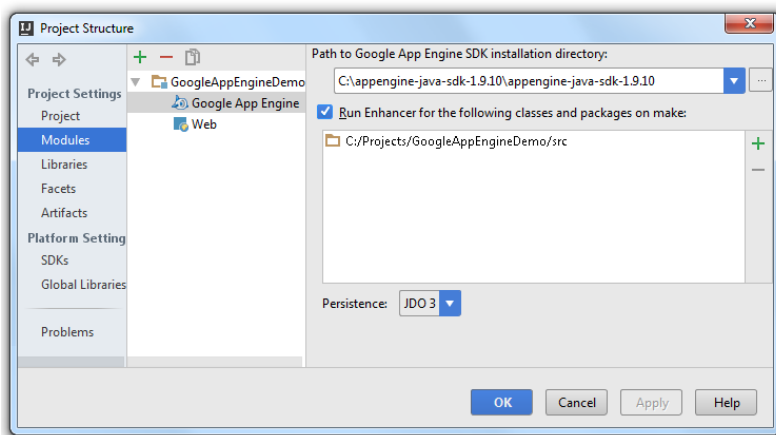

IntelliJ IDEA creates an empty Google App Engine project. Depending on the selected persistence type, IntelliJ IDEA generates `persistence.xml` for JPA or `jdoconfig.xml` for JDO and takes the required libraries from the App Engine SDK.

## Checking Project Structure

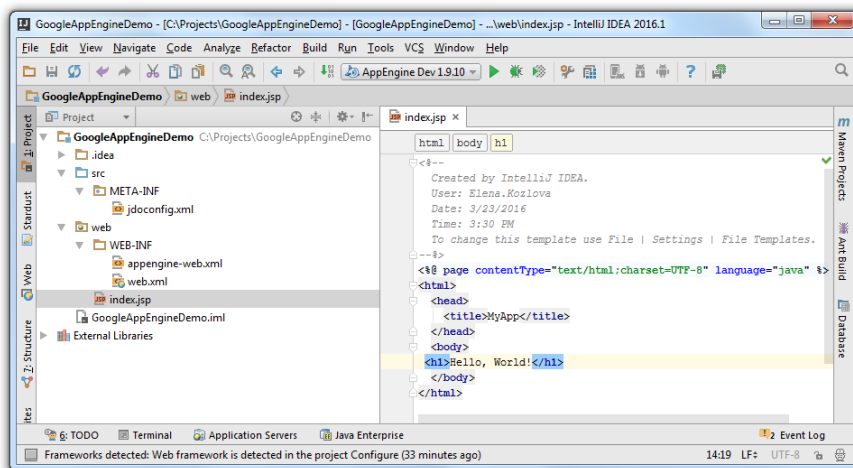

1. On the main menu, select Project Structure | Modules .

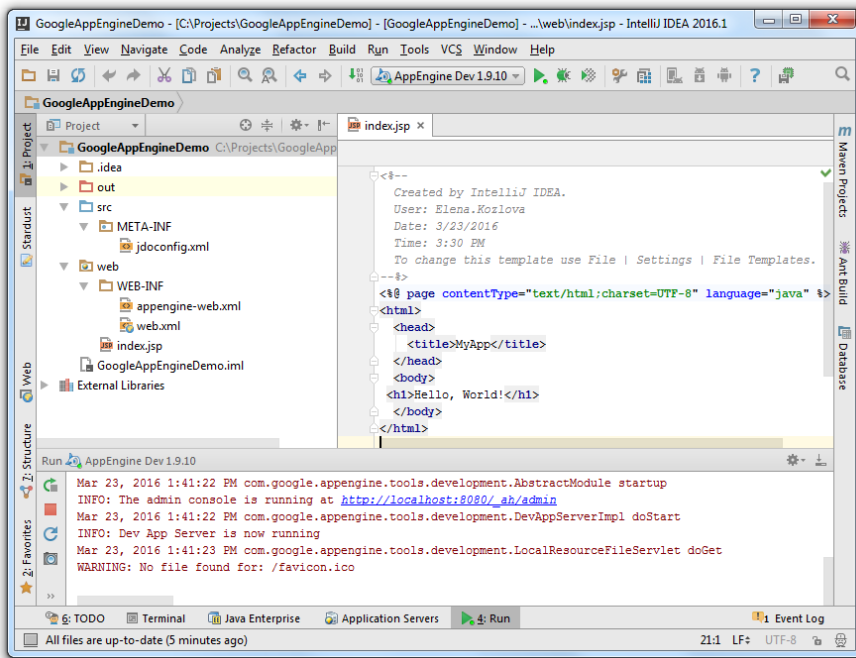

2. Check settings for the Google App Engine facet to make sure everything was configured properly.

## Running the Application

1. Enter your code or (like in our case) you can modify the `index.jsp` file.

2. Press  icon to run the application.

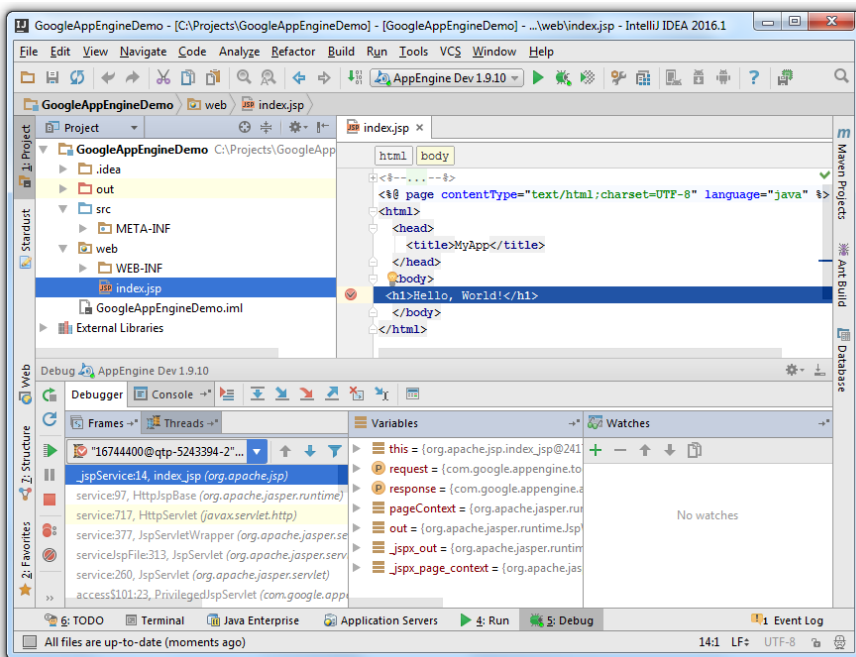

3. View the result in the default browser.

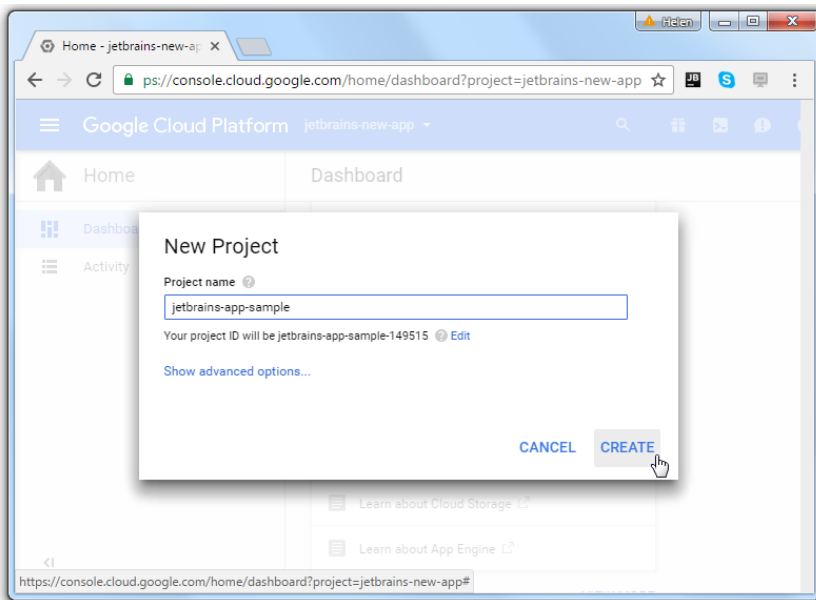

## Debugging the Application

1. On the main menu, select Run|Debug 'AppEngine Dev' or click the  toolbar button.
2. View the results in the Debugger tool window.

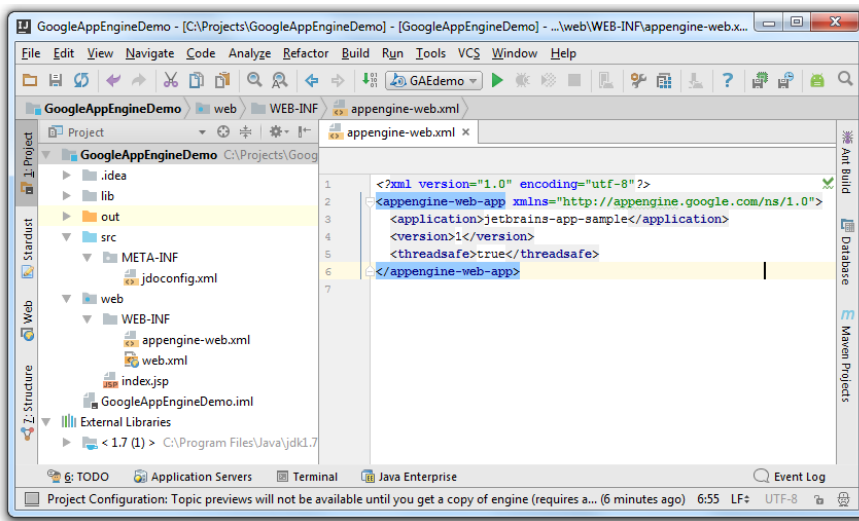

## Configuring Google App Account

1. If you going to upload your application to the cloud or deploy the artifact on the cloud server, create an application at [Google App Engine](https://console.cloud.google.com).

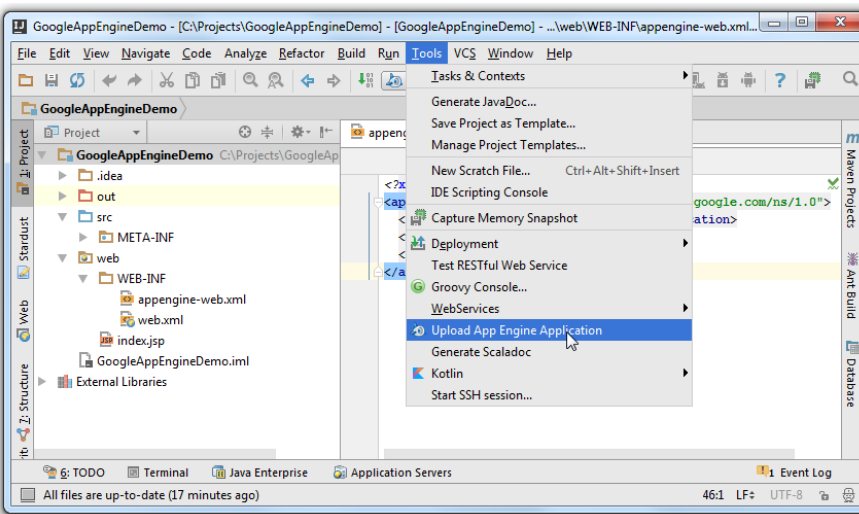

2. Add the name of the created application to the appengine-web.xml file.

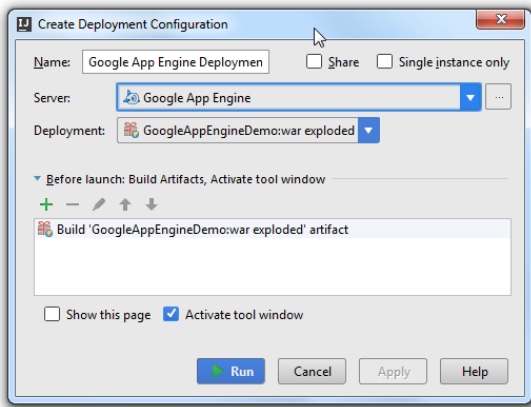

## Deploying Google App Engine Application

1. On the main menu, select Tools | Upload App Engine Application .

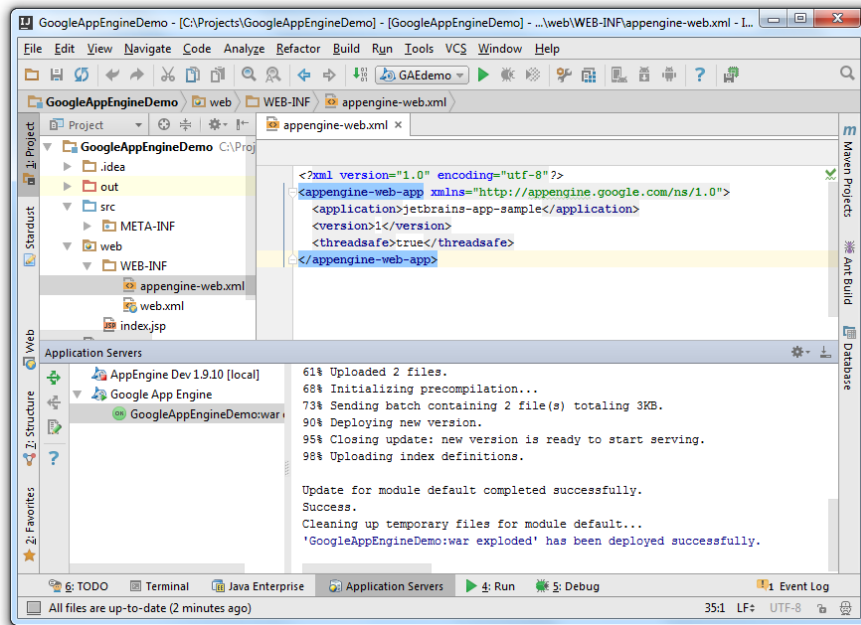

2. In the dialog that opens specify the deployment configuration settings and click Run .

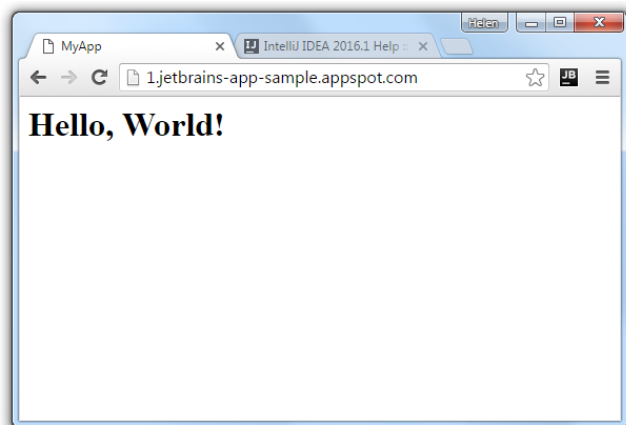

3. During the deployment IntelliJ IDEA might prompt you for your Google Account credentials.

IntelliJ IDEA displays the progress in the Application Servers tool window.

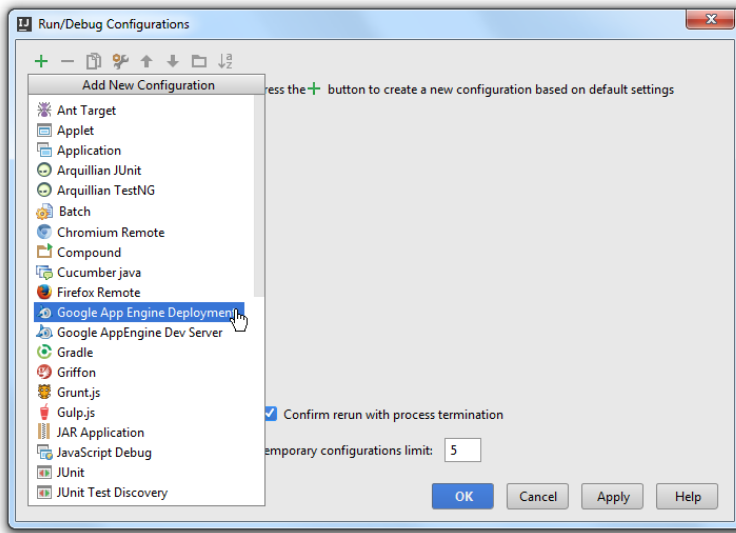

4. View the result in your default browser.

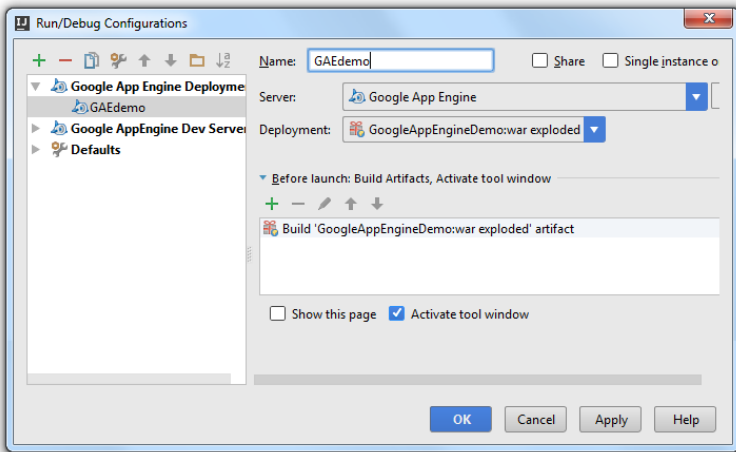

## Using Google App Engine Deployment

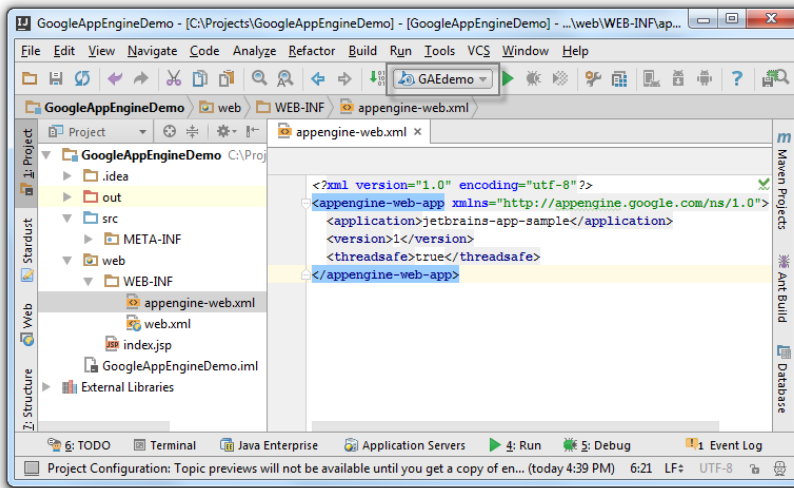

1. Select Run | Edit Configurations .
2. In the Run/Debug Configurations dialog, select + to add a new configuration.
3. From the drop-down list select Google App Engine Deployment .

4. On the right-hand side specify the Google App Engine Deployment settings and click OK .

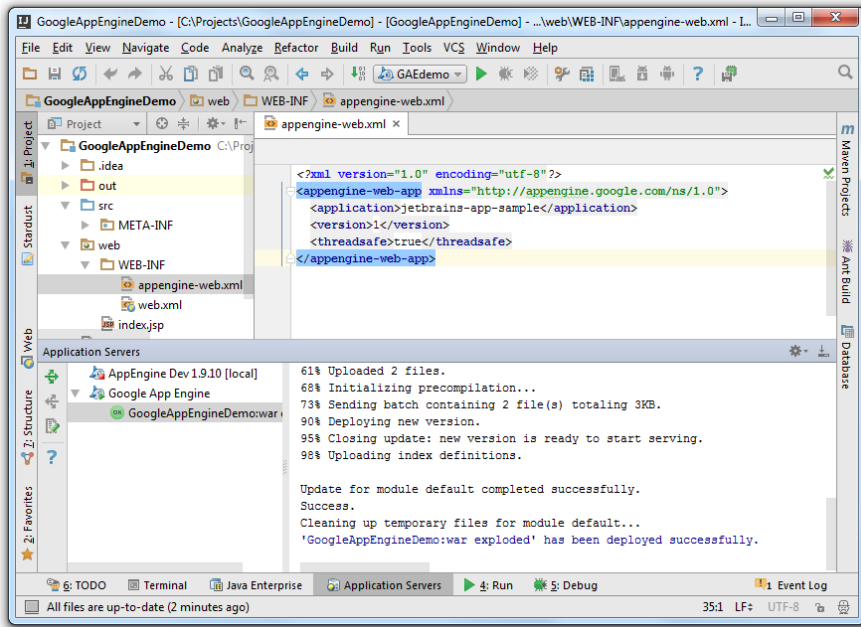

5. The name of the configuration appears on the main tool bar, click ▶ to start deploying.

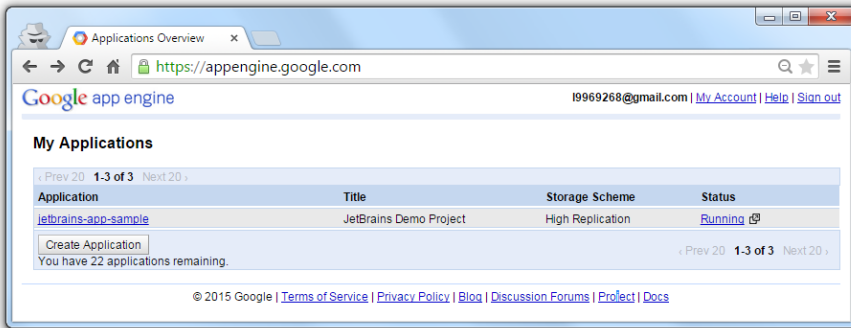

Note that the IntelliJ IDEA might ask for your Google Account password.

6. IntelliJ IDEA displays the progress of deployment in the Application Servers tool window.

7. Open [Google App Engine](https://appengine.google.com) page.

8. On the Application Overview page, click [Running](#) next to your application name to see the result of your deployment.

This feature is only supported in the Ultimate edition.

This tutorial illustrates the Java EE application development workflow.

The application that we are going to develop will be a minimal one. It'll be a one JSP page Java web application. However, the IntelliJ IDEA features shown here are applicable to Java EE applications of any complexity.

- [Before you start](#)
- [Creating a project](#)
- [Exploring the project structure](#)
- [Developing source code](#)
- [Running the application](#)
- [Modifying the code and observing the changes](#)
- [Exploring a run configuration](#)
- [Exploring an artifact configuration](#)
- [Packaging the application into a WAR file](#)
- [Deploying an artifact onto a running server](#)
- [Packaging the application into an EAR: Using Java EE Application support](#)
- [Looking at other features \(tool windows and facets\)](#)

## Before you start

Make sure that the following software is installed on your computer:

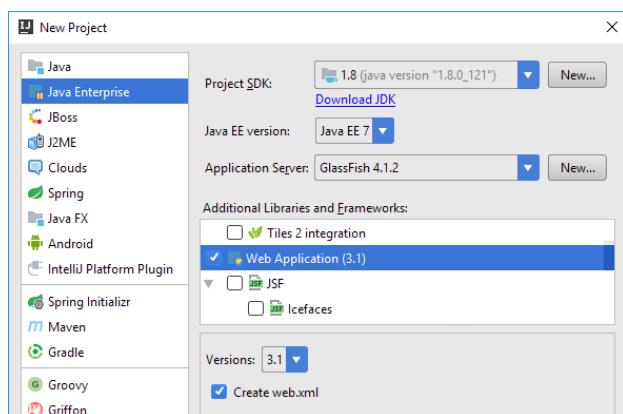

- IntelliJ IDEA ULTIMATE Edition.
- GlassFish Server, version 3.0.1 or later. [Download GlassFish](#) . (You can use any other Java EE-enabled application server. GlassFish is used here just as an example.)
- A web browser.

## Creating a project

1. Click Create New Project on the Welcome screen, or select File | New | Project .  
The New Project wizard opens.
2. In the left-hand pane, select Java Enterprise .
3. Specify the [JDK](#) that you are going to use (the Project SDK field): select one from the list, click New and select the JDK installation folder, or click Download JDK .
4. Specify your application server. (We'll use GlassFish Server.)  
If GlassFish is not defined in IntelliJ IDEA yet, click New to the right of the Application Server field and select Glassfish Server .

In the Glassfish Server dialog, specify the GlassFish Server installation directory.

5. Under Additional Libraries and Frameworks , select the Web Application checkbox.

Click Next .

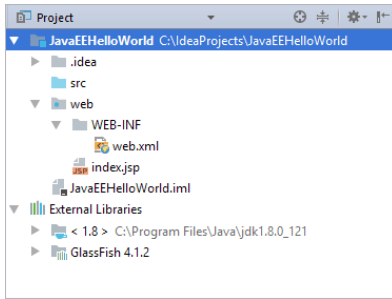

6. Specify the name for your new project (e.g. *JavaEEHelloWorld* ).

Click Finish and wait while IntelliJ IDEA is creating the project.

## Exploring the project structure

When the project is created, you'll see something similar to this in the Project tool window.

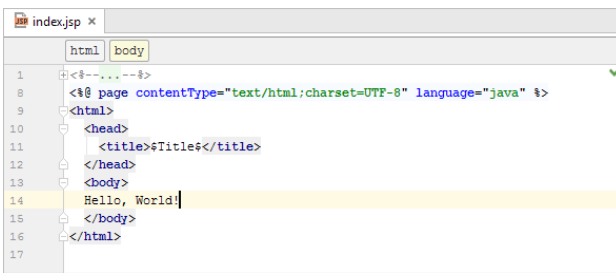

- JavaEEHelloWorld is a module folder (which in this case coincides with the project folder). The `.idea` folder and the file `JavaEEHelloWorld.iml` contain configuration data for your project and module respectively. The folder `src` is for your Java source code. The folder `web` is for the web part of your application. At the moment this folder contains the deployment descriptor `WEB-INF/web.xml` and the file `index.jsp` intended as a starting page of your application.
- External Libraries include your JDK and the JAR files for working with GlassFish.

## Developing source code

Our application will be a single JSP page application. Its only function will be to output the text *Hello, World!*

1. Open `index.jsp` for editing: select the file in the Project tool window and press `F4`.
2. Between `<body>` and `</body>` type `Hello, World!`

The code at this step is ready.

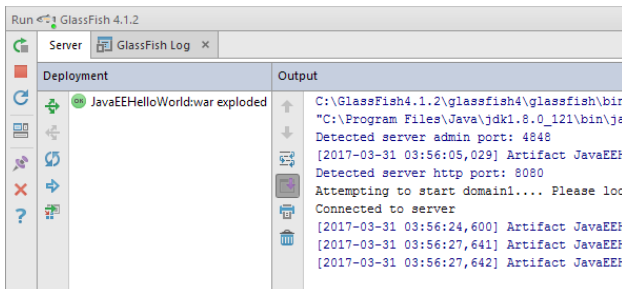

## Running the application

In the upper-right part of the workspace, click .

IntelliJ IDEA compiles your source code and builds an application **artifact**.

After that, the Run tool window opens. IntelliJ IDEA starts the server and deploys the artifact onto it.

Finally, your default web browser starts and you see the application output `Hello, World!` there.

## Modifying the code and observing the changes

1. In `index.jsp`, change `Hello, World!` to `Hello!`.

2. In the Run tool window, click Update .

3. In the Update dialog, select Update resources and click OK . (For more information, see [Application update options](#) .)

4. Switch to the web browser and reload the page to see the changes.

See also, [Updating Applications on Application Servers](#) .

## Exploring a run configuration

When creating the project, we specified GlassFish as an application server. As a result, IntelliJ IDEA created a run configuration for GlassFish.

When we performed the Run command , we started that run configuration. Now let's take a look at the run configuration and see how its settings map onto the events that we've just observed.

1. Click the run configuration selector and select Edit Configurations .

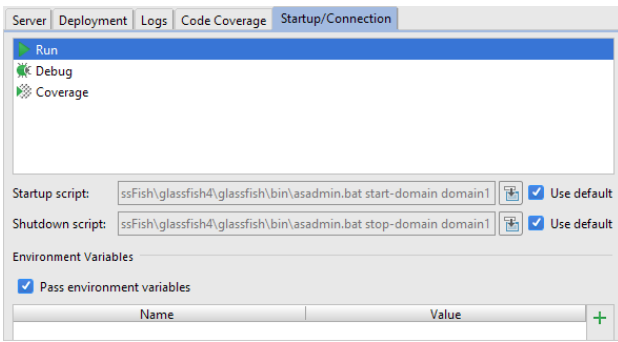

The Run/Debug Configurations dialog opens and the settings for the GlassFish run configuration are shown.

The Before launch task list (in the lower part of the dialog) specifies that the application code should be compiled and the corresponding artifact should be built prior to executing the run configuration.

2. Select the Startup/Connection tab to see how the server is started in the run, debug and code coverage modes.

3. Select the Deployment tab to see which artifacts are deployed after the server is started.

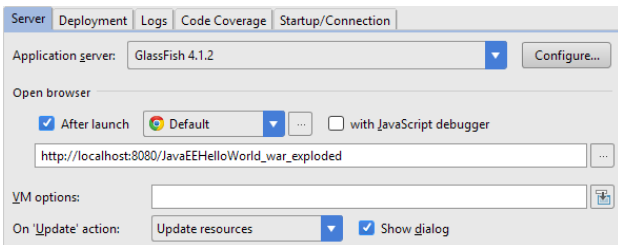

4. Go back to the Server tab.

The settings under Open browser specify that after launch (i.e. after the server is started and the artifacts are deployed onto it) the default web browser should start and go to the specified URL

( `http://localhost:8080/JavaEEHelloWorld_war_exploded` ).

The settings to the right of On 'Update' action specify that on clicking  in the Run tool window the Update dialog should be shown and the Update resources option should be used by default. (The [last used update option](#) becomes the default one).

5. Click OK .

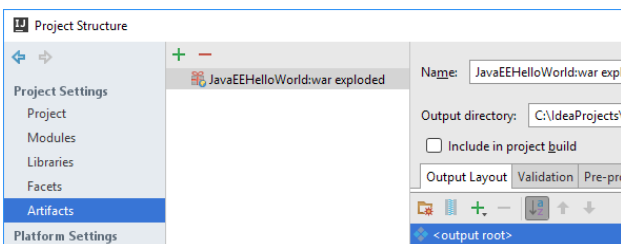

## Exploring an artifact configuration

When creating the project, we indicated that we were going to develop a web application. As a result, IntelliJ IDEA, among other things, created a configuration for building a web application [artifact](#) . Let's have a look at this configuration.

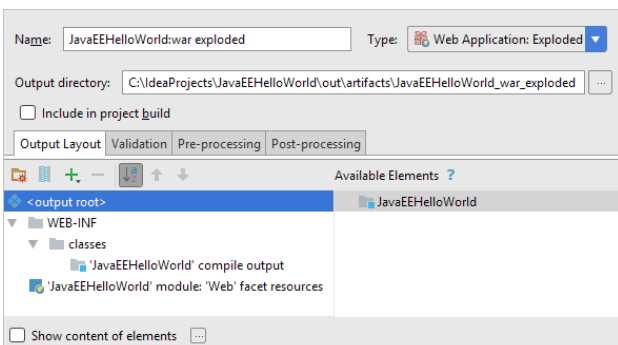

1. Open the Project Structure dialog: File | Project Structure or `Ctrl+Shift+Alt+S` .

2. Under Project Settings , select Artifacts .

The available artifact configurations are shown in the pane to the right under  and  . (There's only one configuration at the moment.)

The artifact settings are shown in the right-hand part of the dialog.

Type. The artifact type is Web Application: Exploded. This is a decompressed web application archive (WAR), a directory structure that is ready for deployment onto a web server.

Output directory. The artifact, when built, is placed into

`<project_folder>/out/artifacts/JavaEEHelloWorld_war_exploded` .

Output Layout. The artifact structure is shown in the left-hand pane of the Output Layout tab.

The `<output root>` corresponds to the output directory. Other elements have the following meanings:

- 'JavaEEHelloWorld' compile output represents compiled Java classes whose sources are located in the `src` directory. These are placed into `WEB-INF/classes` in the output directory.
- 'Web' facet resources represent the contents of the `web` directory.

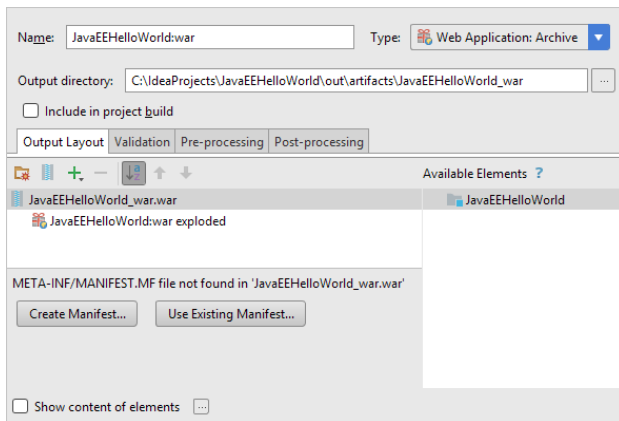

## Packaging the application into a WAR file

When you get to the stage when you are happy with your application, you may want to place it in a [WAR](#) (web application archive). To do that, you should create an appropriate artifact configuration and then build the artifact:

1. Click **+**, point to Web Application: Archive and select For 'JavaEEHelloWorld: war exploded' .

A new artifact configuration is created and its settings are shown in the right-hand part of the dialog.

2. Create a manifest file for your archive: click Create Manifest and agree to the location suggested by IntelliJ IDEA ( `web/META-INF/MANIFEST.MF` ).

3. Click OK in the Project Structure dialog.

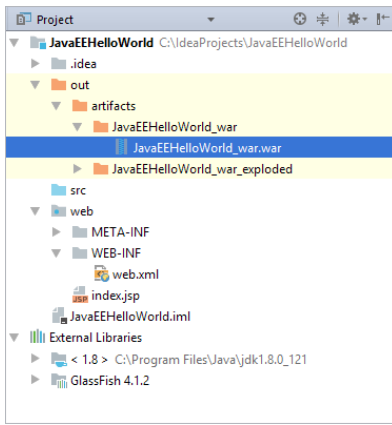

4. Select Build | Build Artifacts .

5. In the Build Artifact popup, point to JavaEEHelloWorld:war and select Build .

Now if you look at the `out/artifacts/JavaEEHelloWorld_war` folder, you'll see the archive there.

## Deploying an artifact onto a running server

Sometimes you need to deploy your app onto a running server. This section provides a how-to example.

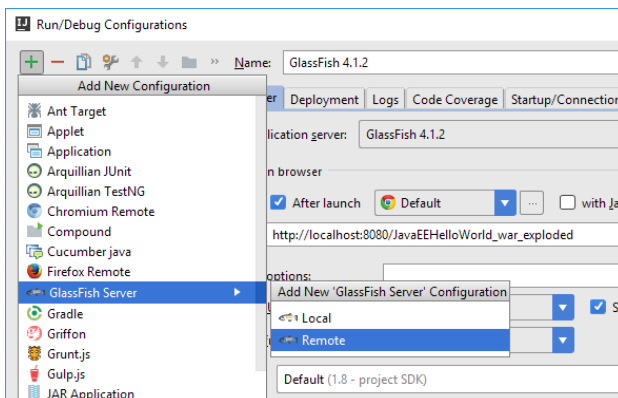

Server run configurations that don't start a server are called *remote*. Such run configurations can be used, for example, for deploying applications to servers that are already running. (See [Local and remote run configurations](#).)

Let's create a run configuration for deploying our WAR artifact to the running server and see how it works. (By now, the server has been started by the run configuration [discussed earlier](#).)

1. Click the run configuration selector and select Edit Configurations.

2. Click **+**, point to GlassFish Server and select Remote.

3. Change the run configuration name *Unnamed* to something more sensible (e.g. *GlassFishRemote*).

4. Specify the artifact to be deployed to the server: select the Deployment tab, click **+** and select Artifact.

In the dialog that opens, select the WAR artifact.

The result should look similar to this:

- Click OK in the Run/Debug Configurations dialog.  
Now let's see how this run configuration works.
- Execute the run configuration: click .

The run configuration output is shown in the Run tool window.

After a while, a new tab in your web browser opens, and you see the application output there.

## Packaging the application into an EAR: Using Java EE Application support

To package your Java EE application into an [EAR](#), you should:

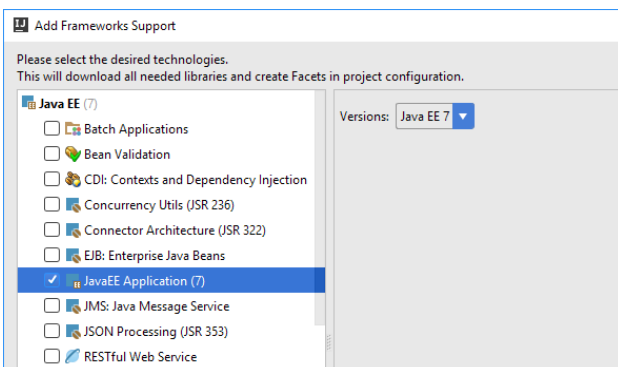

- Create a Java EE [deployment descriptor](#) `application.xml`.
- Configure an EAR [artifact](#).
- Build that artifact.

As we are about to see, IntelliJ IDEA performs most of these tasks for you as part of its Java EE Application support:

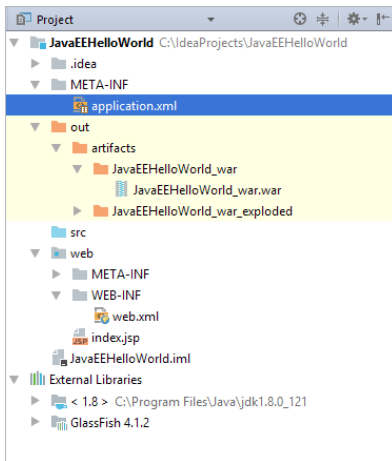

- In the Project tool window, right-click your module folder and select **Add Framework Support**.

- In the dialog that opens, select the JavaEE Application checkbox and click OK.

Note the descriptor file `META-INF/application.xml` created in your module folder.

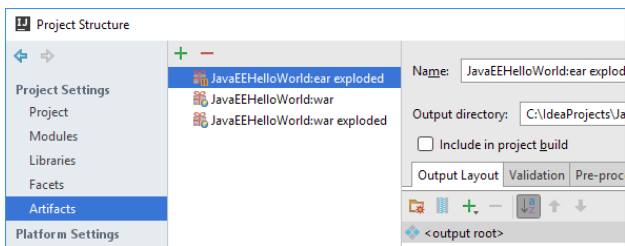

3. Open the file in the editor ( **F4** ).

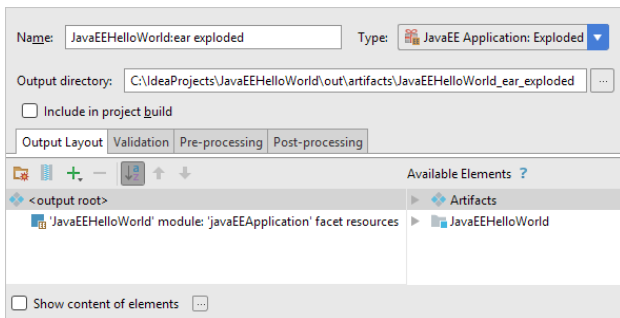

At the moment, the file is almost empty.

4. Now let's look at the artifact configurations.

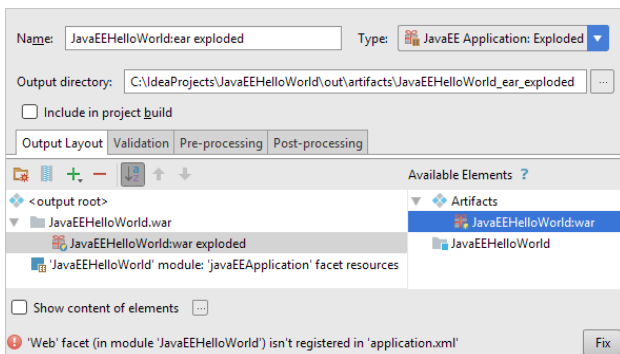

Note that a new configuration appeared, the one for an exploded EAR artifact.

Currently only JavaEE Application facet resources ( META-INF/application.xml ) are included in the artifact.

5. Let's add a copy of the exploded WAR artifact to the EAR artifact structure. To do that, under Available Elements , expand the Artifacts node and double-click the exploded WAR artifact. Here is the result.

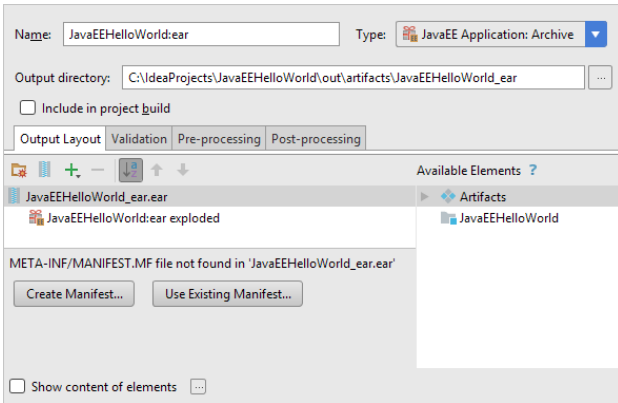

(An alternative way of getting the same result would be + | Artifact | JavaEEHelloWorld: war exploded .)

6. Note the message *Web facet isn't registered in application.xml* . Click Fix . (A bit later, we'll look at the changes made to application.xml by this quick fix.)

7. Create a configuration for an EAR artifact: + | JavaEE Application: Archive | For 'JavaEEHelloWorld:ear exploded' .

- To create a manifest file, click Create Manifest and agree to the default file location ( `<project_folder>/META-INF/MANIFEST.MF` ).

- Click OK in the Project Structure dialog.

See that your `application.xml` has changed. This is the result of applying the quick fix.

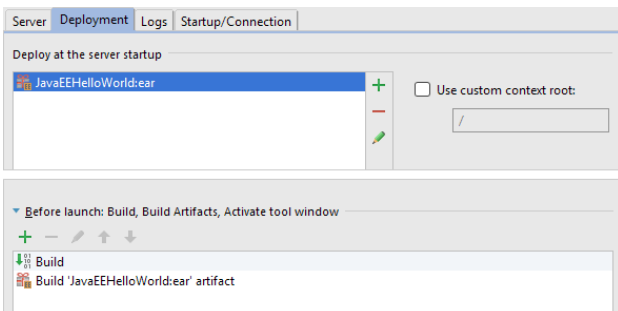

Let's now create a run configuration for building and deploying the EAR artifact.

- Click the run configuration selector and select Edit Configurations . Then, in the Run/Debug Configurations dialog, select `+ | GlassFish Server | Remote` .
- Specify a descriptive name for your run configuration, e.g. `GlassFishRemoteEAR` .

- Include the EAR artifact in the deployment list: switch onto the Deployment tab and select `+ | Artifact | JavaEEHelloWorld:ear` .

Note that the Build 'JavaEEHelloWorld:ear' artifact task is included in the Before launch task list automatically.

- Switch to the Server tab and check the URL in the Open browser section. The part that follows `http://localhost:8080/` should correspond to the `<context-root>` element in your `application.xml` .

4. Click OK in the Run/Debug Configurations dialog.

5. Execute the run configuration (▶).

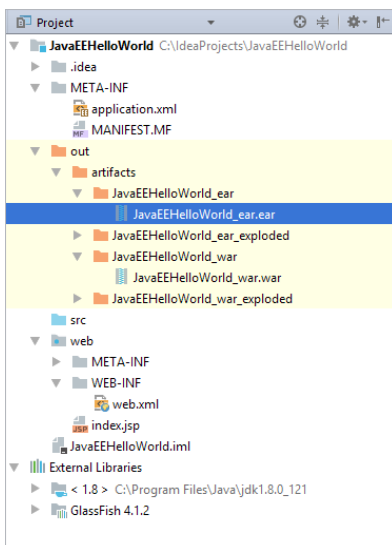

As before, another tab opens in the Run tool window showing the run configuration output.

Then, the application output is shown in the browser.

Now if you look at the Project tool window, you'll see your archive in the `out/artifacts/JavaEEHelloWorld_ear` folder.

## Looking at other features (tool windows and facets)

As part of its Web Application and Java EE Application support, IntelliJ IDEA:

- Made the Web and JavaEE:App tool windows available.
- Created the Web and Java EE Application [facets](#) .

Tool windows. To open the tool windows, you can, for example, select `View | Tool Windows | Web` or `View | Tool Windows | JavaEE:App` .

Very briefly, the Web and JavaEE:App tool windows provide the functions similar to those of the Project tool window but only for your Web and Java EE Application facet resources respectively. For more info, see:

- [Web Tool Window](#)
- [Java EE: App Tool Window](#)

Facets. To view or edit the facet settings, open the Project Structure dialog, select `Modules` , and then select `Web` or `javaEEApplication` under the module node. For more info, see:

- [Web facet page](#)
- [Java EE Application facet page](#)

[JavaFX](#) support in IntelliJ IDEA includes code completion, search, navigation and refactoring in JavaFX-specific source files (including FXML and JavaFX CSS files), integration with [JavaFX Scene Builder](#), JavaFX application packaging capabilities, and more.

- [Preparing for JavaFX Application Development](#)
- [Developing a JavaFX Hello World Application: Coding Examples](#)
- [Opening FXML files in JavaFX Scene Builder](#)
- [Packaging JavaFX Applications](#)
- [Applications with a Preloader: Project Organization and Packaging](#)

On this page:

- [Preparing to develop JavaFX applications](#)
- [Enabled or disabled JavaFX plugin ?](#)
- [Defining JDK 7 in IntelliJ IDEA](#)
- [Specifying the path to the JavaFX Scene Builder executable](#)
- [Creating a project for JavaFX development](#)
- [Exploring project](#)
- [Running the sample application](#)

## Preparing to develop JavaFX applications

### To prepare for JavaFX application development, follow these general steps:

1. Download and install [JDK 7](#) or a later version (earlier JDK versions don't include the JavaFX SDK necessary for JavaFX application development).
2. If you are going to use [JavaFX Scene Builder](#), download and install it as well.
3. Make sure that the JavaFX [plugin](#) is enabled. (JavaFX support in IntelliJ IDEA is based on the JavaFX plugin. This plugin is bundled with the IDE and enabled by default.) See [To make sure that the JavaFX plugin is enabled](#).
4. Define the JDK in IntelliJ IDEA. You can do that separately (see [To define JDK 7 in IntelliJ IDEA](#)) or when creating a project or module (see [Creating a project for JavaFX development](#)).
5. If necessary, specify the path to the JavaFX Scene Builder executable file. If you do so, you'll be able to open your FXML files in the Scene Builder right in IntelliJ IDEA. See [To specify the path to the JavaFX Scene Builder executable file](#).
6. Create a project for your JavaFX application development. You can create the corresponding project from scratch or, if you already have the source files you want to continue working with, you can create a project by importing the corresponding sources. See [Creating a project for JavaFX development](#) or [Configuring projects](#). See also, [Using Scene Builder with IntelliJ IDEA](#).

## Enabled or disabled JavaFX plugin ?

Even though the JavaFX plugin is enabled by default, it's always worth making sure that this plugin is still enabled before you start developing a JavaFX application.

### To make sure that the JavaFX plugin is enabled

1. [Open Settings/Preferences dialog](#) (e.g. `Ctrl+Alt+S`).
2. In the left-hand part of the dialog, select [Plugins](#).
3. In the right-hand part of the dialog, on the [Plugins page](#), type `fx` in the search box. As a result, only the plugins whose names and descriptions contain `fx` are shown in the list of plugins.
4. If the checkbox to the right of JavaFX is not selected, select it.
5. Click OK in the Settings/Preferences dialog.
6. If suggested, restart IntelliJ IDEA.

## Defining JDK 7 in IntelliJ IDEA

Once you have JDK 7 or a later version downloaded and installed, you should define it in IntelliJ IDEA. You can do that separately, the way described in this section. You can also do that at a later time, when creating a project for your JavaFX application development.

### To define JDK 7 in IntelliJ IDEA

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the leftmost pane, under Platform Settings, click [SDKs](#).
3. Above the pane to the right, click `+` and select [JDK](#).
4. In the [dialog that opens](#), select the JDK installation directory and click OK.
5. Click OK in the Project Structure dialog.

## Specifying the path to the JavaFX Scene Builder executable

To be able to open your FXML files in JavaFX Scene Builder right in IntelliJ IDEA, you should specify where the Scene Builder executable file is located. You can do that separately, the way described in this section. You can also do that at a

later time, the first time you open an FXML file in the Scene Builder from within IntelliJ IDEA.

## To specify the path to the JavaFX Scene Builder executable file

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Languages and Frameworks | JavaFX .
2. In the right-hand part of the dialog, on the JavaFX page, click  to the right of the Path to SceneBuilder field.
3. In the [dialog that opens](#) , select the Scene Builder executable file and click OK .
4. Click OK in the Settings/Preferences dialog.

See also, [Opening FXML files in JavaFX Scene Builder](#) .

## Creating a project for JavaFX development

### To create a project for JavaFX application development from scratch

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the [Welcome screen](#) . Otherwise, select File | New | Project .

As a result, the [New Project wizard](#) opens.

2. On the [first page of the wizard](#) , in the left-hand pane, select JavaFX .  
In the right-hand part of the page, specify the [SDK \(JDK\)](#) to be used in your project.

Select the JDK from the list, or click New , select JDK and select the installation folder of the desired JDK.

Note that the JDK version 7 or later should be specified.

Click Next .

3. Specify the project name and location, and click Finish .

## Exploring project

Let's take a quick look at what we've got in the project.

The folder `src` is for your source code. In this folder, there is already a package called `sample` containing three files:

- `Main.java`. This is the main application class for starting the sample application.
- `sample.fxml`. This is the FXML file for defining the user interface.
- `Controller.java`. This is the controller class intended to handle user interactions with the UI.

In addition to the sample application source code, there is a [run/debug configuration](#) for running or debugging the application. The run configuration has the same name as the main application class ( `Main` ) and is shown in the run configuration selector on the toolbar.

There is also an [artifact configuration](#) intended for packaging your application. (This artifact configuration is not visible at the moment). We'll discuss this configuration later (see [Packaging JavaFX Applications](#) ).

## Running the sample application

To make sure that everything is fine with the project, let's run the sample application straight away:

- Click  on the toolbar.

IntelliJ IDEA compiles the source code and then starts the application. The application window appears which, at the moment, is empty.

Close the application window.

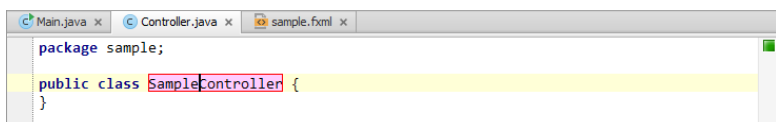

In this topic, we transform the sample application created by IntelliJ IDEA into a very basic JavaFX Hello World application. In this way, we show basic coding assistance features provided by the IDE. (The sample application is created by IntelliJ IDEA automatically when you create a project for your JavaFX application development from scratch, see [Creating a project for JavaFX development](#).)

- [Renaming the Controller class](#)
- [Developing the user interface](#)
- [Completing the code for the SampleController class](#)
- [Running the application](#)
- [Styling the UI with CSS](#)

## Renaming the Controller class

To adjust the sample application to your needs, you may want to start by renaming the files. To see how, let's perform the Rename refactoring for the class `Controller`. We'll rename this class to `SampleController`. You can use a different name if you like.

1. In the editor, place the cursor within the class name and select Refactor | Rename (alternatively, press `Shift+F6`).
2. Place the cursor in front of `Controller` and type `Sample`.

```
package sample;

public class SampleController {
}
```

3. Press `Enter` to indicate that you have completed the refactoring.

Now, switch to `sample.fxml` in the editor and note that the value of the `GridPane` `fx:controller` attribute has changed to `"sample.SampleController"`. (Initially it was `"sample.Controller"`.)

In a similar way you can change the names of other files if necessary.

## Developing the user interface

To show you how IntelliJ IDEA can help you write your code, let's implement a kind of Hello World JavaFX application.

In the user interface (UI), we'll define a button which when clicked will display the text `Hello World!`. To do that, we'll add the following two elements between the opening and closing `<GridPane>` tags in the file `sample.fxml`:

```
<Button text=
    "Say 'Hello World'" onAction=
    "#sayHelloWorld"/>
<Label GridPane.rowIndex=
    "1" fx:id=
    "helloWorld"/>
```

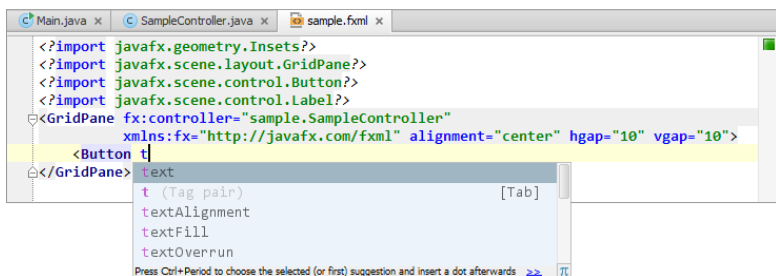

We suggest that you do everything by typing to see how code completion works.

1. Go to the end of the opening `<GridPane>` tag and press `Enter` to start a new line.
2. Type `<B` and select `Button`.

```
<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
    xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
  <B
  </Gr
```

3. Type space, type `t`, and select text.

```
<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
    xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
  <Button t
  </GridPane>
```

4. In a similar way, add the remaining code fragments. The resulting code will look something similar to this:

```
Main.java x SampleController.java x sample.fxml x
<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
  xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
  <Button text="Say 'Hello World'" onAction="#sayHelloWorld"/>
  <Label GridPane.rowIndex="1" fx:id="helloWorld"/>
</GridPane>
```

As you see, `sayHelloWorld` is shown red and `helloWorld` is also highlighted. This means that IntelliJ IDEA cannot resolve the corresponding references.

To resolve the issues, let's use the quick fixes suggested by IntelliJ IDEA.

(In IntelliJ IDEA, it's a standard coding practice when you reference a field, method or class that doesn't yet exist and then use a quick fix to create the corresponding field, method or class.)

## Completing the code for the SampleController class

Now we are going to define the field `helloWorld` in the `SampleController` class. We will also add the corresponding event handler method (`sayHelloWorld`) that will set the text for the `helloWorld` label. When doing so, as already mentioned, we'll use the quick fixes suggested by IntelliJ IDEA.

1. In `sample.fxml`, place the cursor within `helloWorld`. Click the yellow light bulb or press `Alt+Enter`.
2. Select `Create Field 'helloWorld'`.

```
Main.java x SampleController.java x sample.fxml x
<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
  xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
  <Button text="Say 'Hello World'" onAction="#sayHelloWorld"/>
  <Label GridPane.rowIndex="1" fx:id="helloWorld"/>
</GridPane>
```

IntelliJ IDEA switches to `SampleController.java` where the declaration of the field `helloWorld` has been added.

```
Main.java x SampleController.java x sample.fxml x
package sample;

import javafx.scene.control.Label;

public class SampleController {
  public Label helloWorld;
}
```

Note the red border around `Label`. You can edit the field type right away. We are not going to do that now, so press `Enter` to quit the refactoring mode.

Also note the import statement that has just been added (`import javafx.scene.control.Label;`) and the icon to the left of the field declaration. This is a navigation icon; click it to go back to `sample.fxml`.

3. Place the cursor within `sayHelloWorld` and press `Alt+Enter`.
4. Select `Create Method 'void sayHelloWorld(ActionEvent)'`.

```
Main.java x SampleController.java x sample.fxml x
<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
  xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
  <Button text="Say 'Hello World'" onAction="#sayHelloWorld"/>
  <Label GridPane.rowIndex="1" fx:id="helloWorld"/>
</GridPane>
```

The corresponding method declaration is added to `SampleController.java`.

```
Main.java x SampleController.java x sample.fxml x
package sample;

import javafx.event.ActionEvent;
import javafx.scene.control.Label;

public class SampleController {
  public Label helloWorld;

  public void sayHelloWorld(ActionEvent actionEvent) {
  }
}
```

5. Press `Shift+Enter` to quit the refactoring mode and start a new line.
6. Type the following to set the text for the label:

```
helloWorld.setText("Hello World!");
```

```

package sample;

import javafx.event.ActionEvent;
import javafx.scene.control.Label;

public class SampleController {
    public Label helloWorld;

    public void sayHelloWorld(ActionEvent actionEvent) {
        helloWorld.setText("Hello World!");
    }
}

```

At this step, the code of the application is ready. Let's run the application to see the result.

## Running the application

1. To run the application, click  on the toolbar or press `Shift+F10`. The application window now contains the Say 'Hello World' button.

2. Click this button to see that the text Hello World! is shown.

3. Close the application window.

## Styling the UI with CSS

To complete the coding examples, let's change the appearance of the UI by adding a stylesheet and defining a couple of formatting styles in it.

1. In the file `sample.fxml`, add a reference to a (non-existing) CSS file `sample.css`. One way to do that is to add the `stylesheets` attribute within the opening `<GridPane>` tag, e.g.

```

stylesheets=
"/sample/sample.css"

```

```

<?import javafx.geometry.Insets?>
<?import javafx.scene.layout.GridPane?>
<?import javafx.scene.control.Button?>
<?import javafx.scene.control.Label?>
<GridPane fx:controller="sample.SampleController"
    stylesheets="/sample/sample.css"
    xmlns:fx="http://javafx.com/fxml" alignment="center" hgap="10" vgap="10">
    <Button text="Say 'Hello World'" onAction="#sayHelloWorld"/>
    <Label GridPane.rowIndex="1" fx:id="helloWorld"/>
</GridPane>

```

2. As before, use a quick fix to create the CSS file.

3. When the CSS file is created, add the following style definitions into it.

```

.root {
    -fx-background-color: gold;
}

.label {
    -fx-font-size: 20;>
}

```

The first of the styles makes the background in the application window "gold" and the second one - sets the font size for the text `Hello World!` to 20 pixels.

```
Main.java x SampleController.java x sample.fxml x sample.css x
.root {
  -fx-background-color: gold;
}
.label {
  -fx-font-size: 24;
```

4. Run the application again to see the result (Shift+F10).

Now that you've brought the application to a reasonable state, you may want to package it. For corresponding instructions, see [Packaging JavaFX Applications](#).

When you open an FXML file in the editor, there are two tabs underneath the editing area:

- Text. This tab is for developing the markup.
- Scene Builder. This tab is for editing the file in [JavaFX Scene Builder](#). (You should be using the Scene Builder version 2.x.)

If you haven't specified the path to Scene Builder yet, there is the text *Please configure JavaFX Scene Builder path*.

Click the path link and select the Scene Builder executable file in the dialog that opens.

After a while, the FXML file will open in Scene Builder.

If you are using Scene Builder version 1.x, the Scene Builder tab is empty and you should use the following procedure (this works for version 2.x too):

1. Select the FXML file of interest in the Project tool window, or open the file in the editor.
2. From the context menu, select Open In SceneBuilder. (If you are in the editor, this applies to the Text tab.)

You can package your JavaFX application by building the corresponding [artifact](#) . For JavaFX applications, IntelliJ IDEA provides a dedicated artifact type (JavaFx Application). One JavaFx Application artifact configuration is created by IntelliJ IDEA automatically if you create a project as described in [Creating a project for JavaFX development](#) .

Alternatively, you can generate an Ant build file, and then use that build file to package your application.

- [Building an artifact](#)
- [Generating and using an Ant build file](#)

See also, [Applications with a Preloader: Project Organization and Packaging](#) .

## Building an artifact

To build an artifact for your JavaFX application:

- Select Build | Build Artifacts . Then, in the Build Artifacts | Action popup, select the artifact and select Build .
- Alternatively, you can turn on the Build on make option in the artifact configuration. In that case, an artifact will be built when making the project (e.g. Build | Make Project or `Ctrl+F9` ).

By default, the artifact is generated in `<project_folder>\out\artifacts\<artifact_name>` .

See also, [Working with Artifacts](#) , [Artifacts](#) and [Java FX tab](#) .

## Generating and using an Ant build file

1. Generate an Ant build file for your project ( Build | Generate Ant Build ). For more information, see [Generating Ant Build File](#) .
2. Make the necessary changes to the generated build file.
3. Open the Ant Build tool window (e.g. View | Tool Windows | Ant Build ), specify the build file to be used and run the necessary target. For more information, see [Executing Ant Target](#) .

See also, [Ant](#) .

If you intend to package your application with a [preloader](#) , you, generally, should:

1. Create a [project](#) with at least two Java [modules](#) : one module for the application itself and one module for the preloader.  
For additional instructions, see [Configuring projects](#) and [Configuring projects](#) . See also, [Creating a project for JavaFX development](#) .
  2. Develop the code for the application and the preloader.
  3. Create two [artifact configurations](#) .
    - One of the configurations should be of the JavaFxPreloader type. This configuration will be used to build the preloader application (normally, a JAR file). The compilation output of the preloader module should be included in this artifact.
    - The second of the configurations - the one intended for packaging the application - should be of the JavaFx Application type. This artifact should include the compilation output of the application module and a copy of the preloader artifact. The copy of the preloader artifact should be added to the output root of the application artifact. (1. On the Output Layout tab for the application artifact, right-click <output root> and select Add Copy of |Artifact . 2. Select the preloader artifact in the Choose Artifacts dialog.)
- See [Artifacts](#) , [Output Layout Tab](#) and [Java FX tab](#) .
4. Build the application artifact. As a result, a package containing both the application and the preloader will be generated.  
For additional instructions, see [Building an artifact](#) .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports the following toolkits for developing Java mobile applications:

- [J2ME Wireless Toolkit](#) (a.k.a. WTK), versions 1.x and 2.x.
- [DoJa](#), version 1.x.

IntelliJ IDEA integration with those toolkits is based on the [J2ME plugin](#). This plugin is bundled with the IDE and enabled by default.

## Preparing for Java mobile application development

1. Download and install a [JDK](#) and one of the [supported Java mobile toolkits](#).
2. Make sure that the J2ME plugin is enabled, see [Making sure that the J2ME plugin is enabled](#).
3. Define the JDK and the mobile toolkit in IntelliJ IDEA. (In IntelliJ IDEA, the supported Java mobile toolkits are referred to as mobile SDKs). See [Defining a JDK and a mobile SDK in IntelliJ IDEA](#).
4. Create a project with a J2ME module, see [Creating a project with a J2ME module](#).
5. If necessary, configure the compilation settings specific to Java mobile applications, see [Configuring Java mobile-specific compilation settings](#).

See also, [Running and debugging Java mobile applications](#).

## Making sure that the J2ME plugin is enabled

Even though the J2ME plugin is enabled by default, it's always worth making sure that this plugin is still enabled before you start developing a Java mobile application. To do that:

1. Press [Ctrl+Alt+S](#) or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Plugins.
2. In the right-hand part of the dialog, type `j2` in the search box. As a result, only the plugins whose names and descriptions contain `j2` are shown in the list of plugins.
3. If the checkbox to the left of J2ME is not selected, select it.
4. Click OK in the Settings dialog.
5. If suggested, restart IntelliJ IDEA.

This feature is only supported in the Ultimate edition.

To be able to develop Java mobile applications, you should define the JDK and the Java mobile toolkit that you are going to use in IntelliJ IDEA.

## To define a JDK and a mobile SDK in IntelliJ IDEA

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the leftmost pane, under Platform Settings , click SDKs .
3. Above the pane to the right, click **+** and select JDK .
4. In the [dialog that opens](#) , select the installation directory of the JDK to be used and click OK .
5. Click **+** and select Mobile SDK .
6. In the [dialog that opens](#) , select the installation directory of your Java mobile toolkit (WTK or DoJa) and click OK .
7. If necessary, configure your custom profile and specify the preverify options on the [SDK page](#) (in the right-hand part of the dialog).
8. Click OK in the Project Structure dialog.

This feature is only supported in the Ultimate edition.

To develop a Java mobile application, you need a [project](#) with a J2ME [module](#) .

## To create a project with a J2ME module

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the [Welcome screen](#) . Otherwise, select File | New | Project .  
As a result, the [New Project wizard](#) opens.
2. On the [first page of the wizard](#) , in the left-hand pane, select J2ME .  
In the right-hand part of the page, specify the Java ME SDK to be used.
3. If necessary, enable SQL support and select the SQL dialect to be used by default.  
Click Next .
4. On the [next page of the wizard](#) , specify mobile SDK-specific options, and click Next .
5. Specify the name and location settings for your project and module. For more information, see [Project Name and Location](#) .  
Click Finish .

This feature is only supported in the Ultimate edition.

Generally, the compilation process for Java mobile applications includes the following stages:

- Compilation. During this stage a "standard" Java compiler such as javac is used. The related settings are specified as described in [Specifying Compilation Settings](#).
- Preverification. Used at this stage is a preverify utility with an emulator included in the corresponding Java mobile SDK (WTK or DoJa). The related settings are specified as described later on this page.
- Packaging.

### To configure the preverify settings

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Select SDKs and then select your mobile SDK.
3. If you are using WTK, you can specify whether you want to use the default profile (MIDP) and configuration (CLDC) versions for a given emulator, or the custom profile and/or configuration versions. In the second case, list the profile and/or configuration versions in the corresponding fields.
4. For both WTK and DoJa, you can also specify the parameters for the preverify utility. For more information, see [SDKs. Mobile](#).

This feature is only supported in the Ultimate edition.

To be able to run or debug your Java mobile application you should first create the corresponding run/debug configuration. Then, you should start this run/debug configuration in the run or the debug mode.

- [Creating a J2ME run/debug configuration](#)
- [Starting a J2ME run/debug configuration](#)

### To create a J2ME run/debug configuration

1. Select Run | Edit Configurations .
2. In the [Run/Debug Configurations dialog](#) , click  and select J2ME .
3. Specify the configuration settings as necessary and click OK . For more information, see [Run/Debug Configuration: J2ME](#) .

### To start your J2ME run/debug configuration

1. Make sure that the run/debug configuration for your mobile application is selected in the corresponding selector on the toolbar.
2. Now, to start this configuration in the run or the debug mode:
  - Select Run | Run or press  .
  - Select Run | Debug or press  .

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you can develop modern web, mobile, and desktop applications with **JavaScript** and **Node.js**. IntelliJ IDEA supports **JavaScript** and **TypeScript** programming languages, **React** and **Angular** frameworks and provides tight integration with various tools for web development.

On this page you will find a short Getting Started Guide that will walk you step by step from creating a web application to debugging and testing it.

## Creating a new application

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose Static Web again and click Next .
4. On the second page of the wizard, specify the project name and the path to the folder where the project-related files will be stored. Click Finish .

## Starting with an existing JavaScript application

If you are going to continue developing an existing JavaScript application, open it in IntelliJ IDEA, [choose the JavaScript version to use](#) , and configure the libraries in it. Optionally [download the required npm dependencies](#) .

### If the application sources are already on your machine

Click Open on the Welcome screen or choose File | Open on the main menu. In the dialog that opens, select the folder where your sources are stored.

### If the application sources are under version control

1. Click Check out from Version Control on the Welcome screen or choose VCS | Check out from Version Control on the main menu.
2. Select your version control system from the list.
3. In the VCS-specific dialog that opens, type your credentials and the repository to check out the application sources from.

## Choosing the JavaScript language version

To get reliable and efficient coding assistance, you need to specify the language version that will be used in all JavaScript files of your application by default.

### To choose the JavaScript language version

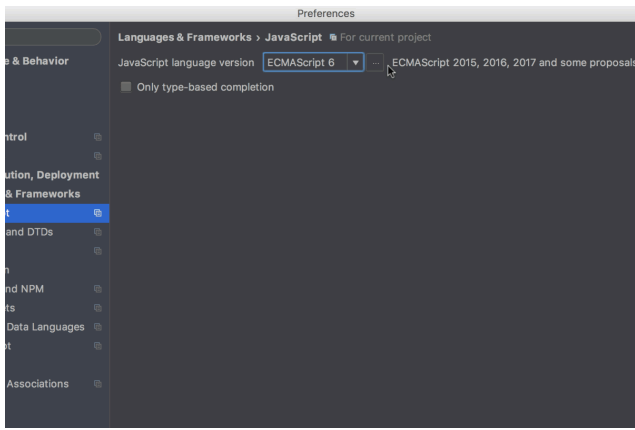

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), choose JavaScript under Languages and Frameworks . The [JavaScript page](#) opens.
2. From the drop-down list, choose one of the supported JavaScript language versions:
  - [ECMAScript 3](#)
  - [ECMAScript 5.1](#)
  - [JavaScript 1.8.5](#)
  - [ECMAScript 6](#) : This version adds support for the features introduced in ECMAScript 2015-2017 as well as some current proposals to the standard.
  - [React JSX](#) : This version adds support for the JSX syntax on top of ECMAScript 6
  - [Flow](#) : This version adds support for the Flow syntax.

## Using multiple JavaScript versions

If you are working on an application that uses both ECMAScript 5.1 and a newer version of ECMAScript, or JSX, or Flow, the easiest way is to choose the highest language version for the whole project from the drop-down list on the [JavaScript page](#) . For example, if you use ES5.1 and JSX, enable JSX (since it is a superset of ES5.1 and ES6).

### To configure different JavaScript language versions for different folders

1. On the [JavaScript page](#) , click  next to the JavaScript language version drop-down list. The JavaScript Language Versions dialog opens.
2. Click  and in the dialog that opens select the folder where you need a custom language version. IntelliJ IDEA brings you back to the JavaScript Language Versions dialog where the selected folder is shown in the Path field.
3. From the Language drop-down list, choose the language version for the files in the selected folder. To all other JavaScript files in the project IntelliJ IDEA will use the version chosen on the [JavaScript page](#) .

## Downloading npm dependencies

**Tip** Alternatively, run `npm install` in the Terminal .

If your application uses some tools, libraries, or frameworks, download the required packages.

1. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#) .
2. Install and enable the [NodeJS](#) plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

### To install a package in an empty project

Open the embedded Terminal ( `View | Tool Windows | Terminal` ) and type `npm install <package name>` at the command prompt.

### If you already have a package.json file in your project

Right-click the `package.json` file in the editor or in the Project tool window and choose `Run 'npm install'` on the context menu.

## Running JavaScript in browser

1. In the editor, open the HTML file with the JavaScript reference. This HTML file does not necessarily have to be the one that implements the starting page of the application.
2. Do one of the following:
  - Choose `View | Open in Browser` on the main menu or press `Alt+F2` . Then select the desired browser from the pop-up menu.
  - Hover your mouse pointer over the code to show the browser icons bar:  Click the icon that indicates the desired browser.

## Debugging JavaScript

IntelliJ IDEA provides a built-in debugger for your client-side JavaScript code that works with Chrome.

You can also debug your client-side JavaScript in Firefox, version 36 and higher. However it is strongly recommended that you use **Chrome** or any other browser of the **Chrome** family. With IntelliJ IDEA, you can debug JavaScript applications running on the built-in server, on an external server, or on a remote server. For details, see [Debugging JavaScript in Chrome](#) and [Debugging JavaScript in Firefox](#) .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with [Angular](#) also known as **Angular 2** . This platform makes it easy to build web, mobile, or desktop applications.

## Before you start

1. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#) .
2. Install and enable the **NodeJS** and **AngularJS** plugins on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Creating a new Angular application

You can use the [angular-cli](#) package or create an empty IntelliJ IDEA project and install Angular in it.

## Generating an Angular application with Angular CLI

[Angular CLI](#) is the recommended way to start building a new Angular application. Angular CLI should be installed globally so it can be used in any IntelliJ IDEA project.

### To install Angular CLI globally

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install -g @angular/cli` at the command prompt.

### To create an application

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose AngularCLI and click Next .
4. On the second page of the wizard, specify the project name and the folder to create it in. In the Node Interpreter field, specify the Node.js interpreter to use. Choose a configured interpreter from the drop-down list or choose Add to configure a new one, see [Configuring Node.js Interpreters](#) In the Angular CLI field, specify the path to the `angular-cli` package.
5. When you click Finish , IntelliJ IDEA generates an Angular-specific project with all the required configuration files.

**Tip** You can also install the `angular-cli` package on the [Node.js and NPM page](#) as described in [NPM](#) .

## Installing Angular in an empty IntelliJ IDEA project

### To create an empty IntelliJ IDEA project

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose Static Web and click Next .
4. On the second page of the wizard, specify the project name and the folder to create it in.
5. When you click Finish , IntelliJ IDEA creates and opens an **empty** project.

### To install Angular in an empty project

1. Open the empty project where you will use **Angular** .
2. Open the embedded Terminal ( View | Tool Windows | Terminal ) and type `npm install @angular/core` at the command prompt. That will install the core **Angular** package with the critical runtime parts of the framework. You may also need to install other packages that are parts of **Angular** , see the [list of packages](#) .

## Starting with an existing Angular application

If you are going to continue developing an existing Angular application, open it in IntelliJ IDEA and download the required dependencies.

### If the application sources are already on your machine

Click Open on the Welcome screen or choose File | Open on the main menu. In the dialog that opens, select the folder where your sources are stored.

### If the application sources are under version control

1. Click Check out from Version Control on the Welcome screen or choose VCS | Check out from Version Control on the main menu.
2. Select your version control system from the list.
3. In the VCS-specific dialog that opens, type your credentials and the repository to check out the application sources from.

### To download the dependencies

Open the embedded Terminal ( View | Tool Windows | Terminal ) and type `npm install` at the command prompt.

## Generating Angular structures

In an **Angular CLI** project, you can have specific structures generated automatically.

1. On the main menu, choose File | New | Angular CLI .
2. In the pop-up list that opens, click the relevant type of structure.
3. In the dialog box that opens, specify the name of the structure to be generated and the path to it relative to the `src/app` folder of your project. If you want to generate a structure in a separate folder, create this folder first. This does not apply to components, which are by default generated in separate folders unless the `--flat` option is specified. If necessary, specify additional options, for example, `--flat` to have a new component generated directly in the specified location without creating a separate folder.

## Using Angular language service

IntelliJ IDEA supports integration with the [Angular language service](#) developed by the **Angular** team to improve code analysis and completion for **Angular-TypeScript** projects. Note that the **Angular language service** works only with the projects that use **Angular 2.3.1** or higher and **TypeScript** version compatible with it. Also make sure you have a `tsconfig.json` file in your project.

To install the `@angular/language-service` package

1. Open the Terminal tool window ( View | Tool Windows | Terminal or `Alt+F12` ).
2. Change the current folder to the project root and at the command prompt run `npm install @angular/language-service --save-dev` .

The **Angular language service** is activated by default so IntelliJ IDEA starts it automatically together with the **TypeScript service** and shows all the errors and warnings in your TypeScript and HTML files both in the editor and in the [TypeScript Tool Window](#) .

To activate or disable the service

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Typescript under Languages & Frameworks .
2. On the [TypeScript](#) page that opens, select the Enable TypeScript Compiler checkbox and click Configure next to it.
3. In the Service options dialog box that opens, select or clear the Use Angular service checkbox.

## Using Angular Material Design components

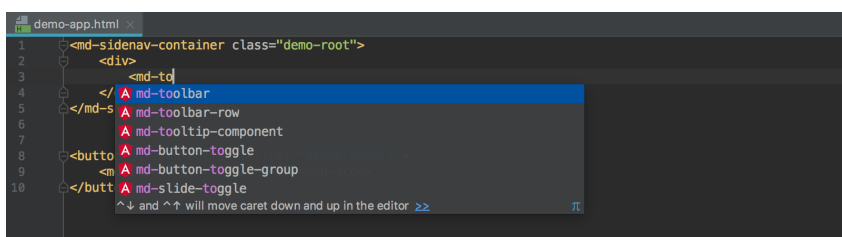

IntelliJ IDEA recognizes [Angular Material](#) components and attributes and provides coding assistance for them.

To install Angular Material

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install --save @angular/material` at the command prompt. For details, see [Getting Started on the Angular Material Official website](#) .

Support of Angular Material in IntelliJ IDEA includes

– Completion for components

– Completion for attributes

– Navigation between a component or an attribute and its declaration ( `Ctrl+B` or Go To | Declaration on the context menu).

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides integration with the [AngularJS framework](#) also known as **Angular 1** . This support involves:

- **AngularJS** -aware code completion for `ng` directives (also including custom directives), controller and application names, and code insights for data bindings inside curly-brace expressions `{{}}` .
- **AngularJS** -specific navigation:
  - Between the name of a controller in HTML and its definition in JavaScript.
  - Between `ngView` or `&routeProvider` and the template.
  - **Go To Symbol** navigation for entities.
- A collection of **AngularJS** built-in live templates.
- **Quick documentation look-up** by pressing `Ctrl+Q` .
- **AngularJS ui-router** diagram.

## Before you start

1. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#) .
2. Install and enable the **NodeJS** and **AngularJS** plugins on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Introduction

You can get **AngularJS** support in a IntelliJ IDEA project in the following ways:

- [Open an existing project with AngularJS sources](#).
- [Generate an AngularJS-specific project stub](#) from the IntelliJ IDEA Welcome Screen . IntelliJ IDEA generates the **AngularJS** -specific project structure with all the required configuration files based on the [AngularJS seed project](#)
- [Create an empty project](#) , and then install **AngularJS** in it either manually, by downloading the **AngularJS** framework, or using the **Bower** package manager. [If you choose manual installation](#) , you will need to configure **AngularJS** as a IntelliJ IDEA JavaScript library. [If you use Bower](#) , IntelliJ IDEA will do this configuration automatically, without any steps from your side.

## Creating an AngularJS project using a seed project

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose AngularJS and click Next .
4. On the second page of the wizard, specify the project name and the folder to create it in.  
From the Version drop-down list, choose the branch <https://github.com/angular/angular.js> to download the project template from. By default, `master` if shown.
5. When you click Finish , IntelliJ IDEA generates the **AngularJS** -specific project structure with all the required configuration files based on the [AngularJS seed project](#)
6. Download the **AngularJS** dependencies that contain the **AngularJS** code and the tools that support development and testing: open the embedded Terminal ( View | Tool Windows | Terminal ) and type `npm install` at the command prompt.  
Learn more about the installation of dependencies in the [Install Dependencies](#) section of the `readme.md` file.

## Configuring AngularJS support in a project

If you already have **AngularJS** sources in your project (for example, in the `bower_components` folder), just open your project and start working. If these sources are **excluded from project** , then you only need to configure **AngularJS** as an [External JavaScript library](#) .

If you do not have any previously downloaded **AngularJS** sources, [create an empty project](#) , and then install **AngularJS** in it either [manually, by downloading the AngularJS framework](#) , or [using the Bower package manager](#) .

## Creating an empty IntelliJ IDEA project

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose Static Web and click Next .
4. On the second page of the wizard, specify the project name and the folder to create it in.
5. When you click Finish , IntelliJ IDEA creates and opens an **empty** project.

## Configuring AngularJS coding assistance in an empty project manually

1. Download the **AngularJS** framework at <http://angularjs.org/> .
2. Open the empty project where you will use **AngularJS** .
3. Configure **AngularJS** as a IntelliJ IDEA JavaScript library, to let IntelliJ IDEA recognize **AngularJS** -specific structures and provide full coding assistance:
  1. [Open the Settings/Preferences dialog box](#) , and click [JavaScript Libraries](#) .
  2. In the Libraries area, click the Add button.
  3. In the [New Library](#) dialog box that opens, specify the name of the library.

4. Click the Add button **+** next to the list of library files and choose Attach Files or Attach Directory on the context menu, depending of whether you need separate files or an entire folder.
5. Select the `Angular.js` or `Angular.min.js` , or an entire directory in the dialog box that opens. IntelliJ IDEA returns to the New Library dialog box where the Name read-only field shows the name of the selected files or folder.
6. In the Type field, specify which version you have downloaded and are going to add.
  - If you added `Angular.js` , choose Debug . This version is helpful in the development environment, especially for debugging.
  - If you added the **minified** `Angular.min.js` , choose Release . This version is helpful in the production environment because the file size is significantly smaller.

Learn more at [Configuring JavaScript Libraries](#) .

## Installing AngularJS in an empty project through Bower

1. Open the empty project where you will use **AngularJS** .
2. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#) .
3. Install [Bower](#) as described in [Bower](#) .
4. Open the embedded Terminal ( View | Tool Windows | Terminal ) and type `bower install angular` at the command prompt to install the package in the current project.

You can also install the `angular` package on the [Bower](#) page of the Settings/Preferences dialog as described in [Installing and Removing Bower Packages](#) .

## Using AngularJS Router state diagrams

You can see a diagram illustrating the relations between views, states, and templates in **AngularJS** applications that use [ui-router](#) .

To generate and view a diagram, open the desired file in the editor, and then choose Diagrams | Show AngularJS ui-router State Diagram on the context menu. IntelliJ IDEA generates a diagram and shows it in a separate editor tab.

To navigate from an element in the diagram to the code that implements this element, select it and choose Jump to Source on the context menu.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

IntelliJ IDEA provides interface for installing, uninstalling, and upgrading client-side libraries and frameworks for your project using the [Bower Package Manager](#) . Alternatively, you can use the tool in the command line mode from the [embedded local terminal](#) .

The easiest way to install the Bower package manager is to use the **Node Package Manager (npm)** , which is a part of [Node.js](#) . See [NPM](#) for details.

Depending on the desired location of the Bower package manager executable file, choose one of the following methods:

- Install the package manager **globally** at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.
- Install the package manager in a specific project and thus restrict its use to this project.
- Install the package manager in a project as a [development dependency](#) .

In either installation mode, make sure that the parent folder of the Bower package manager is added to the `PATH` variable. This enables you to launch the package manager from any folder.

IntelliJ IDEA provides user interface both for **global** and **project** installation as well as supports installation through the command line.

## Before you start

1. Download and install the [Node.js](#) runtime environment.

If you are going to use the command line mode, make sure the path to the parent folder of the **Node.js** executable file and the path to the `npm` folder are added to the `PATH` variable. This enables you to launch the Bower package manager and **npm** from any folder.

2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Installing Bower globally

**Global** installation makes a package manager available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project. Moreover, during installation the parent folder of the package manager is automatically added to the `PATH` variable, which enables you to launch the package manager from any folder.

- Run the installation from the command line in the **global** mode:

1. Open the embedded Terminal ( [View](#) | [Tool Windows](#) | [Terminal](#) ) and switch to the directory where **NPM** is stored or define a `PATH` variable for it so it is available from any folder, see [Installing NodeJS](#) .

2. Type the following command at the command prompt:

```
npm install -g bower
```

The `-g` key makes the package manager run in the **global** mode. Because the installation is performed through **NPM** , the Bower package manager is installed in the `npm` folder. Make sure this parent folder is added to the `PATH` variable. This enables you to launch the package manager from any folder.

For more details on the **NPM** operation modes, see [npm documentation](#) . For more information about installing the Bower package manager, see <https://npmjs.org/package/bower> .

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File](#) | [Settings for Windows and Linux or IntelliJ IDEA](#) | [Preferences for macOS](#), and click [Node.js](#) and [NPM](#) under [Languages & Frameworks](#) .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+` .
3. In the Available Packages dialog box that opens, select the required package to install.
4. Select the Options checkbox and type `-g` in the text box next to it.
5. Optionally specify the product version and click [Install Package](#) to start installation.

## Installing Bower in a project

**Local** installation in a specific project restricts the use of a package manager to this project.

- Run the installation from the command line:

1. Open the embedded Terminal ( [View](#) | [Tool Windows](#) | [Terminal](#) ) and switch to the project root folder.
2. At the command prompt, type `npm install bower` .

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File](#) | [Settings for Windows and Linux or IntelliJ IDEA](#) | [Preferences for macOS](#), and click [Node.js](#) and [NPM](#) under [Languages & Frameworks](#) .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+` .

3. In the Available Packages dialog box that opens, select the required package.
4. Optionally specify the product version and click Install Package to start installation.

## Creating a Bower configuration file bower.json

1. In the command line mode, switch to your project directory.
2. Type the following command at the command prompt:

```
bower init
```

If **Bower** does not start, check the installation: the parent folder or the **Bower** executable file should be specified in the PATH variable.

3. Answer the questions to specify the following basic settings:
  - The testing framework to use.
  - The browsers to be captured automatically.
  - The patterns that define the location of test files to be involved in testing or excluded from it.

For more details, see [Bower: Configuration](#).

## Configuring Bower in IntelliJ IDEA

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Bower under JavaScript.
2. On the [Bower](#) page that opens, specify the location of the Node.js and Bower executable files and the `bower.json` configuration file.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

**Bower packages** can be installed and used only in a specific project. IntelliJ IDEA supports two installation modes: from the command line and through the dedicated user interface.

On this page:

- [Installing a Bower package in the command-line mode](#)
- [Installing a Bower package through the IntelliJ IDEA interface](#)
- [Removing Bower packages](#)
- [Installing a Bower package as a development dependency](#)

## Installing a Bower package in the command-line mode

1. Open the embedded Terminal ( [View | Tool Windows | Terminal](#) ) and switch to the directory where **Bower** is stored or define a `PATH` variable for it so it is available from any folder, see [Installing Bower](#) .
2. Type the following command at the command prompt:

```
bower install <tool name>
```

## Installing a Bower package through the IntelliJ IDEA interface

1. Run **Bower** from IntelliJ IDEA using the Bower page of the Settings dialog box.
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS](#). Expand the [Languages & Frameworks](#) node, and then click [Bower](#) under [JavaScript](#) .
  2. On the Bower page that opens, the [Packages](#) area shows all the **Bower** -dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+` .
  3. In the [Available Packages](#) dialog box that opens, select the required package.
  4. Optionally specify the product version and click [Install Package](#) to start installation.

## Removing Bower packages

Open the [Bower](#) page, select the package to remove, and click `-` .

## Installing a Bower package as a development dependency

If a package is a documentation or a test framework, which are of no need for those who are going to re-use your application, it is helpful to have it excluded from download for the future. This is done by marking the tool as a [development dependency](#) , which actually means adding the package in the `devDependencies` section of the `package.json` file.

With IntelliJ IDEA, you can have a package marked as a **development dependency** right during installation. Do one of the following:

- Run the installation from the command line in the **global** mode: open the embedded Terminal ( [View | Tool Windows | Terminal](#) ) and type `bower install -dev <tool name>` at the command prompt.
- Install the package using the IntelliJ IDEA user interface:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS](#). Expand the [Languages & Frameworks](#) node, and then click [Bower](#) under [JavaScript](#) .
  2. On the Bower page that opens, the [Packages](#) area shows all the Bower-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+` .
  3. In the [Available Packages](#) dialog box that opens, select the required package.
  4. Select the [Options](#) checkbox and type `--dev` in the text box next to it.
  5. Optionally specify the product version and click [Install Package](#) to start installation.

After installation, a Bower package is added to the `devDependencies` section of the `package.json` file.

This feature is only supported in the Ultimate edition.

## Basics

When working in IntelliJ IDEA, you can use various JavaScript libraries and frameworks with full coding assistance at disposal. The only thing you need is "introduce" the required libraries to IntelliJ IDEA so they are recognized and references to them are successfully resolved.

## Predefined and custom libraries

Right from IntelliJ IDEA, you can download and install a number of the most popular JavaScript libraries, such as: [Dojo](#) , [ExtJS](#) , [jQuery](#) , [jQuery UI](#) , [Prototype](#) , and others. Once installed, these libraries, by default, are visible in all files within the project.

You can also download any other JavaScript libraries and frameworks or even develop JavaScript libraries yourself, if necessary. To use such downloaded or self-developed libraries, you need to [set them up as custom IntelliJ IDEA JavaScript libraries](#) . Configured libraries can be used in [code completion](#) , highlighting, [navigation](#) , and [Documentation Lookup](#) .

To enable Documentation Lookup for symbols defined in an external library or framework, [provide a link](#) to its documentation. Upon pressing [\(Shift+F1\)](#) with the cursor positioned at the symbol in question, IntelliJ IDEA invokes this link and opens the documentation page in browser.

For [jQuery](#) , [jQuery UI](#) , [Ext JS](#) , [Prototype](#) , and [Dojo](#) library files, IntelliJ IDEA automatically detects links to the library documentation.

To get all the above mentioned coding assistance for a library or a framework, you need to [configure it as a IntelliJ IDEA library](#) and [specify the library scope](#) by associating the library with your project or its part, so you can reference the library from the files within this scope, get code completion, and retrieve definitions and documentation.

Please note, that configuring a framework as a IntelliJ IDEA library and associating it with a project only ensures coding assistance in the [development environment](#) , that is, while you are working in IntelliJ IDEA. To use a framework or library in the [production environment](#) , make sure the relevant version of the framework is available on the server.

## Visibility and scope

Each IntelliJ IDEA library is characterized by its [visibility](#) status and [scope](#) .

The [scope](#) of a library defines the set of files and folders in which the library is considered as [library](#) , that is, it is write-protected, excluded from check for errors and refactoring, but only affects the completion list and highlighting.

The [visibility](#) status of a library determines whether it can be used in one project ( [Project](#) ) or can be re-used at the IDE level ( [Global](#) ).

– Once configured, a [Global library](#) can be associated with any of IntelliJ IDEA projects. The library itself can be located wherever you need, its settings are stored with other IntelliJ IDEA settings in the dedicated directories under the IntelliJ IDEA home directory.

The [advantage](#) of configuring a framework as a global library is that you can store such library in one location and re-use it in unlimited number of your projects without copying the library under the project root every time.

The [disadvantage](#) of this approach is that to enable team work on a project all the team members should have the library stored on their machines in the same location relative to the project root.

– A [Project library](#) is [visible](#) only within one single project. Therefore a project library can be associated only with this project or its part. This means that project libraries cannot be re-used, so if you later try to use a framework configured as a project library with another project, you will have to configure the library anew.

The [advantage](#) of configuring a JavaScript framework as a project library is that you can share the library definition among other team members through the [project settings](#) so each developer does not have to configure the library separately,

– [Predefined](#) libraries bring JavaScript definitions (also known as "stubs") for the standard DOM, HTML5 and EcmaScript API, as well as for Node.js global objects. These libraries make the basis for coding assistance in accordance with the API provided by the corresponding JavaScript engine. By enabling a certain predefined library you can ensure that your code fits the target environment.

Predefined libraries are by default enabled in the [scope](#) of the entire project. A predefined library can be disabled or [associated with another scope](#) but it cannot be [deleted](#) .

## Viewing the libraries associated with a file

1. Open the file in the editor.
2. Click the Hector icon  on the Status bar. The pop-up window lists the libraries associates with the current file. To change the list, click the Libraries in scope links and edit the scope settings in the [Manage Scope](#) dialog box that opens.

## Downloading and installing a JavaScript-related library from IntelliJ IDEA

IntelliJ IDEA provides a dedicated user interface for downloading and installing the most popular [official](#) JavaScript libraries. Using this interface, you can download and install [Dojo](#) , [ExtJS](#) , [jQuery](#) , [jQuery UI](#) , [Prototype](#) , and other libraries.

Besides the above listed [official](#) libraries, you can download [stubs for TypeScript definition files](#) .

1. Open the [Settings / Preferences Dialog](#) by pressing [\(Ctrl+Alt+S\)](#) or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages and Frameworks node, and then click Libraries under JavaScript .

2. The [JavaScript Libraries](#) page that opens shows a list of all the already available libraries. Click Download .
3. In the Download Library dialog that opens, choose the group of libraries in the drop-down list. The available options are Official libraries and TypeScript community stubs . Depending on your choice, IntelliJ IDEA displays a list of available libraries. Select the one to be downloaded and installed, and click Download and Install . You return to the [JavaScript Libraries](#) page where the new library is added to the list. Click OK to save the settings.

## Configuring a custom JavaScript library

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages and Frameworks node, and then click Libraries under JavaScript .
2. The [JavaScript Libraries](#) page that opens shows a list of all the already available libraries. Click Add .
3. In the [New Library](#) dialog box that opens, specify the name of the library, the framework to configure the library from, and framework version to use.
4. Specify the library [visibility](#) :
  - To enable associating the library with the current project only, choose Current project .
  - To make the library available in any IntelliJ IDEA project, choose Global .
5. Create a list of files to be included in the library:
  1. Click the Add button `+` next to the list of library files and choose Attach Files or Attach Directory on the context menu, depending on whether you need separate files or an entire folder.
  2. Select the required file, files, or entire directory in the dialog box that opens. IntelliJ IDEA returns to the New Library dialog box where the Name read-only field shows the name of the selected library file or the names of relevant library files from the selected directory.
  3. In the Type field, specify which version of library you have downloaded and are going to add.
    - Choose Debug if you are adding a library file with uncompressed code. This version is helpful in the development environment, especially for debugging.
    - Choose Release if you are adding a library file with [minified](#) code. This version is helpful in the production environment because the file size is significantly smaller.

It is recommended that you always have a debug version on hand along with the minified one. Minified code is hard to read and hard for IntelliJ IDEA to handle. When a debug version is available, IntelliJ IDEA automatically detects and ignores the minified file and retrieves definitions and documentation from the debug version.

4. Specify the URL addresses to access the documentation for library files.
  - To add a link to the documentation for a library, select the corresponding library file, click the Specify button in the Documentation URLs area, and specify the documentation URL in the dialog box that opens.

**Tip** For [jQuery](#), [jQuery UI](#), [Ext JS](#), [Prototype](#), and [Dojo](#) library files, IntelliJ IDEA automatically detects the link to the library documentation and suggests it in the Enter documentation URL text box.

- To remove a link, select it in the Documentation URLs and click the Remove button.

## Removing a library file

In the [New Library / Edit Library](#) dialog box, select the required library file and click the Remove button `-` .

## Updating the contents of a library

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages and Frameworks node, and then click Libraries under JavaScript .
2. The [JavaScript Libraries](#) page that opens shows a list of all the already available libraries. Select the required library and click Edit .
3. In the [Edit Library](#) dialog box that opens, [add](#) library files, [remove](#) library files, and [change links to documentation](#) as necessary.

## Deleting a library

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages and Frameworks node, and then click Libraries under JavaScript .
2. The [JavaScript Libraries](#) page that opens shows a list of all the already available libraries. Select the required library and click Remove .

## Specifying the scope to use a library in

The **scope** of a library defines the set of files and folders in which the library is considered as **library** , that is, it is write-protected, excluded from check for errors and refactoring, but only affects the completion list and highlighting.

By default, all [predefined libraries](#) and [libraries downloaded from IntelliJ IDEA](#) provide completion, resolution, highlighting and are treated as libraries in any file within the project. In other words, their usage scope is the whole project.

[Libraries that you create yourself](#) are not considered libraries in any of the files unless you specify their usage scope explicitly.

To specify the scope for a library:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages and Frameworks node, and then click Libraries under JavaScript .
2. The [JavaScript Libraries](#) page that opens shows a list of all the already available libraries. Click Manage Scopes .
3. In the [JavaScript Libraries Usage Scope](#) dialog box that opens, specify the custom JavaScript libraries to use in files and folders within your project. To appoint a library for a file or folder, select the required item in the File/Directory field and choose the relevant library from the Library drop-down list.

The contents of the list depend on the [visibility](#) type of the configured libraries. **Global** libraries are on the list in all IntelliJ IDEA projects. **Project** libraries are on the list only within the project they were originally configured in.

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Example of JavaScript comment](#)
- [Enabling documentation comments](#)
- [Creating a JSDoc comment block](#)

## Introduction

To make your code easy to use by other developers it is considered good practice to provide an HTML documentation of its Application Programming Interface (API). Such documentation can be generated automatically by the [JSDoc](#) tool. All you need, is supply your code with **documentation comments** in accordance with the [JSDoc standard](#) . The tool retrieves information from your comments and renders it in HTML using a built-in template.

You can find a detailed description of the JSDoc syntax with examples and explanation of their use in the article [An Introduction to JSDoc](#) .

IntelliJ IDEA creates stubs of JSDoc comments on typing the opening tag `/**` and pressing `Enter` . If this feature is [applied to a method or a function](#) , `@param` tags are created. In any other places IntelliJ IDEA adds an empty documentation stub.

[TODO patterns](#) and [Closure Compiler](#) annotations inside documentation comments are also recognized and are involved in code completion, intention actions, and other types of coding assistance.

Documentation comments in your source code are available for the [Quick Documentation Lookup](#) and open for review on pressing `Ctrl+Q` .

IntelliJ IDEA checks syntax in the comments and treats it according to the [Code Inspections](#) settings.

## Example of JavaScript comment

Consider the following function:

```
function loadDocs(myParam1, myParam2){}
```

Type the opening documentation comment and press `Enter` to generate the documentation comment stub:

```
/**
 * @param myParam1
 * @param myParam2
 */
```

## Enabling documentation comments

1. Open the Editor | General | Smart Keys page of IntelliJ IDEA settings (`Ctrl+Alt+S` ).
2. In the Enter section, select or clear Insert documentation comment stub check box.
3. **Warning!** The following is only valid when Python Plugin is installed and enabled!

For Python, scroll to the Insert type placeholders in the documentation comment stub option and select or clear the check box as required. Refer to [the option description](#) for details.

## Creating a JSDoc comment block

1. Place the caret before the method or function declaration.
2. Type the opening block comment `/**` and press `Enter` .
3. Describe the listed parameters and return values.

Documentation comment can be created with the dedicated action Fix Doc Comment . It can be invoked by means of [Find Action](#) command.

Press `Ctrl+Shift+A` , with the caret somewhere within a class, method, function, or field, which should be documented, and enter the action name Fix Doc String . The missing documentation stub with the corresponding tags is added. For example:

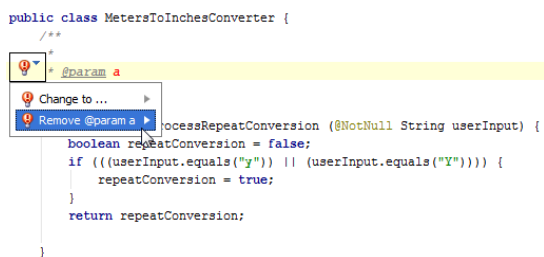

```
/**
 *
 * @param userInput
 * @return
 */
static boolean processRepeatConversion (@NotNull String userInput) {
boolean repeatConversion = false;
if (((userInput.equals("y")) || (userInput.equals("Y")))) {
repeatConversion = true;
}
return repeatConversion;
}
}
```

The next case lays with fixing problems in the existing documentation comments.

For example, if a method signature has been changed, IntelliJ IDEA highlights a tag that doesn't match the method signature, and suggests a quick fix.

For JavaScript, IntelliJ IDEA suggests an intention action UpdateJSDoc comment . You can also press `Ctrl+Shift+A`, and type the action name:

```
public class MetersToInchesConverter {
/**
 * @param a
 */
processRepeatConversion (@NotNull String userInput) {
boolean repeatConversion = false;
if (((userInput.equals("y")) || (userInput.equals("Y")))) {
repeatConversion = true;
}
return repeatConversion;
}
}
```

**Tip** The action Fix doc comment has no keyboard shortcut bound with it. You can [configure keyboard shortcut](#) of your own.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides a built-in debugger for your **client-side** JavaScript code that works with Chrome. The video and the instructions below walk you through the basic steps to get started with this debugger.

Before you start, configure the built-in debugger as described in [Configuring JavaScript Debugger](#) . To use the **Live Edit** functionality that shows the changes in your HTML and CSS in the browser on the fly, install the [JetBrains IDE Support](#) Chrome extension. Find more about that in [Live Edit in HTML, CSS, and JavaScript](#) .

## Debugging an application running on the built-in server

IntelliJ IDEA has a built-in web server that can be used to preview and debug your application. This server is always running and does not require any manual configuration. All the project files are served on the built-in server with the root URL

`http://localhost:<built-in server port>/<project root>` , with respect to the project structure.

**To start debugging :**

1. Set the [breakpoints](#) in the JavaScript code, as required.
2. Open the HTML file that references the JavaScript to debug or select the HTML file in the [Project view](#) .
3. On the context menu of the editor or the selection, choose `Debug <HTML_file_name>` . IntelliJ IDEA generates a debug configuration and starts a debugging session through it. The file opens in the browser, and the [Debug tool window](#) appears.
4. In the Debug tool window, proceed as usual: [step through the program](#) , [stop and resume](#) the program execution, [examine it when suspended](#) , [view actual HTML DOM](#) , etc.

**Tip** To save the automatically generated configuration for further re-use, choose `Save <HTML_file_name>` on the context menu after the debugging session is over.

## Example

Suppose you have a simple application that consists of an `index.html` file and a `MyJavaScript.js` file, where `index.html` references `MyJavaScript.js` . To start debugging this application using the built-in server, open `index.html` in the editor and choose `Debug 'index.html'` on the context menu:

IntelliJ IDEA creates a **run/debug configuration** automatically, and a debugging session starts:

To restart the new run/debug configuration, click  in the upper right-hand corner of the IntelliJ IDEA window or choose `Run | Debug` on the main menu:

## Debugging an application running on an external web server

Often you may want to debug client-side JavaScript running on an external development web server, e.g. powered by Node.js.

**To start debugging**

1. Set the [breakpoints](#) in the JavaScript code, as required.
2. Run the application in the **development mode** . Often you need to run `npm start` for that. When the development server is ready, copy the URL address at which the application is running in the browser - you will need to specify this URL address in the run/debug configuration.
3. Create a debug configuration of the type **JavaScript Debug** :

Choose `Run | Edit Configuration` on the main menu, click  on the toolbar and select **JavaScript Debug** from the pop-up list.

4. In the `Run/Debug Configuration: JavaScript Debug` dialog box that opens, specify the URL address at which the application is running.

This URL can be copied from the address bar of your browser as described in Step 2 above. Click **OK** to save the configuration settings.

5. Choose the newly created configuration in the `Select run/debug configuration` drop-down list on the toolbar and click the `Debug` toolbar button  . The URL address specified in the run configuration opens in the browser and the [Debug tool window](#) appears.
6. In the Debug tool window, proceed as usual: [step through the program](#) , [stop and resume](#) the program execution, [examine it when suspended](#) , [view actual HTML DOM](#) , etc.

See [Debugging React Applications](#) and [Debugging Angular Applications](#) for examples.

## Starting a debugging session with your default Chrome profile

**Tip** Alternatively, always choose this Chrome browser configuration from the Browser list.

You may notice that your debugging session starts in a new window with a custom profile instead of your default one. As a result, the window looks unusual, for example, your bookmarks, the browser history, and the extensions are missing, which altogether breaks your development experience. That happens because IntelliJ IDEA uses [Chrome Debugging Protocol](#) and runs Chrome with the `--remote-debugging-port` option. However, if Chrome is already started, a debugging port can't be opened for any new or existing Chrome instance that has the same profile. To ensure consistent user experience, IntelliJ IDEA always starts a debugging session in a new window with a custom Chrome profile.

To avoid this problem, configure Chrome in IntelliJ IDEA to start with your profile or debug with the [JetBrains Chrome extension](#) as you did before.

### To configure Chrome in IntelliJ IDEA with your profile

1. Save your Chrome profile anywhere on your machine.
2. In the Settings/Preferences dialog (`Ctrl+Alt+S`), choose Web Browsers under Tools. The [Web Browsers](#) page opens.
3. To create a new Chrome configuration, click `+`. A new item appears in the list. In the Path field, specify the path to the Chrome installation folder.
4. Select the new configuration and click `🔍`. The Chrome Settings dialog opens.
5. Select the Use custom profile directory checkbox and specify the path to your Chrome profile in the IntelliJ IDEA settings.
6. Mark your Chrome browser configuration **default** as described in [Choosing the default IntelliJ IDEA browser](#), and don't forget to choose Default from the Browser list when [creating a run/debug configuration](#).

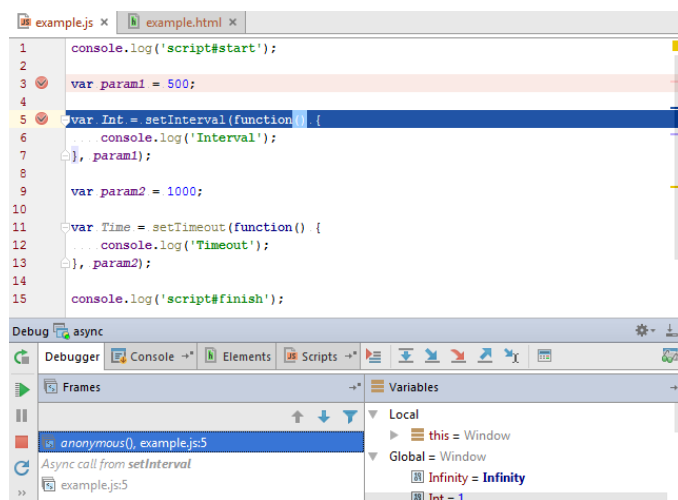

### To debug with the JetBrains Chrome extension

Install the extension and configure the [Live Edit](#) functionality as described in [Live Edit in HTML, CSS, and JavaScript](#).

## Debugging asynchronous code

IntelliJ IDEA supports debugging asynchronous client-side JavaScript code. IntelliJ IDEA recognizes breakpoints inside asynchronous code, stops at them, and lets you step into such code. As soon as a breakpoint inside an asynchronous function is hit or you step into asynchronous code, a new element `Async call from <caller>` is added in the Frames pane of the Debugger tab. IntelliJ IDEA displays a full call stack, including the caller and the entire way to the beginning of the asynchronous actions.

The image below shows an example of a JavaScript debugging session.

The debugger stops at line3(breakpoint), then at line5(breakpoint). On clicking Step into, the debugger will stop at line5 (on `function`), then will move to line6.

The asynchronous debugging mode is turned on by default. To disable asynchronous stack traces, set `js.debugger.async.call.stack.depth` in [Registry](#) to `0`.

## Debugging workers

IntelliJ IDEA supports debugging [Service Workers](#) and [Web Workers](#). IntelliJ IDEA recognizes breakpoints in each **worker** and shows the debug data for it as a separate thread in the **Frame** pane on the **Debugger** tab of the **Debug Tool Window**.

Note that IntelliJ IDEA can debug only [dedicated workers](#), debugging for [shared workers](#) is currently not supported.

1. Set the breakpoints in the **Workers** to debug.
2. If you are using **Service Workers**, make sure the Allow unsigned requests checkbox on the **Debugger** page is selected. Otherwise your **service workers** may be unavailable during a debug session:

3. Create a debug configuration of the type **JavaScript Debug** as described above in [Debugging client-side JavaScript running on an external web server](#) .
4. Choose the newly created configuration in the Select run/debug configuration drop-down list on the tool bar and click the Debug toolbar button  .  
The HTML file specified in the run configuration opens in the chosen browser and the [Debug Tool Window](#) opens with the Frames drop-down list showing all the **Workers** :

To examine the data (variables, watches, etc.) for a **Worker** , select its thread in the list and view its data in the [Variables](#) and [Watches](#) panes. When you select another **Worker** , the contents of the panes are updated accordingly.

This feature is only supported in the Ultimate edition.

Debugging JavaScript in IntelliJ IDEA is supported through the **JavaScript Debugger** plugin. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

Debugging of JavaScript code is supported in [Google Chrome](#) and other browsers of the **Chrome** family.

To ensure successful debugging, it is enough to specify the built-in web server port and accept the default settings that IntelliJ IDEA suggests for other debugger options.

#### To set the built-in web server port

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Debugger under Build, Execution, Deployment . The [Debugger](#) page opens.
2. In the Built-in server area, specify the port where the built-in web server runs. By default this port is set to the default IntelliJ IDEA port `63342` through which IntelliJ IDEA accepts connections from services. You can set the port number to any other value starting with 1024 and higher.

If the Live Edit functionality is enabled, the JetBrains Chrome extension will also use this port to connect to the running page, see [Live Edit in HTML, CSS, and JavaScript](#) for details.

#### Optionally

1. Suppress calls to the files on the built-in server from other computers or from outside IntelliJ IDEA by clearing the Can accept external connections or Allow unsigned requests checkbox respectively.
2. Choose the way to remove breakpoints, the default setting is Click .
3. On the [Data Views](#) page under the Debugger node, configure advanced debugger options: enable or disable [inline Debugging](#) , specify when you want to see tooltips with object values and [expressions evaluation results](#) , etc.
4. Click JavaScript under the Data Views node and on the [JavaScript](#) page that opens, specify the following:
  - Whether you want object node properties to be shown. If so, specify the properties. Use `+` and `-` to manage the list of properties.

This feature is only supported in the Ultimate edition.

Before you start, configure the built-in debugger as described in [Configuring JavaScript Debugger](#) . To use the **Live Edit** functionality that shows the changes in your HTML and CSS in the browser on the fly, install the [JetBrains IDE Support](#) Chrome extension. Find more about that in [Live Edit in HTML, CSS, and JavaScript](#) .

## What is a remote web server?

In IntelliJ IDEA, any server with the **document root** outside the current project is called **remote** . This server may be actually running on a physically remote host or on your machine.

For example, if your project is in `C:/IntelliJ IDEAProjects/MyProject` and the web server document root is `C:/XAMPP/htdocs` , for IntelliJ IDEA this web server is **remote** .

## How do I synchronize my application sources on the server with their local copies in my IntelliJ IDEA project?

To debug an application on a **remote** web server, you need to have the copies of its sources in a IntelliJ IDEA project. To synchronize local and remote sources, create a **deployment configuration** as described in [Creating a Remote Server Configuration](#) and [Configuring Synchronization with a Web Server](#) .

## Debugging an application

1. Set the [breakpoints](#) in the JavaScript code, as required.
2. Create a debug configuration of the type **JavaScript Debug** :

On the main menu, choose **Run | Edit Configuration** , then in the **Edit Configurations** dialog, click **+** on the toolbar and select **JavaScript Debug** from the pop-up list.

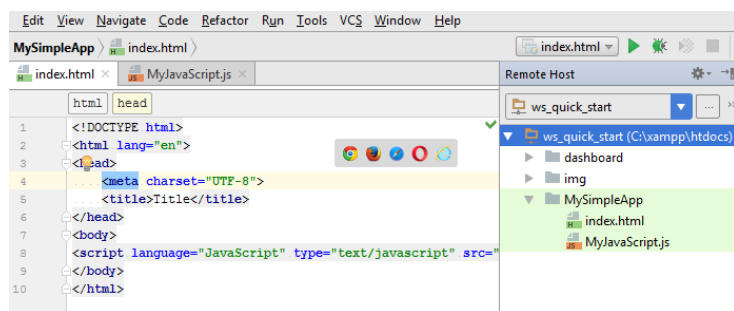

3. In the **Run/Debug Configuration: JavaScript Debug** dialog box that opens, specify the URL address at which the application is running.

This URL address should be a concatenation of the **Web server root URL** and the path to the HTML file relative to the web server document root in accordance with **server access configuration** , see [Configuring Synchronization with a Web Server](#) . Click **OK** to save the configuration settings.

4. Choose the newly created configuration in the **Select run/debug configuration** drop-down list on the tool bar and click the **Debug** toolbar button  . The HTML file specified in the run configuration opens in the chosen browser and the **Debug tool window** appears.
5. In the **Debug tool window**, proceed as usual: [step through the program](#) , [stop and resume](#) the program execution, [examine it when suspended](#) , [view actual HTML DOM](#) , etc.

## Example

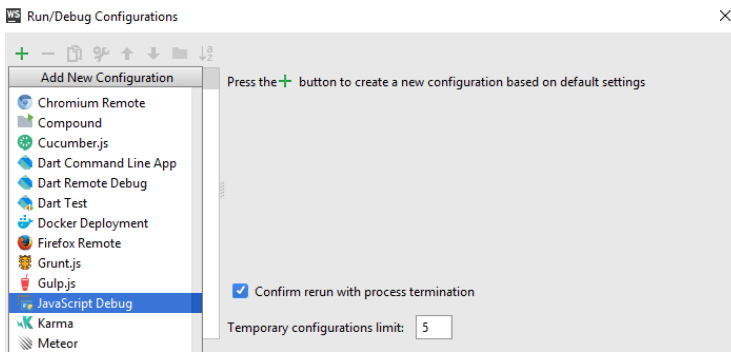

Suppose you have a simple application that consists of an `index.html` file and a `MyJavaScript.js` file, where `index.html` references `MyJavaScript.js` . Let's now deploy our simple application to a local web server, see [Deploying you application](#) . In this example it is Apache:

When using a local web server, such as Nginx or Apache, as in our example, or the web server is on a remote host, you need to create a **Run/Debug configuration** to start the JavaScript debugger. To do that, click the drop-down list at the upper right-hand corner of the IntelliJ IDEA window and choose **Edit Configurations** . Alternatively, choose **Run | Edit Configurations** on the main menu:

In the **Run/Debug Configurations** dialog box that opens, click **+** and choose **JavaScript Debug** from the list:

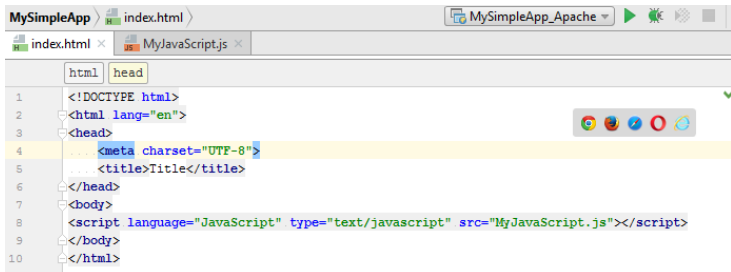

Specify the URL you are running your application at:

In our example, the local project structure and file structure on the server are the same so no mappings are required.

Now we can start debugging: choose the new run/debug configuration from the drop-down list in the upper right-hand corner of the IntelliJ IDEA window, and then click  to the right of the list:

## Configuring mappings

Mappings set correspondence between files on a web server and their local copies.

When do I need mappings?

1. When your application is deployed and running on a remote web server.
2. When you have defined several resource root folders in addition to the project root.

In most cases, IntelliJ IDEA sets path mappings automatically by reusing mappings from the deployment configuration . If your application structure is complicated, additional manual configuration is required.

To configure mappings:

1. Create a debug configuration of the type JavaScript Debug as described in [Debugging an application](#) .
2. In the Remote URLs of local files area, map the files and folders to URL addresses of files and folders on the server according to the currently used deployment configuration , see [Mapping local folders to folders on the server and the URL addresses to access them](#) .

This feature is only supported in the Ultimate edition.

**Tip** Live Edit also works for other file types that contain or generate HTML, CSS, or JavaScript.

IntelliJ IDEA provides a **Live Edit** functionality that lets you preview the changes to your HTML, CSS, or JavaScript code on the fly during a debugging session. The live contents of the page you edit are shown in the `Elements` tab of the **Debug tool window**.

Live Edit works through the **JetBrains Chrome extension** and therefore is available only in [Google Chrome](#).

## Before you start

Install and enable the LiveEdit plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing the JetBrains Chrome Extension

**Tip** When the extension is installed, the `JB` icon is displayed next to the Chrome address bar.

The JetBrains Chrome extension is responsible of **Live Edit** in HTML, CSS, and JavaScript during a debugging session. The extension also shows the **DOM tree** and the source code of the actual page.

To install the JetBrains Chrome extension

1. Open the [JetBrains IDE Support](#) page in **Chrome Web Store**.
2. Click the Add to Chrome button , and then click Add in the Confirm New Extension dialog box that opens. The Add to Chrome button changes to Added to Chrome .

## Activating Live Edit

**Tip** By default, **Live Edit** is disabled.

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click Debugger under Build, Execution, Deployment, and then click Live Edit. The **Live Edit** page opens.
2. Select the Update application in Chrome checkbox. This enables on-the-fly preview of HTML and CSS.
3. To enable **Live Edit** in JavaScript, select the Update on changes checkbox.
4. Set the elapsed time for applying the changes to a running application: accept the default value `300 ms` or specify a custom value using the spin box next to the corresponding field.
5. To configure highlighting, select the Highlight current element in browser on caret change checkbox. Otherwise, during a debugging session, you will have to hold `Shift` and click the element to highlight.
6. To have IntelliJ IDEA restart the server if automatic upload of changes to the client-side code fails, select the Restart if hotswap fails checkbox. See

## Activating, de-activating, and uninstalling JetBrains Chrome extension

Control over the JetBrains Chrome extension is provided through the `chrome://extensions` page:

- To open the page, just type `chrome://extensions` in the Chrome address bar.

Alternatively click Customize and control Google Chrome (  ), choose Settings on the context menu, and then click Extensions on the `chrome://settings` page that opens.

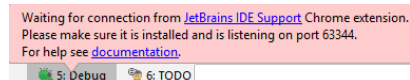

- To deactivate the extension, clear the Enabled checkbox. The checkbox name changes to Enable.
- To activate the extension, select the Enable checkbox.
- To uninstall the extension, click the Remove from Chrome button .

## Changing the default port for connecting to IntelliJ IDEA

During a debugging session with **Live Edit**, the **Chrome extension** listens to the port of the JetBrains IDE from which the extension was invoked. Each IDE including IntelliJ IDEA has its own default port on which it starts.

If for some reason the default IntelliJ IDEA port is already busy, IntelliJ IDEA finds the closest available port and starts on it. This results in a conflict: IntelliJ IDEA is running on a "new" port while the **Chrome extension** still listens to the port of a previously started product.

The conflict reveals when you initiate a debugging session with **Live Edit**: the extension fails to connect through the default port, IntelliJ IDEA waits for connection from the extension and displays the following message with the port number where it is actually running (for example, `current port 63343`):

To fix the problem, specify the actual IntelliJ IDEA port in the Chrome extension options

Right-click  and choose Options on the context menu. A web page with the Chrome extension options opens showing

1. Right-click  and choose Options on the context menu. A web page with the Chrome extension options opens showing the parameters to connect to IntelliJ IDEA.
2. In the IDE Connection area, specify the actual IntelliJ IDEA port in the Port spin box.

## Overriding the default CORS settings

Suppose the page you are debugging with **Live Edit** requests a resource which is, for security reasons, protected against access through [CORS settings](#) . You can enable access to the protected resources by changing the Chrome extension options.

### To override the default CORS settings

1. Right-click  and choose Options on the context menu. A web page with Chrome extension options opens showing the parameters to connect to IntelliJ IDEA.
2. In the Force CORS text box, type the pattern that defines the URL addresses you want to make accessible, for example:  
`http://youtrack.jetbrains.com/rest/*` .

This feature is only supported in the Ultimate edition.

During a debugging session, you can view the HTML source code that implements the actual browser page and its [HTML DOM structure](#) in the Elements tab of the Debug tool window. Moreover, any changes made to the page through the browser are immediately reflected in the Elements tab. To monitor also the changes you make in the editor, install the [JetBrains Chrome extension](#) and enable the [Live Edit](#) functionality as described in [Live Edit in HTML, CSS, and JavaScript](#).

Currently this functionality is supported only for [Google Chrome](#) and only during a debugging session.

#### To view the HTML source and DOM structure of the actual page

1. To start a debugging session, create a run configuration [of the type JavaScript Debug](#) and click  on the toolbar.
2. Switch to the Debug tool window and open the Elements tab. The tab consists of two panes, both of them are read-only.
  - The Text pane shows the HTML source code of the page that is currently opened in the browser. As soon as any change is made to the page in the browser (e.g. clicking an icon), the code in the pane is updated accordingly.
  - The Structure pane shows the DOM structure of the HTML code in the Text pane.

The Structure and the Text panes are mutually synchronized. When you click a node in the DOM structure, IntelliJ IDEA scrolls through the contents of the Text pane. The panes are also synchronized with the browser: as soon as you click a node in the DOM structure or in the Text pane, IntelliJ IDEA highlights the corresponding element in the browser.

3. To view a tree of executed scripts, open the Scripts tab.

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you can debug your client-side JavaScript in Firefox, version 36 and higher, using the Firefox remote debugging functionality. However it is strongly recommended that you use **Chrome** or any other browser of the **Chrome** family.

You can debug an application running on the IntelliJ IDEA built-in web server on an external server.

## Enabling Firefox remote debugging

1. Open your **Firefox** browser, then open Tools | Developer | Toggle Tools .
2. In the Development Tools pane that opens, click Toolbox Options button  on the toolbar and select the Enable remote debugging checkbox under Advanced Settings .

3. Choose Tools | Developer | Developer Toolbar . In the console that opens at the bottom of the browser, type `listen` `<port number>` .

You can set any port number, however it is recommended that you use 6000 and higher. Later you will specify this port number in the run configuration.

## Debugging an application

1. Set the **breakpoints** in the JavaScript code, as required.
2. Create a debug configuration of the type **Firefox Remote** :

Choose Run | Edit Configuration on the main menu, click  on the toolbar and select Firefox Remote from the pop-up list.

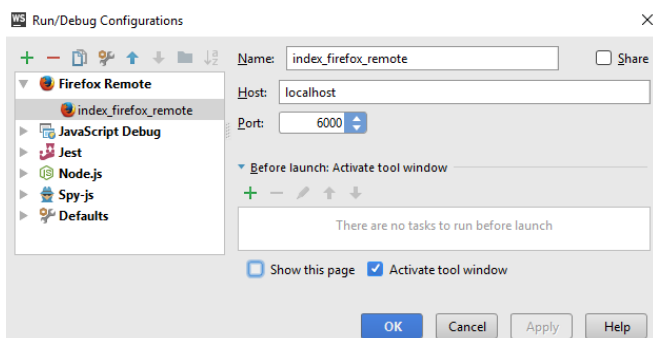

3. In the **Run/Debug Configuration: Firefox Remote** dialog box that opens, type `localhost` in the Host field. In the Port field, type the port that you specified when you **enabled remote debugging in Firefox** . The default value is `6000` .
4. Open your application in Firefox. The browser shows the application after the code execution, that is, the breakpoints you set have no effect yet.
5. Choose the newly created configuration in the Select run/debug configuration drop-down list on the toolbar and click the Debug toolbar button  .
6. In the dialog box that opens, click OK to allow incoming connection from the browser.
7. Refresh the application page in the browser: the page shows the results of code execution up to the first breakpoint.
8. In the Debug tool window, proceed as usual: **step through the program** , **stop and resume** the program execution, **examine it when suspended** , **view actual HTML DOM** , etc.

## Example

Suppose you have a simple application that consists of two files: `index.html` and `index.js` file, where `index.html` references `index.js` . This example shows how you can debug the application when it is running on the IntelliJ IDEA built-in server.

### To start debugging

1. Set the breakpoints in `index.js` .
2. Create a **FireFox Remote** debug configuration, type `localhost` and `6000` in the Host and Port fields respectively:

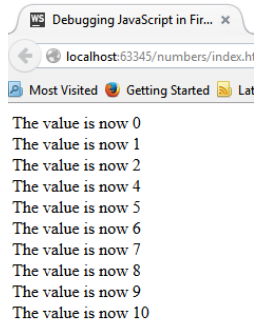

3. Open `index.html` in the editor, choose Open in browser on the context menu, and then choose Firefox from the list:

The browser opens showing the application running on the IntelliJ IDEA port (currently 63345 ):

4. Select the `index_firefox_remote` configuration from the drop-down list on the toolbar and click the Debug toolbar button 

:

Click OK in the Incoming Connection dialog box that opens:

Refresh the application page in the browser.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides basic support of [Flow](#) static type checker that brings type annotations to **JavaScript**. This support involves recognition and syntax highlighting of **Flow** structures on all operating systems.

## Before you start

1. Download and install the [Node.js](#) runtime environment.
2. Configure the Node.js interpreter in IntelliJ IDEA as described in [Configuring a local Node.js interpreter](#).
3. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Flow

**Tip** Learn more from the [Flow Official website](#).

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and at the command prompt, type:

- `npm install --global flow-bin` to install Flow globally.
- `npm install --save-dev flow-bin` to install Flow in the current project.

## Configuring Flow in IntelliJ IDEA

To have IntelliJ IDEA recognize **Flow** structures, provide correct syntax highlighting, report errors properly, and avoid false-positive error highlighting, change the **JavaScript** language level to **Flow**, add a `.flowconfig` configuration file to your project, and supply every file to be checked with a `// @flow` comment on top.

### To change the language level to Flow

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click JavaScript under Languages and Frameworks. The **JavaScript** page opens.
2. From the JavaScript Language Version drop-down list, choose **Flow**.
3. In the Flow package or executable field, specify the path to the `node_modules\flow-bin` package or the Flow binary executable file. To use `node_modules\.bin\flow` make sure the path to Node.js is added to the `PATH` environment variable.
4. In the Use Flow server for: area, specify the basis for coding assistance by selecting or clearing the following checkboxes:
  - Type checking: When this checkbox is selected, syntax and error highlighting is provided based on the data received from the Flow server. When the checkbox is cleared, only the basic internal IntelliJ IDEA highlighting is available.
  - Navigation, code completion, and type hinting: When this checkbox is selected, suggestion lists for reference resolution and code completion contain both suggestions retrieved from integration with Flow and suggestions calculated by IntelliJ IDEA. When the checkbox is cleared, references are resolved through IntelliJ IDEA calculation only.

The checkboxes are available only when the path to the **Flow** executable file is specified.

5. Keep the Save all modified files automatically checkbox selected to ensure that Flow is applied continuously because Flow checks the current files only after all the other modified files are saved.

### To generate a .flowconfig configuration file in your project

open the embedded Terminal (View | Tool Windows | Terminal) and type `flow init` at the command prompt.

### To have a file checked with Flow

Add a `// @flow` comment at the top of it: just type `flow`, press `Tab`, and IntelliJ IDEA will expand it into `// @flow`.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with the [Grunt JavaScript Task Runner](#). IntelliJ IDEA parses `Gruntfile.js` files, recognizing definitions of tasks and targets, lets you build trees of tasks and targets and navigate between a task or a target in the tree and its definition in the `Gruntfile.js` file, and supports running and debugging tasks as well as configuring the task execution mode and output.

With IntelliJ IDEA, you can launch Grunt tasks in the following ways:

- From tasks trees in the dedicated [Grunt tool window](#) which opens when you invoke **Grunt** from a `Gruntfile.js` file. As soon as you invoke **Grunt**, it starts building a tree of tasks according to the `Gruntfile.js` on which it was invoked. If a task has [targets](#), the task is displayed as a node and the targets are listed under it.
- According to a dedicated run configuration, see [Run/Debug Configuration: Grunt.js](#).
- As a before-launch task, from another run configuration.

The result of executing a task is displayed in the [Run tool window](#). The tool window shows the Grunt output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed task is displayed on the title bar of the tool window.

## Before you start

1. Download and install the [Node.js](#) runtime environment.
2. Install and enable the NodeJS plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Grunt

**Tip** You can also install the packages on the [Node.js and NPM page](#) as described in [NPM](#).

To use **Grunt** in a IntelliJ IDEA project, you need two packages:

- A globally installed `grunt-cli` package (Grunt command line interface) for executing Grunt commands.
- A `grunt` package installed in the project to build the project tasks tree and provide coding assistance while editing the `Gruntfile.js` or `Gruntfile.coffee` file. Learn more about `Gruntfile.js` from the [Grunt Official website](#).

To install `grunt-cli` globally

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install -g grunt-cli` at the command prompt.

To install Grunt in a project

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install grunt --save-dev` at the command prompt.

## Running Grunt tasks from the tasks tree

Running Grunt tasks right from the tasks tree is easy and fast, the only disadvantage of this approach is that such important additional options as **force execution** and **verbose mode** are not available in this mode. As a result, you cannot have IntelliJ IDEA, for example, ignore warnings or provide a detailed log.

When you build a tree of tasks for the first time during the current IntelliJ IDEA session, the Grunt tool window is not opened yet.

The task or target execution output will be displayed in the [Run tool window](#). The name of the target is shown in the format `<task name>:<target name>`. The tool window shows the Grunt output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed task is displayed on the title bar of the tool window.

To open the Grunt tool window with a tree of tasks

Select the required `Gruntfile.js` file in the Project tool window or open it in the editor and choose Show Grunt Tasks on the context menu.

To build a tree of tasks from the Grunt tool window

In the Grunt tool window, click  on the toolbar and choose the required `Gruntfile.js` file from the list. IntelliJ IDEA adds a new node and builds a tasks tree under it. The title of the node shows the path to the `Gruntfile.js` file according to which the tree is built.

To re-build a tree

Switch to the required node and click  on the toolbar.

To sort the tasks in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name.

By default, a tree shows the tasks in the order in which they are defined in `Gruntfile.js` (option Definition order).

#### To run a task or a target

Double click the required task or target. Alternatively select it in the tree and press `Enter` or choose Run <task name> on the context menu.

#### To run the default task

Select the root node in the tree, and choose Run default on the context menu of the selection.

#### To run several tasks or targets

Use the multiselect mode: hold `Shift` (for adjacent items) or `Ctrl` (for non-adjacent items) keys and select the required tasks or targets, then choose Run on the context menu of the selection.

#### To navigate to the definition of a task or a target

Select the required task or target in the tree, and choose Jump to source on the context menu of the selection.

## Running and debugging tasks according to a run configuration

Besides using **temporary** run configurations that IntelliJ IDEA creates automatically, you can create and launch your own Grunt.js run configurations.

#### To create a Grunt.js run/debug configuration

1. Choose Run | Edit Configuration on the main menu.
2. Click `+` on the toolbar and select Grunt.js from the pop-up list.
3. In the **Run/Debug Configuration: Grunt.js** dialog box that opens, specify the name of the run configuration, the tasks to run (use blank spaces as separators), the location of the `Gruntfile.js` file to retrieve the definitions of the tasks from, and the path to the `grunt` package installed **locally**, under the project root.  
Specify the location of the Node.js executable file and the Node.js-specific options to be passed to this executable file, see [Node parameters](#) for details.

If applicable, specify the [environment variables](#) for the Node.js executable file.

To have **Grunt** ignore warnings and continue executing the launched task until the task is completed successfully or an error occurs, select the `-f` checkbox. Otherwise, the task execution is stopped by the first reported warning. To have the **verbose** mode applied and thus have a full detailed log of a task execution displayed, select the `--v` checkbox.

#### To run the tasks

Select the newly created run configuration from the list on the main tool bar and `▶` next to the list. IntelliJ IDEA displays the task output in the [Run tool window](#).

#### To debug the tasks

1. Create a **Grunt.js** run/debug configuration [as described above](#).
2. Open the `Gruntfile.js` file in the editor and set the breakpoints in it where necessary.
3. To start a debugging session, select the required debug configuration from the list on the main tool bar and click `⌘` next to the list or choose Run | Debug <configuration name>.
4. In the **Debug tool window** that opens, analyze the suspended task execution, step through the task, etc. as described in [Examining Suspended Program](#) and [Stepping Through the Program](#).

#### To run a Grunt task as a Before-Launch task

1. Open the **Run/Debug Configurations Dialog** dialog by choosing Run | Edit Configurations on the main menu, and select the required configuration from the list or create it anew by clicking `+` and choosing the relevant run configuration type.
2. In the dialog box that opens, click `+` in the Before launch area and choose Run Grunt task from the drop-down list.
3. In the Grunt task dialog box that opens, specify the `Gruntfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Grunt tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `grunt-cli` package.

## Running Grunt tasks automatically

If you have some tasks or targets that you run on a regular basis, you can add the corresponding run configurations to a list of **startup tasks**. The tasks will be executed automatically on the project start-up.

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click Startup Tasks under Tools.
2. On the **Startup Tasks page** that opens, click `+` on the toolbar.
3. From the drop-down list, choose the required **Grunt** run configuration. The configuration is added to the list.  
If no applicable configuration is available in the project, click `+` and choose Edit Configurations. Then define a configuration with the required settings in the **Run/Debug Configuration: Grunt.js** page that opens. When you save the new configuration it is automatically added to the list of startup tasks.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with the [Gulp.js Task Runner](#). IntelliJ IDEA parses `Gulpfile.js` files, recognizing definitions of tasks, lets you build trees of tasks and navigate between a task in the tree and its definition in the `Gulpfile.js` file, and supports running and debugging tasks as well as configuring the task execution mode and output.

`Gulp.js` tasks can be run either from the tasks tree in the dedicated [Gulp Tool Window](#), from the `Gulpfile.js` file, by launching a [Gulp.js run configuration](#), or as a before-launch task from another run configuration.

## Running Gulp.js tasks from the tasks tree

### Before you start

1. Download and install the [Node.js](#) runtime environment.
2. Install and enable the NodeJS plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

### Installing Gulp.js

**Tip** You can also install the packages on the [Node.js](#) and [NPM](#) page as described in [NPM](#).

To use `Gulp` in a IntelliJ IDEA project, you need two packages:

- A globally installed `gulp-cli` package (Gulp command line interface) for executing Gulp commands.
- A `gulp` package installed in the project to build the project tasks tree and provide coding assistance while editing the `Gulpfile.js` file. Learn more about `Gulpfile.js` from the [Gulp.js Official website](#).

#### To install gulp-cli globally

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install --g gulp-cli` at the command prompt.

#### To install Gulp.js in a project

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install gulp --save-dev` at the command prompt.

### Running Gulp.js tasks from the tasks tree

`Gulp.js` starts building a **tasks tree** as soon as you invoke `Gulp.js` by choosing Show Gulp Tasks on the context menu of a `Gulpfile.js` in the Project tool window or of a `Gulpfile.js` opened in the editor. The tree is built according to the `Gulpfile.js` file on which `Gulp.js` was invoked. If you have several `Gulpfile.js` files in your project, you can build a separate tasks tree for each of them and run tasks without abandoning the previously built tasks trees. Each tree is shown under a separate node.

Technically, IntelliJ IDEA invokes `Gulp.js` and processes `Gulpfile.js` according to the [default Gulp.js run configuration](#). However this is done silently and does not require any steps from your side.

The task execution output will be displayed in the [Run tool window](#). The tool window shows the Gulp.js output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed task is displayed on the title bar of the tool window.

## Building a tasks tree

- If the Gulp tool window is not opened yet:

Select the required `Gulpfile.js` file in the Project tool window or open it in the editor and choose Show Gulp Tasks on the context menu.

In either case, the Gulp tool window opens showing the tasks tree built according to the selected or opened `Gulpfile.js` file.

- In the Gulp tool window, click  on the toolbar and choose the required `Gulpfile.js` file from the list. IntelliJ IDEA adds a new node and builds a tasks tree under it. The title of the node shows the path to the `Gulpfile.js` file according to which the tree is built.
- To re-build a tree, switch to the required node and click  on the toolbar.

#### To sort the tasks in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name.

By default, a tree shows the tasks in the order in which they are defined in `Gulpfile.js` (option Definition order).

If your `Gulpfile.js` is written in [ECMA6](#), by default IntelliJ IDEA does not recognize this format and fails to build a tasks tree. To solve this problem, update the [default Gulp.js run configuration](#):

1. Choose Run | Edit Configuration on the main menu.

- Under the Defaults node, click Gulp.js .
- In the [Run/Debug Configuration: Gulp.js](#) dialog box that opens, type `--harmony` in the Node options text box and click OK .

## Running a task

### – To run a task

Double click the required task. Alternatively select it in the tree and press `Enter` or choose Run <task name> on the context menu.

### To run the default task

Select the root node in the tree, and choose Run default on the context menu of the selection.

### To run several tasks

Use the multiselect mode: hold `Shift` (for adjacent items) or `Ctrl` (for non-adjacent items) keys and select the required tasks, then choose Run on the context menu of the selection.

### To navigate to the definition of a task

Select the required task in the tree, and choose Jump to source on the context menu of the selection.

## Running tasks from Gulpfile.js

You can run tasks right from the `Gulpfile.js` file opened in the editor without previously building a tree of tasks.

### To run tasks from Gulpfile.js, do one of the following

- Position the cursor at the definition of the task to run and choose Run <task name> on the context menu of the selection.  
IntelliJ IDEA creates and launches a **temporary** run configuration with the name of the selected task.  
  
The task execution output will be displayed in the [Run tool window](#) . The tool window shows the Gulp.js output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed task is displayed on the title bar of the tool window.
- To save an automatically created temporary run configuration, position the cursor at the definition of the task for which it was created and choose Save <task name> on the context menu of the selection.

## Running and debugging tasks according to a run configuration

Besides using **temporary** run configurations that IntelliJ IDEA creates automatically, you can create and launch your own **Gulp.js** run configurations.

### Creating a Gulp.js run configuration

- Choose Run | Edit Configuration on the main menu.
- Click `+` on the toolbar and select Gulp.js from the pop-up list.
- In the [Run/Debug Configuration: Gulp.js](#) dialog box that opens, specify the name of the run configuration, the tasks to run (use blank spaces as separators), the location of the `Gulpfile.js` file to retrieve the definitions of the tasks from, and the path to the `Gulp` package installed **locally**, under the project root.  
Specify the location of the Node.js executable file and the Node.js-specific options to be passed to this executable file, see [Node parameters](#) for details.

If applicable, specify the [environment variables](#) for the Node.js executable file.

If applicable, in the Arguments field, specify the arguments for tasks to be executed with. Use the following format:

```
--<parameter_name> <parameter_value>
```

For example: `--env development` .

For details about passing task arguments, see <https://github.com/gulpjs/gulp/blob/master/docs/recipes/passing-arguments-from-cli.md>

### Running a task according to a run configuration

- Select the run configuration from the list on the main tool bar and then choose Run | Run <configuration name>

on the main menu or click the Run toolbar button  . The output is displayed in the [Run tool window](#) .

## Debugging Gulp tasks

1. Create a [Gulp.js](#) run/debug configuration [as described above](#) .
2. Open the `Gulpfile.js` file in the editor and set the breakpoints in it where necessary.
3. To start a debugging session, select the required debug configuration from the list on the main tool bar and click  next to the list or choose Run | Debug <configuration name> .
4. In the [Debug tool window](#) that opens, analyze the suspended task execution, step through the task, etc. as described in [Examining Suspended Program](#) and [Stepping Through the Program](#) .

## Running a Gulp task as a Before-Launch task

1. Open the [Run/Debug Configurations Dialog](#) dialog by choosing Run | Edit Configurations on the main menu, and select the required configuration from the list or create it anew by clicking  and choosing the relevant run configuration type.
2. In the dialog box that opens, click  in the Before launch area and choose Run Gulp task from the drop-down list.
3. In the Gulp task dialog box that opens, specify the `Gulpfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Gulp tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `gulp` package.

## Running Gulp.js tasks automatically

If you have some tasks that you run on a regular basis, you can add the corresponding run configurations to a list of **startup tasks** . The tasks will be executed automatically on the project start-up.

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Startup Tasks under Tools .
2. On the [Startup Tasks page](#) that opens, click  on the toolbar.
3. From the drop-down list, choose the required [Gulp.js](#) run configuration. The configuration is added to the list.  
If no applicable configuration is available in the project, click  and choose Edit Configurations . Then define a configuration with the required settings in the [Run/Debug Configuration: Gulp.js](#) page that opens. When you save the new configuration it is automatically added to the list of startup tasks.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA recognizes and provides support for [Handlebars expressions and Mustache templates](#) in dedicated **Handlebars** and **Mustache** files that have the extension `.hbs` or `.mustache` respectively. IntelliJ IDEA distinguishes these file types and processes their contents according to default or custom settings specified on the [Templates page](#) of the Settings/Preferences dialog.

Before you start, install and activate the **Handlebars/Mustache** repository plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Configuring coding assistance for Handlebars expressions and Mustache templates

1. Open the [Templates page](#) ( File | Settings | Languages and Frameworks | JavaScript | Templates for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Templates for macOS). Switch to the Handlebars/Mustache area.
2. Enable or disable tag completion.
  - To have IntelliJ IDEA automatically insert the second closing curly brace ( `}` ) of a **Handlebars expression** as soon as you type the first closing one, select the Automatically insert closing tag checkbox.  
IntelliJ IDEA also recognizes **triple stashes** ( `{{{` ) that prevent escaping values inside expressions. In this case, IntelliJ IDEA automatically inserts two closing curly braces as soon as you type the first closing one.
  - When this check box is cleared, you have to type the closing curly braces and triple stashes manually.
3. To have **Handlebars expressions** and **Mustache templates** automatically reformatted during code generation, refactoring, or reformatting ( `Ctrl+Alt+L` ), select the Enable formatting checkbox.  
If the checkbox is cleared, the original formatting of **Handlebars expressions** and **Mustache templates** is preserved.
4. From the Language for comments drop-down list, select the language to inherit the style for comments from. When you enter a line or block comment by pressing `Ctrl+Slash` or `Ctrl+Shift+Slash`, IntelliJ IDEA inserts the comment delimiters that are used in the chosen language, for example, `{{!--}}` for Handlebars, `/**` for JavaScript, `<!-->` for HTML, etc.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with most popular JavaScript code linters. All these tools register themselves as IntelliJ IDEA code inspections: they check JavaScript code for most common errors and potential problems without running the application. When a tool is activated, it launches automatically on the edited JavaScript file. Problems are highlighted and reported in pop-up information windows, a pop-up window appears when you hover the mouse pointer over a stripe in the Validation sidebar. You can also press `Alt+Enter` to examine errors and apply suggested quick fixes. Learn more about inspections and intention actions at [Code Inspection](#) and [Intention Actions](#).

## JSLint

1. Open the [JSLint page](#) ( File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | JSLint for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | JSLint for macOS).
2. Select the Enable checkbox. After that all the controls on the page become available.
3. Define the set of common mistakes to check the code for. To enable a validation, select the checkbox next to it.

## JSHint

1. Open the [JSHint page](#) ( File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | JSHint for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | JSHint for macOS).
2. Select the Enable checkbox. After that all the controls on the page become available.
3. From the Version drop-down list, choose the version of the tool to apply.  
IntelliJ IDEA comes bundled with **version 2.9.4**, which is used by default. To download another version, choose it from the list.
4. Configure the behaviour of JSHint:
  - To have the code verified according to the rules from a previously created configuration file, select the Use config files checkbox.  
A configuration file is a JSON file with the extension `.jshintrc` that specifies which JSHint options should be enabled or disabled. IntelliJ IDEA will look for a `.jshintrc` file in the working directory. If the search fails, IntelliJ IDEA will search in the parent folder, then again in the parent folder. The process is repeated until IntelliJ IDEA finds a `.jshintrc` or reaches the project root. To have IntelliJ IDEA still run verification when no `.jshintrc` is found in the project, specify the default configuration file to use.
  - To configure verification manually, clear the checkbox and in the Options area select the checkboxes next to the validations you want to enable.

The controls in the area fall into two groups:

- Enforcing options: select the checkboxes in this group to enable very strict behaviour of the verification tool and thus allow only safe JavaScript.
- Relaxing options: select/clear the checkboxes in this area to suppress warnings when certain types of discrepancies are detected.
- Environments: select/clear these checkboxes to specify for which environments you want global properties predefined.

## Closure Linter

Before you start with **Closure Linter**, download and install Python as described on the [Python Official website](#).

1. [Download and install the Closure Linter tool](#).
2. Open the [Closure Linter page](#) ( File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | Closure Linter for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | Closure Linter for macOS).
3. Select the Enable checkbox.
4. Specify the path to the **Closure Linter** executable file:
  - `<Python_home>\Scripts\jslint.exe` for Windows
  - `/usr/local/bin/gjslint` for Linux and macOS
5. Specify the path to the previously created configuration file.

When a configuration file is parsed before the `gjslint` process starts and all the parsed options are passed as arguments to the `gjslint` process, the behaviour of **Closure Linter** may slightly differ depending on whether it is run from IntelliJ IDEA or in the command line mode.

When **Closure Linter** is running inside IntelliJ IDEA, the `gjslint` process is launched in the following way:

```
/path/to/gjslint --flagfile /path/to/config_file --recurse=no /path/to/user_source_file.js
```

Therefore, the following command fails if the configuration file has a space instead of a `=`:

```
--jslint_error indentation
```

## JSCS

## Before you start

1. Install the [Node.js](#) runtime environment and configure it as a Node interpreter as described in [Configuring Node.js Interpreters](#) .
2. Install and enable the [NodeJS](#) repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## To install JSCS globally

1. Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` )
2. Type `npm install jscs -g` at the command prompt.

## To activate and configure JSCS

1. Open the [JSCS page](#) ( File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | JSCS for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | JSCS for macOS).
2. Select the Enable checkbox. After that the controls on the page become available.
3. In the Node Interpreter field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click  and configure a new one as described in [Configuring Node.js Interpreters](#) .
4. In the JSCS Package field, specify the location of the `jscs` package installed in the current project, see [Installing JSCS](#) .
5. Appoint the [configuration](#) to use.

By default, IntelliJ IDEA first looks for a `jscsConfig` property in the `package.json` file of the current project. If no such property is found, IntelliJ IDEA looks for a `.jscsrc` or a `.jscs.json` configuration file. IntelliJ IDEA starts the search from the folder where the file to be checked is stored, then searches in the parent folder, and so on until reaches the project root. Accordingly, you have to define the configuration to apply either as a `jscsConfig` property in the `package.json` file or in a `.jscsrc` or a `.jscs.json` configuration file, or in a custom JSON configuration file.

You can also apply a predefined set of rules, either independently or in combination with a configuration file. In the latter case, the rules from the configuration file override the predefined rules.

- To have IntelliJ IDEA look for a `jscsConfig` property in the `package.json` file or for a `.jscsrc` or a `.jscs.json` file, choose the Search for config(s) option.
  - To use a custom file, choose the Configuration File option and specify the location fo the file in the Path field. Choose the path from the drop-down list, or type it manually, or click the  button and select the relevant file from the dialog box that opens.
  - To have a predefined set or rules applied, choose the desired set from the Code Style Preset drop-down list.
6. If necessary, from the Code Style Preset drop-down list, choose the set of predefined rules associated with the code style you use.

## ESLint

[ESLint](#) brings a wide range of linting rules that can also be extended with plugins. IntelliJ IDEA shows warnings and errors reported by ESLint right in the editor, as you type. You can also use [JavaScript Standard Style](#) with ESLint.

## Before you start

1. Install the [Node.js](#) runtime environment and configure it as a Node interpreter as described in [Configuring Node.js Interpreters](#) .
2. Install and enable the [NodeJS](#) repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## To install ESLint

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and at the command prompt type `npm install eslint --save-dev` or `npm install eslint -g` .

Optionally, install additional plugins, for example, [eslint-plugin-react](#) to lint React applications.

## To activate and configure ESLint

1. Open the [ESLint page](#) ( File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | ESLint for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | ESLint for macOS).
2. Open the [ESLint page](#) ( IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | ESLint ).
3. Select the Enable checkbox. After that the controls on the page become available.
4. In the Node Interpreter field,

specify the Node.js interpreter to use. Choose one of the configured interpreters or click  and configure a new one as described in [Configuring Node.js Interpreters](#).

5. In the ESLint Package field, specify the location of the `eslint` or `standard` package.
6. Appoint the configuration to use.
  - If you choose Automatic search, IntelliJ IDEA looks for a `.eslintrc` file or tries to detect a configuration defined under `eslintConfig` in a `package.json`. IntelliJ IDEA first looks for a `.eslintrc` or `package.json` in the folder with the file to be linted, then in its parent folder, and so on up to the project root. If the search fails, ESLint uses its default embedded configuration file.
  - Choose Configuration File to use a custom file and specify the file location in the Path field.
7. If necessary, in the Extra ESLint Options field, specify additional command line options to run ESLint with using spaces as separators. See [ESLint Command Line Interface Options](#) for details.
8. If necessary, in the Additional Rules Directory field, specify the location of the files with additional code verification rules. These rules will be applied after the rules from `.eslintrc` or the above specified custom configuration file and accordingly will override them.

## Importing Code Style from ESLint

You can import some of the [ESLint code style rules](#) to the IntelliJ IDEA [JavaScript code style settings](#). This integration makes it easier for you to configure the IntelliJ IDEA code formatter so it no longer breaks properly formatted code from the ESLint perspective.

### To import ESLint code style rules

Open an `.eslintrc` JSON file or a `package.json` with the `eslintConfig` field. IntelliJ IDEA shows the question **Apply code style from ESLint?** at the top of the editor. Click Yes to apply the matched rules to the Project code style scheme.

Please note that only the rules that have matching code style settings in IntelliJ IDEA are applied, for example, `indent`, `curly` or `no-trailing-spaces`. Complex object options for these rules are not always applied. Also note that IntelliJ IDEA does not apply rules from the configuration files listed in the `extends` field or rules from plugins.

## JavaScript Standard Style

You can set JavaScript Standard Style as default JavaScript code style for your application so its main rules are applied when you type the code or reformat it. Since Standard is based on ESLint, you can also use Standard via the IntelliJ IDEA ESLint integration. Learn more from [JavaScript Standard Style Official website](#).

### To install JavaScript Standard

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install standard --save-dev` at the command prompt. See also [JavaScript Standard Style: Installation](#).

### To set the JavaScript Standard Style as default

Open the [Code Style. JavaScript](#) page (in the Settings/Preferences dialog (`Ctrl+Alt+S`)), choose Editor | Code Style | JavaScript), click Set from, and then choose Predefined Style | JavaScript Standard Style. The style will replace your current scheme.

### To enable linting with Standard via ESLint

Open the [ESLint](#) page as described above, select the Enable checkbox, and specify the location of the `standard` package in the ESLint Package field.

**TIP** If you open a project where `standard` is listed in the project's `package.json` file, IntelliJ IDEA will enable linting with Standard automatically.

This feature is only supported in the Ultimate edition.

**Tip** To switch between the Documentation pop-up window and the [Documentation tool window](#), press `Ctrl+Q` sequentially.

**Tip** IntelliJ IDEA opens the MDN article in the [default IntelliJ IDEA browser](#).

IntelliJ IDEA lets you get reference for standard JavaScript APIs, for symbols from your project and from its dependencies, as well as for symbols defined in external libraries. The documentation is shown in a Documentation pop-up window that helps navigate to the related symbols via hyperlinks, and provides a toolbar for moving back and forth through the already navigated pages.

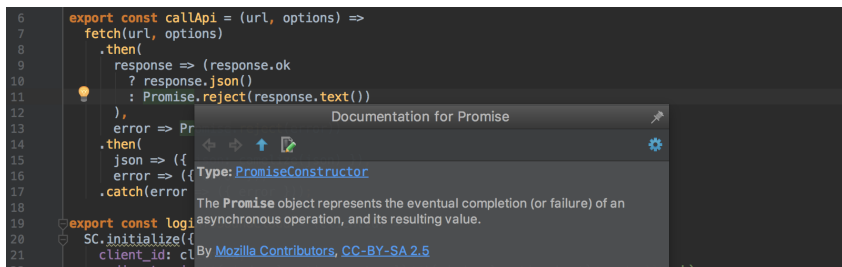

To view documentation for a symbol at caret

Press `Ctrl+Q` or choose View | Quick Documentation Lookup on the main menu. The reference for the symbol is shown in the Documentation pop-up window.

- For a project symbol or for a symbol from the project dependencies, IntelliJ IDEA generates the documentation from the corresponding [JSDoc comment](#).
- For a standard JavaScript object or method, IntelliJ IDEA shows the corresponding JSDoc comment from the built-in [TypeScript definition files](#) (`d.ts`). These files are bundled with IntelliJ IDEA and updated on a regular basis.
- If no comment is found in the `d.ts` files, IntelliJ IDEA shows a summary from the corresponding [MDN article](#).

To view the MDN documentation for a symbol at caret

- In the Documentation window (`Ctrl+Q`), click .

– Alternatively

Press `Shift+F1` or choose View | External Documentation on the main menu.

To view documentation in external JavaScript libraries

1. Download the required libraries or frameworks.
2. [Configure the downloads as libraries](#) at the IntelliJ IDEA level.
3. [Specify links to external documentation](#).
4. Position the cursor at the symbol in question and press `Shift+F1` or choose View | External Documentation on the main menu.

To view reference in a tool window

Pin the Documentation pop-up window. It turns into the [Documentation tool window](#), with the corresponding sidebar icon and more controls.

**Tip** IntelliJ IDEA can show documentation automatically only when you invoke completion explicitly with `Ctrl+Space`.

To show documentation automatically

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click General under Editor, then click Code Completion. The [Code Completion](#) page opens.
2. Select the Auto-display documentation checkbox and specify the elapsed time.

**Tip** See [Zooming in the Editor](#) for details.

To change the font size of quick documentation

- Click  in the upper-right corner of the quick documentation window, and move the slider.
- Alternatively

In the Settings/Preferences dialog (`Ctrl+Alt+S`), click General under Editor and select the Change font size (Zoom) with `Ctrl+Mouse Wheel` checkbox.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides integration with the [Meteor framework](#). Meteor support in IntelliJ IDEA involves:

- Automatic recognition of **Meteor** projects by detecting the `.meteor` folder and excluding the `.meteor/local` folder from project. See [Hiding excluded files](#) for details.
- Attaching the predefined **Meteor** library to the project automatically. This enables syntax highlighting, resolving references, and code completion.
- Support of **Spacebars** via **Handlebars** with completion for `if` and `each` directives. IntelliJ IDEA recognizes **Spacebars** templates, but as a side effect marks HTML files in **Meteor** projects with the **Handlebars/Mustache** icon . IntelliJ IDEA provides navigation between JavaScript source code and templates with [go to Declaration](#) (`Ctrl+B`).
- A dedicated complex **Meteor** run/debug configuration for debugging both the client-side and the server-side code within one debugging session, see [Debugging a Meteor application](#).

## Before you start

Make sure the **Meteor** and the **Handlebars/Mustache** plugins are activated. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

## Installing Meteor

**Tip** macOS 10.6 or higher is required.

The installation procedure depends on the operating system you are using:

- [To install Meteor on Windows](#)

Download the `LaunchMeteor.exe` installer at the [Meteor Official website](#).

- [To install Meteor on macOS or Linux](#)

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `$ curl https://install.meteor.com | /bin/sh` at the command prompt.

Learn more from the [Meteor Official website](#).

## Creating a new Meteor application

If you have no application yet, you can generate a IntelliJ IDEA project with Meteor-specific structure from a Meteor boilerplate template. Alternatively, create an empty IntelliJ IDEA project and configure Meteor support in it as described in [Starting with an existing Meteor application](#) below.

### To create a Meteor project from a boilerplate template

1. Choose `File | New | Project` on the main menu or click the `New Project` button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose `Static Web` in the left-hand pane.
3. In the right-hand pane, choose `Meteor App` and click `Next`.
4. On the second page of the wizard:
  1. Specify the project name and the folder to create it in.
  2. Specify the location of the **Meteor** executable file (see [Installing Meteor](#)).
  3. From the `Template` drop-down list, choose the sample to generate. To have a basic project structure generated, choose the `Default` option.

### To create an empty IntelliJ IDEA project

1. Choose `File | New | Project` on the main menu or click the `New Project` button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose `Static Web` in the left-hand pane.
3. In the right-hand pane, again choose `Static Web` and click `Next`.
4. On the second page of the wizard, specify the project folder and name and click `Finish`.

## Starting with an existing Meteor application

If you are going to continue developing an existing Meteor application, open it in IntelliJ IDEA, configure Meteor in it, and download the required dependencies as described in [Downloading Meteor dependencies](#) below.

### If the application sources are already on your machine

Click `Open` on the Welcome screen or choose `File | Open` on the main menu. In the dialog that opens, select the folder where your sources are stored.

### If the application sources are under version control

1. Click Check out from Version Control on the Welcome screen or choose VCS | Check out from Version Control on the main menu.
2. Select your version control system from the list.
3. In the VCS-specific dialog that opens, type your credentials and the repository to check out the application sources from.

#### To configure Meteor support in an existing project

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), choose JavaScript under Languages and Frameworks , then choose Meteor . The **Meteor** page opens.
2. Specify the path to the **Meteor** executable file. If you followed the standard installation procedure, IntelliJ IDEA detects the file automatically.
3. To involve the `.meteor/local` folder and its contents in indexing, clear the Automatically exclude ".meteor/local" directory on open project checkbox. For details, see [Hiding excluded files](#) below.
4. Make sure the Automatically import Meteor packages as external library checkbox is selected.
  - When the checkbox is selected, IntelliJ IDEA automatically imports the external packages from the `meteor/packages` file. As a result, IntelliJ IDEA provides full range coding assistance: resolves references to **Meteor** built-in functions, for example, `check(true)` , and to functions from third-party packages, provides proper syntax and error highlighting, supports debugging with source maps, etc.
  - When this checkbox is cleared, IntelliJ IDEA does not automatically import the external packages from the `meteor/packages` file. As a result no coding assistance is provided. To improve the situation, open the `meteor/packages` file in the editor and click the Import packages as library link or run the `meteor --update` command.
5. Make sure IntelliJ IDEA has attached the **Meteor** library to the project.

In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), choose JavaScript under Languages and Frameworks , then choose Libraries . On the [JavaScript. Libraries](#) page opens, make sure the checkbox next to the **Meteor** project library in the Libraries list is selected.

## Importing Meteor packages

Besides the predefined **Meteor** library that ensures basic **Meteor** -specific coding assistance, you can download additional [packages](#) that are defined in the `.meteor/local/packages` file.

#### To download additional Meteor packages

1. Open the `.meteor/local/packages` file in the editor.
2. Click the Import Meteor Packages link in the upper right-hand corner of the screen.
3. In the dialog box that opens, specify the packages to download depending on the type of the application you are going to develop in your project.
  - Client
  - Server
  - Cordova: choose this option to import the packages that support development of **Meteor** applications for **iOS** and **Android** , see [Meteor Cordova Phonegap Integration](#) for details.

## Hiding excluded files

the `.meteor/local` folder, which is intended for storing the built application, is automatically marked as **excluded** and is not involved in indexing. By default, **excluded** files are shown in the project tree. To hide the `.meteor/local` folder, click the  button on the toolbar of the Project tool window and remove a tick next to the Show Excluded Files option.

## Running a Meteor application

**Tip** Technically, IntelliJ IDEA creates separate run configurations for the server-side and the client-side code, but you specify all your settings in one dedicated **Meteor** run configuration.

IntelliJ IDEA runs Meteor applications according to a run configuration of the type **Meteor** . If you created your application from a boilerplate template, IntelliJ IDEA generates a **Meteor** run configuration for you.

#### To create a Meteor run configuration

1. On the main menu, choose Run | Edit Configurations , click **+** and choose Meteor from the list. The [Run/Debug Configuration: Meteor](#) opens.
2. In the Configuration tab, specify the path to the Meteor executable file according to the installation (see [Installing Meteor](#) ).
3. Specify the folder under which the application files to run are stored. This folder must have a `.meteor` subfolder in the root so IntelliJ IDEA recognizes your application as a **Meteor project** . By default, the working directory is the project root folder.

#### Optionally

1. In the Program Arguments field, specify the command line additional parameters to be passed to the executable file on start up, if applicable. These can be, for example, `--dev` , `--test` , or `--prod` to indicate the environment in which the application is running ( **development** , **test** , or **production** environments) so different resources are loaded on start up.
2. By default, IntelliJ IDEA shows the application output in the Run tool window. To view the results of the client-side code execution, in the Browser / Live Edit tab select the After Launch checkbox and choose the browser to open from the drop-

down list. In the text box below, specify the URL address to open the application at. The default value is `http://localhost:3000` .

#### To run a Meteor application

1. Select the required run configuration from the list on the main tool bar and then choose Run | Run <configuration name> on the main menu or click the Run toolbar button  .
2. View the application output in the Run tool window or in the browser if you configured the browser to open on application start [as described above](#) .

## Debugging a Meteor application

**Tip** The debugger also pauses at the breakpoints set in the sources stored in the `/packages` folder. This functionality is supported both for the client side and for the server side code.

With IntelliJ IDEA, you can debug both the **client-side** and the **server-side** of **Meteor** JavaScript code within one debugging session. A debugging session is initiated only through a dedicated **Meteor** run configuration.

Technically, several Meteor projects that implement different applications can be combined within one single IntelliJ IDEA project. To run and debug these applications independently, create a separate run configuration for each of them with the relevant working directory. To avoid port conflicts, these run configurations should use different ports. In the Program Arguments field, specify a separate port for each run configuration in the format `--port=<port_number>` .

#### To debug a Meteor application

1. Set the [breakpoints](#) in the code where necessary.
2. Create a Meteor run/debug configuration [as described above](#) . In the Browse / Live Edit tab, select the After launch checkbox, choose Chrome from the list, and select the with JavaScript debugger checkbox.
3. To initiate a debugging session, select the required debug configuration from the list on the main tool bar and click  next to the list or choose Run | Debug <configuration name> . The Debug tool window opens showing two tabs: one for debugging the server-side code marked with  and the other one for debugging the client-side code marked with  .
4. [Explore the suspended program](#) and [step through the program](#) .
5. Optionally, preview the changes to the application on the fly [as described below](#) .

## Previewing changes in the browser

**Tip** If automatic upload still fails, restart the application by clicking  on the toolbar.

During a debugging session, you can preview the changes to your HTML, CSS, or JavaScript code on the fly. The live contents of the page you edit are shown in the `Elements` tab of the [Debug tool window](#) . The update policy depends on which part of your application you are editing.

#### To preview the changes to the client-side code

- Switch to the <Configuration name> JavaScript  tab and click  on the toolbar.
- Alternatively, select the Enable Meteor Hot code push checkbox on the [Meteor](#) page to configure automatic upload of updates. Learn more from the [Meteor Official website](#) .

#### To preview the changes to the server-side code

- Switch to the <Configuration name>  tab and click  on the toolbar.
- Alternatively, configure automatic upload with the [Live Edit](#) functionality as described in [Live Edit in HTML, CSS, and JavaScript](#) . It is recommended that you select the Restart if hotswap fails checkbox on the [Live Edit](#) page, then IntelliJ IDEA will attempt to restart the server when automatic upload fails.

This feature is only supported in the Ultimate edition.

The term **minification** or **compression** in the context of JavaScript means removing all unnecessary characters, such as **spaces** , **new lines** , **comments** without changing the functionality of the source code. At the development and debugging stage, these characters improve the code readability. However at the production stage, they become unnecessary for code execution but only increase the size of code to be transferred.

IntelliJ IDEA integrates with [Closure Compiler](#) , [YUI Compressor](#) , and [UglifyJS](#) , so you can compress your JavaScript application sources on the fly.

## Before you start

1. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#) .
2. If you are going to use YUI Compressor or Closure Compiler, download and install [Java Runtime Environment \(JRE\)](#) :
  - JRE version 1.4 or higher for YUI Compressor.
  - JRE version 7 for Closure Compiler.

## Installing a minification tool

- To install UglifyJS

Open the built-in IntelliJ IDEA Terminal ( View | Tool Windows | Terminal ) and type `npm install uglify-js` or `npm install uglify-js@<version>` . Learn more from [UglifyJS Official website](#) .

- To install YUI Compressor

Follow the instructions on [YUI Compressor Official website](#) .

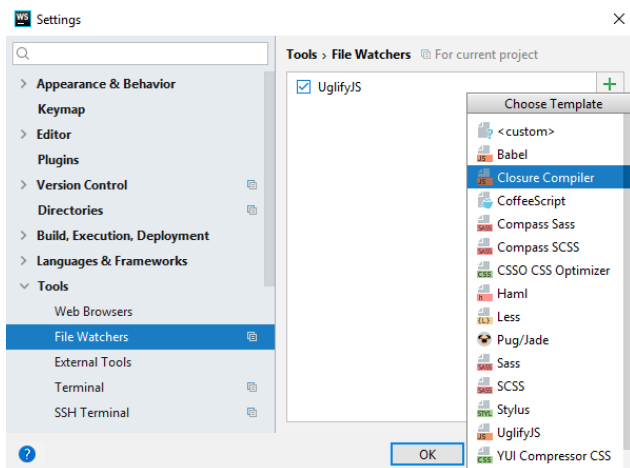

- To install Closure Compiler

Follow the instructions on [Closure Compiler Official website](#) .

## Integrating a minification tool with IntelliJ IDEA

To use a minifier in IntelliJ IDEA, you need to configure it as a [File Watcher](#) . For each supported minifier, IntelliJ IDEA provides a predefined File Watcher template. To run a minifier in your project, create a project-specific File Watcher based on the relevant template.

1. Open the [File Watchers page](#) by choosing File | Settings | Tools | File Watchers for Windows and Linux or IntelliJ IDEA | Preferences | Tools | File Watchers for macOS.
2. Click  and choose the tool-specific File Watcher template from the list:

3. In the [New Watcher Dialog](#) that opens, specify the path to the relevant executable file or `.jar` archive in the Program field:
  - `compiler.jar` for Closure Compiler.
  - `yuicompressor-<version>.jar` for YUI Compressor JS.
  - `uglifyjs.cmd` for UglifyJS.
4. Optionally, [customize the behaviour of the File Watcher](#) .
5. Make sure the checkbox next to the File Watcher is selected, which indicates that the File Watcher is enabled.

## Running a minification tool

When a minification File Watcher is [enabled](#) , minification starts automatically as soon as a JavaScript file in the File Watcher's scope is [changed or saved](#) .

IntelliJ IDEA creates a separate file with the generated output. The file has the name of the source JavaScript file and the extension `min.js` . The location of the generated file is defined in the Output paths to refresh text box of the [New Watcher dialog](#) . However, in the Project Tree , by default it is shown under the source JavaScript file which is now displayed as a node. To change the default presentation, [configure file nesting](#) in the Project tool window.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports visualization of imports and exports within a context both in JavaScript and TypeScript projects.

On this page:

- [Building a module dependency diagram](#)
- [Analyzing a module dependency diagram](#)
- [Navigating from the diagram to the source code](#)

## Building a module dependency diagram

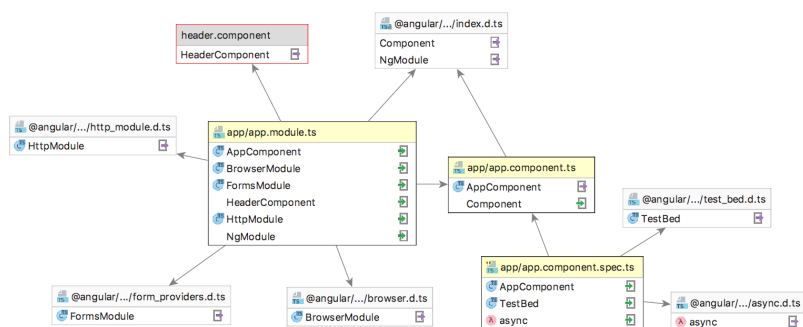

To build a diagram, choose Diagrams | Show Diagram on the context menu of a JavaScript, TypeScript, or HTML file or of a folder.

If the action is invoked on a folder where multiple types of diagrams can be built, additionally choose JavaScript Module Dependency Diagram from the Select Diagram Type pop-up list.

The action is not available on the `node_modules` folders and on folders that are marked as **Excluded**.

## Analyzing a module dependency diagram

IntelliJ IDEA analyzes the `import` and `require` statements and `script` tags in the selected file or in all the files in the selected folder recursively and in a separate tab displays a diagram that shows how these files depend on each other:

- A diagram consists of a number of rectangles. Each of them shows the name of the analyzed selected file and a list of detected imports. If an import is resolved, an icon that indicates the type of the imported symbol (e.g. or ) is shown next to it.
- An arrow from an analyzed file points at the target file from which the detected imports are made. If the target file is a library, its name is displayed on the grey background. If an import from a library is not resolved, the target file is displayed as a grey rectangle with red border.
- Resolved imports and exports are marked with the or icons respectively.

## Navigating from the diagram to the source code

IntelliJ IDEA supports navigation from the diagram:

- To jump from a diagram to a file, right-click the file and choose Jump to source on the context menu.
- To navigate to a specific `import` statement in the source code, right-click the required file in the diagram, choose Jump to on the context menu, and then choose the symbol to jump to from the Select Navigation Target pop-up list:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js and PhoneGap/Cordova plugins are installed and enabled!

In IntelliJ IDEA, you can develop applications intended for running on various mobile platforms, including [Android](#), using the [PhoneGap](#), [Apache Cordova](#), and [Ionic](#) frameworks.

On this page:

- [Before you start](#)
- [Installing PhoneGap/Cordova/Ionic](#)
- [Preparing to use PhoneGap/Cordova/Ionic in a project](#)
  - [Generating a PhoneGap/Cordova/Ionic application stub](#)
  - [Enabling PhoneGap/Cordova/Ionic integration in an existing project](#)
- [Creating and launching a PhoneGap/Cordova/Ionic run configuration](#)

## Before you start

1. Make sure the **PhoneGap/Cordova** and the **NodeJS** plugins are enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
2. Download and install [Node.js](#) because NPM, which is a part of the framework, is also the easiest way to download **PhoneGap** and **Cordova**.
3. Download and install an emulator tool. These tools are specific for the target platform and the operating system you use:
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/ios/index.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/android/index.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/blackberry10/home.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/osx/index.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/ubuntu/index.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/win8/index.html>
  - <http://cordova.apache.org/docs/en/latest/guide/platforms/wp8/home.html>

## Installing PhoneGap/Cordova/Ionic

**Tip** Alternatively, install your package on the [Node.js](#) and [NPM](#) page as described in [NPM](#).

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type one of the following commands at the command prompt:

```
npm install -- global phonegap
npm install -- global cordova
npm install -- global ionic
```

## Preparing to use PhoneGap/Cordova/Ionic in a project

To start your development, you need a IntelliJ IDEA project with the **PhoneGap/Cordova/Ionic** -specific structure. You can have an application stub that meets these requirements generated automatically or open an existing **PhoneGap/Cordova/Ionic** project in IntelliJ IDEA and configure **PhoneGap/Cordova/Ionic** support in it.

## Generating a PhoneGap/Cordova/Ionic application stub

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose PhoneGap/Cordova App and click Next.
4. On the second page of the wizard, specify the project name and the folder to create it in. Specify the location of the executable file `phonegap.cmd`, or `cordova.cmd`, or `ionic.cmd` (see [Installing PhoneGap/Cordova/Ionic](#)).

When you click Finish, IntelliJ IDEA generates a skeleton of a **PhoneGap/Cordova/Ionic** application with the framework-specific structure.

## Enabling PhoneGap/Cordova/Ionic integration in an existing project

1. Open the desired **PhoneGap/Cordova/Ionic** project in IntelliJ IDEA by choosing File | Open on the main menu or clicking Open on the Welcome Screen.
2. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click PhoneGap/Cordova under JavaScript.
3. On the [PhoneGap/Cordova](#) page that opens:
  1. Check the location of the executable file `phonegap.cmd`, or `cordova.cmd`, or `ionic.cmd` or specify the path to it if IntelliJ IDEA has not detected the executable file automatically.  
IntelliJ IDEA detects the installed version and displays it in the PhoneGap/Cordova Version read-only field,

- In the PhoneGap/Cordova Working Directory field, specify the folder under which the PhoneGap/Cordova/Ionic application files to run are stored.
- In the Plugins area, configure a list of plugins to use in your development by installing required packages. The list shows all the PhoneGap/Cordova/Ionic plugins that are currently installed on your computer, both at the global and at the project level.
  - To install a plugin, click the Install button **+**. In the Available Packages dialog box that opens, select the required package.
 

To have the plugin installed globally so it is accessible from all your IntelliJ IDEA projects, select the Options checkbox and type `--global` in the text box. Click Install Package .
  - To remove a plugin, select it in the list and click the Uninstall button **-**.
  - To upgrade a plugin to the latest available version, select the plugin in the list and click the Upgrade button **↕**.

See [Apache Cordova Plugins](#) and [PhoneGap Plugins](#) for information about plugins and their use.

## Creating and launching a PhoneGap/Cordova/Ionic run configuration

PhoneGap/Cordova/Ionic applications are executed according to a dedicated run/debug configuration.

- On the main menu, choose Run | Edit Configurations . In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button **+**, and choose PhoneGap/Cordova on the context menu.
- In the Run/Debug Configuration: PhoneGap/Cordova dialog box that opens, specify the following:
  - The name of the configuration.
  - In the PhoneGap/Cordova Executable Path field, specify the location of the executable file `phonegap.cmd` , `cordova.cmd` , or `ionic.cmd` (see [Installing PhoneGap/Cordova/Ionic](#) ).
  - In the PhoneGap/Cordova Working Directory field, specify the folder under which the PhoneGap/Cordova/Ionic application files to run are stored.
  - From the Command drop-down list, choose the command to run. The contents of the drop-down list, depend on the actually used framework, namely, on the executable file specified in the PhoneGap/Cordova Executable Path field. The available options are:
    - For PhoneGap :
      - emulate
      - run
      - prepare
      - serve
      - remote build
      - remote run

See <https://www.npmjs.org/package/phonegap> for a list of PhoneGap -specific commands with descriptions.
    - For Cordova :
      - emulate
      - run
      - prepare
      - serve

See <https://www.npmjs.org/package/cordova> for a list of Cordova -specific commands with descriptions.
    - For Ionic :
      - emulate
      - run
      - prepare
      - serve

See <https://www.npmjs.org/package/ionic> for a list of Ionic -specific commands with descriptions.
- From the Platform drop-down list, choose the platform for running on which the application is intended. The available options are:
  - Android
  - ios To emulate this platform, you need to install the [ios-sim command line tool](#) globally. You can do it through the Node Package Manager (npm) , see [NPM](#) or by running the `sudo npm install ios-sim -g` command, depending on your operating system.
  - amazon-fireos
  - firefoxos
  - blackberry10
  - ubuntu
  - wp8
  - windows8
  - browser

Learn more about targeted platforms at

[http://docs.phonegap.com/en/edge/guide\\_platforms\\_index.md.html#Platform%20Guides](http://docs.phonegap.com/en/edge/guide_platforms_index.md.html#Platform%20Guides) and

[http://cordova.apache.org/docs/en/4.0.0/guide\\_cli\\_index.md.html#The%20Command-Line%20Interface](http://cordova.apache.org/docs/en/4.0.0/guide_cli_index.md.html#The%20Command-Line%20Interface) .

6. For **Cordova** and **Ionic** , specify the targeted virtual or physical Android device to run the application on: select the Specify Target checkbox and select the required device from the drop-down list. The list shows all the virtual and physical devices that are currently configured on our machine. See

[http://docs.phonegap.com/en/edge/guide\\_platforms\\_android\\_index.md.html#Android%20Platform%20Guide](http://docs.phonegap.com/en/edge/guide_platforms_android_index.md.html#Android%20Platform%20Guide) for details.

If IntelliJ IDEA displays the following error message: **Cannot detect ios-sim in path** , make sure you have installed the `ios-sim` , see Before you start .

3. To run a **PhoneGap/Cordova/Ionic** application, select the required run configuration from the list on the main tool bar and then choose Run | Run <configuration name> on the main menu or click the Run toolbar button  .

This feature is only supported in the Ultimate edition.

## Overview

**React** is a JavaScript library for building complex interactive User Interfaces from encapsulated components. Learn more about the library from [React Official website](#).

IntelliJ IDEA integrates with React providing assistance in configuring, editing, linting, running, debugging, and maintaining your applications.

## Before you start

1. Download, install, and configure [Node.js](#) as described in [Configuring Node.js Interpreters](#).
2. Install and activate the **NodeJS** repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Creating a new React application

- Tip** Alternatively, open the built-in Terminal and type:
1. `create-react-app <application-name>` to create an application.
  2. `cd <application-name>` to switch to the application folder.
  3. `npm start` to start the Node.js server.

You can use the [create-react-app](#) package or create an empty IntelliJ IDEA project and install React in it.

## Generating a React application with create-react-app

[Create React App](#) is the recommended way to start building a new React single page application. As a result, your development environment is preconfigured to use webpack, Babel, ESLint, and other tools.

### To install create-react-app globally

Open the built-in Terminal ( View | Tool Windows | Terminal ) and type `npm install -g create-react-app` at the command prompt.

### To create an application

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, choose React App and click Next.
4. On the second page of the wizard, specify the project name and the folder to create it in. In the Node Interpreter field, specify the Node.js interpreter to use. Choose a configured interpreter from the drop-down list or choose Add to configure a new one, see [Configuring Node.js Interpreters](#). In the create-react-app field, specify the path to the `create-react-app` package.
5. **Optionally:**

Specify a custom package to use instead of [react-scripts](#) during the project generation. This can be one of the packages forked from `react-scripts`, for example, [react-awesome-scripts](#), [custom-react-scripts](#), [react-scripts-ts](#), etc.

6. When you click Finish, IntelliJ IDEA generates a **React**-specific project with all the required configuration files.

Learn more about installing React and creating React applications from [React Official website](#).

**Tip** IntelliJ IDEA guarantees running and debugging Jest tests only with the `react-scripts` package.

## Installing React in an empty IntelliJ IDEA project

**Tip** You can also install the packages on the [Node.js and NPM page](#) as described in [NPM](#).

In this case, you will have to configure the build pipeline yourself as described in [Building a React application](#) below.

### To create an empty IntelliJ IDEA project

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Static Web in the left-hand pane.
3. In the right-hand pane, again choose Static Web and click Next.
4. On the second page of the wizard, specify the project folder and name and click Finish.

### To install React in an empty project

1. Open the empty project where you will use **React**.
2. Open the embedded Terminal ( View | Tool Windows | Terminal ) and type `npm install --save react react-dom`.

Learn more about adding React to a project from [React Official website](#).

## Starting with an existing React application

If you are going to continue developing an existing React application, open it in IntelliJ IDEA and download the required dependencies.

### If the application sources are already on your machine

Click Open on the Welcome screen or choose File | Open on the main menu. In the dialog that opens, select the folder where your sources are stored.

### If the application sources are under version control

1. Click Check out from Version Control on the Welcome screen or choose VCS | Check out from Version Control on the main menu.
2. Select your version control system from the list.
3. In the VCS-specific dialog that opens, type your credentials and the repository to check out the application sources from.

### To download the dependencies

Open the embedded Terminal ( View | Tool Windows | Terminal ) and type `npm install` at the command prompt.

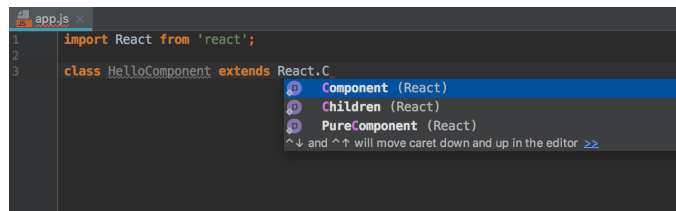

## Completing code

IntelliJ IDEA provides code completion for React APIs and [JSX](#) in JavaScript code. Code completion works for React methods, React-specific attributes, HTML tags and component names, [React events](#), component properties, etc. Learn more from [React Official website](#).

To get code completion for React methods and React-specific attributes, you need to have the `react.js` library file somewhere in your project. Usually the library is already in your `node_modules` folder.

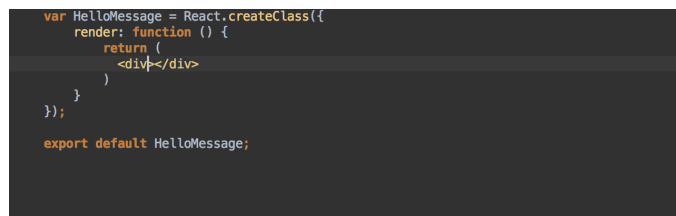

### Completing React methods, attributes, and events

By default, the code completion popup is displayed automatically as you type. For example:

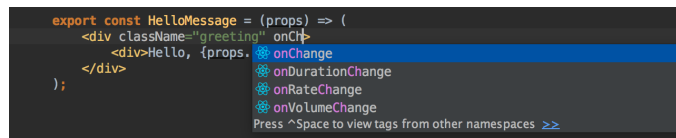

```
app.js
1 import React from 'react';
2
3 class HelloComponent extends React.C
  Component (React)
  Children (React)
  PureComponent (React)
  ^ and ^+ will move caret down and up in the editor >>
```

In JSX tags, IntelliJ IDEA provides coding assistance for [React-specific attributes](#), such as `className` or `classID`, and [non-DOM attributes](#), such as `key` or `ref`. Moreover, autocompletion also works for names of classes defined in the project's CSS files:

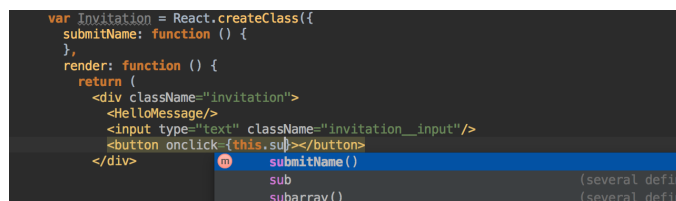

```
var HelloMessage = React.createClass({
  render: function () {
    return (
      <div></div>
    )
  }
});
export default HelloMessage;
```

All [React events](#), such as `onClick` or `onChange`, can also be completed automatically together with curly braces (`{=}`):

```
export const HelloMessage = (props) => (
  <div className="greeting" onClick=
  <div>Hello, {props. onChange
  </div>
);
  onDurationChange
  onRateChange
  onVolumeChange
  Press ^Space to view tags from other namespaces >>
```

Completion also works for JavaScript expressions inside curly braces. This applies to all the methods and functions that you have defined:

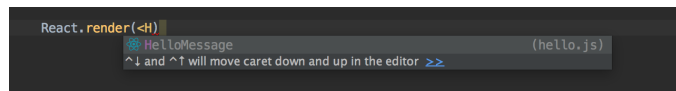

```
var Invitation = React.createClass({
  submitName: function () {
  },
  render: function () {
    return (
      <div className="invitation">
        <HelloMessage/>
        <input type="text" className="invitation_input"/>
        <button onClick={this.sub}></button>
      </div>
    );
  }
});
```

### Completing HTML tags and component names

IntelliJ IDEA provides code completion for HTML tags and component names that you have defined inside methods in

JavaScript or inside other components:

```
React.render(<H
  HelloMessage (hello.js)
  ^↓ and ^↑ will move caret down and up in the editor >>
```

Completion also works for imported components with ES6 style syntax:

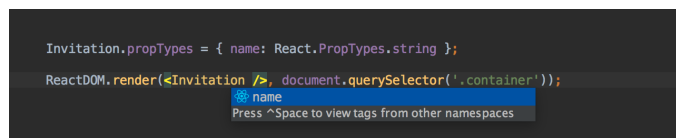

```
import HelloMessage from './hello.js';

var Invitation = React.createClass({
  render: function() {
    return (
      <div>
        <H
        HelloMessage (hello.js)
        ^↓ and ^↑ will move caret down and up in the editor >>
      </div>
    );
  }
});
```

### Completing component properties

IntelliJ IDEA provides code completion for component properties defined using `propTypes` and resolves them so you can quickly jump or preview their definitions:

```
Invitation.propTypes = { name: React.PropTypes.string };

ReactDOM.render(<Invitation />, document.querySelector('.container'));

name
Press ^Space to view tags from other namespaces
```

When you autocomplete the name of a component, IntelliJ IDEA adds all its required properties automatically. If some of the required properties are missing in the usage of a component, IntelliJ IDEA warns you about that.

### Using Emmet in JSX

With IntelliJ IDEA, you can use [Emmet](#) not only in HTML but also in your JSX code taking advantage of some special React twists. For example, the abbreviation `div.my-class` expands in JSX to `<div className="my-class"></div>` but not to `<div class="my-class"></div>` as it would in HTML:

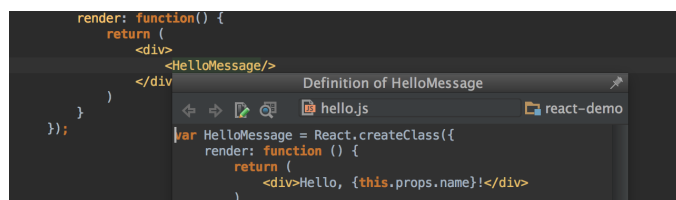

```
import HelloMessage from './hello.js';

var Invitation = React.createClass({
  submitName: function () {
  },
  render: function () {
    return |
  }
});
```

### Navigating through a React application

Besides the [basic navigation](#), IntelliJ IDEA helps you jump between React-specific code elements.

- To jump to the definition of a method or a JavaScript expression inside curly braces `{ }`, select the method or expression and press `Ctrl+B`.
- To jump to the definition of a component, select the component name and press `Ctrl+B`.
- To view documentation for a component, press `Ctrl+Shift+I`.

```
render: function() {
  return (
    <div>
      <HelloMessage/>
    </div>
  );
}

Definition of HelloMessage
hello.js
var HelloMessage = React.createClass({
  render: function () {
    return (
      <div>Hello, {this.props.name}!</div>
    );
  }
});
```

### Linting a React application

- Tip** To customize the list of inspections, open the Editor | Inspections page of IntelliJ IDEA settings (`Ctrl+Alt+S`), and disable the inspections you don't want to see or change their severity levels.
- Tip** If you created your application with `create-react-app`, your development environment is already preconfigured to use ESLint.
- Tip** Learn more about using ESLint with IntelliJ IDEA from [JavaScript Code Quality Tools: ESLint](#)

All the IntelliJ IDEA built-in [code inspections](#) for JavaScript and HTML also work in JSX code. IntelliJ IDEA alerts you in case of unused variables and functions, missing closing tags, missing statements, and much more:

```

12  render() {
13      var name = this.state.name;
14      return (
15          <div>
16              <div className="invitation">
17                  <HelloMessage name="Katy">/>
18                  <div>Please invite your friend to join:</div>
19                  <input type="text" onChange={this.handleChange} placeholder="Name" />
20              </div>
21              <button>Send invitation
22          </div>
23      )
24  }

```

For some inspections IntelliJ IDEA provides quick-fixes, for example, suggests adding a missing method. To view the quick-fix pop-up, press `Alt+Enter`.

## Using ESLint

Besides providing built-in code inspections, IntelliJ IDEA also integrates with linters, such as [ESLint](#), for JSX code. [ESLint](#) brings a wide range of linting rules that can also be extended with plugins. IntelliJ IDEA shows warnings and errors reported by ESLint right in the editor, as you type. You can also use [JavaScript Standard Style](#) with ESLint.

To have ESLint properly understand React JSX syntax, you need [eslint-plugin-react](#). With this plugin, you are warned, for example, when the display name is not set for a React component, or when some dangerous JSX properties are used:

```

invitation.js
1  import React from 'react';
2  import ReactDOM from 'react-dom';
3  import {HelloMessage} from './hello';
4
5  class Invitation extends React.Component {
6
12
13  handleChange(event) {...}
16

```

### To get started with ESLint in IntelliJ IDEA

1. In the built-in Terminal ( View | Tool Windows | Terminal ), type `npm install --save-dev eslint` and `npm install --save-dev eslint-plugin-react`.
2. Add a ESLint configuration file `.eslintrc` to your project.
3. Open the [ESLint page](#) : in the Settings/Preferences dialog (`Ctrl+Alt+S`), choose Languages and Frameworks | JavaScript | Code Quality Tools | ESLint . Select the Enable checkbox. IntelliJ IDEA will automatically locate ESLint in your project's `node_modules` folder and then use the `.eslintrc` configuration by default.

### Example of .eslintrc structure (ESLint 1.x with react plugin)

- In the `ecmaFeatures` object, add `"jsx" = true`. Here you can also specify additional language features you'd like to use, for example ES6 classes, modules, etc.
- In the `plugins` object, add `react`.
- In the `rules` object, you can list [ESLint built-in rules](#) that you would like to enable, as well as [rules available via the react plugin](#).

```

{
  "parser": "babel-eslint",
  "env": {
    "browser": true
  },
  "ecmaFeatures": {
    "jsx": true
  },
  "plugins": [
    "react"
  ],
  "rules": {
    "semi": 2
  }
}

```

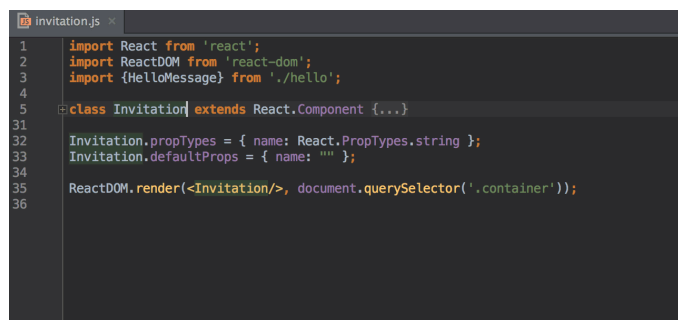

Learn more about ESLint and `react` plugin configuration from [ESLint Official website](#).

## Refactoring a React application

Besides the [common IntelliJ IDEA refactorings](#), in a React application you can also run `Rename` for React components:

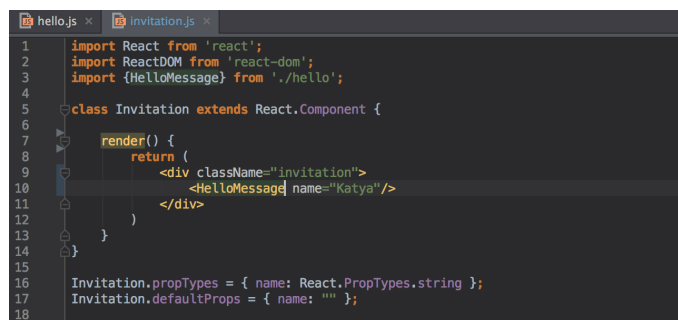

Place the cursor within the component name and press `Shift+F6` . Below is an example of renaming a component that is defined and used in only one file:

```
1 import React from 'react';
2 import ReactDOM from 'react-dom';
3 import {HelloMessage} from './hello';
4
5 class Invitation extends React.Component {...}
6
31
32 Invitation.propTypes = { name: React.PropTypes.string };
33 Invitation.defaultProps = { name: "" };
34
35 ReactDOM.render(<Invitation/>, document.querySelector('.container!'));
36
```

In the same way, you can rename components defined in one file and then imported to another file using a named export:

```
1 import React from 'react';
2 import ReactDOM from 'react-dom';
3 import {HelloMessage} from './hello';
4
5 class Invitation extends React.Component {
6
7   render() {
8     return (
9       <div className="invitation">
10        <HelloMessage name="Katya"/>
11      </div>
12    );
13  }
14 }
15
16 Invitation.propTypes = { name: React.PropTypes.string };
17 Invitation.defaultProps = { name: "" };
18
```

## Running and debugging a React application

**Tip** Only for applications created with `create-react-app` .

**Tip** Only for applications created with `create-react-app` .

The recommended way to start building a new React single page application is [Create React App](#) . Only in this case your development environment is preconfigured to use webpack and Babel. Otherwise, you need to [configure a build pipeline](#) first.

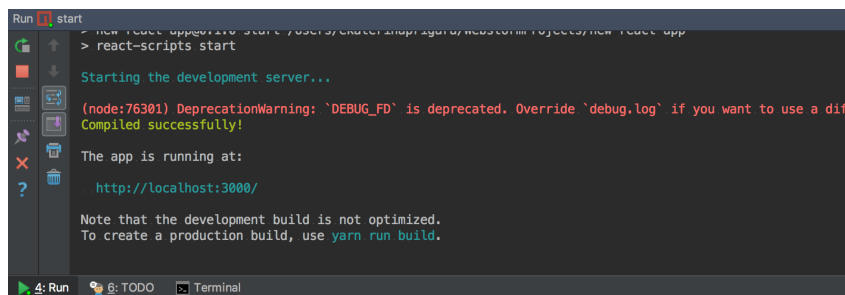

### To run a React application

In the `npm tool window` ( `View | Tool Windows | npm` ), double-click the `start` task. Alternatively, select the task and choose `Run 'start'` on the context menu.

Thanks to the [Webpack Hot Module Replacement](#) , when the development server is running, your application is automatically reloaded as soon as you change any of the source files and save the updates.

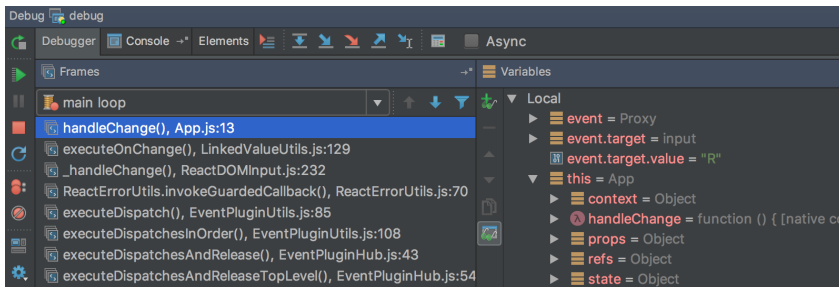

### To debug a React application

1. Start the application in the development mode by double-clicking the `start` task in the `npm tool window`.
2. Wait till the application is compiled and the Webpack development server is ready. Open your browser at `http://localhost:3000/` to view the application.
3. Copy the URL address at which the application is running ( `http://localhost:3000/` by default), you will later need this URL when creating a debug configuration.

```
Run start
> new React app... start /Users/.../react-scripts start
> react-scripts start
Starting the development server...
(node:76381) DeprecationWarning: 'DEBUG_FD' is deprecated. Override 'debug.log' if you want to use a dif
Compiled successfully!
The app is running at:
http://localhost:3000/
Note that the development build is not optimized.
To create a production build, use yarn run build.
```

4. Create a new JavaScript debug configuration: choose `Run | Edit Configurations` , click `+` , and choose `JavaScript Debug` from the list. In the `Run/Debug Configuration: JavaScript Debug` dialog, paste the saved URL ( `http://localhost:3000/` ) in the URL field. Save the configuration.
5. Set the breakpoints in your code and start a debugging session by clicking `🐞` next to the list of configurations.
6. When the first breakpoint is hit, switch to the `Debug Tool Window` and proceed as usual: [step through the program](#) , [stop and resume](#) program execution, [examine it when suspended](#) , explore the call stack and variables, set watches, evaluate variables, [view actual HTML DOM](#) , etc.

## Building a React application

**Tip** If you created your application with [create-react-app](#) your development environment is already preconfigured to use Webpack and Babel.

You need to set up the build process if you [installed React in an existing IntelliJ IDEA project](#). Learn about various ways to configure a build pipeline for your React application from [React Official website](#).

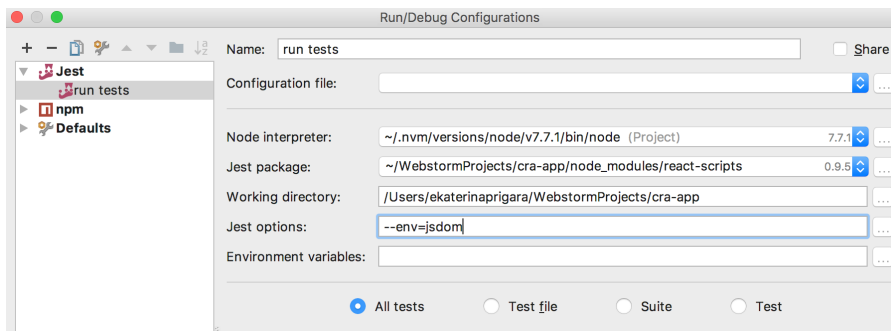

## Testing a React application

You can run and debug [Jest tests](#) in React applications [created with create-react-app](#). Before you start, make sure the `react-scripts` package is added to the `dependencies` object of your `package.json`.

You can run and debug Jest tests via a run/debug configuration, or right from the editor, or from the Project tool window, see [Jest](#) for details.

### To create a Jest run/debug configuration

1. Open the [Run/Debug Configuration](#) dialog box (Run | Edit Configurations on the main menu).
2. Click on the toolbar and select Jest from the list. The [Run/Debug Configuration: Jest](#) dialog box opens.
3. Specify the [Node interpreter](#) to use and the working directory of the application.  
By default, the Working directory field shows the project root folder. To change this predefined setting, specify the path to the desired folder or choose a previously used folder from the list.
4. In the Jest package field, specify the path to the `react-scripts` package.
5. In the Jest options field, type `--env=jsdom`.

### To run tests

1. Select the Jest run/debug configuration from the list on the main toolbar and click to the right of the list.
2. The test server starts automatically without any steps from your side. View and analyze messages from the test server in the Run tool window.
3. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#).

### To debug tests

1. Select the Jest run/debug configuration from the list on the main toolbar and click to the right of the list.
2. In the [Debug Tool Window](#) that opens, proceed as usual: [step through the tests](#), [stop and resume](#) test execution, [examine the test when suspended](#), etc.

**Tip** Alternatively, select a test file in the Project tool window and choose [Create <file name>](#) on the context menu.

## Some known limitations

- When you open an application during a debugging session for the first time, it may happen that some of the breakpoints in the code executed on page load are not hit. The reason is that to stop on a breakpoint in the original source code, IntelliJ IDEA needs to get the source maps from the browser. However the browser can pass these source maps only after the page has been fully loaded at least once. As a workaround, reload the page in the browser yourself.
- If you are using `webpack-dev-server` from Webpack version earlier than 2, it is recommended that you disable the Safe write feature in IntelliJ IDEA. Otherwise the application won't be updated on-time when changed. This issue is fixed in Webpack 2.

This feature is only supported in the Ultimate edition.

[Refactoring](#) means updating the structure of the source code without changing the behaviour of the application. Refactoring helps you keep your code solid, [dry](#), and easy to maintain.

## Move refactorings

Besides [moving files and folders](#), IntelliJ IDEA lets you move JavaScript top-level symbols. The [Move Symbol Refactoring](#) works for classes, functions, and variables in ES6 modules.

To move a class, a function, or a variable

1. Select the symbol to move.
2. Press `F6` or choose Refactor | Move on the context menu or on the main menu.
3. In the dialog box that opens, specify the destination file.

**Tip** Alternatively, choose Refactor | Refactor This or press `Ctrl+Shift+Alt+T`, then choose Move from the list.

In the example below, the function `changeSelectedPlaylists` is moved from the `PlayerActions.js` file to the `PlaylistsActions.js` file. Note that an import statement for the types that `changeSelectedPlaylists` requires is added to `PlaylistsActions.js`. Also all the imports of `changeSelectedPlaylists` in the other files are updated.

## Pull Class Members Up refactoring

The [Pull Class Members Up](#) refactoring moves class methods upwards in the class hierarchy – from the current class to a superclass.

**Example:** moving a class method to a superclass

Suppose you have a class `AccountingDepartment` that extends an abstract class `Department`.

```
class Department {
  name;
  printName() {
    console.log("Department name: " + this.name);
  }
}

class AccountingDepartment extends Department {
  printMeeting() {
    console.log("The Accounting Department meets each Monday at 10am.");
  }
  generateReports() {
    console.log("Generating accounting reports...");
  }
}
```

In this example, the [Pull Class Members Up](#) refactoring moves the `printMeeting()` meeting from `AccountingDepartment` to its superclass `Department`.

```

class Department {
    name;
    printName() {
        console.log("Department name: " + this.name);
    }
    printMeeting() {
        console.log("The Accounting Department meets each Monday at 10am.");
    }
}

class AccountingDepartment extends Department {
    generateReports() {
        console.log("Generating accounting reports...");
    }
}

```

#### To move the methods of a class to a superclass

1. Place the cursor anywhere inside the class from which you want to pull the members up.
2. Choose Refactor | Pull Members Up on the main menu or on the context menu. The Pull Members Up dialog opens.
3. From the drop-down list, choose the superclass where you want to move the methods.
4. To pull a method up, select the checkbox next to it in the Members to be pulled up list.

## Rename refactorings

Besides [Renaming files and folders](#) , which is available in the context of any language, you can also rename classes, functions, variables, and parameters. IntelliJ IDEA changes the name of the symbol in its declaration and by default all its usages in the current project.

#### To rename a function, a class, or a variable

1. In the editor, select the symbol to rename and press `Shift+F6` or choose Refactor | Rename on the context menu or on the main menu.
2. In the [Rename dialog](#) that opens, type the new name of the symbol.
3. Optionally, select the Search in comments and strings and Search for text occurrences checkboxes to rename the usages of the function or the class in comments, string literals, and text.
4. If necessary, [preview and apply the changes](#) .

#### To rename a parameter

1. Select the parameter in the editor and press `Shift+F6` or choose Refactor | Rename on the context menu or on the main menu.
2. In the text box with red canvas around the selected parameter, type the new parameter name.
3. Press `Enter` to run the refactoring.

## Extract refactorings

IntelliJ IDEA provides various **Extract** refactorings to introduce parameters, variables, constants, fields, methods, and functions. To run any of these refactorings, select the expression to refactor and choose Refactor | Extract | <target> . You can select an entire expression or place the cursor anywhere inside it and IntelliJ IDEA will help you with the selection.

### Extract Parameter

**Tip** See [Extract Parameter example 1](#) above.

**Tip** See [Extract Parameter example 2](#) above.

**Tip** See [Choosing the parameter type \(optional\)](#) below.

**Tip** See [Choosing the parameter type \(required\)](#) below.

Use the **Extract Parameter** refactoring to replace an expression in the calls of a function with a parameter. IntelliJ IDEA will update the declaration and the calls of the function accordingly. The default value of the new parameter can be initialized inside the function body or passed through function calls.

Suppose you have a piece of code with a hardcoded `1` in the function `calculate_sum(i)` . With the Extract Parameter refactoring, you can replace this hardcoded `1` with a `i2` parameter. The new `i2` parameter can be extracted as **optional** or as **required** .

#### Example 1: Extracting an optional parameter

A new parameter `i2` is extracted as an optional parameter. The new parameter is initialized in the body of `calculate_sum(i)` and the call of `calculate_sum(i)` in `show_sum()` is not changed.

```
function calculate_sum(i) {
    alert('Adding ' + 1 + ' to ' + i);
    return 1 + i;
}

function show_sum() {
    alert('Result: ' + calculate_sum(5));
}

function calculate_sum(i, i2) {
    i2 = i2 || 1;
    alert('Adding ' + i2 + ' to ' + i);
    return i2 + i;
}

function show_sum() {
    alert('Result: ' + calculate_sum(5));
}
```

### Example 2: Extracting a required parameter

A new parameter `i2` is extracted as a required parameter, the call of `calculate_sum(i)` in `show_sum()` is changed accordingly.

```
function calculate_sum(i) {
    alert('Adding ' + 1 + ' to ' + i);
    return 1 + i;
}

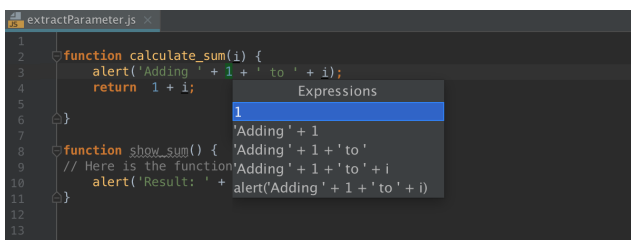

function show_sum() {
    alert('Result: ' + calculate_sum(5));
}

function calculate_sum(i, i2) {
    alert('Adding ' + i2 + ' to ' + i);
    return i2 + i;
}

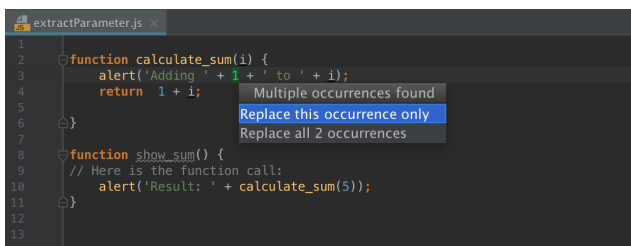

function show_sum() {
    alert('Result: ' + calculate_sum(5, 1));
}
```

### To extract a parameter

1. In the editor, place the cursor within the expression that you want to convert into a parameter and press `Ctrl+Alt+P` or choose Refactor | Extract | Parameter on the context menu or on the main menu.
2. If several expressions are detected in the current cursor location, select the required one in the Expressions list.

3. If more than one occurrence of the selected expression is found, choose Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu.

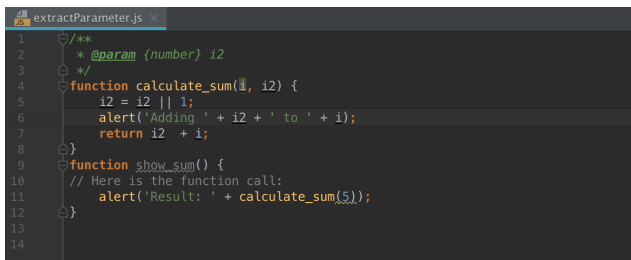

Finally, the pop-up window for configuring the refactoring appears.

4. Select the Generate JSDoc to have a JSDoc comment block generated. This may be helpful if you need to specify a custom default parameter value. Learn more from the [JSDoc Official website](#).
5. Choose the type of the new parameter (**optional** or **required**) and specify its default value, if applicable:
  - If the Optional parameter checkbox is selected, the parameter will be initialized with the default value in the function body.
  - If the Optional parameter checkbox is cleared, the default parameter value will be passed through the existing function calls. All the function calls will change according to the new function signature and a parameter initialization will be added to the function body.

Initially, IntelliJ IDEA accepts the expression where the refactoring is invoked as the default value. In most cases you do not need to change it. If it is still necessary, specify another default value in the JSDoc comment in the format `@param <parameter name> - <default value>` .

- Accept one of the suggested parameter names by double-clicking it in the pop-up list or specify a custom name in the text box with red canvas. Press `Enter` when ready.

```
1  /*+
2  * @param {number} i2
3  */
4  function calculate_sum(i, i2) {
5      i2 = i2 || 1;
6      alert("Adding " + i2 + " to " + i);
7      return i2 + i;
8  }
9  function show_sum() {
10     // Here is the function call:
11     alert("Result: " + calculate_sum(5));
12 }
13
14
```

Also note that in the ES6 code, the new default function parameter syntax `function calculate_sum(i, i2 = 1)` will be applied instead of `i2 = i2 || 1;` . Learn more about default function parameters from the [https://developer.mozilla.org website](https://developer.mozilla.org/website) .

### Choosing the refactoring mode

You can extract a parameter right in the editor (in the in-place mode) as described above or use the Extract Parameter dialog . These two approaches are rather similar, the difference is as follows:

- [Previewing the results of the refactoring](#) .

In the dialog box, you can click Preview and examine the expected changes in the dedicated tab of the Find tool window. In the in-place mode, this functionality is not available.

- [Specifying the default parameter value](#) .

In the dialog box, IntelliJ IDEA suggests the default parameter value in the Value field where you can accept the suggestion or specify another value. In the in-place mode, IntelliJ IDEA treats the expression where the refactoring is invoked as the default parameter value. To specify another value, you have to use a JSDoc comment block.

By default, IntelliJ IDEA runs the Extract Parameter refactoring in the in-place mode. To use the Extract Parameter dialog box, open the Settings/Preferences dialog (`Ctrl+Alt+S`) and click Editor | General . On the [General page](#) that opens, clear the Enable in-place mode checkbox in the Refactorings area.

## Extract Variable

Use the **Extract Variable** refactoring to replace an expression with a [function-scoped variable \(var\)](#) , a [block-scoped variable \(let\)](#) , or a [constant](#) . This refactoring makes your source code easier to read and maintain. It also helps you avoid using hardcoded constants without any explanations about their values or purposes.

Suppose you have a function with a partially hardcoded expression in the `return` statement:

```
Parenizor.method('toString', function () {
    return '(' + this.getValue() + ')';
})
```

With the Extract Variable refactoring, you can replace the `'(' + this.getValue() + ')'` expression with a variable, for example, `string` . The scope of the extracted variable depends on the statement used in its declaration (`var` or `let`) and the context in which the new variable is declared (inside or outside a function).

### Example 1: Extracting a block-scoped variable with a let statement declaration

A variable `string` is extracted from the `'(' + this.getValue() + ')'` expression in the `return` statement. The new variable is declared with a `let` statement inside `Parenizor.method('toString', function ())` .

<pre>Parenizor.method('toString', function () {     return '(' + this.getValue() + ')'; })</pre>	<pre>Parenizor.method('toString', function () {     let string = '(' + this.getValue() + ')';     return string; })</pre>
--	---

### Example 2: Extracting a variable and declaring it outside any function

A variable `appName` is extracted from the `navigator.appName` expression and declared with a `var` statement outside any function.

```

var browserName = "N/A";
if (navigator.appName.indexOf("Netscape") != -1) {
    browserName = "NS";
} else if (navigator.appName.indexOf("Microsoft") != -1) {
    browserName = "MSIE";
} else if (navigator.appName.indexOf("Opera") != -1) {
    browserName = "O";
}

```

```

var browserName = "N/A";
var appName = navigator.appName;
if (appName.indexOf("Netscape") != -1) {
    browserName = "NS";
} else if (appName.indexOf("Microsoft") != -1) {
    browserName = "MSIE";
} else if (appName.indexOf("Opera") != -1) {
    browserName = "O";
}

```

1. In the editor, select the expression to convert into a variable and press **Ctrl+Alt+S** or choose **Refactor | Extract | Variable on the context menu or on the main menu.**

2. If several expressions are detected in the current cursor location, select the required one in the Expressions list.

3. If more than one occurrence of the selected expression is found, choose Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu.

Finally, the pop-up window for configuring the refactoring appears.

4. In the pop-up menu, choose the statement to use in the declaration of the new variable:

- Choose var to introduce a [function-scoped variable](#).
- Choose let to introduce a [block-scoped variable](#), see [Example 2](#) above.
- Choose const to introduce a [constant](#).

5. Accept one of the suggested variable names by double-clicking it in the pop-up list or specify a custom name in the text box. Press **Enter** when ready.

### Choosing the refactoring mode

You can extract a variable right in the editor (in the in-place mode) [as described above](#) or use the Extract Variable dialog. By default, IntelliJ IDEA runs the Extract Variable refactoring in the in-place mode. To use the Extract Variable dialog box, open the Settings/Preferences dialog (**Ctrl+Alt+S**) and click Editor | General. On the [General page](#) that opens, clear the Enable in-place mode checkbox in the Refactorings area.

### Extract Field

**Tip** This refactoring is available only within classes.

The **Extract Field** refactoring declares a new field and initializes it with the selected expression. The original expression is replaced with the usage of the field.

In the examples below, the same field, `_calcArea`, is extracted. The examples illustrate three different ways to initialize the extracted field.

**Example 1:** The extracted field is initialized in the enclosing method

```

class Rectangle {
    constructor(height, width) {
        this.height = height;
        this.width = width;
    }

    get area() {
        return this.calcArea();
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

```

class Rectangle {
    constructor(height, width) {
        this.height = height;
        this.width = width;
    }

    _calcArea;

    get area() {
        this._calcArea = this.calcArea();
        return this._calcArea;
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

Example 2: The extracted field is initialized in its declaration

```

class Rectangle {
    constructor(height, width) {
        this.height = height;
        this.width = width;
    }

    get area() {
        return this.calcArea();
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

```

class Rectangle {
    constructor(height, width) {
        this.height = height;
        this.width = width;
    }

    _calcArea = this.calcArea();

    get area() {
        return this._calcArea;
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

Example 3: The extracted field is initialized in the constructor of the class

```

class Rectangle {
    constructor(height, width) {
        this.height = height;
        this.width = width;
    }

    get area() {
        return this.calcArea();
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

```

class Rectangle {
    constructor(height, width) {
        this._calcArea = this.calcArea();
        this.height = height;
        this.width = width;
    }

    _calcArea;

    get area() {
        return this._calcArea;
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

#### To extract a field

1. In the editor, select the expression to convert into a field and press `Ctrl+Alt+F` or choose Refactor | Extract | Field on the context menu or on the main menu. The [Extract Field Dialog](#) opens.
2. Accept one of the suggested names from the list or type a custom one.
3. Choose where the new field will be initialized:
  - Current method , see [Example 1](#) above.
  - Field declaration , see [Example 2](#) above.
  - Class constructor , see [Example 3](#) above.

## Extract Method

**Tip** The selected code fragment can be a set of statements or an expression used somewhere in the code.

The **Extract Method** refactoring lets you create a named method or function with the extracted code. When the **Extract Method** refactoring is invoked, IntelliJ IDEA detects the variables that are the input for the selected code fragment and the variable that is the output for it. The detected output variable is used as the return value for the extracted method or function.

In the examples below, a function is extracted from the `c = a + b;` expression.

### Example 1: Extracting a globally scoped function from an expression inside another function

The `c = a + b;` expression, where the refactoring is invoked, is inside the `MyFunction()` function. The global destination scope is chosen.

#### Example 1.1: A function declaration is generated

<pre>function MyFunction(a,b) {   c = a + b;   return (c * c); } result = MyFunction(4,6); document.write(result);</pre>	<pre>function extracted(a, b) {   c = a + b; }  function MyFunction(a,b) {   extracted(a, b);   return (c * c); } result = MyFunction(4,6); document.write(result);</pre>
--	---

### Example 1.2: The extracted function is declared inside an expression

<pre>function MyFunction(a,b) {   c = a + b;   return (c * c); } result = MyFunction(4,6); document.write(result);</pre>	<pre>let extracted = function (a, b) {   c = a + b; };  function MyFunction(a,b) {   extracted(a, b);   return (c * c); } result = MyFunction(4,6); document.write(result);</pre>
--	---

### Example 2: Extracting a globally scoped function from an expression outside any function

The `c = a + b;` expression, where the refactoring is invoked, is outside any function. Therefore no choice of the destination scope is available.

#### Example 2.1: A function declaration is generated

<pre>c = a + b;</pre>	<pre>function extracted() {   c = a + b; }  extracted();</pre>
-----------------------	--

### Example 2.2: The extracted function is declared inside an expression

<pre>c = a + b;</pre>	<pre>let extracted = function () {   c = a + b; };  extracted();</pre>
-----------------------	--

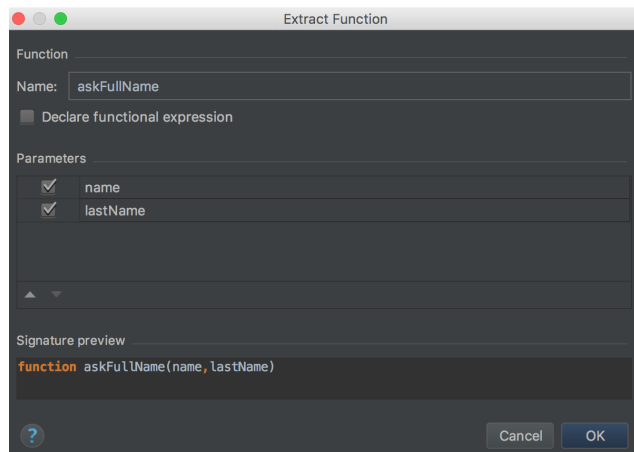

### Example 3: Extracting a function with a definition inside the enclosing function

The `c = a + b;` expression, where the refactoring is invoked, is inside the `MyFunction()` function. The function `MyFunction` destination scope is chosen.

```
function MyFunction(a,b) {
  c = a + b;
  return (c * c);
}
result = MyFunction(4,6);
document.write(result);
```

```
function MyFunction(a,b) {
  function extracted() {
    c = a + b;
  }

  extracted();
  return (c * c);
}
result = MyFunction(4,6);
document.write(result);
```

#### To extract a function

1. In the editor, select a code fragment to convert into a function and press `Ctrl+Alt+M` or choose Refactor | Extract | Method on the context menu or on the main menu.
2. If the selected expression is inside a function, choose the destination scope from the pop-up list:
  - If you choose global, the extracted function will be declared outside any function. See [Example 1](#) above.
  - To define the extracted function inside the current enclosing function, choose function <current enclosing function name>. See [Example 3](#) above.
3. In the [Extract Function](#) dialog box that opens, specify the name of the new function.
4. Choose how the function will be declared. By default, the Declare functional expression checkbox is cleared and IntelliJ IDEA generates a [function declaration](#). See [Example 1.1](#) and [Example 2.1](#) above.

[To declare the extracted function inside an expression](#), select the Declare functional expression checkbox. See [Example 1.2](#) and [Example 2.2](#) above.

5. When extracting a [globally scoped function](#), configure the set of variables to be passed as parameters. By default, all the variables from the specified scope are listed in the Parameters area.
  - To have a variable included in the parameter set, select the checkbox next to it.
  - To change the order of parameters, use the Move Up and Move Down buttons.
6. In the Signature preview read-only area, check the declaration of the new function.

## Inline refactorings

Inline refactorings are opposite to [Extract refactorings](#).

### Example 1: Inline Variable

The **Inline Variable** refactoring replaces a redundant usage of a variable or a constant with its initializer. This type of refactoring is available only for block-scoped and function-scoped variables.

```
Parenizor.method('toString', function () {
  var string = '(' + this.getValue() + ')';
  return string;
})
```

```
Parenizor.method('toString', function () {
  return '(' + this.getValue() + ')';
})
```

### Example 2: Inline Function

The **Inline Method / Inline Function** refactoring results in placing the body of a method or a function into the body of its caller(s); the method/function itself is deleted.

In the example below, the body of `Sum()` is placed in the body of `Multiplication()` and `Division()` .

```
function Sum(a, b) {
  return a + b;
}

function Multiplication(a, b) {
  c = Sum(a, b);
  d = c * c;
  return d;
}

function Division(a, b) {
  c = Sum(a, b);
  d = Multiplication(a, b);
  result = c / d;
  return result;
}

function Multiplication(a, b) {
  c = a + b;
  d = c * c;
  return d;
}

function Division(a, b) {
  c = a + b;
  d = Multiplication(a, b);
  result = c / d;
  return result;
}
```

To run an **Inline refactoring**:

1. In the editor, place the cursor at the symbol to be inlined and press `Ctrl+Alt+N` or choose Refactor | Inline on the context menu or on the main menu.

## Change Signature refactoring

**Tip** You can also add a parameter using the [Extract Parameter](#) refactoring.

**Tip** To perform the refactoring right away, click Refactor .

**Tip** See [Example 1](#) and [Example 2](#) above.

**Tip** See [Example 3](#) above.

Use the **Change Signature** refactoring to change the function name, to add, remove, reorder, and rename parameters, and to propagate new parameters through the hierarchy of calls.

The examples below show different ways to run the Change Signature refactoring. In all the cases, the function `result()` is renamed to `generate_result()` and a new parameter `input` is added to this function. The examples show how the function call, the calling function (`show_result()`), and other code fragments may be affected depending on the refactoring settings.

### Example 1: Renaming a function, adding a parameter, and passing its value through the function call

In this example, the function `result()` is renamed to `generate_result()`, a parameter `input` is added, and the value `100` is passed as a parameter in the function call.

```
function result() {
}

function show_result() {
  alert('Result: ' + result());
}

function generate_result(input) {
}

function show_result() {
  alert('Result: ' + generate_result(100));
}
```

### Example 2: Renaming a function and adding a default parameter

In this example, the function `result()` is renamed to `generate_result()`. A default parameter `input` is added with the value `100`. The new parameter is initialized in the `generate_result()` in the format `function generate_result(input = 100) {}` for ES6 language level or `input = input || 100` for ES5.

```
function result() {
}

function show_result() {
  alert('Result: ' + result());
}

function generate_result(input = 100) {
}

function show_result() {
  alert('Result: ' + generate_result());
}
```

### Example 3: Renaming a function, adding a default parameter, and propagating the parameter to the function call

In this example, the function `result()` is renamed to `generate_result()`. A default parameter `input` is added with the value `100`. The new parameter is initialized in the `generate_result()` in the format `function generate_result(input = 100) {}` for ES6 language level or `input = input || 100` for ES5. The `input` parameter is propagated through the calling function `show_result()` so the function call is changed accordingly.

```
function result() {  
}  
  
function show_result() {  
    alert('Result: ' + result());  
}
```

```
function generate_result(input = 100) {  
}  
  
function show_result() {  
    alert('Result: ' + generate_result());  
}
```

#### To invoke Change Signature

In the editor, place the cursor within the name of the function to refactor and press `Ctrl+F6` or choose Refactor | Change Signature on the context menu or on the main menu. The [Change Signature dialog](#) opens.

#### To rename a function

In the [Change Signature dialog](#) (`Ctrl+F6`), edit the Name field.

#### To manage the function parameters

In the [Change Signature dialog](#) (`Ctrl+F6`), use the table of parameters and the buttons to the right of it:

- To add a new parameter, click `+` (`Alt+Insert`) and specify the name of the new parameter and its default value or the value to be passed through function calls.
- To remove a parameter, click any of the cells in the corresponding row and click `-` (`Alt+Delete`).
- To reorder the parameters, use `↑` (`Alt+Up`) and `↓` (`Alt+Down`).
- To rename a parameter, edit the Name field.
- If necessary, [propagate the new parameter](#) to the functions that call the current function.

#### To propagate a parameter along the hierarchy of calls

1. In the [Change Signature dialog](#) (`Ctrl+F6`), select the parameter and click `⌵`. The Select Methods to Propagate New Parameters dialog opens. The left-hand pane shows the hierarchy of function calls. When you select a function, the right-hand pane shows its code and the code of the function it calls in the Caller Method and Callee Method fields respectively.
2. In the left-hand pane, select the checkboxes next to the functions where you want to propagate the parameter and click OK.

#### To preview the changes and complete the refactoring

1. In the [Change Signature dialog](#) (`Ctrl+F6`), click Preview.
2. In the Refactoring Preview tab of the [Find tool window](#), [view the expected changes](#), make the necessary adjustments, and click Do Refactor when ready.

**Spy-js** is a tool for JavaScript developers that lets you simply debug/trace/profile JavaScript running on different platforms/browsers/devices. The tool fills gaps that existing browser development tools have and tackles common development tasks from a different angle.

The tool also traces **Node.js**, server-side, applications.

## Preparing for tracing with Spy-js

1. Download and install [Node.js](#) because it is used by the **Spy-js** trace server.
2. Make sure the **Spy-js** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Spy-js basics

With **Spy-js**, you can trace both Web applications and **Node.js** applications. Although the **Spy-js** UI in either case is the same, the mechanisms of the tracing differ.

In order to trace a script, **Spy-js** has to modify it on the fly. The modification does not affect the logic of the script, it is just inserting instrumentation instructions that report back to **Spy-js** UI about what functions have been invoked when the script executes.

- To modify **website scripts**, **Spy-js** has to act as a proxy server that "sits" between your browser and the website you are tracing. When you open a traced website in your browser, **Spy-js** receives the script request, requests the script from your website, receives the script, makes the required modifications, and sends it back to your browser where the script executes, and sends the runtime information to the **Spy-js** UI.

The proxy server can be configured automatically by selecting the Automatically configure system proxy checkbox in the [Run/Debug Configuration: Spy-js](#) dialog or manually. See how to configure proxy settings manually on [Windows](#), [Mac](#), [Ubuntu](#), [iOS](#), [Android](#), [Windows Phone](#). Please note that some desktop browsers have their own screens for proxy settings configuration.

- In case of a **Node.js application**, **Spy-js** cannot get between the **NodeJS server** and the scripts if the application is already running. Therefore to trace a **Node.js application**, **spy-js** launches the **NodeJS** server and the application itself. This enables **Spy-js** to intercept and modify script requests and scripts, whereupon the tracing procedure runs as when tracing a website script.

You can also trace applications with **ECMAScript6**, **CoffeeScript**, and **TypeScript** code: **Spy-js** recognizes **source maps** that set correspondence between the original code and the JavaScript code generated during compilation. See [Compiling CoffeeScript to JavaScript](#) and [Using File Watchers](#) for details.

A **Spy-js** session is initiated from IntelliJ IDEA through a run configuration. See [Initiating a Spy-js Session](#).

## Spy-js UI

All the tracing-related activities, such as viewing captured events, examining their call stacks, navigating to the source code, etc. are performed in the dedicated [Spy-js Tool Window](#), in particular in its [Trace Run Tab](#). The tab consists of a toolbar and three panes:

- Events Pane

The pane shows a tree of captured events. The top-level nodes represent **documents** that are Web pages involved in tracing. When you hover the mouse over a **document**, IntelliJ IDEA displays a tooltip with the URL address of the **document**, the browser in which it is opened, and the operating system the browser is running on. The **document** node is also supplied with an icon that indicates the browser in which it is opened.

Under each **document** node, events detected on the page and scripts started from it are listed. Events of the same type are grouped into visual containers. The header of a container displays the name of the events grouped in it, the average execution time across all the events within the container, and the number of events inside the container. You can expand each node and inspect the individual events in it.

Script file names have different colour indicators to help distinguishing between them when working with the Event Stack pane. By hovering your mouse over a script file name, you can see the full script URL.

Once an event is clicked, its call stack is displayed in the Event Stack pane. The stack is represented by a tree of function calls.

- Event Stack Pane

Once an event in the Events pane is clicked, its call stack is displayed in the Event Stack pane. The stack is represented by a tree of function calls. Each tree node represents the invoked function. Node text contains the total execution time, the script file name and the function name. When you click a node, the Quick Evaluation pane shows additional function call details, parameter values and return value, occurred exception details if there was one during the function execution.

The pane is synchronized with the editor, so you can navigate from an item in the stack tree to the corresponding **trace file** or **source file**.

- A **trace file** is a write-protected prettified version of the script selected in the Events pane or the script whose function is double clicked in the Event Stack pane. A **trace file** is named `<file name>.js.trace`. When you double click an item in the stack tree or select it and choose Jump to Trace on the context menu of the selection, the corresponding **trace file** opens in the editor with the cursor positioned at the clicked function. Another approach is to press the Autoscroll to Trace toggle button and select various stack nodes. In this case, the trace file opens when you click an event or script in the Events pane.

You can not only jump to a function but also to the place in the code where it was called from. To do that, select the required item and choose Jump to Caller on the context menu.

The contents of the file are highlighted to display the code execution path of the selected stack node.

- When you are tracing an application with **ECMAScript 6**, **CoffeeScript**, and **TypeScript** code, **Spy-js** also generates **mapped trace files**. These are **ECMAScript 6**, **TypeScript**, or **CoffeeScript** trace files with the extensions `.ts.trace`, `.coffee.trace`, or `.js.trace`. The fragments of code in these files are highlighted as if they were really executed.

- You can also navigate to the **source file** displayed as is, without prettifying, by selecting an item in the Event Stack pane and choosing Jump to Source on the context menu of the selection. If the traced site is mapped with a IntelliJ IDEA project, IntelliJ IDEA detects the corresponding local file according to the mapping and opens this file in the editor. If you are tracing a site that is not mapped to a IntelliJ IDEA project, IntelliJ IDEA opens the read-only **page source**, just as if you chose View Page Source in the browser.

When the traced site is mapped with a IntelliJ IDEA project, IntelliJ IDEA opens the **source file** on any attempt to edit the opened **trace file**.

- Quick Evaluation Pane

When you click a node in the Event Stack pane, the Quick Evaluation pane shows additional function call details, parameter values and return value, occurred exception details if there was one during the function execution.

## Initiating a Spy-js tracing session

The way you initiate a tracing session depends on the type of the application you are going to trace.

### Launching a tracing session of a Web application

To a trace an application with **CoffeeScript** or **TypeScript** code, you need to compile the original code into JavaScript, see [and TypeScript](#) for details.

1. Create a run configuration of the type **Spy-js**. To do that, choose Run | Edit Configurations on the main menu, click the Add New Configuration toolbar button , and choose Spy-js on the context menu. In the [Run/Debug Configuration: Spy-js](#) dialog box that opens, specify the following:

1. The location of the Node interpreter.
2. The **trace server port**. This port number must be the same as your system proxy port. If the Automatically configure system proxy checkbox is selected, the specified port number is automatically set for the system proxy server. Otherwise you will have to specify the value of the field in the system proxy settings manually. The **trace server port** is filled in automatically. To avoid port conflicts, it is recommended that you accept the suggested value and keep the Automatically configure system proxy checkbox selected.
3. The way to configure the proxy server.  
To have the system proxy server activated automatically with the port specified in the Trace server port field, select the Automatically configure system proxy checkbox.

Clear the Automatically configure system proxy checkbox to specify proxy settings manually. See how to configure proxy settings manually on [Windows](#), [Mac](#), [Ubuntu](#), [iOS](#), [Android](#), [Windows Phone](#). Please note that some desktop browsers have their own screens for proxy settings configuration.

4. From the Use dropdown list, choose the way to specify the way to configure a tracing session.

- To have **Spy-js** apply its internal predefined configuration, choose Default configuration.

- To have your custom manually created configuration applied, choose the Configuration file option and then specify the location of your custom configuration file in the Configuration field below.

A **configuration file** is a JavaScript file with the extension `.js` or `.conf.js` that contains valid JavaScript code that meets the [Spy-js configuration requirements](#). If IntelliJ IDEA detects files with the extension `.conf.js` in the project, these files are displayed in the drop-down list.

Type the path to the configuration file manually or click the Browse button  and choose the location in the dialog box that opens. Once specified, a configuration file is added to the drop-down list so you can get it next time from the list instead of specifying the path.

2. To launch a tracing session, click the Run toolbar button . The [Spy-js Tool Window](#) opens with an empty Trace Run tab and a Trace Proxy Server tab informing you about the status of the proxy server.
3. Switch to the browser and refresh the page to start debugging from. **Spy-js** starts capturing events on this page and the Spy-js tool window shows them in the Events pane.

### Launching a tracing session of a Node.js application

1. Create a run configuration of the type **Spy-js for Node.js**. To do that, choose Run | Edit Configurations on the main menu, click the Add New Configuration toolbar button , and choose Spy-js for Node.js on the context menu. In the [Run/Debug Configuration: Spy-js for Node.js](#) dialog box that opens, specify the following:

1. The location of the **Node interpreter**.
2. The **Node parameters**, that is, the Node.js-specific command line options to be passed to the NodeJS executable file. For example, to enable tracing **ECMAScript 6** scripts, specify `--harmony` as a Node parameter. Note that Node.js must be version 0.11.13 or higher.
3. The [working directory](#) of the application. All references in the **starting file file**, for example, `imports`, will be resolved relative to this folder, unless such references use full paths.  
By default, the field shows the **project root folder**. To change this predefined setting, choose the desired folder from the drop-down list, or type the path manually, or click the Browse button  and select the

location in the dialog box, that opens.

4. The **JavaScript file** to start the application with.

If you are going to trace CoffeeScript, specify the path to the generated JavaScript file. The file can be generated externally or through compilation using file watchers. For more details, see [Compiling CoffeeScript to JavaScript](#).

5. The **application parameters**: the Node.js-specific arguments to be passed to the application start file through the [process.argv](#) array.
6. The **environment variables** for the Node.js executable file, if applicable. See [Run/Debug Configuration: Spy-js for Node.js](#) for details.
7. The **configuration file** with the configuration settings to apply to the tracing session.  
A **configuration file** is a JavaScript file with the extension `.js` or `.conf.js` that contains valid JavaScript code that meets the [Spy-js configuration requirements](#). If IntelliJ IDEA detects files with the extension `.conf.js` in the project, these files are displayed in the drop-down list.

Type the path to the configuration file manually or click the Browse button  and choose the location in the dialog box that opens. Once specified, a configuration file is added to the drop-down list so you can get it next time from the list instead of specifying the path.

8. The **trace server port**. This port number must be the same as your system proxy port. If the Automatically configure system proxy checkbox is selected, the specified port number is automatically set for the system proxy server. Otherwise you will have to specify the value of the field in the system proxy settings manually. The **trace server port** is filled in automatically. To avoid port conflicts, it is recommended that you accept the suggested value and keep the Automatically configure system proxy checkbox selected.
2. To launch a tracing session, click the Run toolbar button . The **Spy-js** tool and the Node.js application start. The [Spy-js Tool Window](#) opens showing the captured events in the Trace Run tab.

## Saving and loading tracing sessions

You can save an image of a tracing session and load this image at any time later. The `.json` files that store the calls and properties of the session are compressed into a `zip` archive. Upon request, when you choose Load trace, the `.json` files are extracted from the archive and loaded into **Spy-js**.

Note that a loaded image does not restore the session because no scripts are actually executed. All you can do is analyze the flow and properties of previously executed code.

### To save an image of a tracing session

- Click the  button on the Events toolbar, and then choose Save trace from the list. IntelliJ IDEA compresses all the affected `.json` files in a `zip` archive and opens the folder where the archive is saved.

### To load an image of a previous tracing session

1. Initiate a tracing session of the same type as the session you are going to load the image of: a **Spy-js** or a **Spy-js for Node.js** respectively, see [Initiating a Spy-js Tracing Session](#) above. We need to have this **fake** session running because otherwise **Spy-js** would be inactive and thus the **load trace** functionality would be unavailable.  
Of course you can load a trace while actually tracing an application, but in this case the currently running session will be lost after loading.
2. When the session starts, click the  button on the Events toolbar and choose Load Trace from the list.
3. In the dialog box that opens, choose the location of the `zip` archive with the image of the desired session. **Spy-js** stops the running and shows the loaded trace in a new tab named Loaded <loaded session>.  
Note that a loaded image does not restore the session because no scripts are actually executed. All you can do is analyze the flow and properties of previously executed code.

## Configuring the range of events to display

By default, the **Spy-js** tool captures all events on all opened Web pages, excluding **https secure** web sites, unless you have specified a URL address explicitly in the run configuration. The Events pane of the **Spy-js** tool window shows all captured events. If for some reasons you do not want to have all events captured, you can suppress capturing some of them by applying user-defined event filters. All the available filters are listed upon clicking the Capture Events button  on the toolbar, the currently applied filter is marked with a tick. By default the Capture All predefined filter is applied. To stop capturing events without stopping the application, choose Mute All. The application is still running but the Events pane shows the last captured event. This is helpful if you want to analyze a script and therefore need it to be displayed in the Events pane instead of being removed as new events are captured. You can define new custom filters or add event patterns to existing filters on the fly.

### Defining a new event filter

1. Click the Capture Events button  on the toolbar, and then choose Edit Capture Exclusions from the list.
2. In the [Spy-js Capture Exclusions Dialog](#) that opens, click Add  on the left-hand pane.
3. In the right-hand pane, specify the filter name in the Exclusion name field and configure a list of exclusion

rules.

To add a rule, click **+**, the Add Condition to Exclusion dialog box opens. Type a pattern in the Value/pattern text box, in the Condition type drop-down list specify whether the pattern should be applied to event types or script names. Note that [glob pattern matching](#) is used. When you click OK, IntelliJ IDEA brings you to the [Spy-js Capture Exclusions Dialog](#).

To edit a rule, select it in the list, click **✎**, and update the rule in the dialog box that opens. To remove a rule, select it in the list and click **-**.

## Creating exclusion rules on the fly

While navigating through the tree of already captured events in the Events pane, you may come across some events or scripts that you definitely do not want to trace. You can create a filter as described above but in this case you will have to leave the pane. With IntelliJ IDEA, you can create an exclusion rule based on any event or script, as soon as you have detected such event or script, right from the Events pane. The rule will be either added to the currently applied filter or a new filter will be created if the current setting is Capture All.

- To add an event to an exclusion filter on the fly, select the event to exclude and choose Mute `<event name>` event or Mute `<script name>` file.

If a user-defined filter is currently applied, the new rule is added to it silently. If Capture All is currently active, the [Spy-js Capture Exclusions Dialog](#) opens, where you can create a new filter based on the selected event or script or choose an existing filter and add the new rule to it.

## Setting timestamp labels

Timestamp labels help you to analyze your code execution within a specific period of time. For example, you can set two timestamp labels and view which events were captured between them. Or on the contrary, you can locate the events that were not captured within a certain period of time although you expected them to be and thus detect performance problems.

- To set a timestamp label, choose Add Label on the context menu in the Events pane. A label **Labelled at `<timestamp>`** is added under the document node.

## Synchronization and navigation between the panes and the editor

The Events and Event Stack panes are synchronized: when you click an event or script in the Events pane, its call stack is displayed in the Event Stack pane. To have also the corresponding trace file opened in the editor, press the Autoscroll to Trace toggle button on the toolbar.

The Event Stack pane is synchronized with the editor: when you click an item in the stack tree twice, the corresponding trace file opens in the editor with the cursor positioned at the clicked function.

To synchronize the Events pane directly with the editor, press the Autoscroll to Trace toggle button on the toolbar. In this case, as soon as you click a node in the Events pane, its call stack is displayed in the Event Stack pane and the corresponding trace file is opened in the editor. With the Autoscroll to Trace mode turned on, when you navigate through the Event Stack the corresponding files are also automatically opened in the editor with the corresponding functions highlighted.

## Navigating from an event or a script to the trace file

A **trace file** is a write-protected prettified version of the script selected in the Events pane or the script whose function is double clicked in the Event Stack pane. A **trace file** is named `<file name>.js.trace`. To navigate from an event or a script to the trace file, do one of the following:

- Activate automatic navigation:
  1. In the Events pane, press the Autoscroll to Trace toggle button on the toolbar.
  2. Click the required event or script.
- In the Event Stack pane, click the required item in the call stack twice or choose Jump to Trace on the context menu. The trace file opens with the cursor positioned at the clicked function.

## Navigating from an event or script to the source file

You can also navigate to the **source file** displayed as is, without prettifying.

- In the Event Stack pane, select the required item in the call stack and choose Jump to Source on the context menu of the selection.

If the traced site is mapped with a IntelliJ IDEA project, IntelliJ IDEA detects the corresponding local file according to the mapping and opens this file in the editor. If you are tracing a site that is not mapped to a IntelliJ IDEA project, IntelliJ IDEA opens the read-only **page source**, just as if you chose View Page Source in the browser.

## Navigating from a function to its call

To navigate from a function to the place in the code where it was called from:

- In the Event Stack pane, select the required item in the call stack and choose Jump to Caller on the context menu of the selection.

## Navigating through ECMAScript 6, TypeScript, or CoffeeScript

Spy-js supports **source maps**, which means that you can now jump from the Event Stack pane right to the original source code in **ECMAScript 6**, **TypeScript** or **CoffeeScript** and observe what code fragments were executed.

Spy-js also generates **mapped trace files**. These are **ECMAScript 6**, **TypeScript**, or **CoffeeScript** trace files with the extensions `.ts.trace`, `.coffee.trace`, or `.js.trace`. The fragments of code in these files are highlighted as if they were really executed.

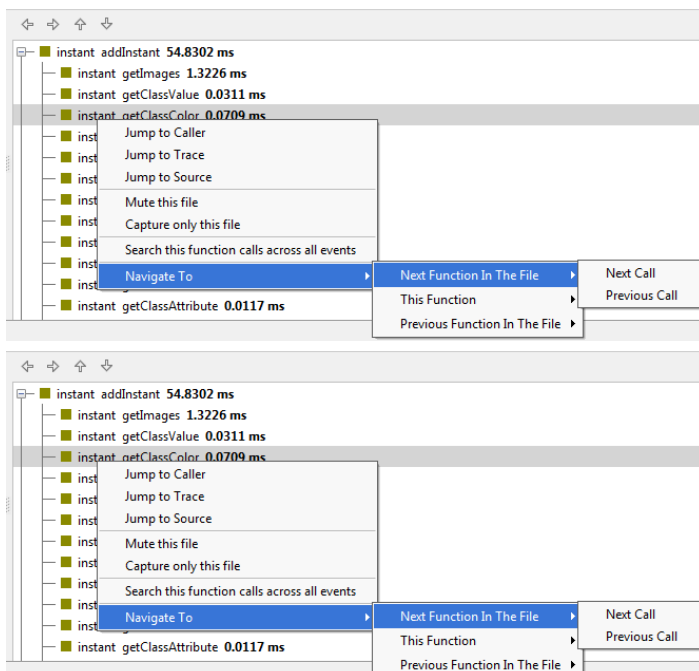

1. Configure the way source maps are treated by clicking  on the toolbar of the Events stack and choosing the following options on the context menu:
  - Choose **Enable Source Map Look-up** to enable navigation to the **ECMAScript 6**, **TypeScript** or **CoffeeScript** source code using the source maps generated during compilation.
  - Choose **Enable source map generation**, to generate source maps for everything to map the instrumented code. Choose this option if you are going to debug the original code in **Chrome Dev Tools** or **Firefox FireBug** development tools.
  - Choose **Always open source mapped trace if available**, to have **Spy-js** try to open the **mapped trace file** when you invoke navigation from an event to its caller.
2. To navigate from a function to the source code, select the function in question in the Event Stack pane and choose one of the following options on the context menu of the selection:
  - To navigate to the **ECMAScript 6**, **TypeScript** or **CoffeeScript** source code, choose **Jump to Source** on the context menu of the selection.
  - To navigate to the JavaScript trace file, choose **Jump to Trace**.
  - To navigate to the mapped trace file (**ECMAScript 6**, **TypeScript** or **CoffeeScript**), choose **Jump to Mapped Trace**.
3. To navigate from a function to its call, select the function in the Event Stack and choose **Jump to Caller**.
  - If the **Always open source mapped trace if available** option is selected, the corresponding mapped trace file opens.
  - If the **Always open source mapped trace if available** option is not selected, the JavaScript trace file opens.

Alternatively, you can navigate to the executed JavaScript code by choosing **Jump to Trace**.

## Advanced trace navigation

With **advanced trace navigation**, you can move through the whole stack based on calls and locate the functions that have not been called, that is, locate the fragments of code that have not been executed and analyze the reason for them to be skipped.

The following six actions are available: move to the next/previous call of the next/current/previous function in a trace file. The full list of actions is available from the context menu in the Event Stack pane. Moving to the next and previous calls of the selected function, to the previous call of the previous function, and to the next call of the next function are also available from the navigation toolbar of the Event Stack pane.

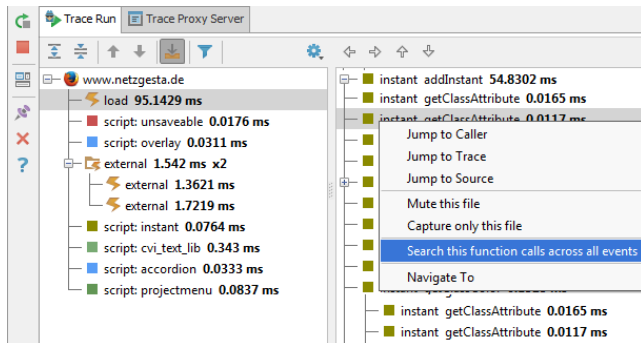

When you choose one of these actions, the cursor jumps to the call in the stack. If the **Autoscroll to Trace** toggle button is pressed, the corresponding trace file opens automatically with the cursor positioned at the call.

## Advanced trace search

**Advanced trace search** lets you navigate between the calls of a function within the whole trace (across all the traced events). This means that if you are tracing 5 pages in the browser and the Events pane, accordingly, shows 5 document nodes, IntelliJ IDEA searches for the calls of the selected function under all these nodes and displays the number of found calls of the function in the Status bar.

- To invoke the search for the calls of a function in all document nodes, select the function in question in the Event Stack pane and choose Search this function calls across all events on the context menu of the selection. The number of found calls is displayed in the Status bar, and the toolbar shows four previously hidden navigation chevron buttons.

- Use the chevron buttons to navigate within the found calls:
  - To jump to the first detected call, click .
  - To jump to the last detected call, click .
  - To jump to the next detected call, click . The Status bar shows a message: Occurrence <number> of <total number of detected calls>.
  - To jump to the previous detected call, click .

The search results are reset and the search toolbar is hidden when you invoke another advanced search or navigation.

Also keep in mind that the number of call occurrences is calculated when you choose the Search this function calls across all events option. As you analyze the detected calls, the time passes, new events are captured, and the first detected call can happen to be already removed from the stack which means that it is no longer available for navigation.

## Expanding the basic completion list with runtime data (Spy-js autocompletion)

The term **Spy-js autocompletion** denotes expanding the **basic completion list** with suggestions retrieved from the runtime data. The **Spy-js autocompletion** functionality is available from **source** files for the code that has already been executed (highlighted green in the corresponding **trace** file).

When you position the caret at a symbol in the source file and press **Ctrl+Space**, **Spy-js** retrieves data from the browser or from the running Node.js application and merges it with the basic completion list according to the following rules:

1. If an object both is present on the basic completion list and is retrieved from the runtime, the variant that provides more information about parameters, attributes, their type, etc. remains on the list.
2. Objects retrieved by **Spy-js** are shown on top of the list and marked with the  icon. If a retrieved object is specific for a browser, the object is marked with the  icon and with the icon of this browser.

## Activating Spy-js autocompletion

By default, the functionality is turned off. To activate it:

- Click the  button on the Events toolbar, and then choose Enable Spy-js autocomplete and magnifier from the list.

## Evaluating expressions without running a debugging session (Spy-js magnification)

The term **Spy-js magnification** denotes **evaluating expressions** without actually running a debugging session. When you click the expression in question or position the caret at it and press **Ctrl+Alt+F8**, a tooltip is displayed below the expression showing the expression value. If **Spy-js** retrieves several values, click  icon in the tooltip to expand the list of

values.

The **magnification** functionality is available from **source** files for both executed and not yet executed code.

By default, the functionality is turned off.

## Activating Spy-js magnification

By default, the functionality is turned off. To activate it:

- Click the  button on the Events toolbar, and then choose Enable Spy-js autocomplete and magnifier from the list.

## Viewing dependency diagrams

With **Spy-js**, you can build and examine runtime application/event diagrams for client-side and **Node.js** applications.

### To view the dependency diagrams

1. Generate a diagram:

- To build a diagram with the dependencies within the entire application, select the document node and choose Show application dependency diagram on the context menu of the selection.
- To build a diagram with the dependencies of a single event, select the required event in the Events pane and choose Show event dependency diagram .

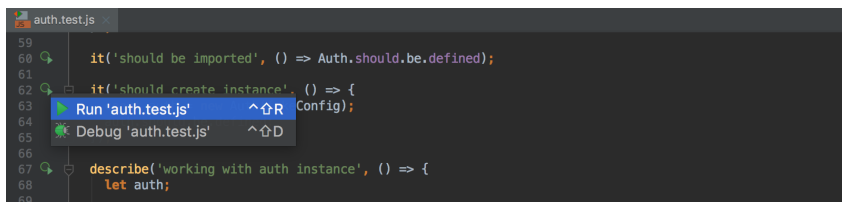

2. Analyze the diagram:

- The diagram is opened in a separate editor tab. The nodes in the diagram represent your project files, while the edges represent the fact that there's one or more functions in the source file that invoke functions in the target file.
- To examine the details of a node or an edge, select the node or the edge in question and view its Details tree in a dedicated pane in the upper right-hand corner of the editor. The pane displays the connecting function combinations, along with event(s) the calls are made within and the number of calls made.

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you can run and debug JavaScript unit tests using [Mocha](#), [Karma](#), [Jest](#), [Protractor](#), and [Cucumber.js](#).

You can see the test results in a treeview and easily navigate to the test source from there. Test status is shown next to the test in the editor with an option to quickly run or debug it:

For Karma and Mocha you can also see a code coverage report right in IntelliJ IDEA.

## Navigation

You can quickly jump from the source code to the related test file with the Go to test action (`Ctrl+Shift+T` or `Navigate | Test`). For example, from `auth.js` you can jump to `auth.test.js`.

## Running and debugging tests

Before you start with testing JavaScript, make sure the chosen test runner is installed and set up in your project as described on the corresponding page.

To quickly run or debug a single test with Mocha, Karma, or Jest

Click  or  in the left gutter and choose Run <test\_name> or Debug <test\_name> from the pop-up list.

To run or debug tests using a run/debug configuration

1. In the **Run/Debug Configuration** dialog box ( `Run | Edit Configurations` ), click , select the appropriate configuration type, and fill in the required fields.
2. Save the configuration and click , , or  on the toolbar.

For a more detailed overview, see:

- [Cucumber.js](#)
- [Jest](#)
- [JSTestDriver](#)
- [Karma](#)
- [Mocha](#)
- [Protractor](#)

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports integration with the [Cucumber.js test framework](#) . IntelliJ IDEA recognizes [features](#) written in the [Gherkin](#) language.

## Before you start

1. Make sure the [Node.js](#) runtime environment is installed on your computer.
2. Install and enable the NodeJS, Cucumber.js, and Gherkin repository plugins on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Installing Cucumber.js

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type one of the following commands at the command prompt:

- `npm install cucumber` for local installation in your project.
- `npm install -g cucumber` for global installation.
- `npm install --save-dev cucumber` to install Cucumber.js as a [development dependency](#) .

See also [Cucumber.js demo on the Cucumber.js official website](#) .

**Tip** You can also install the `cucumber` package on the [Node.js and NPM page](#) as described in [NPM](#) .

## Running tests

**Tip** If you create a run/debug configuration from the editor by choosing Create Scenario:<Scenario\_name> on the context menu of the scenario to run, IntelliJ IDEA fill in the name of the scenario in the Name Filter text box automatically.

Cucumber.js tests are launched only through a run/debug configuration.

### To create a Cucumber.js run configuration

1. Open the [Run/Debug Configuration](#) dialog box ( Run | Edit Configurations on the main menu).
2. Click **+** on the toolbar and select Cucumber.js from the list. The [Run/Debug Configuration: Cucumber.js](#) dialog box opens.
3. In the Feature file or directory text box, specify the tests to run. Type the path to a specific `.feature` file or to a folder, if you want to run a bunch of features.
4. In the Executable path text box, specify the location of the `cucumber-js.cmd` , `cucumber-js.bat` , or other depending on your operating system. The location depends on the installation mode.

### Optionally

- Specify the command line arguments to be passed to the executable file, such as `-r ( --require LIBRARY|DIR )` , `-t ( --tags TAG_EXPRESSION )` , or `--coffee` . For details, see native built-in help available through the `cucumber-js --help` command.
- In the Name Filter text box, type the name of a specific scenario to run instead of all the scenarios from the feature file or directory.

**Tip** Alternatively, select a test file in the Project tool window and choose Create <file name> on the context menu.

### To run tests via a run configuration :

1. Select the Cucumber.js run/debug configuration from the list on the main toolbar and click **▶** to the right of the list.
2. The test server starts automatically without any steps from your side. View and analyze messages from the test server in the Run tool window.
3. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#) .

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose Go To | Test or Go To | Test Subject on the context menu, or just press

`Ctrl+Shift+T` .

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.` , `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

### To jump from a test result to the test

Select the test name in the Test Runner tab and choose Jump to Source on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

This feature is only supported in the Ultimate edition.

Jest is a testing platform for client-side JavaScript applications and [React](#) applications specifically. Learn more about the platform from [Jest Official website](#).

You can run and debug tests with Jest right in IntelliJ IDEA. You can see the test results in a treeview and easily navigate to the test source from there. Test status is shown next to the test in the editor with an option to quickly run it or debug it.

## Before you start

1. Make sure the [Node.js](#) runtime environment is installed on your computer.
2. Install and enable the NodeJS repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Jest

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install --save-dev jest` at the command prompt.

See also [Getting Started on the Jest official website](#).

**Tip** You can also install the `jest` package on the [Node.js and NPM page](#) as described in [NPM](#).

## Running tests

With IntelliJ IDEA, you can quickly run a single Jest test right from the editor or create a run/debug configuration to execute some or all of your tests.

### To run a single test from the editor

Click  or  in the left gutter and choose Run <test\_name> from the pop-up list. You can also see whether a test has passed or failed right in the editor, thanks to the **test status** icons  in the left gutter.

### To create a Jest run configuration

1. Open the [Run/Debug Configuration](#) dialog box (Run | Edit Configurations on the main menu).
2. Click  on the toolbar and select Jest from the list. The [Run/Debug Configuration: Jest](#) dialog box opens.
3. Specify the [Node interpreter](#) to use and the location of the `jest`, `react-scripts`, `react-script-ts`, `react-super-scripts`, or `react-awesome-scripts` package.
4. Specify the working directory of the application.  
By default, the Working directory field shows the project root folder. To change this predefined setting, specify the path to the desired folder or choose a previously used folder from the list.
5. Optionally specify the `jest.config` file to use: choose the relevant file from the drop-down list, or click  and choose it in the dialog that opens, or just type the path in the text box. If the field is empty, IntelliJ IDEA looks for a `package.json` file with a `jest` key. The search is performed in the file system upwards from the **working directory**. If no appropriate `package.json` file is found, then the [Jest default configuration](#) is used.
6. Optionally configure rerunning the tests automatically on changes in the related source files. To do that, add the `--watch` flag in the Jest options field.

**Tip** Alternatively, select a test file in the Project tool window and choose Create <file name> on the context menu.

### To run tests via a run configuration

1. Select the Jest run/debug configuration from the list on the main toolbar and click  to the right of the list.
2. The test server starts automatically without any steps from your side. View and analyze messages from the test server in the Run tool window.
3. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#).

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose Go To | Test or Go To | Test Subject on the context menu, or just press

`Ctrl+Shift+T`.

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.`, `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

### To jump from a test result to the test

Select the test name in the Test Runner tab and choose Jump to Source on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

## Snapshot testing

IntelliJ IDEA integration with Jest supports such a great feature as snapshot testing. If a snapshot does not match the rendered application the test fails. This indicates that either some changes in your code have caused this mismatch or the snapshot is outdated and needs to be updated. To update the snapshot for a failed test, use the Click to update snapshot link in the Test Runner tab of the Run tool window:

## Debugging tests

With IntelliJ IDEA, you can quickly start debugging a single Jest test right from the editor or create a run/debug configuration to debug some or all of your tests.

To start debugging a single test from the editor

Click or in the left gutter and choose Debug <test\_name> from the pop-up list.

To launch test debugging via a run/debug configuration

1. Create a Jest run/debug configuration [as described above](#).
2. Select the Jest run/debug configuration from the list on the main toolbar and click to the right of the list.
3. In the **Debug Tool Window** that opens, proceed as usual: [step through the tests](#), [stop and resume](#) test execution, [examine the test when suspended](#), etc.

## Monitoring code coverage

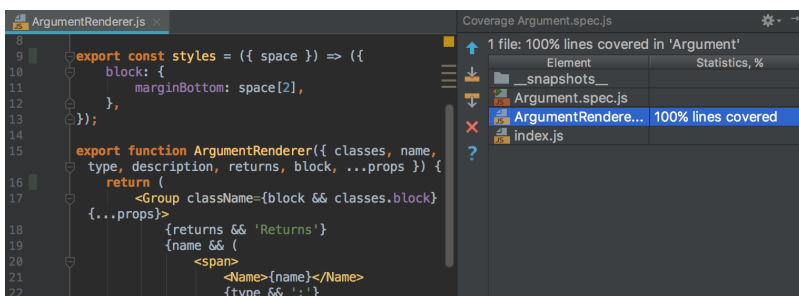

With IntelliJ IDEA, you can also monitor how much of your code is [covered with Jest tests](#). IntelliJ IDEA displays this statistics in a dedicated tool window and marks covered and uncovered lines visually right in the editor.

To run tests with coverage

1. Create a Jest run/debug configuration [as described above](#).
2. Select the Jest run/debug configuration from the list on the main toolbar and click to the right of the list.

Alternatively, quickly run a specific suite or a test with coverage from the editor: click or in the left gutter and choose Run <test\_name> with Coverage from the pop-up list.

3. Monitor the code coverage in the **Coverage** tool window. The report shows how many files were covered with tests and the percentage of covered lines in them. From the report you can jump to the file and see what lines were covered – marked green – and what lines were not covered – marked red:

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports integration with the [JSTestDriver test framework](#) .

## Before you start

1. Configure your testing framework as [IntelliJ IDEA JavaScript library](#) .
2. Make sure the **JSTestDriver** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .  
Through this plugin, IntelliJ IDEA provides the JSTestDriver server and the assertion framework. During the test creation, the plugin detects the unit testing framework and suggests the **Add <test framework> support** [intention action](#) .

## Configuring a testing framework in a project

1. Download the framework of your choice and [configure it as a IntelliJ IDEA JavaScript library](#) .
2. Do one of the following:
  - [Add the project folder to the library scope](#) .
  - Enable the framework support on-the-fly during test creation using the **Add <test framework> support** intention action.
  - To use Jasmine, add `jasmine-jstd-adapter` to the configuration file.  
Open `jsTestDriver.conf` and type the following code in it:

```
load:  
lib/jasmine/jasmine.js  
lib/jasmine-jstd-adapter/JasmineAdapter.js
```

## Creating a test runner configuration file manually

A test runner configuration file defines the test and production files to load the loading order. IntelliJ IDEA treats any file with the extension `*.jstd` or `*.conf` as a test runner configuration file.

### To create a configuration file

1. In the Project tree, select the parent folder of the production and test folders, and choose **New | File** on the context menu.
2. In the New File dialog box, that opens, type the name of the configuration file with the extension `jstd` or `conf` .
3. Open the new file in the editor and specify the full path to the current folder and the paths to the files to load relative to it.  
Use wildcards in file name patterns.
4. Complete the configuration file using [YAML](#) , see [description of test runner configuration files](#) .

## Running tests

With IntelliJ IDEA, you can quickly run a single JSTestDriver test right from the editor or create a run/debug configuration to execute some or all of your tests.

### To run a single test from the editor

Click  or  in the left gutter and choose **Run <test\_name>** from the pop-up list. You can also see whether a test has passed or failed right in the editor, thanks to the **test status** icons  in the left gutter.

**Note** The arrows appear only if the test framework used in your tests is associated with the project, so IntelliJ IDEA can recognize the tests.

### To create a JSTestDriver run configuration

1. Open the [Run/Debug Configuration](#) dialog box ( **Run | Edit Configurations** on the main menu).
2. Click  on the toolbar and select JSTestDriver from the list. The [Run/Debug Configuration: JSTestDriver](#) dialog box opens.
3. Specify the tests to run, the path to the configuration file, and the activities to perform before test execution.

**Tip** Alternatively, select a test file in the Project tool window and choose **Create <file name>** on the context menu.

### To start the IntelliJ IDEA default JSTestDriver test server

1. Make sure you have at least one configuration file in your project.
2. Open the [JSTestDriver Server](#) tool window ( **View | Tool Windows | JSTestDriver Server** ), and click  on the toolbar.

### To stop the server when you are through with unit testing

Click the Stop the local server toolbar button  .

**Tip** To use a test server running on another machine or listening to a custom port, start it according to the server-specific instructions and specify its URL address in the Server area of the [Run/Debug Configuration: JSTestDriver](#) dialog box.

### To capture a browser

1. [Start the JSTestDriver Server](#) if it is not running yet and then switch to the JSTestDriver Server tool window.
2. To start a local browser with the Remote Console of the JSTestDriver , do one of the following:
  - Click the icon that indicates the browser of your choice.
  - If the browser is already opened, copy the contents of the Capture a browser using the URL read-only field and paste the URL in the address bar.In either case, the icon that indicates the chosen browser becomes active.
3. Switch to the JSTestDriver Server tool window and click the icon that indicates the browser you just opened. IntelliJ IDEA displays a message informing you that it is ready for executing tests.

**Tip** You can have several browsers captured. However to debug your tests, appoint a browser for debugging in the Debug tab of the [Run/Debug Configuration: JSTestDriver](#) dialog box.

### To run tests via a run configuration

1. Select the JSTestDriver run/debug configuration from the list on the main toolbar and click  to the right of the list.
2. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#) .

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose Go To | Test or Go To | Test Subject on the context menu, or just press

`Ctrl+Shift+T` .

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.` , `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

### To jump from a test result to the test

Select the test name in the Test Runner tab and choose Jump to Source on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

## Debugging tests

A debugging session for JSTestDriver tests is started only through a run/debug configuration.

### To start debugging tests

1. Create a JSTestDriver run/debug configuration [as described above](#) .
2. Select the JSTestDriver run/debug configuration from the list on the main toolbar and click  to the right of the list.
3. In the [Debug Tool Window](#) that opens, proceed as usual: [step through the tests](#) , [stop and resume](#) test execution, [examine the test when suspended](#) , etc.

## Monitoring code coverage

With IntelliJ IDEA, you can also monitor how much of your code is [covered with Karma tests](#) . IntelliJ IDEA displays this statistics in a dedicated tool window and marks covered and uncovered lines visually right in the editor.

### To launch tests with coverage

1. Create a JSTestDriver run/debug configuration [as described above](#) .
2. [Start the JSTestDriver server](#) and [capture a browser](#) to run the tests in.
3. Select the JSTestDriver run/debug configuration from the list on the main toolbar and click  to the right of the list.
4. Monitor the code coverage in the [Coverage](#) tool window.

### To exclude files from coverage analysis

1. Create a JSTestDriver run/debug configuration [as described above](#) .
2. In the Coverage tab, specify the paths to the files to exclude.

This feature is only supported in the Ultimate edition.

You can run and debug tests with [Karma](#) right in IntelliJ IDEA. You can see the test results in a treeview and easily navigate to the test source from there. Test status is shown next to the test in the editor with an option to quickly run it or debug it.

## Before you start

1. Make sure the [Node.js](#) runtime environment is installed on your computer.
2. Install and enable the NodeJS and Karma repository plugins on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Karma and plugins

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type one of the following commands at the command prompt:

- `npm install` if Karma and all the required plugins are already defined in `package.json`.
- To install Karma and the required plugins (e.g. `karma-jasmine` or `jasmine-core` ) as [development dependencies](#)

```
npm install --save-dev karma
npm install --save-dev <required_karma_plugin> <another_required_karma_plugin>
```

Learn more on the [Karma official website](#).

**Tip** You can also install the `karma` package on the [Node.js and NPM page](#) as described in [NPM](#).

## Generating a Karma configuration file

Karma tests are run according to a `karma.conf.js` configuration file which is generated in the interactive mode. If you already have `karma.conf.js` in your project, just skip this step. For more details on Karma configuration, see [Karma official website](#).

### To create a Karma configuration file

1. Open the Terminal and start the `karma.conf.js` generation wizard by typing one of the following depending on your operating system:
  - For macOS and Linux:

```
./node_modules/karma/bin/karma init
```

- For Windows:

```
npm install -g karma-cli
```

```
karma init
```

2. Answering the questions of the wizard, specify the testing framework to use and the browsers to be captured automatically. See also [Karma Files: Pattern matching](#).

## Running tests

With IntelliJ IDEA, you can quickly run a single Karma test right from the editor or create a run/debug configuration to execute some or all of your tests.

### To run a single test from the editor

Click  or  in the left gutter and choose Run <test\_name> from the pop-up list. You can also see whether a test has passed or failed right in the editor, thanks to the [test status](#) icons  in the left gutter.

### To create a Karma run configuration

1. Open the [Run/Debug Configuration](#) dialog box ( Run | Edit Configurations on the main menu).
2. Click  on the toolbar and select Karma from the list. The [Run/Debug Configuration: Karma](#) dialog box opens.
3. Specify the [Node interpreter](#) to use, the location of the `karma` package, and the path to `karma.conf.js`.

**Tip** Alternatively, select a test file in the Project tool window and choose Create <file name> on the context menu.

### To run tests via a run configuration

1. Select the Karma run/debug configuration from the list on the main toolbar and click  to the right of the list.
2. The Karma test server starts automatically without any steps from your side. View and analyze messages from the test server in the Karma Server tab of the Run tool window.
3. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#).

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose **Go To | Test** or **Go To | Test Subject** on the context menu, or just press

`Ctrl+Shift+T` .

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.`, `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

To jump from a test result to the test

Select the test name in the Test Runner tab and choose **Jump to Source** on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

## Debugging tests

With IntelliJ IDEA, you can quickly start debugging a single Karma test right from the editor or create a run/debug configuration to debug some or all of your tests.

To start debugging a single test from the editor

Click  or  in the left gutter and choose **Debug <test\_name>** from the pop-up list.

To launch test debugging via a run/debug configuration

1. Create a Karma run/debug configuration [as described above](#) .
2. Select the Karma run/debug configuration from the list on the main toolbar and click  to the right of the list.
3. In the **Debug Tool Window** that opens, proceed as usual: [step through the tests](#) , [stop and resume](#) test execution, [examine the test when suspended](#) , etc.

## Monitoring code coverage

With IntelliJ IDEA, you can also monitor how much of your code is [covered with Karma tests](#) . IntelliJ IDEA displays this statistics in a dedicated tool window and marks covered and uncovered lines visually right in the editor. To monitor coverage, you need to install the `karma-coverage` package and update `karma.conf.js` .

To install karma-coverage

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install --save-dev karma-coverage` .

To add karma-coverage definition to the configuration file

Open `karma.conf.js` in the editor and add the following information to it:

1. Locate the `reporters` definition and add `coverage` to the list of values in the format:

```
reporters: [ 'progress', 'coverage' ]
```

2. Add a `preprocessors` definition and specify the coverage scope in the format:

```
preprocessors: { '**/*.js': [ 'coverage' ] }
```

To launch tests with coverage

1. Create a Karma run/debug configuration [as described above](#) .
2. Select the Karma run/debug configuration from the list on the main toolbar and click  to the right of the list. Alternatively, use the test icons in the editor to quickly run a specific suite or a test with coverage:

3. Monitor the code coverage in the **Coverage** tool window. Note that for **Karma** tests, the Coverage tool window does not show the **Generate Coverage Report** toolbar button  because a coverage report is actually generated on the disk every time **Karma** tests are run. The format of a coverage report can be configured in the configuration file, for example:

```
// karma.conf.js
module.exports = function(config) {
  config.set({ ...
  // optionally, configure the reporter
  coverageReporter: { type: 'html', dir: 'coverage/' }
  ...
});};
```

The following `type` values are acceptable:

- `html` produces a bunch of HTML files with annotated source code.
- `lcovonly` produces an `lcov.info` file.
- `lcov` produces HTML + `.lcov` files. This format is applied by default.
- `cobertura` produces a `cobertura-coverage.xml` file for easy Hudson integration.
- `text-summary` produces a compact text summary of coverage, typically to the console.
- `text` produces a detailed text table with coverage for all files.

This feature is only supported in the Ultimate edition.

You can run and debug tests with [Mocha](#) right in IntelliJ IDEA. You can see the test results in a treeview and easily navigate to the test source from there. Test status is shown next to the test in the editor with an option to quickly run it or debug it.

## Before you start

1. Make sure the [Node.js](#) runtime environment is installed on your computer.
2. Install and enable the NodeJS repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Mocha

Open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type one of the following commands at the command prompt:

- `npm install mocha` for local installation in your project.
- `npm install -g mocha` for global installation.
- `npm install --save-dev mocha` to install Mocha as a [development dependency](#).

See also [Getting Started on the Mocha official website](#).

**Tip** You can also install the `mocha` package on the [Node.js and NPM page](#) as described in [NPM](#).

## Running tests

With IntelliJ IDEA, you can quickly run a single Mocha test right from the editor or create a run/debug configuration to execute some or all of your tests.

### To run a single test from the editor

Click  or  in the left gutter and choose Run <test\_name> from the pop-up list. You can also see whether a test has passed or failed right in the editor, thanks to the **test status** icons  in the left gutter.

### To create a Mocha run configuration

1. Open the [Run/Debug Configuration](#) dialog box (Run | Edit Configurations on the main menu).
2. Click the  on the toolbar and select Mocha from the list. The [Run/Debug Configuration: Mocha](#) dialog box opens.
3. Specify the [Node interpreter](#) to use and the location of the `mocha` package.
4. Specify the working directory of the application.  
By default, the Working directory field shows the project root folder. To change this predefined setting, specify the path to the desired folder or choose a previously used folder from the list.
5. Optionally configure rerunning the tests automatically on changes in the related source files. To do that, add the `--watch` flag in the Extra Mocha options field.
6. Specify the tests to run. This can be a specific test or suite, an entire test file, or a folder with test files. You can also define patterns to run only the tests from the matching files.
7. Choose the [interface](#) used in the test to run.

**Tip** Alternatively, select a test file in the Project tool window and choose Create <file name> on the context menu.

### To run tests via a run configuration

1. Select the Mocha run/debug configuration from the list on the main toolbar and click  to the right of the list.
2. The test server starts automatically without any steps from your side. View and analyze messages from the test server in the Run tool window.
3. Monitor test execution in the Test Runner tab of the Run tool window as described in [Monitoring and Managing Tests](#).

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose Go To | Test or Go To | Test Subject on the context menu, or just press

`Ctrl+Shift+T`.

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.`, `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

### To jump from a test result to the test

Select the test name in the Test Runner tab and choose Jump to Source on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

## Debugging tests

With IntelliJ IDEA, you can quickly start debugging a single Mocha test right from the editor or create a run/debug configuration to debug some or all of your tests.

### To start debugging a single test from the editor

Click or in the left gutter and choose Debug <test\_name> from the pop-up list.

### To launch test debugging via a run/debug configuration

1. Create a Mocha run/debug configuration [as described above](#).
2. Select the Mocha run/debug configuration from the list on the main toolbar and click to the right of the list.
3. In the [Debug Tool Window](#) that opens, proceed as usual: [step through the tests](#), [stop and resume](#) test execution, [examine the test when suspended](#), etc.

## Monitoring code coverage

With IntelliJ IDEA, you can also monitor how much of your code is [covered with Mocha tests](#). IntelliJ IDEA displays this statistics in a dedicated tool window and marks covered and uncovered lines visually right in the editor. To monitor coverage, you need to install [nyc](#), the command-line interface for [Istanbul](#).

### To install nyc

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12`) and type `npm install --save-dev nyc`.

**Tip** You can also install Istanbul itself, version 1.1.0 or later. These versions have support for ES6 and TypeScript.

### To run tests with coverage

1. Create a Mocha run/debug configuration [as described above](#).
2. Select the Mocha run/debug configuration from the list on the main toolbar and click to the right of the list.

Alternatively, quickly run a specific suite or a test with coverage from the editor: click or in the left gutter and choose Run <test\_name> with Coverage from the pop-up list.

3. Monitor the code coverage in the [Coverage](#) tool window. The report shows how many files were covered with tests and the percentage of covered lines in them. From the report you can jump to the file and see what lines were covered – marked green – and what lines were not covered – marked red:

You can run and debug tests with [Protractor](#) right in IntelliJ IDEA. You can see the test results in a treeview and easily navigate to the test source from there.

## Before you start

1. Make sure the [Node.js](#) runtime environment is installed on your computer.
2. Install and enable the NodeJS repository plugin on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Installing Protractor

You can install Protractor locally, in your project, or globally. Global installation is preferable.

### To install Protractor globally

1. Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install -g protractor` at the command prompt.
2. To download the necessary binaries, type `webdriver-manager update` .

See also [Getting Started on the Protractor official website](#) .

**Tip** You can also install the `protractor` package on the [Node.js and NPM page](#) as described in NPM.

## Running tests

Protractor tests are launched only through a run/debug configuration.

### To create a Protractor run configuration

1. Open the [Run/Debug Configuration](#) dialog box ( Run | Edit Configurations on the main menu).
2. Click `+` on the toolbar and select Protractor from the list. The [Run/Debug Configuration: Protractor](#) dialog box opens.
3. Specify the Node interpreter to use, the location of the `protractor` package, and the path to the `protractor.conf.js` configuration file. If you followed the standard installation, IntelliJ IDEA detects all these paths and displays them in the corresponding fields.

**Tip** Alternatively, select a test file in the Project tool window and choose Create <file name> on the context menu.

### To run tests via a run configuration

1. Select the Protractor run/debug configuration from the list on the main toolbar and click `▶` to the right of the list. The [Selenium Server](#) starts automatically without any steps from your side.
2. View and analyze messages from the server in the <current\_run\_configuration\_name> tab of the Run tool window.

## Navigation

With IntelliJ IDEA, you can jump between a file and the related test file. Navigation from a test result in the [Test Runner Tab](#) to the test is also supported.

### To jump between a file and the related test file

Open the file in the editor and choose Go To | Test or Go To | Test Subject on the context menu, or just press

`Ctrl+Shift+T` .

**Tip** The test file should follow popular naming conventions, e.g. have a `.test.` , `.spec.` or `_spec.` suffix and should be located either next to the source file or in a `test` folder.

### To jump from a test result to the test

Select the test name in the Test Runner tab and choose Jump to Source on the context menu.

The test file opens in the editor with the cursor placed at the test definition.

## Debugging tests

A debugging session for Protractor tests is started only through a run/debug configuration.

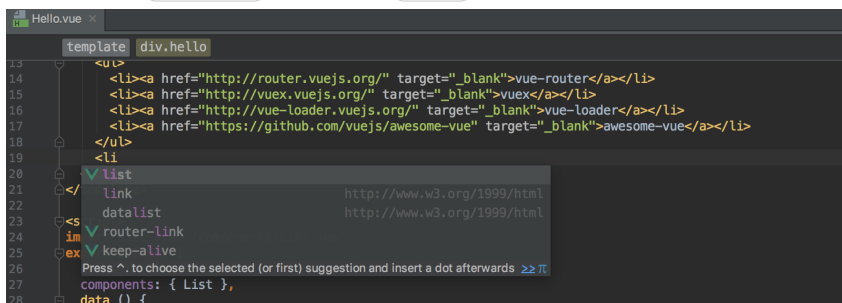

### To start debugging tests

1. Create a Protractor run/debug configuration [as described above](#) .
2. Select the Protractor run/debug configuration from the list on the main toolbar and click `🐛` to the right of the list.
3. In the [Debug Tool Window](#) that opens, proceed as usual: [step through the tests](#) , [stop and resume](#) test execution, [examine the test when suspended](#) , etc.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides intelligent support for the [Vue.js](#) framework including:

- Recognition of the `.vue` file type and a dedicated `.vue` file template for Vue.js components.
- Support for `script`, `style`, and `template` blocks in `.vue` files. IntelliJ IDEA by default provides code completion for ECMAScript 6 inside script blocks and for CSS inside style block. IntelliJ IDEA also recognizes the `lang` attribute inside the `script` and `style` tags and allows you to use TypeScript, Pug, and CSS preprocessors instead.
- Completion for Vue.js directives in templates.
- Adding closing curly braces (`}`) in Vue.js templates automatically.
- Code completion (`Ctrl+Space`) and navigation (`Ctrl+B`) for Vue components inside the `template` tag:

- Code completion and navigation to the definition for Vue.js properties, properties in the data object, computed properties, and methods.
- A collection of Live templates for Vue.js adapted from the [collection created by Sarah Drasner](#).

### Before you start

Install and enable the [Vue.js](#) plugin. The [Vue.js](#) plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

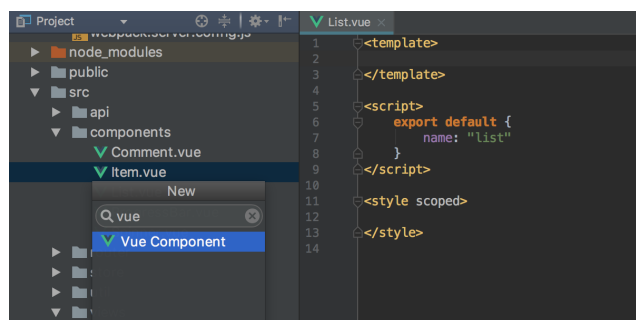

**Tip** Alternatively, follow the [Vue.js installation instructions](#).

### To start working with Vue.js

- Just open an existing project. All [Vue.js](#)-related features will work without any additional configuration.
- To get better code completion for [Vue](#) API, install the `vue` package in your project via `npm` if it is not installed yet: open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and type `npm install vue` at the command prompt.

### To create a Vue.js component

In the Project view, select the parent folder for the new component and choose [Vue Component](#) from the list.

### To use a [Vue.js Live template](#)

1. Type the template's abbreviation or press `Ctrl+J` and select it from the list of available templates.
2. To expand the template, press `Tab`.
3. To move from one variable to another inside the template, press `Tab` again.

This feature is only supported in the Ultimate edition.

In this section:

- [JavaServer Faces \(JSF\)](#)
  - [JSF support](#)
- [Preparing for JSF Application Development](#)
- [Defining Navigation Rules](#)

## JSF support

IntelliJ IDEA's support for [JavaServer Faces](#) (JSF) includes:

- JSF-aware coding assistance with [code completion](#).
- JSF [code formatting](#) and folding as well as syntax and error highlighting.
- Graphical editor for defining page navigation rules.
- JSF 2.0 support, in particular:
  - Annotated Managed Beans support with code completion, rename refactoring, usage search, go to declaration, and more. Possibility to reference managed beans directly from Java code.
  - Improved template support (completion, validation and navigation for the `name` attribute of the `ui:define` tag).
  - Support for ActionSources and ValueHolders.
  - Support for the `targets` attribute of composite components.
  - Extended support for EL in composite components implementation, and more.
- Dedicated [JSF tool window](#) that aggregates all JSF-related configurations in a single place, and lets you easily analyze and navigate to both annotated and xml elements.
- `@ResourceDependencies` and `@ResourceDependency` annotations support.
- Simplified navigation rules support including completion for neighbor pages and absolute paths, usage search, and rename refactoring.
- Resource Handlers support: code completion, syntax and error highlighting, usage search and refactorings.
- Composite components support: code completion, refactorings, usage search and more.
- Code completion, error highlighting, and basic refactorings for the most popular JSF component libraries, including:
  - [RichFaces](#)
  - [ICEfaces](#)
  - [PrimeFaces](#)
  - [OpenFaces](#)

This feature is only supported in the Ultimate edition.

To prepare for JSF application development, you should:

- Make sure that the Java EE: Java Server Faces [plugin](#) is enabled. This plugin is bundled with the IDE and enabled by default. However, you may have disabled it for some reason by now.
- Create a [project](#) or [module](#) with JSF support enabled, or enable JSF support in an existing module.

On this page:

- [Making sure that the Java Server Faces plugin is enabled](#)
- [Enabling JSF support when creating a project or module](#)
- [Enabling JSF support for an existing module](#)

## Making sure that the Java Server Faces plugin is enabled

1. [Open the Settings dialog](#) (e.g. `Ctrl+Alt+S`).
2. In the left-hand part of the dialog, select [Plugins](#).
3. In the right-hand part of the dialog, on the [Plugins page](#), type `faces` in the search box. As a result, only the plugins whose names and descriptions contain `faces` are shown in the list of plugins.
4. If the checkbox to the right of Java EE: Java Server Faces is not selected, select it.
5. Click OK in the Settings dialog.
6. If suggested, restart IntelliJ IDEA.

## Enabling JSF support when creating a project or module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project.  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module.  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java Enterprise. In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.
3. If, at this step, you are ready to specify the application server you are going to deploy your application to (e.g. to test the application behavior), do so. This will result in the corresponding server-specific [run/debug configuration](#) for your module generated automatically. Otherwise, to be able to run your application, you will have to create the run/debug configuration yourself.  
Select the server from the list or click New and select the server of interest. Then, specify the server settings:
  - For a server installed locally, specify the path to the server installation directory. (Click  to select the directory in the [corresponding dialog](#).)
  - For a hosted server (Cloud Foundry or CloudBees), specify your user account details.
4. Under Additional Libraries and Frameworks, select the Web Application checkbox.  
Select the version of the Servlet specification to be supported from the Versions list.  
  
If you want the deployment descriptor `web.xml` file to be created, select the Create web.xml checkbox.
5. Select the JSF checkbox.  
If you want the configuration file `faces-config.xml` to be created, select the Create faces-config.xml checkbox.

Select the required library option and, if necessary, specify the associated settings. You can choose to:

- Download and use a JSF implementation library (Mojarra).  
To do that, under Libraries, select Download.

Now, to view or modify the associated options, click [Configure](#), and in the Downloading Options dialog that opens:

- Select the library version.
- Specify the library name.
- Select the [library level](#) (global, project, or module).
- Under Files to download, select which of the files you want to download.
- Under Copy downloaded files to, specify the path to the destination folder. If you want to change the default path, click  and specify the folder location in the [dialog that opens](#).
- Use a JSF library IntelliJ IDEA is already aware of.  
To do that, click Use library and select the required library from the list.

If necessary, configure the library settings (for example, change its name). This is done in the Edit Library dialog which you can open by clicking [Configure](#).

- Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click Create . Select the required JAR files in the [dialog that opens](#) .  
(For multiple selection, keep the `Ctrl` key pressed.)
  - If necessary, configure the new library (for example, change its name or [level](#) ). To do that, click Configure and specify the required settings in the Create Library dialog.
  - Postpone setting up the library until a later time. In this case, select Set up library later .
6. If you are going to use a JSF component library or libraries (e.g. PrimeFaces, RichFaces, etc.), select the corresponding checkbox or checkboxes and specify the associated options. The procedure is similar to that for the JSF implementation library.  
Click Next .
7. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click Finish .

As a result, your new module will contain:

- The `web` and `WEB-INF` directories.
- The file `index.xhtml` in the `web` directory. With minor modifications, you can use this file as a starting page of your application.
- In the `WEB-INF` directory, if specified:
  - `web.xml` , the Web application deployment descriptor.
  - `faces-config.xml` , the JSF configuration file.

- If specified, the JSF library or libraries included in the [module dependencies](#) .
- An [artifact](#) specification for you module.
- If you have specified the server, a [run/debug configuration](#) for running your application in the context of that server.

## Enabling JSF support for an existing module

1. [Open the Project tool window](#) (e.g. View | Tool Windows | Project ).
2. Right-click the module and select Add Framework Support .
3. In the left-hand pane of the Add Frameworks Support dialog, select the Web Application checkbox.  
In the right-hand part of the dialog, select the version of the Servlet specification to be supported from the Versions list.  
  
If you want the deployment descriptor `web.xml` file to be created, select the Create web.xml checkbox.
4. Select the JSF checkbox.  
If you want the configuration file `faces-config.xml` to be created, select the Create faces-config.xml checkbox.

Select the required library option and, if necessary, specify the associated settings. You can choose to:

- Download and use a JSF implementation library (Mojarra).  
To do that, under Libraries , select Download .

Now, to view or modify the associated options, click Configure , and in the Downloading Options dialog that opens:

- Select the library version.
- Specify the library name.
- Select the [library level](#) (global, project, or module).
- Under Files to download , select which of the files you want to download.
- Under Copy downloaded files to , specify the path to the destination folder. If you want to change the default path, click `⋮` and specify the folder location in the [dialog that opens](#) .

- Use a JSF library IntelliJ IDEA is already aware of.  
To do that, click Use library and select the required library from the list.

If necessary, configure the library settings (for example, change its name). This is done in the Edit Library dialog which you can open by clicking Configure .

- Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click Create . Select the required JAR files in the [dialog that opens](#) .  
(For multiple selection, keep the `Ctrl` key pressed.)

If necessary, configure the new library (for example, change its name or [level](#) ). To do that, click Configure

and specify the required settings in the Create Library dialog.

– Postpone setting up the library until a later time. In this case, select Set up library later .

5. If you are going to use a JSF component library or libraries (e.g. PrimeFaces, RichFaces, etc.), select the corresponding checkbox or checkboxes and specify the associated options. The procedure is similar to that for the JSF implementation library.

6. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

Navigation diagrams provide additional support for managing the rules of navigation between the pages of your application. In certain cases, they are a useful alternative to editing the contents of `faces-config.xml`.

With `faces-config.xml` open in the editor, use the Navigation tab to view and draw the diagram. Your drawing is automatically synchronized with the contents of `faces-config.xml` (and vice versa).

For detailed information about the available controls and context menu commands, see [Diagram Toolbar and Context Menu](#).

## Using the navigation diagram to create the navigation rules

1. Open `faces-config.xml` in the [editor](#).
2. Click the Navigation tab.
3. Drag the required pages (one by one) from the [Project Tool Window](#) onto the Navigation tab.
4. Use the mouse to draw the navigation lines between the pages. As a result, the corresponding navigation rules are created. (Switch onto the Text tab to see those rules.)

This feature is only supported in the Ultimate edition.

- [Java Persistence API \(JPA\)](#)
- [Hibernate](#)
- [Working with the Persistence Tool Window](#)

This feature is only supported in the Ultimate edition.

- [Overview of JPA support](#)
- [Enabling JPA Support](#)
- [Working with the Persistence Tool Window](#)
- [Working with the JPA console](#)

This feature is only supported in the Ultimate edition.

For working with [Java Persistence API](#) (JPA), IntelliJ IDEA provides:

- The Java EE: EJB, JPA, Servlets [plugin](#) . This plugin is bundled with the IDE and enabled by default. See [Making sure that the Java EE: EJB, JPA, Servlets plugin is enabled](#) .
- An ability to turn on JPA support for a [module](#) . You can do that when creating a project or module, or for an existing project or module. See [Enabling JPA Support](#) .
- A JPA [facet](#) for managing JPA configuration ( `persistence.xml` ) and object/relational mapping ( `orm.xml` ) files. See [Hibernate and JPA Facet Pages](#) .
- The Persistence tool window that shows your JPA project items and lets you create new configuration files and persistent classes, navigate to related source code in the editor, open diagrams and consoles, and more. See [Working with the Persistence Tool Window](#) .
- An ability to generate managed entity classes and object/relational mappings for them by importing a database schema, an EJB deployment descriptor file `ejb-jar.xml` or a Hibernate object/relational mapping file `.hbm.xml` . See [Generating managed entity classes and O/R mappings](#) .
- Entity-relationship (ER) diagrams.  
The ER diagrams are accessed from the Persistence tool window (see [Opening entity-relationship diagrams](#) ) and provide about the same set of functions as the tool window.  
  
Those functions are accessed as context menu commands. The context menus are different for the entity classes and the main diagram area (which corresponds to a `<persistence-unit>`).
- A JPA console that lets you write and run JPQL queries, and analyze the query results. See [Working with the JPA console](#) .
- [Code completion](#) in Java code including JPA annotations and their attributes, and also in JPA configuration and O/R mapping XML files.
- JPA-specific [code inspections](#) .
- Navigation markers in the left margin of the editor e.g. for jumping from entity classes to corresponding fragments in mapping files.

This feature is only supported in the Ultimate edition.

- [Overview](#)
- [Making sure that the Java EE: EJB, JPA, Servlets plugin is enabled](#)
- [Enabling JPA support when creating a project or module](#)
- [Enabling JPA support for an existing module](#)

## Overview

To be able to use JPA support, you should:

- Make sure that the Java EE: EJB, JPA, Servlets [plugin](#) is enabled. (This plugin is bundled with the IDE and enabled by default.)
- Enable JPA support at a [module](#) level. You can do that when creating a new project or module. You can also enable JPA support for an existing module. In all such cases, IntelliJ IDEA will (some of the following will be offered as options):
  - Create a JPA configuration file `persistence.xml` .
  - Download the library files that implement the framework and add them to the [dependencies](#) of the corresponding module.
  - Generate entity classes and object/relational mappings for your database tables (if you have an appropriate [data source](#) available).
  - Create a JPA [facet](#) . You'll be able to use that facet for specifying the default configuration and object-relational mapping files, and JPA implementation provider.
  - Make the Persistence tool window available.

## Making sure that the Java EE: EJB, JPA, Servlets plugin is enabled

1. [Open the Settings / Preferences dialog](#) (e.g. `Ctrl+Alt+S` ).
2. In the left-hand part of the dialog, select [Plugins](#) .
3. In the right-hand part of the dialog, on the [Plugins page](#) , type `jpa` in the search box. As a result, only the plugins whose names and descriptions contain `jpa` are shown.
4. If the checkbox to the right of Java EE: EJB, JPA, Servlets is not selected, select it.
5. Click [OK](#) .
6. If suggested, restart IntelliJ IDEA.

## Enabling JPA support when creating a project or module

1. Do one of the following:
    - If you are going to create a new project: click [Create New Project](#) on the [Welcome screen](#) or select [File | New | Project](#) . As a result, the [New Project wizard](#) opens.
    - If you are going to add a module to an existing project: open the project you want to add a module to, and select [File | New | Module](#) . As a result, the [New Module wizard](#) opens.
  2. On the first page of the wizard, in the left-hand pane, select [Java](#) . In the right-hand part of the page, specify the [JDK](#) that you are going to use.
  3. Under [Additional Libraries and Frameworks](#) , select the [JavaEE Persistence](#) checkbox.
  4. Select the version of `persistence.xml` to be created. (`persistence.xml` is a JPA configuration file.)  
If necessary, select the Java persistence provider, i.e. the JPA implementation provider. (This setting, initially, will only affect the `<provider>` element in `persistence.xml` .)  
  
If there is a database defined in IntelliJ IDEA as a data source, you can select to import the database schema. This will result in creating the necessary JPA entity classes and object/relational mappings for them.
  5. Select the required library option and, if necessary, specify the associated settings. You can choose to:
    - Download JPA implementation files and arrange those files in a [library](#) .  
To do that, under [Libraries](#) , select [Download](#) . Optionally, click [Configure](#) to edit the library settings. (The [Downloading Options dialog](#) will open.)
    - Use a library that is already defined IntelliJ IDEA.  
To do that, click [Use library](#) and select the required library from the list. Optionally, click [Configure](#) to edit the library settings. (The [Edit Library dialog](#) will open.)
    - Create a new library using the appropriate JAR files available on your computer.  
To do that, click [Use library](#) and then click [Create](#) . Select the required JAR files in the [dialog that opens](#) . (For multiple selection, keep the `Ctrl` key pressed.) Optionally, click [Configure](#) to edit the library settings. (The [Create Library dialog](#) will open.)
    - Postpone setting up the library until a later time. In this case, select [Set up library later](#) .
- Click [Next](#) .
6. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click [Finish](#) .

If you selected to import a database schema, the [Import Database Schema dialog](#) opens, and you can specify the entity classes to be generated and associated settings.

## Enabling JPA support for an existing module

1. In the [Project Tool Window](#) , right-click the necessary module and select Add Framework Support .
2. In the left-hand pane of the Add Frameworks Support dialog that opens, select the JavaEE Persistence checkbox.
3. Select the version of `persistence.xml` to be created. ( `persistence.xml` is a JPA configuration file.)  
If necessary, select the Java persistence provider, i.e. the JPA implementation provider. (This setting, initially, will only affect the `<provider>` element in `persistence.xml` .)

If there is a database defined in IntelliJ IDEA as a data source, you can select to import the database schema. This will result in creating the necessary JPA entity classes and object/relational mappings for them.

4. Select the required library option and, if necessary, specify the associated settings. You can choose to:
  - Download JPA implementation files and arrange those files in a [library](#) .  
To do that, under Libraries , select Download . Optionally, click Configure to edit the library settings. (The [Downloading Options dialog](#) will open.)
  - Use a library that is already defined IntelliJ IDEA.  
To do that, click Use library and select the required library from the list. Optionally, click Configure to edit the library settings. (The [Edit Library dialog](#) will open.)
  - Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click Create . Select the required JAR files in the [dialog that opens](#) . (For multiple selection, keep the `Ctrl` key pressed.) Optionally, click Configure to edit the library settings. (The [Create Library dialog](#) will open.)
  - Postpone setting up the library until a later time. In this case, select Set up library later .
5. Click OK .

If you selected to import a database schema, the [Import Database Schema dialog](#) opens, and you can specify the entity classes to be generated and associated settings.

This feature is only supported in the Ultimate edition.

Use the JPA console to write and run JPQL queries, analyze the query results, and also to perform other, associated tasks.

- [Updating the table view](#)
- [Viewing the query](#)
- [Closing a console](#)

See also, [JPA Console Tool Window](#) .

## Prerequisite

For the JPA console to be fully functional, you should associate your persistence unit with the corresponding [data source](#) , see [Associating persistence units and session factories with data sources](#) .

## Opening the JPA console

1. Open the Persistence tool window (e.g. View | Tool Windows | Persistence ).
2. Expand the JPA facet node.
3. Select the persistence unit for which you want to open the console or any node within that persistence unit.
4. Do one of the following:
  - Click  on the title bar.
  - Select Console from the context menu.
  - Press `Ctrl+Shift+F10` .

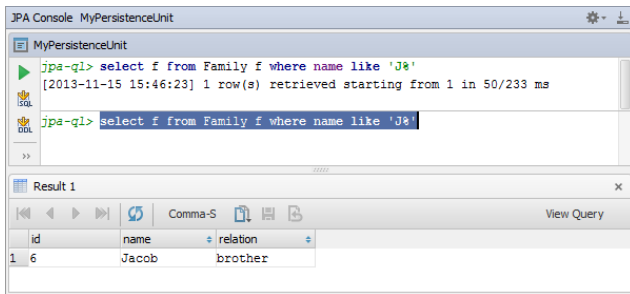

5. If asked to choose the console, select JPA Console .

As a result, the JPA Console tool window opens and the input pane is shown. This is where you compose your JPQL queries.

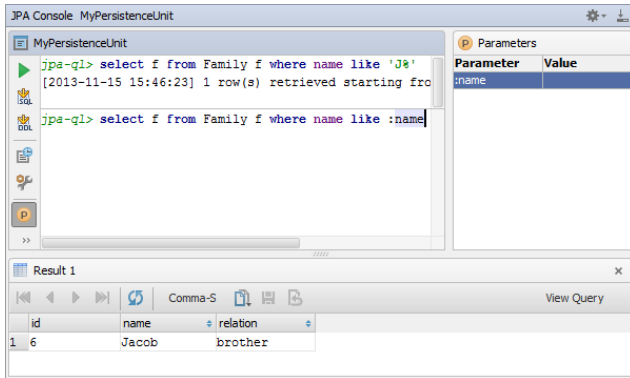

When you run your first query (  ), the output pane opens above the input pane. Basically, this is the log of operations performed in the console.

If your query retrieves data (e.g. `select` ), also the Result pane opens showing the retrieved data in table format.

Additionally, you can open the Parameters pane (P) to manage parameters in your queries.

## Running the console with custom JVM options

The JPA console is a Java process. If necessary, you can start it with custom JVM options:

1. Create an Application run configuration: Run | Edit Configurations | + | Application .  
In the VM options field, specify the options that you want to pass to the JVM at its start. The rest of the run configuration settings don't matter and you don't need to specify them.
2. When [starting the console](#), IntelliJ IDEA will now display an additional Configurations popup with the following options:
  - <default>. This option corresponds to an ordinary way of starting the console.
  - <YourRunConfigurationName>. Select this option to start the console with the VM options you have specified.

## Viewing and modifying console settings

Before actually starting to use a console, you may want to take a look at the console settings and adjust them to your needs.

- To access these settings, click on the toolbar of the JPA Console tool window. (Alternatively, `Ctrl+Alt+S` | Tools | Database .)

As a result, the [Database page](#) of the Settings / Preferences dialog will open. The settings for the JPA console are on the following pages:

- [Data Views](#)
- [CSV Formats](#)

## Composing JPQL queries

When composing your queries in the input pane, use auto-completion and highlighting of JPQL keywords, and object and property names.

See also, [Navigating to the declaration of a class or field](#) .

## Navigating to the declaration of a class or field

When composing a query, it's sometimes useful to take a look at the declaration of a class or field for an object or property referenced in the input pane. To navigate to the corresponding declaration, do one of the following:

- Place the cursor within the name of the object or property of interest. Then use `Ctrl+B` . (Alternatively, you can use `Navigate | Declaration` from the main menu.)
- Press and hold the `Ctrl` key, and point to the name of interest. When the text turns into a hyperlink, click the hyperlink.

As a result, the necessary source file opens in the editor and the cursor is placed within the declaration of the corresponding class or the getter method for the corresponding field.

## Running a query

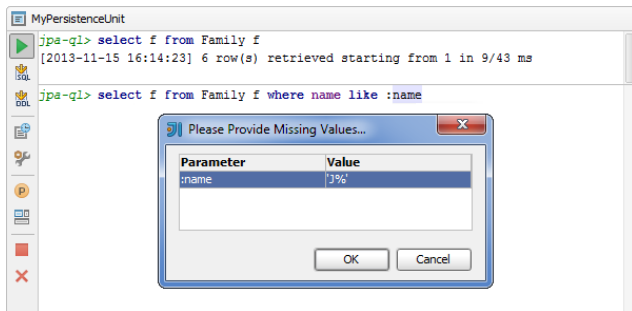

To run the current query, do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Enter`.

## Running parameterized queries

Your queries can contain parameters, however, by the time you run such queries the values of the parameters must be specified. There are the following ways of specifying the parameter values:

- Click  on the toolbar or press `Ctrl+Enter` to run the query. In the dialog that opens, specify the parameter values and click OK.

( To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press `Enter` or switch to a different cell. To quit the editing mode and restore an initial value, press `Escape` .)

- Alternatively, you can open the Parameters pane  on the toolbar and specify the corresponding values there. (The values are edited in the same way as in the corresponding dialog.) Then run the query  on the toolbar or `Ctrl+Enter` ).

Parameter values can be specified just as text or numbers, or as [Groovy](#) expressions that contain object references and method calls. For example, the value for the `date` parameter in the query

```
SELECT o
FROM Order o
WHERE o.date > :date
```

could be specified as

```
new java.sql.Date(System.currentTimeMillis() - 24*3600*1000)
```

## Running auto-memorized queries

As you run JPQL queries in the console, IntelliJ IDEA memorizes them. So, at a later time, you can view the queries you have already run and, if necessary, run them again.

To open the dialog where the auto-memorized queries are shown (the History dialog), do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Alt+E`.

There are two panes in the History dialog. The left-hand pane shows the list of the queries that you have run. For "long" queries, only their beginnings are shown. When you select a query in this pane, the overall query is shown in the pane to the right.

You can filter the information: just start typing. As a result, only the queries that contain the typed text will be shown.

You can copy the queries from the History dialog into the input pane of the console. To copy a query, do one of the following:

- Double-click the query to be copied.
- Select the query of interest and press `Enter`.
- Select the query and click OK.

(Once the query is in the input pane, you can run it straight away.)

You can delete unnecessary memorized queries. To delete a query, select the query in the History dialog and press

`Delete` .

## Terminating query execution

To terminate execution of the current query, do one of the following:

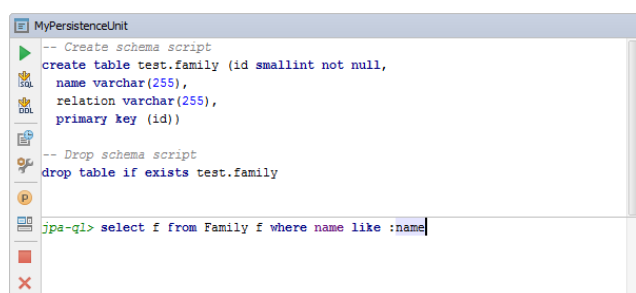

- Click  on the toolbar.
- Press `Ctrl+F2` .

## Generating SQL statements and DDL SQL scripts

You can generate SQL statements for your JPQL queries and DDL SQL scripts for your persistence unit:

- To generate an SQL equivalent of the current query, do one of the following:
  - Click  on the toolbar.
  - Press `Ctrl+Shift+Enter` .
- To generate DDL SQL statements (`CREATE TABLE` , `ALTER TABLE` and `DROP TABLE` ) for all the objects (classes) associated with the corresponding persistence unit, do one of the following:
  - Click  on the toolbar.
  - Press `Ctrl+Shift+Alt+Enter` .

The generated SQL statements are shown in the output pane.

```
MyPersistenceUnit
-- Create schema script
create table test.family (id smallint not null,
  name varchar(255),
  relation varchar(255),
  primary key (id))
-- Drop schema script
drop table if exists test.family

jpa-gi> select f from Family f where name like :name
```

## Hiding or showing the toolbar

To hide or show the toolbar of the Result pane:

- Click  on the title bar of the JPA Console tool window and click Show Toolbar .

## Pinning the Result tab

If one and the same tab is used to show your query results, and you get the result that you want to keep, you can pin the tab to the tool window. To do that:

- Right-click the tab and select Pin Tab .

See also, [Show query results in new tab](#) .

## Switching between subsets of rows

If only a subset of the rows that satisfy the query is currently shown, to switch between the subsets, use:

-  First Page
-  Previous Page (`Ctrl+Alt+Up` )
-  Next Page (`Ctrl+Alt+Down` )
-  Last Page

See also, [Making all rows visible simultaneously](#) .

## Making all rows visible simultaneously

If you want all the rows that satisfy the query to be shown simultaneously:

1. Click  on the toolbar of the JPA Console tool window.
2. Switch to the Database | Data Views page, specify `0` in the Result set page size field, and click OK .
3. Click  or press `Ctrl+F5` to refresh the table view.

See also, [Updating the table view](#) and [Result set page size](#) .

## Navigating to a specified row

To switch to a row with a specified number:

1. Do one of the following:

- Press `Ctrl+G`.
- Right-click the table and select Go To | Row from the context menu.
- Select Navigate | Row from the main menu.

2. In the dialog that opens, specify the row number and click OK.

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this: .

The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance: . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

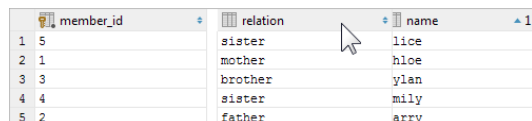

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order: .

Finally, when you click the cell for the third time, the initial state is restored. That is, sorting by the corresponding column is canceled: .

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#).

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row.

	member_id	relation	name
1	5	sister	lice
2	1	mother	hloe
3	3	brother	ylan
4	4	sister	mily
5	2	father	arry

See also, [Restoring the initial table view](#).

## Hiding and showing columns

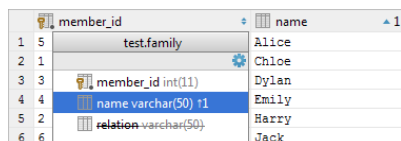

To hide a column, right-click the corresponding header cell and select Hide column.

To show a hidden column:

1. Do one of the following:

- Right-click any of the cells in the header row and select Column List.
- Press `Ctrl+F12`.

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name	relation
1	5	Alice	
2	1	Chloe	
3	3	Dylan	
4	4	Emily	
5	2	Harry	
6	6	Jack	

2. Select (highlight) the column name of interest and press `Space`.

3. Press `Enter` or `Escape` to close the list.

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#).

## Restoring the initial table view

Click  on the toolbar to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the corresponding query, and all the columns are shown.

## Using the Structure view to sort data, and hide and show columns

When working with the Result pane, the table structure view is available as the corresponding popup.

The structure view shows the list of all the columns and lets you sort the data as well as hide and show the columns.

To open the structure popup, do one of the following:

- Right-click a cell in the table header row and select Column List.
- Press `Ctrl+F12`.

In the popup, select the column of interest and do one of the following:

- To sort the data by this column in the ascending order, press `Shift+Alt+Up`.
- To sort the data in the descending order, press `Shift+Alt+Down`.

- To cancel sorting by this column, press `Ctrl+Shift+Alt+Backspace` .
- To hide the column (or show a hidden column), press `Space` . (The names of hidden columns are shown struck through.)

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

The shortcuts for sorting table data (`Shift+Alt+Up` , `Shift+Alt+Down` and `Ctrl+Shift+Alt+Backspace` ) can be used in the Result pane without opening the structure view.

See also, [Sorting data](#) , [Hiding and showing columns](#) and [Restoring the initial table view](#) .

## Copying table data to the clipboard or saving them in a file

When copying table data to the clipboard or saving them in a file, the data are converted into one of the available output formats. This can be SQL `INSERT` or `UPDATE` statements, [TSV or CSV](#) , an HTML table or [JSON](#) data. See [Specifying data output format and options](#) .

To copy or save the data, use:

- Copy (available in the Edit and the context menu, the keyboard equivalent is `Ctrl+C` ). This command copies the data for the selected cells onto the clipboard.
- Dump Data | To Clipboard (available in the context menu and can also be accessed by means of  on the toolbar). This command copies the data for the whole table onto the clipboard.
- Dump Data | To File (available in the context menu and can also be accessed by means of  on the toolbar). This command saves the data for the whole table in a file. Before actually saving the data, the dialog is shown which lets you select the output format and see how your data will look in a file.

## Specifying data output format and options

To specify the output format and options for the Copy and Dump Data commands (see [Copying table data to the clipboard or saving them in a file](#) ), do one of the following:

- Click `Tab-separated (TSV)` on the toolbar.
- Right-click the table and point to Data Extractor: <current\_format> .

In the menu that opens, the output formats are in the upper part: SQL Inserts , SQL Updates , etc. (The options that look like file names are also the output formats or, to be more exact, the scripts that implement corresponding data converters.)

The output option are:

- Allow Transposition. This option affects only delimiter-separated values formats (TSV, CSV). If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. `Ctrl+C` ), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). This is the option for SQL INSERTs and UPDATEs. When on, auto-increment fields are not included.
- Add Table Definition (SQL). This is also the option for SQL INSERTs and UPDATEs. When on, the table definition (CREATE TABLE) is added.

Additionally:

- Configure CSV Formats. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

## Saving a LOB in a file

If a cell contains a [binary large object](#) (a.k.a. BLOB or LOB), you can save such a LOB in a file.

1. Right-click the cell that contains the LOB of interest and select Save LOB To File .
2. In the dialog that opens, specify the name and location of the destination file and click OK .

## Updating the table view

To refresh the table view, do one of the following:

- Click  on the toolbar.
- Right-click the table and select Reload Page from the context menu.
- Press `Ctrl+F5` .

Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

## Viewing the query

To see the query that was used to generate the table:

– Click View Query on the toolbar.

If necessary, you can select the query text and copy it to the clipboard ( `Ctrl+C` ).

To close the pane where the query is shown, press `Escape` .

## Closing a console

To close a console, do one of the following:

– Click  on the toolbar.

– Press `Ctrl+Shift+F4` .

This feature is only supported in the Ultimate edition.

- [Overview of Hibernate support](#)
- [Enabling Hibernate Support](#)
- [Working with the Persistence Tool Window](#)
- [Working with the Hibernate console](#)

This feature is only supported in the Ultimate edition.

For working with [Hibernate](#), IntelliJ IDEA provides:

- The Hibernate Support [plugin](#). This plugin is bundled with the IDE and enabled by default. See [Making sure that the Hibernate Support plugin is enabled](#).
- An ability to turn on Hibernate support for a [module](#). You can do that when creating a project or module, or for an existing project or module. See [Enabling Hibernate Support](#).
- A Hibernate [facet](#) for managing Hibernate configuration files ( `hibernate.cfg.xml` ). See [Hibernate and JPA Facet Pages](#).
- The Persistence tool window that shows your Hibernate project items and lets you create new configuration files and persistent classes, navigate to related source code in the editor, open diagrams and consoles, and more. See [Working with the Persistence Tool Window](#).
- An ability to generate managed entity classes and object/relational mappings for them by importing a database schema or an EJB deployment descriptor file `ejb-jar.xml`. See [Generating managed entity classes and O/R mappings](#).
- Entity-relationship (ER) diagrams.  
The ER diagrams are accessed from the Persistence tool window (see [Opening entity-relationship diagrams](#)) and provide about the same set of functions as the tool window.

Those functions are accessed as context menu commands. The context menus are different for the entity classes and the main diagram area (which corresponds to a `<session-factory>`).

- A Hibernate console that lets you write and run HQL queries, and analyze the query results. See [Working with the Hibernate console](#).
- [Code completion](#) in Java code including Hibernate annotations and their attributes, and also in Hibernate configuration and O/R mapping XML files.
- Hibernate-specific [code inspections](#).
- Navigation markers in the left margin of the editor e.g. for jumping from entity classes to corresponding fragments in mapping files.

This feature is only supported in the Ultimate edition.

- [Overview](#)
- [Making sure that the Hibernate Support plugin is enabled](#)
- [Enabling Hibernate support when creating a project or module](#)
- [Enabling Hibernate support for an existing module](#)

## Overview

To be able to use Hibernate support, you should:

- Make sure that the Hibernate Support [plugin](#) is enabled. (This plugin is bundled with the IDE and enabled by default.)
- Enable Hibernate support at a [module](#) level. You can do that when creating a new project or module. You can also enable Hibernate support for an existing module. In all such cases, IntelliJ IDEA will (some of the following will be offered as options):
  - Create a Hibernate configuration file `hibernate.cfg.xml` and a class with a `main()` method that outputs the records for your managed entities.
  - Download the library files that implement the framework and add them to the [dependencies](#) of the corresponding module.
  - Generate entity classes and object/relational mappings for your database tables (if you have an appropriate [data source](#) available).
  - Create a Hibernate [facet](#). You'll be able to use that facet for managing your configuration `hibernate.cfg.xml` files.
  - Make the Persistence tool window available.

## Making sure that the Hibernate Support plugin is enabled

1. [Open the Settings / Preferences dialog](#) (e.g. `Ctrl+Alt+S`).
2. In the left-hand part of the dialog, select [Plugins](#).
3. In the right-hand part of the dialog, on the [Plugins page](#), type `hib` in the search box. As a result, only the plugins whose names and descriptions contain `hib` are shown.
4. If the checkbox to the right of Hibernate Support is not selected, select it.
5. Click [OK](#).
6. If suggested, restart IntelliJ IDEA.

## Enabling Hibernate support when creating a project or module

1. Do one of the following:
    - If you are going to create a new project: click [Create New Project](#) on the [Welcome screen](#) or select [File | New | Project](#). As a result, the [New Project wizard](#) opens.
    - If you are going to add a module to an existing project: open the project you want to add a module to, and select [File | New | Module](#). As a result, the [New Module wizard](#) opens.
  2. On the first page of the wizard, in the left-hand pane, select [Java](#). In the right-hand part of the page, specify the [JDK](#) that you are going to use.
  3. Under [Additional Libraries and Frameworks](#), select the [Hibernate](#) checkbox.
  4. If necessary, select to create a configuration file (`hibernate.cfg.xml`) and a main class (a class with a `main()` method that outputs the records for your managed entities).  
If there is a database defined in IntelliJ IDEA as a data source, you can select to import the database schema. This will result in creating the necessary entity classes and object/relational mappings for them.
  5. Select the required library option and, if necessary, specify the associated settings. You can choose to:
    - Download Hibernate implementation files and arrange those files in a [library](#).  
To do that, under [Libraries](#), select [Download](#). Optionally, click [Configure](#) to edit the library settings. (The [Downloading Options dialog](#) will open.)
    - Use a library that is already defined in IntelliJ IDEA.  
To do that, click [Use library](#) and select the required library from the list. Optionally, click [Configure](#) to edit the library settings. (The [Edit Library dialog](#) will open.)
    - Create a new library using the appropriate JAR files available on your computer.  
To do that, click [Use library](#) and then click [Create](#). Select the required JAR files in the [dialog that opens](#). (For multiple selection, keep the `Ctrl` key pressed.) Optionally, click [Configure](#) to edit the library settings. (The [Create Library dialog](#) will open.)
    - Postpone setting up the library until a later time. In this case, select [Set up library later](#).
- Click [Next](#).
6. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#).  
Click [Finish](#).

If you selected to import a database schema, the [Import Database Schema dialog](#) opens, and you can specify the entity classes to be generated and associated settings.

## Enabling Hibernate support for an existing module

1. In the [Project Tool Window](#) , right-click the necessary module and select Add Framework Support .
2. In the left-hand pane of the Add Frameworks Support dialog that opens, select the Hibernate checkbox.
3. If necessary, select to create a configuration file ( [hibernate.cfg.xml](#) ) and a main class (a class with a `main()` method that outputs the records for your managed entities).

If there is a database defined in IntelliJ IDEA as a data source, you can select to import the database schema. This will result in creating the necessary entity classes and object/relational mappings for them.

4. Select the required library option and, if necessary, specify the associated settings. You can choose to:
  - Download Hibernate implementation files and arrange those files in a [library](#) .  
To do that, under Libraries , select Download . Optionally, click Configure to edit the library settings. (The [Downloading Options dialog](#) will open.)
  - Use a library that is already defined IntelliJ IDEA.  
To do that, click Use library and select the required library from the list. Optionally, click Configure to edit the library settings. (The [Edit Library dialog](#) will open.)
  - Create a new library using the appropriate JAR files available on your computer.  
To do that, click Use library and then click Create . Select the required JAR files in the [dialog that opens](#) . (For multiple selection, keep the `Ctrl` key pressed.) Optionally, click Configure to edit the library settings. (The [Create Library dialog](#) will open.)
  - Postpone setting up the library until a later time. In this case, select Set up library later .
5. Click OK .

If you selected to import a database schema, the [Import Database Schema dialog](#) opens, and you can specify the entity classes to be generated and associated settings.

This feature is only supported in the Ultimate edition.

Use the Hibernate console to write and run HQL queries, analyze the query results, and also to perform other, associated tasks.

- [Prerequisites](#)
- [Opening the Hibernate console](#)
- [Viewing and modifying console settings](#)
- [Composing HQL queries](#)
- [Navigating to the declaration of a class or field](#)
- [Running a query](#)
- [Running parameterized queries](#)
- [Running auto-memorized queries](#)
- [Terminating query execution](#)
- [Generating SQL statements and DDL SQL scripts](#)
- [Hiding or showing the toolbar](#)
- [Pinning the Result tab](#)
- [Switching between subsets of rows](#)
- [Making all rows visible simultaneously](#)
- [Navigating to a specified row](#)
- [Sorting data](#)
- [Reordering columns](#)
- [Hiding and showing columns](#)
- [Restoring the initial table view](#)
- [Using the Structure view to sort data, and hide and show columns](#)
- [Copying table data to the clipboard or saving them in a file](#)
- [Specifying data output format and options](#)
- [Saving a LOB in a file](#)
- [Updating the table view](#)
- [Viewing the query](#)
- [Closing a console](#)

See also, [Hibernate Console Tool Window](#) .

## Prerequisites

For the Hibernate console to be fully functional, you should:

- Associate your session factory with the corresponding [data source](#) , see [Associating persistence units and session factories with data sources](#) .
- If you are using custom entity class/db table name mappings which are not fully reflected in your code and/or configuration files, specify the corresponding NamingStrategy implementation, see [Associating a session factory with a NamingStrategy implementation class \(Hibernate\)](#) .

## Opening the Hibernate console

1. Open the Persistence tool window (e.g. View | Tool Windows | Persistence ).
2. Expand the Hibernate facet node.
3. Select the session factory for which you want to open the console or any node within that session factory.
4. Do one of the following:
  - Click  on the title bar.
  - Select Console from the context menu.
  - Press `Ctrl+Shift+F10` .

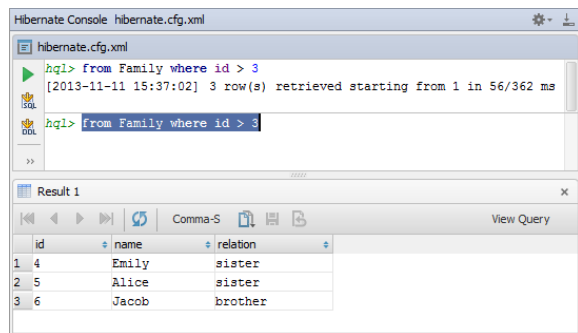

As a result, the Hibernate Console tool window opens and the input pane is shown. This is where you compose your HQL queries.

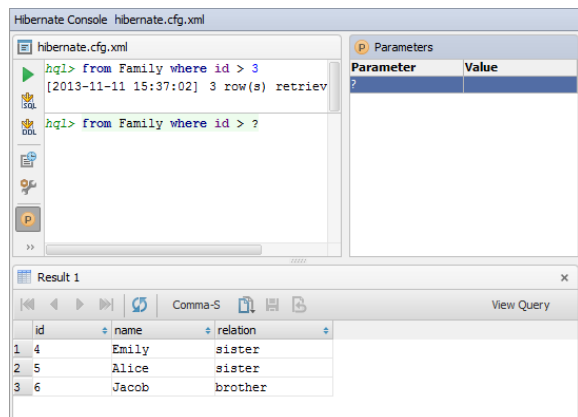

When you run your first query (  ), the output pane opens above the input pane. Basically, this is the log of operations performed in the console.

If your query retrieves data (e.g. `from` , `select` ), also the Result pane opens showing the retrieved data in table format.

Additionally, you can open the Parameters pane (  ) to manage parameters in your queries.

## Viewing and modifying console settings

Before actually starting to use a console, you may want to take a look at the console settings and adjust them to your needs.

- To access these settings, click  on the toolbar of the Hibernate Console tool window. (Alternatively, `Ctrl+Alt+S` | Tools | Database .)

As a result, the [Database page](#) of the Settings / Preferences dialog will open. The settings for the Hibernate console are on the following pages:

- [Data Views](#)
- [CSV Formats](#)

## Composing HQL queries

When composing your queries in the input pane, use auto-completion and highlighting of HQL keywords, and object and property names.

See also, [Navigating to the declaration of a class or field](#) .

## Navigating to the declaration of a class or field

When composing a query, it's sometimes useful to take a look at the declaration of a class or field for an object or property referenced in the input pane. To navigate to the corresponding declaration, do one of the following:

- Place the cursor within the name of the object or property of interest. Then use `Ctrl+B` . (Alternatively, you can use [Navigate | Declaration](#) from the main menu.)
- Press and hold the `Ctrl` key, and point to the name of interest. When the text turns into a hyperlink, click the hyperlink.

As a result, the necessary source file opens in the editor and the cursor is placed within the declaration of the corresponding class or the getter method for the corresponding field.

## Running a query

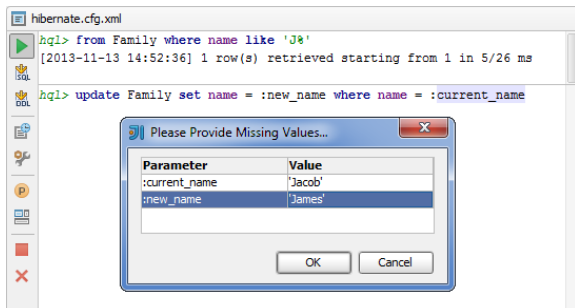

To run the current query, do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Enter`.

## Running parameterized queries

Your queries can contain parameters, however, by the time you run such queries the values of the parameters must be specified. There are the following ways of specifying the parameter values:

- Click  on the toolbar or press `Ctrl+Enter` to run the query. In the dialog that opens, specify the parameter values and click OK.

(To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press `Enter` or switch to a different cell. To quit the editing mode and restore an initial value, press `Escape`.)

- Alternatively, you can open the Parameters pane ( on the toolbar) and specify the corresponding values there. (The values are edited in the same way as in the corresponding dialog.) Then run the query  on the toolbar or `Ctrl+Enter`).

Parameter values can be specified just as text or numbers, or as [Groovy](#) expressions that contain object references and method calls. For example, the value for the `date` parameter in the query

```
SELECT o
FROM Order o
WHERE o.date > :date
```

could be specified as

```
new java.sql.Date(System.currentTimeMillis() - 24*3600*1000)
```

## Running auto-memorized queries

As you run HQL queries in the console, IntelliJ IDEA memorizes them. So, at a later time, you can view the queries you have already run and, if necessary, run them again.

To open the dialog where the auto-memorized queries are shown (the History dialog), do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Alt+E`.

There are two panes in the History dialog. The left-hand pane shows the list of the queries that you have run. For "long" queries, only their beginnings are shown. When you select a query in this pane, the overall query is shown in the pane to the right.

You can filter the information: just start typing. As a result, only the queries that contain the typed text will be shown.

You can copy the queries from the History dialog into the input pane of the console. To copy a query, do one of the following:

- Double-click the query to be copied.
- Select the query of interest and press `Enter`.
- Select the query and click OK.

(Once the query is in the input pane, you can run it straight away.)

You can delete unnecessary memorized queries. To delete a query, select the query in the History dialog and press

`Delete`.

## Terminating query execution

To terminate execution of the current query, do one of the following:

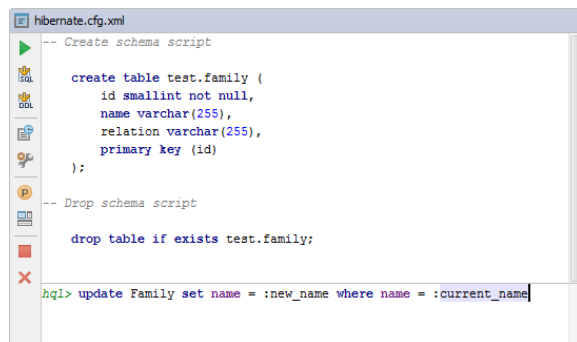

- Click  on the toolbar.
- Press `Ctrl+F2`.

## Generating SQL statements and DDL SQL scripts

You can generate SQL statements for your HQL queries and DDL SQL scripts for your session factory:

- To generate an SQL equivalent of the current query, do one of the following:
  - Click  on the toolbar.
  - Press `Ctrl+Shift+Enter`.
- To generate DDL SQL statements ( `CREATE TABLE` , `ALTER TABLE` and `DROP TABLE` ) for all the objects (classes) associated with the corresponding session factory, do one of the following:
  - Click  on the toolbar.
  - Press `Ctrl+Shift+Alt+Enter`.

The generated SQL statements are shown in the output pane.

```
hibernate.cfg.xml
-- Create schema script

create table test.family (
  id smallint not null,
  name varchar(255),
  relation varchar(255),
  primary key (id)
);

-- Drop schema script

drop table if exists test.family;

hql> update Family set name = :new_name where name = :current_name
```

## Hiding or showing the toolbar

To hide or show the toolbar of the Result pane:

- Click  on the title bar of the Hibernate Console tool window and click Show Toolbar.

## Pinning the Result tab

If one and the same tab is used to show your query results, and you get the result that you want to keep, you can pin the tab to the tool window. To do that:

- Right-click the tab and select Pin Tab.

See also, [Show query results in new tab](#).

## Switching between subsets of rows

If only a subset of the rows that satisfy the query is currently shown, to switch between the subsets, use:

-  First Page
-  Previous Page ( `Ctrl+Alt+Up` )
-  Next Page ( `Ctrl+Alt+Down` )
-  Last Page

See also, [Making all rows visible simultaneously](#).

## Making all rows visible simultaneously

If you want all the rows that satisfy the query to be shown simultaneously:

1. Click  on the toolbar of the Hibernate Console tool window.
2. Switch to the Database | Data Views page, specify `0` in the Result set page size field, and click OK.
3. Click  or press `Ctrl+F5` to refresh the table view.

See also, [Updating the table view](#) and [Result set page size](#).

## Navigating to a specified row

To switch to a row with a specified number:

1. Do one of the following:
  - Press `Ctrl+G`.

- Right-click the table and select Go To | Row from the context menu.
  - Select Navigate | Row from the main menu.
2. In the dialog that opens, specify the row number and click OK .

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  .

Finally, when you click the cell for the third time, the initial state is resorted. That is, sorting by the corresponding column is canceled:  .

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#) .

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row.

	member_id	relation	name
1	5	sister	Alice
2	1	mother	Chloe
3	3	brother	Dylan
4	4	sister	Emily
5	2	father	Harry

See also, [Restoring the initial table view](#) .

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

To show a hidden column:

1. Do one of the following:
  - Right-click any of the cells in the header row and select Column List .
  - Press `Ctrl+F12` .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

2. Select (highlight) the column name of interest and press `Space` .
3. Press `Enter` or `Escape` to close the list.

See also, [Restoring the initial table view](#) and [Using the Structure view to sort data, and hide and show columns](#) .

## Restoring the initial table view

Click  on the toolbar to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the corresponding query, and all the columns are shown.

## Using the Structure view to sort data, and hide and show columns

When working with the Result pane, the table structure view is available as the corresponding popup.

The structure view shows the list of all the columns and lets you sort the data as well as hide and show the columns.

To open the structure popup, do one of the following:

- Right-click a cell in the table header row and select Column List .
- Press `Ctrl+F12` .

In the popup, select the column of interest and do one of the following:

- To sort the data by this column in the ascending order, press `Shift+Alt+Up` .
- To sort the data in the descending order, press `Shift+Alt+Down` .
- To cancel sorting by this column, press `Ctrl+Shift+Alt+Backspace` .
- To hide the column (or show a hidden column), press `Space` . (The names of hidden columns are shown struck through.)

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

The shortcuts for sorting table data ( `Shift+Alt+Up` , `Shift+Alt+Down` and `Ctrl+Shift+Alt+Backspace` ) can be used in the Result pane without opening the structure view.

See also, [You can sort table data by any of the columns by clicking the cells in the header row.](#) , [Hiding and showing columns](#) and [Restoring the initial table view](#) .

## Copying table data to the clipboard or saving them in a file

When copying table data to the clipboard or saving them in a file, the data are converted into one of the available output formats. This can be SQL `INSERT` or `UPDATE` statements, [TSV or CSV](#) , an HTML table or [JSON](#) data. See [Specifying data output format and options](#) .

To copy or save the data, use:

- Copy (available in the Edit and the context menu, the keyboard equivalent is `Ctrl+C` ). This command copies the data for the selected cells onto the clipboard.
- Dump Data | To Clipboard (available in the context menu and can also be accessed by means of  on the toolbar). This command copies the data for the whole table onto the clipboard.
- Dump Data | To File (available in the context menu and can also be accessed by means of  on the toolbar). This command saves the data for the whole table in a file. Before actually saving the data, the dialog is shown which lets you select the output format and see how your data will look in a file.

## Specifying data output format and options

To specify the output format and options for the Copy and Dump Data commands (see [Copying table data to the clipboard or saving them in a file](#) ), do one of the following:

- Click `Tab-separated (TSV)` on the toolbar.
- Right-click the table and point to Data Extractor: <current\_format> .

In the menu that opens, the output formats are in the upper part: SQL Inserts , SQL Updates , etc. (The options that look like file names are also the output formats or, to be more exact, the scripts that implement corresponding data converters.)

The output option are:

- Allow Transposition. This option affects only delimiter-separated values formats (TSV, CSV). If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. `Ctrl+C` ), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). This is the option for SQL INSERTs and UPDATEs. When on, auto-increment fields are not included.
- Add Table Definition (SQL). This is also the option for SQL INSERTs and UPDATEs. When on, the table definition (CREATE TABLE) is added.

Additionally:

- Configure CSV Formats. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

## Saving a LOB in a file

If a cell contains a [binary large object](#) (a.k.a. BLOB or LOB), you can save such a LOB in a file.

1. Right-click the cell that contains the LOB of interest and select Save LOB To File .
2. In the dialog that opens, specify the name and location of the destination file and click OK .

## Updating the table view

To refresh the table view, do one of the following:

- Click  on the toolbar.
- Right-click the table and select Reload Page from the context menu.
- Press `Ctrl+F5` .

Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

## Viewing the query

To see the query that was used to generate the table:

- Click View Query on the toolbar.

If necessary, you can select the query text and copy it to the clipboard ( `Ctrl+C` ).

To close the pane where the query is shown, press `Escape` .

## Closing a console

To close a console, do one of the following:

- Click  on the toolbar.
- Press `Ctrl+Shift+F4` .

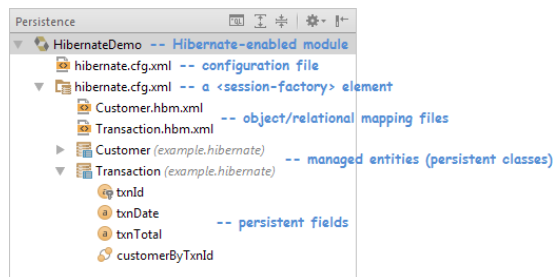

This feature is only supported in the Ultimate edition.

- [Overview of the tool window](#)
- [Opening the Persistence tool window](#)
- [Generating managed entity classes and O/R mappings](#)
- [Using the New command](#)
- [Opening entity-relationship diagrams](#)
- [Associating persistence units and session factories with data sources](#)
- [Associating a session factory with a NamingStrategy implementation class \(Hibernate\)](#)
- [Starting a JPQL or an HQL console](#)

See also, [Persistence Tool Window](#).

## Overview of the tool window

The Persistence tool window shows your JPA and Hibernate project items, and lets you create configuration files, <persistence-unit> and <session-factory> elements, persistent classes and fields (see [Using the New command](#)), navigate to related source code in the editor (F4), open consoles and entity-relationship diagrams, and more.

## Opening the Persistence tool window

For the tool window to be available, there must be a JPA- or Hibernate-enabled module in your project, i.e. a module with a JPA or Hibernate facet. See [Enabling JPA Support](#) or [Enabling Hibernate Support](#).

To open the tool window, do one of the following:

- Select View | Tool Windows | Persistence
- If the tool window bars are currently shown, click the Persistence button (normally located in the lower-left part of the workspace).
- Point to  or  in the lower-left corner of the workspace and select Persistence.

## Generating managed entity classes and O/R mappings

You can generate managed entity classes and object/relational mappings for them by importing:

- A database schema represented by a [data source](#).
- An EJB facet with an associated deployment descriptor file `ejb-jar.xml`. The facet should be available in the same project. When retrieving the information from `ejb-jar.xml`, only the <entity> elements are processed.
- Only for JPA: a Hibernate object/relational mapping file (`.hbm.xml`). The file should be in the same project.

To perform the import:

1. Right-click a module, persistence unit or session factory, point to Generate Persistence Mapping and select one of the following options:
  - By Database Schema
  - By Entity Beans
  - By Hibernate Mappings (this option is not available for Hibernate-enabled modules and session factories)
2. In the [dialog that opens](#), specify the source of import and the output options.

Example: Using a database as a source

1. Right-click a module, persistence unit or session factory, point to Generate Persistence Mapping and select By Database Schema.
2. In the Import Database Schema dialog that opens:
  - [General Settings](#). Select the data source to be used as a source. Specify the destination package for your entity classes, and the prefix and the suffix for the class names.
  - [Database Schema Mapping](#). Select the tables and columns to be mapped, edit the class and field names (the Map As column), and specify the field types (the Mapped Type column).
  - [Generation Settings](#). Specify the target <persistence-unit> or <session-factory>, and select the necessary output options.

## Using the New command

The New command lets you create XML configuration files, <persistence-unit> and <session-factory> elements, entity classes, embeddables, mapped superclasses, entity listeners and object-relational mappings, persistent fields in entity classes along with getter and setter method for them, etc.

The New command can be accessed by using the context or the File menu, or the keyboard shortcut `Alt+Insert` . The command options depend on which item is currently selected.

Example: Creating an entity class

1. Right-click a persistence unit or session factory, point to New , and select Entity .
2. In the New Entity dialog that opens, specify:
  - Create class: the name of the class.
  - Destination package: the package in which the class should be created.
  - Target destination directory: the destination [source root folder](#) (if there is more than one).
3. For JPA, the Select Metadata Targets dialog is shown. Select the files in which you want to add the mapping info for the class:
  - Object/relational mapping XML files: the info will be added as an `<entity>` element within `<entity-mappings>` .
  - The class file itself (.java): the `@Entity` annotation will be added.

IntelliJ IDEA will also add the info to `persistence.xml` either as a `<class>` or a `<mapping-file>` element.

For Hibernate, the Select Metadata Targets dialog is not shown. The `@Entity` annotation is added to the class and the `<mapping class="">` element is added to `hibernate.cfg.xml` .

## Opening entity-relationship diagrams

To open an entity-relationship diagram, right-click a persistence unit, session factory, entity or field, and select ER Diagram from the context menu.

See also, [Diagram Toolbar and Context Menu](#) and [General Techniques of Using Diagrams](#) .

## Associating persistence units and session factories with data sources

You can associate a `<persistence-unit>` or `<session-factory>` element with a [data source](#) . If you do so:

- Your source code that references database tables will automatically be validated against the corresponding data source.
- When using the JPA or Hibernate console, you won't need to additionally specify the database connection settings. The corresponding settings configured for the associated DB data source will automatically be used.

If the `<persistence-unit>` or `<session-factory>` elements are generated by importing a database schema, the association between the corresponding elements and the data source is set automatically.

To associate a persistence unit or session factory with a data source:

1. Right-click a module, persistence unit, session factory or entity, and select Assign Data Sources .
2. In the dialog that opens, click the necessary Data Source cell and select the data source from the list. (To remove an association with a data source, select `<none>` .)

## Associating a session factory with a NamingStrategy implementation class (Hibernate)

1. Right-click a module, session factory or entity, and select Assign Naming Strategies .
2. In the dialog that opens, click the necessary Naming Strategy cell and select the implementation class from the list.

## Starting a JPQL or an HQL console

Right-click a persistence unit or session factory, or any node within it, and select Console .

See also:

- [Working with the JPA console](#)
- [Working with the Hibernate console](#)

In this section:

- Kotlin
  - [Prerequisite](#)
  - [Kotlin support in IntelliJ IDEA](#)
- [Creating Kotlin-JVM Project](#)
- [Creating Kotlin-JavaScript Project](#)
- [Converting a Java File to Kotlin File](#)
- [Mixing Java and Kotlin in One Project](#)

## Prerequisite

Before you start working with Kotlin, make sure that the Kotlin plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

## Kotlin support in IntelliJ IDEA

Kotlin support in IntelliJ IDEA includes:

- Dedicated file type, denoted with  icon.
- [File and Code Templates](#) for creating Kotlin symbols, which allows producing the Kotlin classes , interfaces , enums  and objects .
- Project types: [Kotlin-JVM](#) and [Kotlin-JavaScript](#). To learn how to create these projects, refer to the sections [Creating Kotlin-JVM Project](#) and [Creating Kotlin-JavaScript Project](#).
- Ability to configure Kotlin modules in a project for JVM, JavaScript, Maven or Gradle.

For details, refer to [this tutorial](#).

- [Kotlin compiler configuration](#).
- Dedicated [Kotlin](#), [Kotlin Script](#) and [Kotlin-JavaScript](#) run/debug configurations.

## To create a Kotlin-JVM project, follow these steps

1. On the main menu, choose File | New | Project .
2. In the [New Project](#) dialog box, select the project type **Kotlin-JVM** .
3. Click Next .
4. On the next page of the wizard, specify the following:
  - Project name and location.
  - Kotlin runtime library. Select the desired library from the drop-down list, or, if missing, click Create .If necessary, click [»](#) ( More settings )and specify the settings as required.
5. Click Finish .

The project is created and opens in a window according to your choice .

## To create a Kotlin-JavaScript project, follow these steps

1. On the main menu, choose File | New | Project .
2. In the [New Project](#) dialog box, select the project type **Kotlin-JavaScript** .
3. Click Next .
4. On the next page of the wizard, specify the following:
  - Project name and location
  - Project SDK. Use one of the options from the drop-down list, or, if the required SDK is missing, click New .
  - Kotlin runtime library. Select the desired library from the drop-down list, or, if missing, click Create .If necessary, click [» \( More settings \)](#) and specify the settings as required.
5. Click Finish

The project is created and opens in a window according to your choice .

IntelliJ IDEA enables you to convert a Java file to Kotlin.

## To convert Java file to Kotlin

1. On the main menu, point to Code menu.
2. Choose Convert Java File to Kotlin File .

Note that the resulting Kotlin file appears in place of the original Java file.

On this page:

- [Creating Java files in Kotlin projects](#)
- [Creating Kotlin files in Java projects](#)

## Creating Java files in Kotlin projects

### To create a Java file in a Kotlin project, follow these steps

1. Create a Kotlin project as described in the sections [Creating Kotlin-JVM Project](#) or [Creating Kotlin-JavaScript Project](#).
2. In the [Project Tool Window](#), select the target package or directory, where you want the Java class to be created.
3. Press `Alt+Insert`, choose Java Class from the pop-up menu, select its kind, and specify its name.

## Creating Kotlin files in Java projects

### To create a Kotlin file in a Java project, follow these steps

1. In a Java project, select the target location, press `Alt+Insert` and choose Kotlin file from the pop-up menu.
2. If this is first time you create a Kotlin file in a Java project, the banner shows:

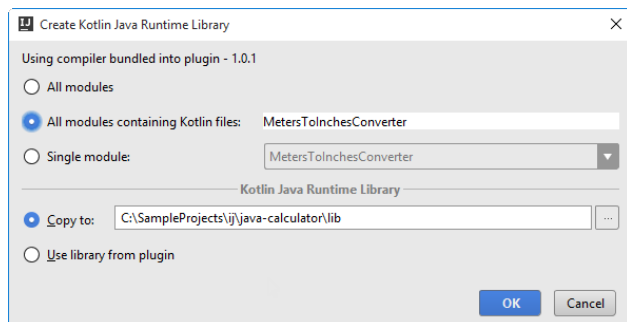

Click the link `Configure`, and select the desired configurator:

In the dialog box `Create Kotlin Java Runtime Library` that opens, do the following:

- Choose the modules to configure (if there are several modules in a project)
- Specify which Kotlin run-time library should be used.

Note that in the future the configuration action is not required.

**Warning!** The following is only valid when Markdown Support Plugin is installed and enabled!

## Introduction

IntelliJ IDEA makes it possible to work with the [Markdown](#) files.

The Markdown files are marked with  icon.

## Prerequisites

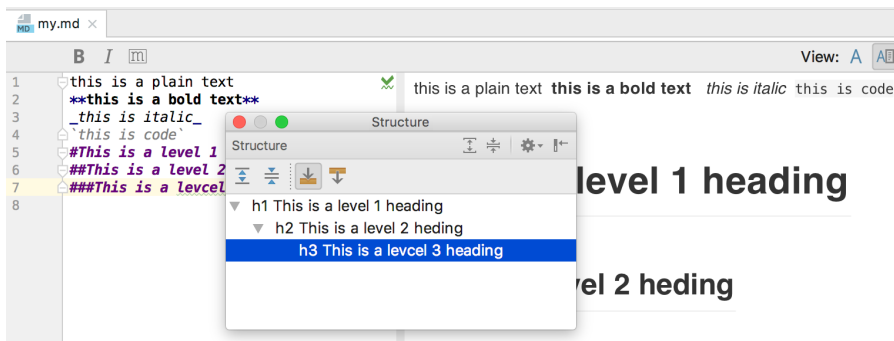

Before you start working with Markdown, make sure that the Markdown Support plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

Markdown Support plugin is bundled with IntelliJ IDEA since version 2016.3.

## Changes to the UI

With the Markdown Support enabled, the page [Markdown](#) appears in the Languages and Frameworks section of the Settings/Preferences dialog.

Note also, that [Structure view](#) shows the headings of the various levels:

## Creating a Markdown file

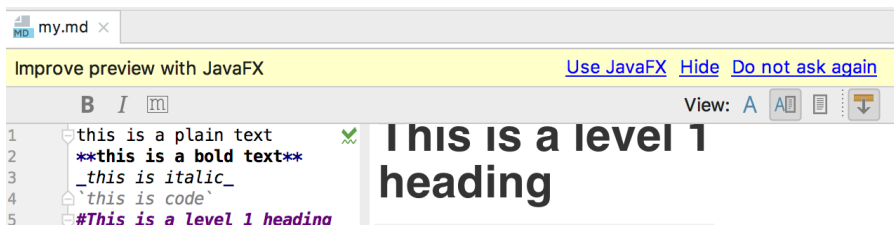

### To create a Markdown file, follow these steps

1. Do one of the following:
  - Choose File | New on the main menu.
  - Right-click the target directory where the new file should be created, and choose New on the context menu.
  - Press `Alt+Insert`
2. Choose File .
3. In the New File dialog box, specify the new file name and extension `.md` .

The new file `<name>.md` , marked with  icon, is created and opens for editing.

## Markdown editor

The editor of a `<name>.md` file by default shows the following:

Click one of the links to get rid of the banner. It's recommended to choose the link Use JavaFX .

The editor is divided into two panes: the editor itself and the preview. Each of the panes can be hidden.

## Editor pane

<b>B</b>	Toggle bold mode	Inserts two asterisks before and after the selected text to render bold font.
<b>I</b>	Toggle italic mode	Inserts underscores before and after the selected text to render italic font.
<b>M</b>	Toggle monospaced (code span) mode	Inserts single apostrophes before and after the selected text to render monospaced font.

## Toolbar

<b>A</b>	Show editor only	Shows editor only with Markdown syntax.
----------	------------------	---

	Show editor and preview	Shows editor with Markdown syntax and the corresponding preview. The results of editing are immediately reflected in the preview pane.
	Show preview only	Shows preview that renders the Markdown syntax. Editing is not possible, and the buttons  ,  and  are disabled.
	Auto-scroll preview	Press this button if you want to automatically scroll from the source code in the editor to the respective location in the <a href="#">preview</a> .

In this section:

- Markup Languages and Style Sheets
  - [Supported markup and template languages](#)
  - [Parsing Web contents](#)
- [Emmet](#)
- [Style Sheets](#)

**Note** In this part you will find information that is specific for the web content files only!

## Supported markup and template languages

IntelliJ IDEA supports editing of files in the following markup and template languages:

- XML
- HTML/XHTML
- JSP/JSPX
- **These features are only supported in the Ultimate edition.**
- CSS
- [Sass, SCSS](#)
- [Slim](#)
- [Less](#)
- [Jade](#)
- [YAML](#)
- [Stylus](#)
- [Compass](#)
- [Handlebars expressions and Mustache templates](#)

The markup languages and style sheets are integrated into IntelliJ IDEA and can use the most powerful editing features:

- Validation and syntax highlighting.
- [Code completion](#) ( `Ctrl+Space` ).
- [Indentation](#) ( `Ctrl+Alt+I` , `Ctrl+Alt+L` ).
- [Formatting](#) ( `Ctrl+Alt+L` ) according to the [code style](#) .
- [Intention actions](#) ( `Alt+Enter` ).
- [Viewing code structure](#) ( `Alt+7` ).
- [Navigation in the source code](#) ( `Ctrl+B` ).
- [Integrated documentation](#) ( `Ctrl+Q` ).
- [Search for usages](#) ( `Alt+F7` ).
- [Commenting and uncommenting lines](#) ( `Ctrl+Slash` , `Ctrl+Shift+Slash` ).
- [Unwrapping and removing tags](#) ( `Ctrl+Shift+Delete` ).

All these features work if IntelliJ IDEA successfully locates the DTD or schema file. In this case, all the files are validated against the DTD or schema, and the editing conveniences become available. Without a DTD or schema, only the well-formedness check is possible.

These features for web contents work same way as for the other source files. Refer to [Keyboard shortcuts](#) .

## Parsing Web contents

IntelliJ IDEA parses Web contents files according to the following specifications:

- HTML : specification is configurable in the Default HTML language level in the [Schemas and DTDs](#) page of the Settings/Preferences dialog. By default, specification HTML 5.0 from W3C is assumed.
- CSS : specification CSS 3.0. The most common selectors are supported: universal selector `*` , type selectors `.a` , descendant selectors `.a.b` , child selectors `.a .b` , ID selectors `#b` , pseudo-classes and class selectors `DIV.warning` .
- IntelliJ IDEA uses Xerces 2.11 , an XML parser developed by Apache Software Foundation Group.

With IntelliJ IDEA, you can edit HTML and CSS code faster by applying **Emmet** features. Just type an [Emmet abbreviation](#) in HTML and press Tab to expand it into the markup. **Emmet** also works in the **CSS** and **JSX** context.

IntelliJ IDEA provides two types of **Emmet** support.

- Native
- Support of additional templates

In this section:

- [Enabling Emmet Support](#)
- [Configuring Abbreviation Expansion Key](#)
- [Enabling Support of Additional Live Templates](#)
- [Expanding Emmet Templates with User Defined Templates](#)
- [Surrounding a Code Block with an Emmet Template](#)
- [Navigating Between Edit Points](#)

In this section:

- [Basics](#)
- [Enabling and configuring native Emmet support in the HTML or XML context](#)
- [Enabling native Emmet support in the JavaScript context](#)
- [Enabling and configuring native Emmet support in the CSS context](#)

## Basics

Native Emmet support allows you to generate XML/HTML, JavaScript (JSX Harmony) and CSS structures based on [abbreviations](#). IntelliJ IDEA supports basic **Emmet** and [Emmet version 1.1](#) features, such as:

- New syntax for writing RGBA colors.
- Implied attributes.
- Default attributes.
- Boolean attributes.
- The **Update Tag** action.

**Emmet** is supported in HTML/XML, JavaScript (JSX Harmony) and in the CSS contexts. This support is configured separately on the [Emmet. HTML](#), [Emmet. JSX](#) and [Emmet. CSS](#) pages respectively.

## Enabling and configuring native Emmet support in the HTML or XML context

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click XML under Emmet. The [Emmet](#) page opens.
2. To enable the **Emmet** support in the HTML or XML context, select the Enable XML/HTML Emmet checkbox. When this checkbox is cleared, all the other controls on this page become disabled.
3. To have IntelliJ IDEA show a pop-up window with a preview of the entered abbreviation before actually expanding it, select the Enable abbreviation preview checkbox.
4. Specify how Emmet in IntelliJ IDEA will treat URL addresses by selecting or clearing the Enable automatic URL recognition while wrapping text with `<a>` tag checkbox.

- If this checkbox is cleared and you attempt to wrap an URL address with the `<a>` tag, IntelliJ IDEA simply encloses the URL address in `<a href=""></a>` and positions the cursor inside the double quotes in the `href` attribute. For example, wrapping `http://www.jetbrains.com` will result in `<a href=" | ">http://www.jetbrains.com</a>`:

```
<a href=" | ">http://www.jetbrains.com</a>
```

- If this checkbox is selected and you attempt to wrap an URL address with the `<a>` tag, IntelliJ IDEA inserts the URL address inside the double quotes as the value of the `href` attribute and encloses the URL in `<a href=" <wrapped URL>"></a>`. For example, wrapping `http://www.jetbrains.com` will result in `<a href="http://www.jetbrains.com">http://www.jetbrains.com</a>`. Moreover, IntelliJ IDEA highlights the wrapped URL green as a recognized URL:

```
<a href="http://www.jetbrains.com">http://www.jetbrains.com</a>
```

## Enabling native Emmet support in the JavaScript context

This feature is only supported in the Ultimate edition.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS.
2. Under the Languages and Frameworks node, click [JavaScript](#), and select the language level JSX Harmony.
3. Expand the Editor node, and then click JSX under Emmet. The [JSX](#) page opens.
4. To enable the **Emmet** support in the JavaScript context, select the Enable JSX Emmet checkbox.

## Enabling and configuring native Emmet support in the CSS context

This feature is only supported in the Ultimate edition.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click CSS under Emmet. The [Emmet. CSS](#) page opens.
2. To enable the **Emmet** support in the CSS context, select the Enable CSS Emmet checkbox. When this checkbox is cleared, all the other controls on this page become disabled.
3. Configure the way unknown abbreviations are treated by selecting or clearing the Enable fuzzy search among CSS abbreviations checkbox: When this checkbox is selected, every unknown abbreviation will be scored against available template names. The match with the best score will be used to resolve the template. For example, with this option enabled, the following abbreviations can be equal to:

- `ov:h`
- `ov-h`
- `o-h`
- `oh`

4. Configure the way unrecognized properties are treated by selecting or clearing the Enable expansion of unknown properties ('unknown' to 'unknown:;') checkbox:
  - When this checkbox is selected, any entered word will be expanded into the same word followed with a colon and a semicolon;
  
  - When this checkbox is cleared, only known properties (for example, `color` ) will be expanded this way ( `color;` )
5. Configure inserting browser-specific prefixes using the Auto insert CSS vendor prefixes checkbox: If this checkbox is selected, the CSS properties listed in the table below are expanded into constructs that contain pre-pending vendor prefixes. Learn more at [Vendor prefixes](#) .  
If this checkbox is cleared, the entire table of properties is disabled.
6. Configure the use of properties in different browsers using the Properties and vendor prefixes table. The table contains a list of CSS properties and vendor prefixes that correspond to various browsers.
  - To enable or disable a property in a browser, select or clear the checkbox under the browser column.
  - To add a new property to the list, click the Add button `+` or press `Alt+Insert` . Then type the name of the property in the dialog box that opens and enable it in the relevant browsers.
  - To delete one or more properties from the list, select them and press Remove `-` or press `Alt+Delete` .

Shortcut key for expanding Emmet selectors and live templates is configurable. You can re-define this default setting for each specific live template.

### Configuring a shortcut to expand abbreviations

1. Open the [Settings / Preferences Dialog](#) by pressing  or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Emmet under Editor .
2. On the [Emmet](#) page that opens, choose the desired option from the Expand abbreviation with drop-down list.

### Configuring a shortcut to expand a live template with

1. To re-define the expansion key for a live template, open the [Live Templates](#) page, expand one of the Zen Coding nodes, and select the desired template. The focus moves to the [Template Text](#) area.
2. From the Expand with drop-down list, select the key to expand the template with.  
This setting does not override the default setting specified for native Emmet support; you will just get the ability to expand the template using either of the specified keys.

Support of additional templates includes more than 200 different HTML, CSS, and XSL live templates. All of them are listed under the Emmet nodes on the [Live Templates](#) page of the Settings/Preferences dialog box.

**Warning!** Emmet support for CSS and XSL is provided in the Ultimate edition only!

### To enable support of additional HTML, CSS, and XSL live templates

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Live Templates under Editor .
2. On the [Live Templates](#) page that opens, select the checkboxes next to the relevant template groups.

In this section:

- [Introduction](#)
- [Expanding Emmet templates](#)

## Introduction

You can expand Emmet templates with your own live templates.

Suppose you have a template entry with the following template text:

```
<entry type="$TYPES$">$END$ <entry>
```

To generate a list of entries, you just need to type “`entry-list<entry[number=$]*5`” and press `TAB`. By default, the `number` attribute will be generated before `type`. To customize the position where it is generated, you need to add the `ATTRS` variable to your template, for example:

```
<entry type="$TYPES$" $ATTRS$>$END$ <entry>
```

The `ATTRS` variable must have an empty string as the default value and should be skipped.

## Expanding Emmet templates

**Warning!** Emmet support for CSS and XSL is provided in the Ultimate edition only!

### To expand an Emmet template with a user-defined template

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Live Templates under Editor.
2. On the [Live Templates](#) page that opens, expand the required `Zen Coding` template group, for example, `Zen HTML`, `Zen CSS`, or `Zen XSL`.
3. Select the template to expand. The focus moves to the [Template Text](#) area where the fields show the settings of the selected template.
4. In the Template Text field, add the required text and variables to the template body.
5. Click the Edit Variables button. In the [Edit Template Variables](#) dialog box that opens, specify the default variable values in the Default value field and select the Skip if defined checkbox where necessary.

## To surround a block of code with an Emmet template, follow these steps

1. Open the desired file for editing and select a block of code to be surrounded.
2. Press `Ctrl+Alt+J` , or choose Code | Surround with | Live Template on the main menu .
3. In the Select Template pop-up menu, choose Emmet :

4. Type the desired Emmet abbreviation, and press `Enter` .  
Note the drop-down list to the right. Clicking the down arrow reveals a history list of the recently applied Emmet live templates:

Also mind the color indication. If you type a valid Emmet abbreviation, the background is green. However, when a non-existent abbreviation is entered, the background becomes red:

**Warning!** Emmet support for JavaScript, CSS and XSL is provided in the Ultimate edition only!

In the HTML and XML context, you can navigate between **edit points**, that is, between important points of code where editing is possible.

- To move the cursor to the previous edit point, choose Navigate | Previous Emmet Edit Point, or press

`Shift+Alt+Open Bracket` .

- To move the cursor to the next edit point, choose Navigate | Next Emmet Edit Point, or press

`Shift+Alt+Close Bracket` .

This feature is only supported in the Ultimate edition.

In addition to the editing techniques that are common for all file types, IntelliJ IDEA provides specific techniques for CSS , Sass , SCSS and Less files.

In particular, it is possible to easily change color values without the necessity to memorize and type color codes.

The `color` properties are marked with the icons of the corresponding color in the left gutter area of the editor. Use these icons to view colors and change color values. When you point with your mouse cursor to the color icon, the pop-up window appears, showing the color and its code.

### To choose color value in a style sheet

1. Open the desired style sheet for editing.
2. Type `color:` , and then press `Ctrl+Space`.
3. Select the desired color value from the suggestion list, or choose color... to pick a custom one:

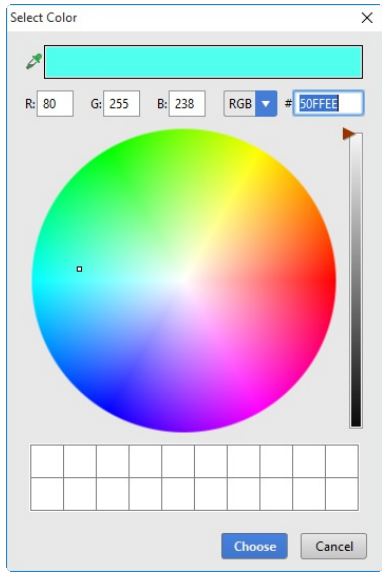

### To change color value in a style sheet

1. Open the desired style sheet for editing, and locate color property to be changed.
2. Do one of the following:
  - If the color icon is shown, just double-click is in the left gutter of the editor.
  - If the color icon is not shown, then press `Alt+Enter`, or click to reveal the list of intention actions, and choose Change color intention action:

3. In the Choose color dialog box, pick the desired new color, and click Choose :

This feature is only supported in the Ultimate edition.

Sass , Less , and SCSS code is not processed by browsers that work with CSS code. Therefore to be executed, Sass , Less , or SCSS code has to be translated into CSS. This operation is referred to as **compilation** and the tools that perform it are called **compilers** .

IntelliJ IDEA integrates with compilers that translate Sass , Less , and SCSS code into CSS. To use a compiler in IntelliJ IDEA, you need to configure it as a [File Watcher](#) . For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template. To run a compiler in your project, create a project-specific File Watcher based on the relevant template.

## Before you start

1. Make sure the [Less Support](#) , [Sass Support](#) , and [CSS Support](#) plugins are activated. The plugins are activated by default. If the plugins are disabled, enable them on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .
2. Install and enable the [NodeJS](#) repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. Download and install the [Node.js](#) runtime environment.
4. Configure the Node.js interpreter in IntelliJ IDEA as described in [Configuring a local Node.js interpreter](#) .

## Installing the Sass/SCSS compiler

Sass and SCSS compilers are managed through the [Ruby Gem manager](#) .

1. [Download and install Ruby](#) .
2. Specify a `path` variable for the folder where the Ruby executable file and the `gem.bat` file are stored. This lets you launch [Ruby](#) and [Gem Manager](#) from any folder and ensures that [Ruby](#) is successfully launched during compilation.
3. Type the following command at the command prompt:

```
gem install sass
```

The tool is installed to the folder where Ruby executable file and the `gem.bat` file are stored.

## Installing the Less compiler

The easiest way to install the Less compiler is to use the [Node Package Manager \(npm\)](#) , which is a part of [Node.js](#) . See [NPM](#) for details.

Depending on the desired location of the Less compiler executable file, choose one of the following methods:

- Install the compiler [globally](#) at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.
- Install the compiler in a specific project and thus restrict its use to this project.
- Install the compiler in a project as a [development dependency](#) .

In either installation mode, make sure that the parent folder of the Less compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

IntelliJ IDEA provides user interface both for [global](#) and [project](#) installation as well as supports installation through the command line.

## Installing the Less compiler globally

[Global](#) installation makes a compiler available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.

Moreover, during installation the parent folder of the compiler is automatically added to the `PATH` variable, which enables you to launch the compiler from any folder.

- Run the installation from the command line in the [global](#) mode:
  1. Open the embedded Terminal ( [View](#) | [Tool Windows](#) | [Terminal](#) ) and switch to the directory where [NPM](#) is stored or define a `PATH` variable for it so it is available from any folder, see [Installing NodeJs](#) .
  2. Type the following command at the command prompt:

```
npm install -g less
```

The `-g` key makes the compiler run in the [global](#) mode. Because the installation is performed through [NPM](#) , the Less compiler is installed in the `npm` folder. Make sure this parent folder is added to the `PATH` variable. This enables you to launch the compiler from any folder.

For more details on the [NPM](#) operation modes, see [npm documentation](#) . For more information about installing the Less compiler, see <https://npmjs.org/package/less> .

- Run [NPM](#) from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File](#) | [Settings for Windows and Linux or IntelliJ IDEA](#) | [Preferences for macOS](#), and click [Node.js](#) and [NPM](#) under [Languages & Frameworks](#) .
  2. On the [Node.js](#) and [NPM](#) page that opens, the [Packages](#) area shows all the Node.js-dependent packages that are currently installed on your computer, both at the [global](#) and at the [project](#) level. Click [+](#) .

3. In the Available Packages dialog box that opens, select the required package to install.
4. Select the Options checkbox and type `-g` in the text box next to it.
5. Optionally specify the product version and click Install Package to start installation.

## Installing the Less compiler in a project

Local installation in a specific project restricts the use of a compiler to this project.

– Run the installation from the command line:

1. Open the embedded Terminal ( View | Tool Windows | Terminal ) and switch to the project root folder.
2. At the command prompt, type `npm install less` .

– Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the **Settings / Preferences Dialog** by pressing `(Ctrl+Alt+S)` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Node.js and NPM under Languages & Frameworks .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+** .
3. In the Available Packages dialog box that opens, select the required package.
4. Optionally specify the product version and click Install Package to start installation.

**Project level** installation is helpful and reliable in **template-based projects** of the type **Node Boilerplate** or **Node.js Express** , which already have the `node_modules` folder. The latter is important because **NPM** installs the Less compiler in a `node_modules` folder. If your project already contains such folder, the Less compiler is installed there.

Projects of other types or **empty** projects may not have a `node_modules` folder. In this case **npm** goes upwards in the folder tree and installs the Less compiler in the first detected `node_modules` folder. Keep in mind that this detected `node_modules` folder may be **outside** your current project root.

Finally, if no `node_modules` folder is detected in the folder tree either, the folder is created right under the current project root and the Less compiler is installed there.

In either case, make sure that the parent folder of the Less compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

## Creating a file watcher

IntelliJ IDEA provides a common procedure and user interface for creating **File Watchers** of all types. The only difference is in the predefined templates you choose in each case.

1. Install and enable the File Watchers repository plugin.

The plugin is **not** bundled with IntelliJ IDEA, but it is available from the [IntelliJ IDEA plugin repository plugin repository](#) . See [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) for details.

2. To start creating a File Watcher, open the Settings/Preferences dialog box by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS on the main menu, and then click File Watchers under the Tools node. The [File Watchers page](#) that opens, shows the list of **File Watchers** that are already configured in the project.

3. Click the Add button **+** or press `(Alt+Insert)` . Depending on the tool you are going to use, choose the appropriate predefined template from the pop-up list:

- Less
- Sass
- SCSS

4. In the Program text box, specify the path to the compiler executable file or archive depending on the chosen predefined template.

- `lessc.cmd` for Less If you installed the tool through the **Node Package Manager** , IntelliJ IDEA locates the required file itself at `<node.js_home>/node_modules/bin/lessc.cmd` and fills in the field automatically. Otherwise, type the path manually or click the Browse button `(...)` and choose the file location in the dialog box that opens.
- `sass.bat` for Sass
- `scss.bat` for SCSS

If you installed the **Sass** and **SCSS** tools through **Ruby** , IntelliJ IDEA locates the required files itself at `<ruby_home>/bin/sass.bat` `<ruby_home>/bin/scss.bat` respectively and fills in the field automatically. Otherwise, type the path manually or click the Browse button `(...)` and choose the file location in the dialog box that opens.

5. Proceed as described on page [Using File Watchers](#) .

## Compiling the code

When you open a Less, Sass, or SCSS file, IntelliJ IDEA checks whether an applicable file watcher is available in the current project. If such file watcher is configured but disabled, IntelliJ IDEA displays a pop-up window that informs you about the configured file watcher and suggests to enable it.

If an applicable file watcher is configured and enabled in the current project, IntelliJ IDEA starts it automatically upon the event specified in the [New Watcher dialog](#) .

- If the Auto-save edited files to trigger the watcher checkbox is selected, the File Watcher is invoked as soon as any changes are made to the source code.
- If the Auto-save edited files to trigger the watcher checkbox is cleared, the File Watcher is started upon save ( File | Save

All, `Ctrl+S` ) or when you move focus from IntelliJ IDEA (upon frame deactivation).

IntelliJ IDEA creates a separate file with the generated output. The file has the name of the source `Sass`, `Less`, or `SCSS` file and the extension `css`. The location of the generated files is defined in the Output paths to refresh text box of the [New Watcher dialog](#). However, in the Project Tree, they are shown under the source file which is now displayed as a node.

This feature is only supported in the Ultimate edition.

[Stylus](#) code is not processed by browsers that work with CSS code. Therefore to be executed, Stylus code has to be translated into CSS. This operation is referred to as **compilation** and the tools that perform it are called **compilers**.

IntelliJ IDEA integrates with a compiler that translates **Stylus** code into CSS. To use the compiler in IntelliJ IDEA, you need to configure it as a **File Watcher**. For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template. To run a compiler in your project, create a project-specific File Watcher based on the relevant template.

The easiest way to install the Stylus compiler is to use the **Node Package Manager (npm)**, which is a part of [Node.js](#). See [NPM](#) for details.

Depending on the desired location of the Stylus compiler executable file, choose one of the following methods:

- Install the compiler **globally** at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.
- Install the compiler in a specific project and thus restrict its use to this project.
- Install the compiler in a project as a [development dependency](#).

In either installation mode, make sure that the parent folder of the Stylus compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

IntelliJ IDEA provides user interface both for **global** and **project** installation as well as supports installation through the command line.

## Before you start

1. Download and install the [Node.js](#) runtime environment.

If you are going to use the command line mode, make sure the path to the parent folder of the **Node.js** executable file and the path to the `npm` folder are added to the `PATH` variable. This enables you to launch the Stylus compiler and **npm** from any folder.

2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing the Stylus compiler globally

**Global** installation makes a compiler available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.

Moreover, during installation the parent folder of the compiler is automatically added to the `PATH` variable, which enables you to launch the compiler from any folder.

- Run the installation from the command line in the **global** mode:

1. Open the embedded Terminal ( [View | Tool Windows | Terminal](#) ) and switch to the directory where **NPM** is stored or define a `PATH` variable for it so it is available from any folder, see [Installing NodeJS](#).
2. Type the following command at the command prompt:

```
npm install -g stylus
```

The `-g` key makes the compiler run in the **global** mode. Because the installation is performed through **NPM**, the Stylus compiler is installed in the `npm` folder. Make sure this parent folder is added to the `PATH` variable. This enables you to launch the compiler from any folder.

For more details on the **NPM** operation modes, see [npm documentation](#). For more information about installing the Stylus compiler, see <https://npmjs.org/package/stylus>.

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS](#), and click **Node.js and NPM** under **Languages & Frameworks**.
2. On the **Node.js and NPM** page that opens, the **Packages** area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+**.
3. In the **Available Packages** dialog box that opens, select the required package to install.
4. Select the **Options** checkbox and type `-g` in the text box next to it.
5. Optionally specify the product version and click **Install Package** to start installation.

## Installing the Stylus compiler in a project

**Local** installation in a specific project restricts the use of a compiler to this project.

- Run the installation from the command line:

1. Open the embedded Terminal ( [View | Tool Windows | Terminal](#) ) and switch to the project root folder.
2. At the command prompt, type `npm install stylus`.

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing [File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS](#), and click **Node.js and NPM** under **Languages & Frameworks**.
2. On the **Node.js and NPM** page that opens, the **Packages** area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+**.

3. In the Available Packages dialog box that opens, select the required package.
4. Optionally specify the product version and click Install Package to start installation.

Project level installation is helpful and reliable in [template-based projects](#) of the type **Node Boilerplate** or **Node.js Express** , which already have the `node_modules` folder. The latter is important because **NPM** installs the Stylus compiler in a `node_modules` folder. If your project already contains such folder, the Stylus compiler is installed there.

Projects of other types or **empty** projects may not have a `node_modules` folder. In this case **npm** goes upwards in the folder tree and installs the Stylus compiler in the first detected `node_modules` folder. Keep in mind that this detected `node_modules` folder may be **outside** your current project root.

Finally, if no `node_modules` folder is detected in the folder tree either, the folder is created right under the current project root and the Stylus compiler is installed there.

In either case, make sure that the parent folder of the Stylus compiler is added to the `PATH` variable. This enables you to launch the compiler from any folder.

## Creating a file watcher

IntelliJ IDEA provides a common procedure and user interface for creating **File Watchers** of all types. The only difference is in the predefined templates you choose in each case.

1. Install and enable the File Watchers repository plugin.

The plugin is `not` bundled with IntelliJ IDEA, but it is available from the [IntelliJ IDEA plugin repository plugin repository](#) . See [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) for details.

2. To start creating a File Watcher, open the Settings/Preferences dialog box by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS on the main menu, and then click File Watchers under the Tools node. The [File Watchers page](#) that opens, shows the list of **File Watchers** that are already configured in the project.
3. Click the Add button **+** or press `(Alt+Insert)` and choose the Stylus predefined template from the pop-up list.
4. In the Program text box, specify the path to the executable file:
  - `stylus` for macOS and Unix.
  - `stylus.bat` for Windows.

Type the path manually or click the Browse button  and choose the file location in the dialog box that opens.

5. Proceed as described on page [Using File Watchers](#) .

## Compiling the code

When you open a Stylus file, IntelliJ IDEA checks whether an applicable file watcher is available in the current project. If such file watcher is configured but disabled, IntelliJ IDEA displays a pop-up window that informs you about the configured file watcher and suggests to enable it.

If an applicable file watcher is configured and enabled in the current project, IntelliJ IDEA starts it automatically upon the event specified in the [New Watcher dialog](#) .

- If the Auto-save edited files to trigger the watcher checkbox is selected, the File Watcher is invoked as soon as any changes are made to the source code.
- If the Auto-save edited files to trigger the watcher checkbox is cleared, the File Watcher is started upon save ( File | Save All , `(Ctrl+S)` ) or when you move focus from IntelliJ IDEA (upon frame deactivation).

IntelliJ IDEA creates a separate file with the generated output. The file has the name of the source **Stylus** file and the extension `css` . The location of the generated files is defined in the Output paths to refresh text box of the [New Watcher dialog](#) . However, in the Project Tree , they are shown under the source file which is now displayed as a node.

This feature is only supported in the Ultimate edition.

In addition to the full range of [common refactorings](#), IntelliJ IDEA provides the following CSS-specific refactorings:

- [Extract Variable in Sass](#)

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Example](#)
- [Extracting a variable in-place](#)
- [Extracting a variable using the dialog box](#)

## Introduction

You can replace a Sass expression with a local or global variable.

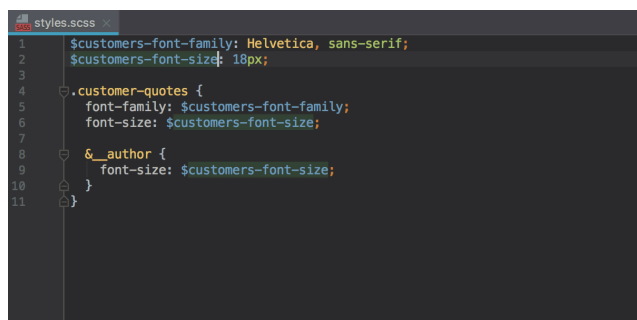

To perform this refactoring, you can use:

- [In-place refactoring](#) . In this case you specify the new name right in the editor.
- [Refactoring dialog](#) , where you specify all the required information. To make such a dialog accessible, you have to clear the check box [Enable in-place mode](#) in the editor settings.

## Example

### Before/After

<pre>\$blue: #3bbfce \$margin: 16px  .border padding: \$margin / 2 margin: \$margin / 2 border-color: \$blue</pre>	<pre>\$blue: #3bbfce \$margin: 16px; \$var: \$margin / 2  .border padding: \$var margin: \$var border-color: \$blue</pre>
--	---

## Extracting a variable in-place

### To extract a variable using in-place refactoring

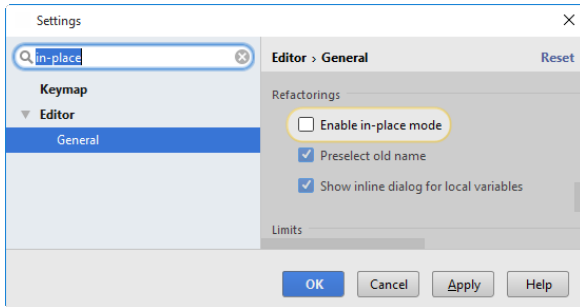

1. In the editor, select the expression to be replaced with a variable. You can do that yourself or use the **smart expression selection** feature to let IntelliJ IDEA help you. So, do one of the following:
  - Highlight the expression. Then choose Refactor | Extract | Variable on the main menu or on the context menu.  
Alternatively, press `Ctrl+Alt+V` .
  - Place the cursor before or within the expression. Choose Refactor | Extract Variable on the main menu or on the context menu. or press `Ctrl+Alt+V` . In the Expressions pop-up menu, select the expression. To do that, click the required expression. Alternatively, use the Up and Down arrow keys to navigate to the expression of interest, and then press `Enter` to select it.
2. If more than one occurrence of the selected expression is found, select Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu.  
To select the required option, just click it. Alternatively, use the `Up` and `Down` arrow keys to navigate to the option of interest, and press `Enter` to select it.
3. Select the place in the source code, where the new variable will be declared. The declaration can be global (a variable is available throughout the whole file), or local (a variable is declared immediately before use, and is available in the current block only).
4. Specify the name of the variable. Do one of the following:
  - Select one of the suggested names from the pop-up list. To do that, double-click the suitable name.  
Alternatively, use the `Up` and `Down` arrow keys to navigate to the name of interest, and `Enter` to select it. When finished, press `Escape` .
  - Edit the name by typing. The name is shown in the box with red borders and changes as you type. When finished, press `Escape` .

**Note** The Expressions pop-up menu contains all the expressions appropriate for the current cursor position in the editor.

## Extracting a variable using the dialog box

### To extract a variable using the dialog box

If the Enable in place refactorings check box is cleared in the Editor settings, the Extract Variable refactoring is performed by means of the [Extract Variable Dialog](#) dialog box

1. Select the desired expression, and invoke Extract Variable refactoring as described above .
2. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the **Up** and **Down** arrow keys to navigate to the expression of interest, and then press **Enter** to select it.
3. In the [Extract Variable dialog for Sass](#) :
  - Specify the variable name. You can select one of the suggested names from the list or type the name in the Name field.
  - Specify the place for declaration. Select the desired place (global or local) from the drop-down list.
  - If more than one occurrence of the selected expression is found, you can select to replace all the found occurrences by selecting the corresponding checkbox. If you want to replace only the current occurrence, clear the Replace all occurrences checkbox.
  - Click OK .

This feature is only supported in the Ultimate edition.

The term **minification** or **compression** in the context of CSS means removing all unnecessary characters, such as **spaces** , **new lines** , **comments** without changing the functionality of the source code. At the development and debugging stage, these characters improve the code readability. However at the production stage, they become unnecessary for code execution but only increase the size of code to be transferred.

IntelliJ IDEA integrates with the [YUI Compressor](#) CSS minification tool. To use the minifier in IntelliJ IDEA, you need to configure it as a [File Watcher](#) . For each supported minifier, IntelliJ IDEA provides a predefined File Watcher template. To run a minifier in your project, create a project-specific File Watcher based on the relevant template.

## Installing and configuring the YUI Compressor

1. Download and install the [Node.js](#) runtime environment.

If you are going to use the command line mode, make sure the path to the parent folder of the **Node.js** executable file and the path to the `npm` folder are added to the `PATH` variable. This enables you to launch the CSS minifier and `npm` from any folder.

2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

3. Download and install the minification tool. The easiest way is to use the **Node Package Manager (npm)** , which is a part of [Node.js](#) .

1. Switch to the directory where the **Node Package Manager (npm)** is stored or define a `path` variable for it so it is available from any folder.

2. Type the following command at the command prompt:

```
npm install yuicompressor
```

If you use the **Node Package Manager (npm)** , the minifier is installed under **Node.js** so `Node.js` , which is required for starting the tool, will be specified in the path to it.

## Creating a file watcher

IntelliJ IDEA provides a common procedure and user interface for creating **File Watchers** of all types. The only difference is in the predefined templates you choose in each case.

1. To start creating a File Watcher, open the Settings/Preferences dialog box by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS on the main menu, and then click File Watchers under the Tools node. The [File Watchers page](#) that opens, shows the list of **File Watchers** that are already configured in the project.

2. Click the Add button **+** or press `Alt+Insert` and choose the YUI Compressor CSS predefined template from the pop-up list.

3. In the Program text box, specify the path to the `yuicompressor-<version>.jar` file. If you installed the tool through the **Node Package Manager** , IntelliJ IDEA locates the required file itself and fills in the field automatically. Otherwise, type the path manually or click the Browse button `...` and choose the file location in the dialog box that opens.

4. Proceed as described on page [Using File Watchers](#) .

## Minifying the code

When a minification File Watcher is **enabled** , minification starts automatically as soon as a CSS file in the File Watcher's scope is **changed or saved** .

IntelliJ IDEA creates a separate file with the generated output. The file has the name of the source CSS file and the extension `min.css` . The location of the generated file is defined in the Output paths to refresh text box of the [New Watcher dialog](#) . However, in the Project Tree , by default it is shown under the source CSS file which is now displayed as a node. To change the default presentation, [configure file nesting](#) in the Project tool window.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports development in projects structured in compliance with the [Compass framework](#). This framework uses Sass and SCSS extensions of CSS.

## Preparing for Compass development

The **Compass** framework is installed through the **Ruby Gem manager**, therefore you need to install **Ruby** first.

1. [Download and install Ruby](#).
2. Specify a `path` variable for the folder where the Ruby executable file and the `gem.bat` file are stored. This lets you launch **Ruby** and **Gem Manager** from any folder and ensures that **Ruby** is successfully launched during compilation.
3. **Install and enable** the Sass Support plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).
4. Install **Compass**.
  1. The installation is performed in the command line mode. To start the built-in **Terminal**, hover your mouse pointer over  in the lower left corner of the IDE, then choose Terminal from the menu (see [Working with Embedded Local Terminal](#) for details).
  2. Type the following command at the command prompt:

```
gem install compass
```

The tool is installed to the folder where Ruby executable file and the `gem.bat` file are stored.

## Setting up a Compass project

You can have a project set up according to the Compass requirements in two ways: create a new Compass project or create an empty project and introduce a Compass-specific structure in it. In either case, a project is set up through command line commands. Of course, you can set up a Compass project externally and then open it in IntelliJ IDEA.

During project set-up, a `conf.rb` configuration file is generated. You will need to specify the location of this file when integrating Compass with IntelliJ IDEA.

– To set up the Compass-specific structure in an existing project:

1. Open the desired project in IntelliJ IDEA.
2. Open the built-in Terminal by hovering your mouse pointer over  in the lower left corner of IntelliJ IDEA and choosing Terminal from the menu.
3. At the command prompt, type:

```
compass init
```

– To create a Compass project from scratch:

1. Open the desired project in IntelliJ IDEA.
2. Open the built-in Terminal by hovering your mouse pointer over  in the lower left corner of IntelliJ IDEA and choosing Terminal from the menu.
3. Switch to the folder that will be the parent for the new project folder. Type the following command:

```
cd <parent folder name>
```

4. At the command prompt, type:

```
compass create <the name of the project to be created>
```

## Integrating Compass with IntelliJ IDEA

To develop a Compass-specific project in IntelliJ IDEA, you need to specify the Compass executable file `compass` and the project configuration file `config.rb`. You can do it either through the Compass Support page of the Settings dialog box or on the fly using an intention action that opens the Compass Support dialog box.

1. Open the Compass page or dialog box by doing one of the following:

- Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Compass under Languages & Frameworks.
- 1. In a `.sass` or `.scss` file, type the following **import** statement:

```
@import 'compass'
```

2. Click the red bulb icon or press `Alt+Enter` . Then choose Configure Compass from the suggestion list.

The Compass Support dialog box opens.

2. To activate Compass support, select the Enable Compass support checkbox.
3. In the Compass executable file text box, specify the location of the `compass` executable file under the Ruby installation. Type the path manually, for example, `C:\Ruby200-x64\bin\compass` , or choose it from the drop-down list, or click the Browse button `⋮` and choose the location of the `compass` file in the dialog box that opens.
4. In the Config path field, specify the location of the project Compass configuration file `config.rb` . Type the path manually, for example, `C:\my_projects\compass_project\config.rb` , or choose it from the drop-down list, or click the Browse button `⋮` and choose the location of the `compass` file in the dialog box that opens. The Compass configuration file `config.rb` is generated during project set-up through `compass create` or `compass init` commands.

## Creating a Compass Sass or a Compass SCSS compiler

Sass and SCSS are not processed by browsers that work with CSS code. Therefore to be executed, Sass or SCSS code has to be translated into CSS. This operation is referred to as **compilation** and the tools that perform it are called **compilers** .

IntelliJ IDEA integrates with a compiler that translates Sass and SCSS code from a Compass project without changing the Compass-specific project structure. To use the compiler in IntelliJ IDEA, you need to configure it as a [File Watcher](#) . For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template. To run a compiler in your project, create a project-specific File Watcher based on the relevant template.

IntelliJ IDEA provides a common procedure and user interface for creating **File Watchers** of all types. The only difference is in the predefined templates you choose in each case.

1. Install and enable the File Watchers repository plugin. The plugin is not bundled with IntelliJ IDEA, but it is available from the [IntelliJ IDEA plugin repository plugin repository](#) . See [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) for details.
2. To start creating a File Watcher, open the Settings/Preferences dialog box by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS on the main menu, and then click File Watchers under the Tools node. The [File Watchers page](#) that opens, shows the list of **File Watchers** that are already configured in the project.
3. Click the Add button `+` or press `Alt+Insert` and choose the compass sass or compass scss predefined template from the pop-up list.
4. In the Program text box, specify the path to the executable file:
  - `compass.bat` for Windows
  - `compass` for Unix and macOSType the path manually or click the Browse button `⋮` and choose the file location in the dialog box that opens.
5. In the Arguments text box, type one of the following depending on the operating system used:
  - For macOS:
    - `compile $ProjectFileDir$` to process an entire directory
    - `compile $ProjectFileDir$ $FilePath$` to process a single file
  - For Windows:
    - `compile $UnixSeparators($ProjectFileDir$)$` to process an entire directory
    - `compile $UnixSeparators($FilePath$)$` to process a single file
  - For Linux (Ubuntu):
    - `compile $ProjectFileDir$` to process an entire directory
    - `compile $ProjectFileDir$ $FilePath$` to process a single file
6. Proceed as described on page [Using File Watchers](#) .

## Running a Compass Sass or Compass SCSS compiler

When you open a Sass or SCSS file, IntelliJ IDEA checks whether an applicable file watcher is available in the current project. If such file watcher is configured but disabled, IntelliJ IDEA displays a pop-up window that informs you about the configured file watcher and suggests to enable it.

If an applicable file watcher is configured and enabled in the current project, IntelliJ IDEA starts it automatically upon the event specified in the [New Watcher dialog](#) .

- If the Auto-save edited files to trigger the watcher checkbox is selected, the File Watcher is invoked as soon as any changes are made to the source code.
- If the Auto-save edited files to trigger the watcher checkbox is cleared, the File Watcher is started upon save ( File | Save All , `Ctrl+S` ) or when you move focus from IntelliJ IDEA (upon frame deactivation).

IntelliJ IDEA creates a separate file with the generated output. The file has the name of the source Sass or SCSS file and the extension `css` . The location of the generated files is defined in the Output paths to refresh text box of the [New Watcher](#)

[dialog](#) . However, in the Project Tree , they are shown under the source file which is now displayed as a node.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides facilities to run CSS-specific code quality inspections through integration with the [Stylelint](#) code verification tool. The tool registers itself as an IntelliJ IDEA code inspection: it checks CSS code for most common mistakes and discrepancies without running the application. When a tool is activated, it launches automatically on the edited CSS file. Discrepancies are highlighted and reported in pop-up information windows, a pop-up window appears when you hover the mouse pointer over a stripe in the Validation sidebar. You can also press `Alt+Enter` to examine errors and apply suggested quick fixes. Learn more about inspections and intention actions at [Code Inspection](#) and [Intention Actions](#).

## Before you start

1. Integration with IntelliJ IDEA is supported through the CSS plugin. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).
2. [Stylelint](#) is run through [Node.js](#), therefore make sure the [Node.js](#) runtime environment is downloaded and installed on your computer. The runtime environment also contains the [Node Package Manager \(npm\)](#) through which [Stylelint](#) is installed.
3. Integration with [Node.js](#) and [NPM](#) is supported through the [Node.js](#) plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing Stylelint

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click [Node.js](#) and [NPM](#) under Languages & Frameworks.
2. On the [Node.js](#) and [NPM](#) page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+`.
3. In the Available Packages dialog box that opens, select the `stylelint` package and click Install Package. Learn more about installing tools through [NPM](#) in [NPM](#).

## Activating and configuring Stylelint

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click [Stylelint](#) under Stylesheets. The [Stylelint](#) page opens.
2. Select the Enable checkbox to activate [Stylelint](#). After that the controls in the dialog box become available.
3. In the Node Interpreter field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click `...` and configure a new one as described in [Configuring Node.js Interpreters](#).
4. In the Stylelint Package field, specify the location of the `stylelint` package installed globally or in the current project, see [Stylelint](#).

This feature is only supported in the Ultimate edition.

For HTML, XHTML, JSP, JSPX files, IntelliJ IDEA suggests a way to explore all styles applied to an arbitrary tag.

The results for each tag are displayed in the dedicated tabs of the CSS Styles tool window. Using this tool window, you can view the list of styles applied to a tag, and the definition of these styles. Besides that, you can navigate from style to the corresponding tag in the source code.

## To show styles that are used for a tag

1. Open the desired file in the editor, and right-click the tag you want to explore for applied styles.
2. On the context menu, choose Show Applied Styles for Tag .
3. View results in a dedicated tab in the CSS Styles tool window:

IntelliJ IDEA brings powerful XML editing support that includes:

- Validation and syntax highlighting.
- **Code completion** ( `Ctrl+Space` ).
- **Indentation** ( `Ctrl+Alt+I` , `Ctrl+Alt+L` ).
- **Formatting** ( `Ctrl+Alt+L` ) according to the [XML code style](#) .
- **Intention actions** ( `Alt+Enter` ).
- **Viewing code structure** ( `Alt+7` ).
- **Navigation in the source code** ( `Ctrl+B` ).
- **Integrated documentation** ( `Ctrl+Q` ).
- **Search for usages** ( `Alt+F7` ).
- **Commenting and uncommenting lines** ( `Ctrl+Slash` , `Ctrl+Shift+Slash` ).
- **Unwrapping and removing tags** ( `Ctrl+Shift+Delete` ).
- **Generating schemas from instance documents** and vice versa.
- **Generating DTD files** .

A [Data Type Definition \(DTD\)](#) is required for running [structure validation checks](#) on a Web content file. IntelliJ IDEA can scan any XML file for the existing elements and attributes and generate a DTD for it.

### **To generate a DTD for an XML file**

1. Open the desired file in the active editor tab.
2. On the main menu, choose Tools | XML Actions | Generate DTD From XML File . The resulting DTD is added as a section above the first line of the file.

## To generate an XML instance document from an XML Schema

1. With the desired Schema ( `.xsd` ) file opened in the active editor tab, choose Tools | XML Actions | Generate XML Document from XSD Schema on the main menu.
2. In the [Generate Instance Document from Schema](#) dialog box that opens configure the XML instance document generation procedure:
  - In the Schema Path text box, specify the location of the Schema to base the XML document generation on. By default, the field shows the full path to the current file. Accept this suggestion or click the Browse button  and select the desired file in the dialog that opens.
  - In the Instance Document Name text box, specify the name of the output file to place the generated XML in.

**Warning!** IntelliJ IDEA suggests the name of the source XML document with the `.xml` extension. If you type another name, make sure the extension is correct.
  - Specify the location of the generated document. By default, it will be placed in the same directory as the source Schema file. To specify another location, click the Browse button  and select the desired path in the dialog that opens.
  - From the Element Name drop-down list, select the local name of the global element to be used as the root of the generated XML document.
  - Specify whether to take restriction and uniqueness particles into consideration by selecting the corresponding checkboxes.

An [XSD \(XML Schema Definition\) Schema](#) is required for running [structure validation checks](#) on a Web content file. IntelliJ IDEA can scan any XML file for the existing elements and attributes and generate a Schema for it.

## To have a Schema generated based on an XML instance document

1. With the desired XML document opened in the active editor tab, choose Tools | XML Actions | Generate XSD Schema from XML File on the main menu.
2. In the [Generate Schema From Instance Document](#) dialog box that opens configure the Schema generation procedure:
  - In the Instance Document Path text box, specify the location of the file to be used as the basis for Schema generation. By default, the field shows the full path to the current file. Accept this suggestion or click the Browse button  and select the desired file in the dialog that opens.
  - In the Result Schema File Name text box, specify the name of the output file to place the generated Schema in.

**Warning** IntelliJ IDEA suggests the name of the source XML document with the `.xsd` extension. If you type another name, make sure the extension is correct.

- Specify the location of the generated Schema. By default, the generated Schema file will be placed in the same directory as the source XML instance document. To specify another location, click the Browse button  and select the desired path in the dialog that opens.
- From the Design Type drop-down list, select the way to declare elements and complex types.
- From the Detect Simple Content Type drop-down list, select the type to use for leaf text.
- In the Detect Enumerations Limit text box, type the number of occurrences to cause the Schema enumeration appearance.

**Tip** To suppress Schema enumeration, specify 0.

Your XML file may reference an external XML schema (XSD) or DTD file, e.g.

```
<root xmlns="http://www.example.org"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.example.org http://www.example.org/xsds/example.xsd">
```

or

```
<!DOCTYPE root SYSTEM "http://www.example.org/dtds/example.dtd">
```

If the referenced URL or the namespace URI is "unfamiliar", it's marked as an error.

For situations like this, IntelliJ IDEA provides the following [intention actions](#) :

- Fetch External Resource. IntelliJ IDEA downloads the referenced file and associates it with the URL (or the namespace URI). The error highlighting disappears. The XML file is validated according to the downloaded schema or DTD. (The associations of the URLs and the namespace URIs with the schema and DTD files are shown on the [Schemas and DTDs page](#) in the Settings dialog.)
- Manually Setup External Resource. Use this option when you already have an appropriate schema or DTD file available locally. The [Map External Resource dialog](#) will open and you'll be able to select the file for the specified URL or namespace URI. The result of the operation is the same as in the case of fetching the resource.
- Ignore External Resource. The URL or the namespace URI is added to the Ignored Schemas and DTDs list. (This list is shown on the [Schemas and DTDs page](#) in the Settings dialog.) The error highlighting disappears. IntelliJ IDEA won't validate the XML file, however, it will check if the XML file is well-formed.

There is one more intention action that you may find useful: Add Xsi Schema Location for External Resource . This intention action lets you complete your root XML elements. If the namespace is already specified, IntelliJ IDEA can add a couple of missing attributes.

For example, if you have a fragment like this:

```
<root xmlns="http://www.example.org">
```

and perform the intention action on the value of the `xmlns` attribute, the result will be:

```
<root xmlns="http://www.example.org"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.example.org >
```

At this step, you'll be able to add the schema URL, and then map the URL (or the namespace URI) onto an appropriate schema file, or add the URL (or the URI) to the Ignored Schemas and DTDs list.

On this page:

- [Types of validity checks](#)
- [Choosing the default HTML language level](#)
- [Choosing the default schema to validate XML files](#)
- [Running full validation on an XML file](#)

## Types of validity checks

IntelliJ IDEA performs two different [validity](#) checks:

- **On-the-fly validation** is available for all Web content files and is performed as you edit the file. IntelliJ IDEA checks well-formedness, that is, detects various violations of syntax requirements, such as unclosed tags, wrong end-tag name, duplicate tags, unresolved links, etc. All encountered errors are highlighted in the editor. However, this form of code validation is rather *soft*, that is, not all requirements are taken into account.
- **Full validation** involves structure validation in addition to well-formedness check. Full validation is available for files that are associated with an [XSD \(XML Schema Definition\) Schema](#) or contain a [Data Type Definition \(DTD\)](#). IntelliJ IDEA checks whether the structure of your XML file complies with the structure defined in the corresponding DTD or Schema. The results of full validation are provided as a [Message View](#).

## Choosing the default HTML language level

Normally, an HTML or an XHTML file has the `<!DOCTYPE>` declaration which states the **language level** of the used in the source code from the file. This language level is used as a standard against which the contents of the file are validated. If an HTML or an XHTML file does not have a `<!DOCTYPE>` declaration, the contents of the file will be validated against the default standard (schema).

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Default XML Schemas under Schemas and DTDs. The [Default XML Schemas](#) page opens.
2. In the Default HTML Language Level area, choose the default schema to validate HTML and XHTML files without a `<!DOCTYPE>` declaration. The available options are:
  - HTML 4 or HTML 5 : Choose one of these options to have files treated as HTML 4 or HTML 5 and validated against one of these standards.
  - Other doctype : Choose this option to have HTML files by default validated against a custom DTD or schema and specify the URL of the DTD or schema to be used.Note that code completion is available in this field: press `Ctrl+Space` to see the list of suggested URLs.

choose the [XSD \(XML Schema Definition\) Schema](#) to validate XML files. The available options are:

- XML Schema 1.1 See [W3C XML Schema Definition Language \(XSD\) 1.1 Part 1: Structures](#) and [W3C XML Schema Definition Language \(XSD\) 1.1 Part 2: Datatypes](#) for details.
- XML Schema 1.0 See [XML Schema Part 1: Structures Second Edition](#) and [XML Schema Part 2: Datatypes Second Edition](#) for details.

## Choosing the default schema to validate XML files

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Default XML Schemas under Schemas and DTDs. The [Default XML Schemas](#) page opens.
2. In the Default XML Schema Version area, choose the [XSD \(XML Schema Definition\) Schema](#) to validate XML files. The available options are:
  - XML Schema 1.1 See [W3C XML Schema Definition Language \(XSD\) 1.1 Part 1: Structures](#) and [W3C XML Schema Definition Language \(XSD\) 1.1 Part 2: Datatypes](#) for details.
  - XML Schema 1.0 See [XML Schema Part 1: Structures Second Edition](#) and [XML Schema Part 2: Datatypes Second Edition](#) for details.

## Running full validation on an XML file

1. Open the desired XML file in the editor, or just select it in the [Project](#) tool window.
2. On the context menu, choose Validate.

In this section:

- XML-Java Binding
  - [Introduction](#)
  - [Using JAXB and XmlBeans](#)
- [Generating Java Code from XML Schema](#)
- [Generating Xml Schema From Java Code](#)
- [Generating Marshallers](#)
- [Generating Unmarshallers](#)

## Introduction

This section describes how to:

- Get a Java representation of an [XML Schema](#)
- Have an [XML Schema](#) generated on the basis of a Java class
- [Unmarshal](#) XML instance documents into Java content trees and vice versa.

With IntelliJ IDEA, this transformation can be done using one of the following data binders:

- [Java Architecture for XML Binding \(JAXB\)](#)
- [XMLBeans](#)

## Using JAXB and XmlBeans

### **To use JAXB and XmlBeans, perform the following preliminary steps:**

1. Download and install the XMLBeans tool.
2. On the [Plugins settings](#) page of the Settings/Preferences dialog box, make sure that the Web Services bundled plugin is enabled.
3. On the [Web Services](#) page of the Settings/Preferences dialog box, specify the installation directory of XmlBeans and one of the following Web Services engines:
  - [Metro](#)
  - [GlassFish](#)
  - [Java API for XML Web Services Reference Implementation \(JAX-WS RI\)](#)
  - [Java Web Services Development Pack \(JWS DP\)](#)

On this page:

- [Introduction](#)
- [Using JAXB](#)
- [Using XmlBeans](#)

## Introduction

This topic describes how to get a Java representation of an [XML Schema](#), which involves mapping the elements of the XML Schema to members of a Java class. With IntelliJ IDEA, this transformation can be done using one of the following data binders:

- [JAXB](#) generates classes and groups them in Java packages. A package consists of a Java class name and an `ObjectFactory` class. The latter is a factory that is used to return instances of a bound Java class.
- [XmlBeans](#) converts an XML Schema into a Java class, compiles it, and places in the specified output `.jar` file.

## Using JAXB

### To generate a Java class from an XML Schema using JAXB

1. In the active editor tab, open the desired Schema (`.xsd`) file or an XML document which contains the desired Schema. Then choose Tools | JAXB | Generate Java Code From XML Schema Using JAXB on the main menu.
2. In the [Generate Java from Xml Schema using JAXB](#) dialog box that opens configure the generation procedure:
  - In the Schema/DTD/WSDL Path drop-down list, specify the file to be used as the basis for code generation. By default, the field shows the full path to the current file. Accept this suggestion or click the Browse button  and select the desired file in the Select XML Schema File for JAXB Generation that opens.
  - From the Output Path drop-down list, select the module source directory to place the generated Java class in.
  - In the Package Prefix drop-down list, specify the package to include the generated stubs in.
  - Using the checkboxes, configure additional options, such as generating annotation, setting the read-only status, downloading and installing additional libraries.

## Using XmlBeans

### To generate and compile a Java class from an XML Schema using XmlBeans

1. In the active editor tab, open the desired Schema (`.xsd`) file or an XML document which contains the desired Schema. Then choose Tools | XmlBeans | Generate Java Code From XML Schema Using XmlBeans on the main menu.
2. In the [Generate Java Code From XML Schema using XmlBeans](#) dialog box that opens configure the generation procedure:
  - In the Schema Path drop-down list, specify the file to be used as the basis for code generation. By default, the field shows the full path to the current file. Accept this suggestion or click the Browse button  and select the desired file in the Select XML Schema /WSDL File for Generation dialog box that opens.
  - In the Output Path drop-down list, specify the name of the `.jar` file to place the generated and compiled Java code in. By default, IntelliJ IDEA suggests to create a new file `types.jar`. To overwrite an existing file, click the Browse button  and choose the desired file in the Select XML Schema / Wsdl File for generation dialog box that opens.
  - To have missing libraries downloaded and installed automatically, select the Add necessary libraries in order for generated code compile and work checkbox.

This topic describes how to have an [XML Schema](#) generated on the basis of a Java class, which involves mapping the members of the Java class to the elements of the XML Schema. With IntelliJ IDEA, this transformation can be done using the [JAXB](#) .

## To generate an XML Schema from a Java class using JAXB

1. Open the [Generate XML Schema From Java Using JAXB](#) dialog box by doing one of the following:
  - In the [Project](#) tool window, select the name of the desired class and choose Web Services | Generate XML Schema From Java Using JAXB on the context menu.
  - With the desired class opened in the active editor tab, choose Tools | JAXB | Generate XML Schema From Java Using JAXB on the main menu.
2. Specify the method parameter and return types to be reflected in the generated Schema:
  - To have all the class methods involved, clear the Include parameter and return type of the following methods checkbox.
  - To select specific methods to be involved, select the Include parameter and return type of the following methods checkbox, then select the Add to JAXB generation checkbox next to the desired methods.

With IntelliJ IDEA, you can have marshal code stubs generated using [JAXB](#) or [XMLBeans](#) binding tools.

### **To generate marshal code using JAXB**

1. Position the cursor where you need the marshaller to be generated.
2. Do one of the following:
  - On the main menu, choose Tools | JAXB | JAXB Client Code | Generate JAXB marshal code (Java object to XML)
  - On the context menu, choose WebServices | JAXB Client Code | Generate JAXB marshal code (Java object to XML)

### **To generate marshal code using XMLBeans**

1. Position the cursor where you need the marshaller to be generated.
2. Do one of the following:
  - On the main menu, choose Tools | XMLBeans | XMLBeans Client Code | Generate XMLBeans marshal code (Java object to XML)
  - On the context menu, choose WebServices | XMLBeans Client Code | Generate XMLBeans marshal code (Java object to XML)

With IntelliJ IDEA, you can have unmarshal code stubs generated using [JAXB](#) or [XMLBeans](#) binding tools.

### **To generate unmarshal code using JAXB**

1. Position the cursor where you need the unmarshaller to be generated.
2. Do one of the following:
  - On the main menu, choose Tools | JAXB | JAXB Client Code | Generate JAXB unmarshal code (Java object from XML) .
  - On the context menu, choose WebServices | JAXB Client Code | Generate JAXB unmarshal code (Java object from XML) .

### **To generate unmarshal code using XMLBeans**

1. Position the cursor where you need the unmarshaller to be generated.
2. Do one of the following:
  - On the main menu, choose Tools | XMLBeans | XMLBeans Client Code | Generate XMLBeans unmarshal code (Java object from XML) .
  - On the context menu, choose WebServices | XMLBeans Client Code | Generate XMLBeans unmarshal code (Java object from XML) .

IntelliJ IDEA lets you refactor your XML code.

The XML refactoring support is based on the Refactor-X plugin. This plugin is bundled with the IDE and enabled by default.

To access XML refactoring commands, you can use the main menu or the context menu in the editor: Refactor | XML Refactorings | <Refactoring\_Name> .

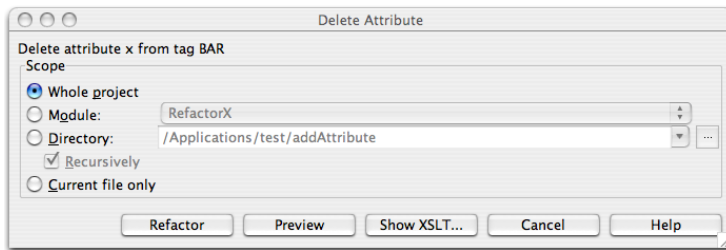

The following refactorings are available:

- Delete Attribute
- Replace Attribute With Tag
- Replace Tag With Attribute
- Add Attribute
- Add Subtag
- Move Attribute In
- Move Attribute Out
- Change Attribute Value
- Convert Contents To Attribute
- Expand Tag
- Collapse Tag
- Merge Tags
- Split Tags
- Delete Tag
- Unwrap Tag
- Wrap Tag
- Wrap Tag Contents

The Delete Attribute refactoring allows you to delete a set of attribute definitions on a set of XML tag. If this refactoring is invoked, all attributes matching the selected attribute name on tags with the selected tag name may be removed. This bulk removal of attributes may be useful as XML schemas evolve.

## Deleting an attribute

1. In the editor, place the cursor within the attribute to be deleted.
2. Select Refactor | XML Refactorings | Delete Attribute from the main or the context menu.

3. Determine the scope of the deletion. All attributes matching name of the attribute selected on the tag selected will be deleted, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
4. Press Preview button to make IntelliJ IDEA to search for usages of the selected attribute Find window.
5. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

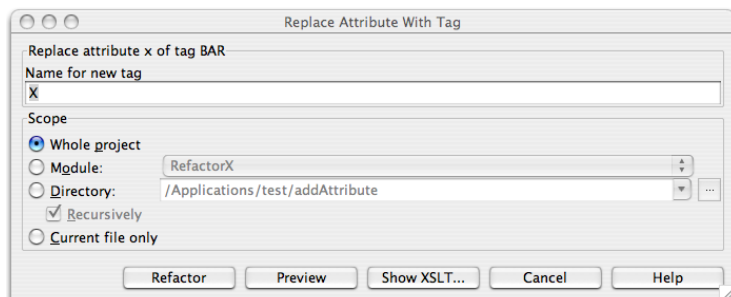

Please note the following:

- Pressing Preview opens the Refactoring preview window displaying all found usages of the attributes to be removed. In this window you can exclude/include usages you want to refactor.
- Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.
- The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Replace Attribute with Tag refactoring allows you to replace attribute definitions on a set of XMLs tag with equivalent sub-tags. If this refactoring is invoked, all attributes matching the selected attribute name on tags with the selected tag name may be removed, and equivalent sub-tags created. This bulk transformation of attributes to tags is useful as XML schemas evolve.

## Converting an attribute into a tag

1. In the editor, place the cursor within the attribute to be converted.
2. Select Refactor | XML Refactorings | Replace Attribute with Tag from the main or the context menu.

3. Determine the name of the tags to replace the selected attributes.
4. Determine the scope of the replacement. All attributes matching name of the attribute selected on the tag selected will be replaced, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected attribute Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the attributes to be replaced. In this window you can exclude/include usages you want to refactor.

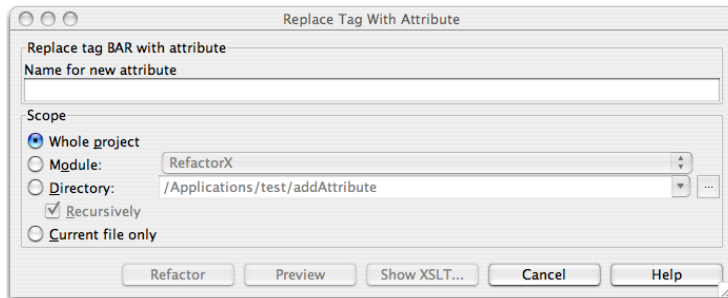

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Replace Tag with Attribute refactoring allows you to replace sub-tags definitions on a set of XMLs tag with equivalent attributes. If this refactoring is invoked, all tags matching the selected tag's name on tags with the selected parent tag name may be removed, and equivalent attributes created. This bulk transformation of sub-tags to attributes is useful as XML schemas evolve.

## Converting a tag into an attribute

1. In the editor, place the cursor within the tag to be converted.
2. Select Refactor | XML Refactorings | Replace Tag with Attribute from the main or the context menu.

3. Determine the name of the attributes to replace the selected tags.
4. Determine the scope of the replacement. All tags matching name of the tag selected on the parent tag selected will be replaced, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected tag Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the tags to be replaced. In this window you can exclude/include usages you want to refactor.

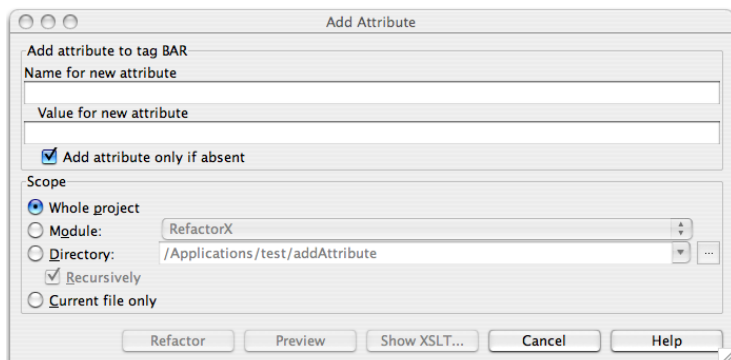

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Add Attribute refactoring allows you to add an attribute to a set of XML tags. If this refactoring is invoked, attributes matching the requested attribute name and value will be added to tags with the selected tag name. Optionally, the requested attribute may be added only to tags that do not already contain the selected attribute. This bulk addition of attributes is useful as XML schemas evolve.

## Adding an attribute

1. In the editor, place the cursor within the corresponding tag.
2. Select Refactor | XML Refactorings | Add Attribute from the main or the context menu.

3. Determine the name of the attribute to add to the selected tags.
4. Determine the value of the attribute to add to the selected tags.
5. Determine whether tags that already contain the requested attribute will be ignored, or will have their values changed.
6. Determine the scope of the addition. All tags matching name of the selected will be replaced, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
7. Click Preview to make IntelliJ IDEA search for usages of the selected attribute.
8. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Clicking Preview opens the Refactoring preview window with all found usages of the attributes to be replaced. In this window you can exclude/include usages you want to refactor.

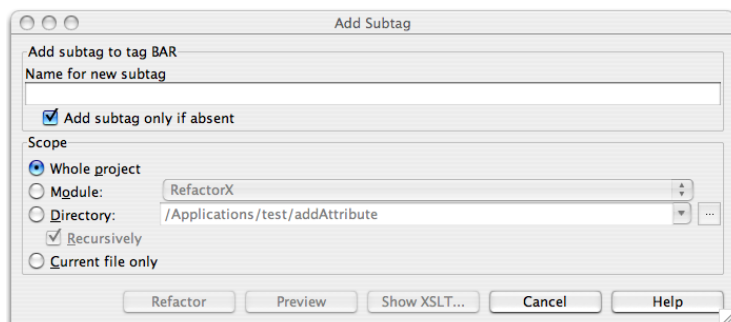

Pressing Show XSLT... opens the XSLT preview window, displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Add Subtag refactoring allows you to add a subtag to a set of XML tags. If this refactoring is invoked, subtags matching with requested subtag name will be added to tags with the selected tag name. Optionally, the requested subtag may be added only to tags that do not already contain the selected subtag. This bulk addition of subtags is useful as XML schemas evolve.

## Adding a subtag

1. In the editor, place the cursor within the corresponding tag.
2. Select Refactor | XML Refactorings | Add Subtag from the main or the context menu.

3. Determine the name of the subtag to add to the selected tags.
4. Determine whether tags that already contain the requested subtag will be ignored, or will have their values changed.
5. Determine the scope of the addition. All tags matching name of the selected will be replaced, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
6. Press Preview button to make IntelliJ IDEA to search for usages of the selected subtag Find window.
7. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the subtags to be replaced. In this window you can exclude/include usages you want to refactor.

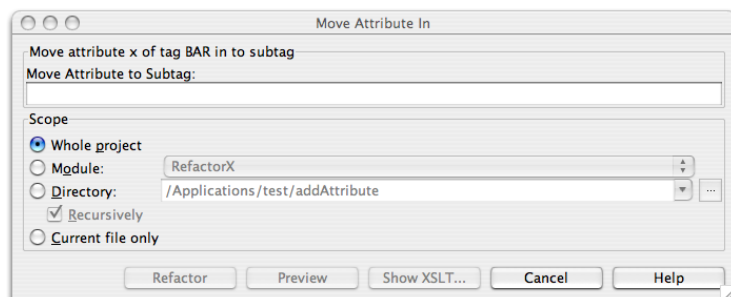

Pressing Show XSLT... opens the XSLT preview window displaying an small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Move Attribute In refactoring allows you to move attributes defined on a set of XML tags inward to a set of subtags. If this refactoring is invoked, all attributes matching the selected attribute name on tags with the selected tag name may be moved inward toward a subtag of a given name. This bulk modification of attribute values may be useful as XML schemas evolve.

## Moving an attribute into a subtag

1. In the editor, place the cursor within the attribute to be moved.
2. Select Refactor | XML Refactorings | Move Attribute In from the main or the context menu.

3. Determine the subtag to move the attribute to.
4. Determine the scope of the change. All attributes matching the name of the attribute selected on the tag selected will be modified, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected attribute Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the attributes to be changed. In this window you can exclude/include usages you want to refactor.

Pressing Show XSLT... opens the XSLT preview window displaying an small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Move Attribute Out refactoring allows you to move attributes defined on a set of XML tags outward to their parent tags. If this refactoring is invoked, all attributes matching the selected attribute name on tags with the selected tag name may be moved outward. This bulk modification of attribute values may be useful as XML schemas evolve.

## Moving an attribute to a parent tag

1. In the editor, place the cursor within the attribute to be moved.
2. Select Refactor | XML Refactorings | Move Attribute Out from the main or the context menu.

3. Determine the scope of the change. All attributes matching the name of the attribute selected on the tag selected will be modified, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
4. Press Preview button to make IntelliJ IDEA to search for usages of the selected attribute Find window.
5. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the attributes to be changed. In this window you can exclude/include usages you want to refactor.

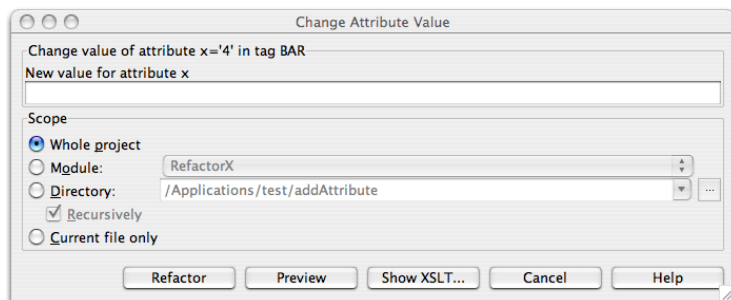

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Change Attribute Value refactoring allows you to change the values an attribute defined on a set of XML tags. If this refactoring is invoked, all attributes matching the selected attribute name and selected attribute value on tags with the selected tag name may have their values changed. This bulk modification of attribute values may be useful as XML schemas evolve.

## Changing a value of an attribute

1. In the editor, place the cursor within the attribute whose value you want to change.
2. Select Refactor | XML Refactorings | Change Attribute Value from the main or the context menu.

3. Determine the new value for the attribute.
4. Determine the scope of the change. All attributes matching the name and value of the attribute selected on the tag selected will be modified, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected attribute Find window.
6. Cstepck OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the attributes to be changed. In this window you can exclude/include usages you want to refactor.

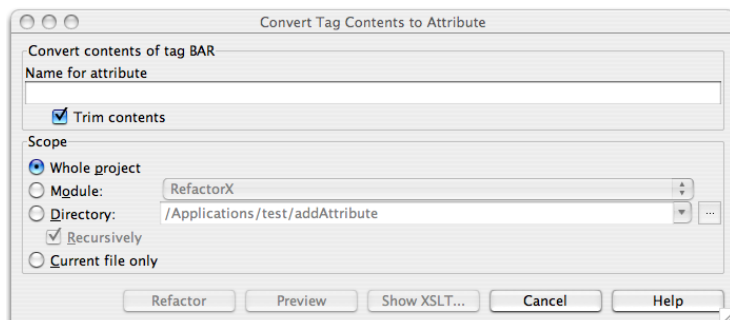

Pressing Show XSLT... opens the XSLT preview window displaying an small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Convert Tag Contents to Attribute refactoring allows you to replace the contents of a set of XMLs tag with equivalent attributes. If this refactoring is invoked, all tags matching the selected tag's name will have their textual contents removed, and equivalent attributes created. This bulk transformation of tag contents to attributes is useful as XML schemas evolve.

## Converting tag contents into attributes

1. In the editor, place the cursor within the tag whose contents you want to convert.
2. Select Refactor | XML Refactorings | Convert Tag Contents to Attribute from the main or the context menu.

3. Determine the name of the attributes to be created from the selected tag contents.
4. Determine the scope of the replacement. All tags matching name of the selected will have their contents converted to attributes, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected tag Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the tags to be converted. In this window you can exclude/include usages you want to refactor.

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Expand Tag intention allows you expand an empty XML tag into an equivalent start tag and end tag.

The Collapse Tag intention allows you collapse an XML tag whose contents are only white space, into an empty XML tag.

The Merge Tag intention allows you to merge two sequential and compatible XML tags into one larger tag. The tags to merge must have the same name and attributes. To merge two tags, simply select the first tag to merge, and invoke the intention with `Alt+Enter`. Then select Merge Tags, and the tags will be merged. Merging effectively replaces the two tags with a new tag. The new tag will have the same attributes as the original tags, and its contents will be created by appending the contents of the first tag with the contents of the second.

The Split Tag intention allows you split a large XML tag into two smaller XML tags. To split tags, simply select the child tag you wish the split to occur on in the body of the tag, and invoke the intention with `Alt+Enter`. Then select Split Tags, and the tag will be split. Splitting a tag will create two sequential tags, both with the same name and attributes as the original tag. The contents of the first tag will be whatever comes before the selected child tag, with everything else becoming the contents of the second tag.

The Delete Tag refactoring allows you to delete a set of XML tags. If this refactoring is invoked, all tags matching the selected tag name on tags with the selected tag name may be removed. This bulk removal of tags may be useful as XML schemas evolve.

## Deleting a tag

1. In the editor, place the cursor within the tag to be deleted.
2. Select Refactor | XML Refactorings | Delete Tag from the main or the context menu.

3. Determine the scope of deletion. All tags matching name of the tag selected will be deleted, if they are in scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
4. Click Preview to make IntelliJ IDEA search for usages of the selected tag.
5. Click OK to continue. If you do not select the Preview checkbox, all usages will be changed immediately.

Clicking Preview opens the Refactoring preview window displaying all found usages of the tags to be removed. In this window you can exclude/include usages you want to refactor.

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Unwrap Tag refactoring allows you to unwrap a set of XML tags, replacing them with their contents, if any. If this refactoring is invoked, all tags matching the selected tag name may be unwrapped. This bulk unwrapping of tags may be useful as XML schemas evolve. Note that top-level tags will not be unwrapped, as this may make XML documents invalid.

## Unwrapping a tag

1. In the editor, place the cursor within the tag to be unwrapped.
2. Select Refactor | XML Refactorings | Unwrap Tag from the main or the context menu.

3. Determine the scope of the unwrapping. All tags matching name of the tag selected will be unwrapped, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
4. Press Preview button to make IntelliJ IDEA to search for usages of the selected tag Find window.
5. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

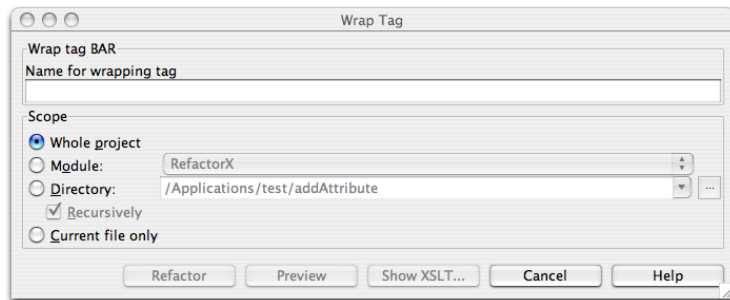

Please note the following:

- Pressing Preview opens the Refactoring preview window displaying all found usages of the tags to be unwrapped. In this window you can exclude/include usages you want to refactor.
- Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.
- The Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Wrap Tag refactoring allows you to wrap a set of XML tags in a newly created parent. If this refactoring is invoked, all tags matching the selected tag name may be wrapped. This bulk wrapping of tags may be useful as XML schemas evolve.

## Wrapping a tag

1. In the editor, place the cursor within the tag to be wrapped.
2. Select Refactor | XML Refactorings | Wrap Tag from the main or the context menu.

3. Determine the name of the new tags which will wrap the selected tags.
4. Determine the scope of the wrapping. All tags matching the name of the tag selected will be wrapped, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected tag Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

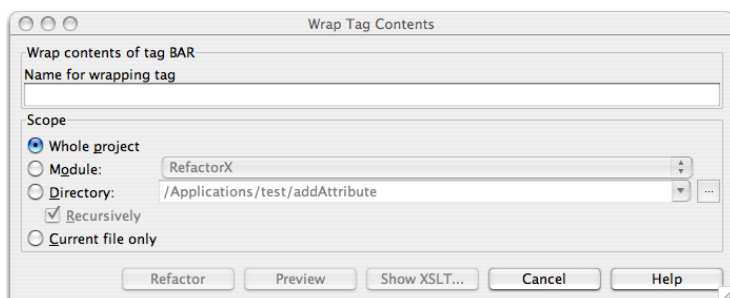

Please note the following:

- Pressing Preview opens the Refactoring preview window displaying all found usages of the tags to be wrapped. In this window you can exclude/include usages you want to refactor.
- Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.
- Refactoring preview window may appear anyway, if the files to be affected are read-only.

The Wrap Tag Contents refactoring allows you to wrap the contents of a set of XML tags in newly created tag. If this refactoring is invoked, all tags matching the selected tag name will have their contents wrapped. This bulk wrapping of tag contents may be useful as XML schemas evolve.

## Wrapping tag contents

1. In the editor, place the cursor within the tag whose contents you want to wrap.
2. Select Refactor | XML Refactorings | Wrap Tag Contents from the main or the context menu.

3. Determine the name of the new tags which will wrap the contents of the selected tags.
4. Determine the scope of the wrapping. All tags matching name of the tag selected will be wrapped, if they are in the selected scope. Scopes available include the current file, the entire project, or a specified directory or module. Directory scopes can either include sub-directories, or not, based on whether the Recursively checkbox is selected. If the Limit to files with DTD:... checkbox is selected, the scope will be limited to those files with the same DOCTYPE as the current file.
5. Press Preview button to make IntelliJ IDEA to search for usages of the selected tag Find window.
6. Click OK to continue. If you do not select the Preview option, all usages will be changed immediately.

Pressing Preview opens the Refactoring preview window displaying all found usages of the tags to be wrapped. In this window you can exclude/include usages you want to refactor.

Pressing Show XSLT... opens the XSLT preview window displaying a small fragment of XSLT equivalent to the refactoring requested. This fragment can be used by XSLT processors to perform the requested refactoring on files external to your IntelliJ IDEA project.

Refactoring preview window may appear anyway, if the files to be affected are read-only.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

**Tip** To get guidance in Node development, see [HowToNode.org](https://www.howtonode.org).

[Node.js](#) is a lightweight runtime environment for executing JavaScript on the server side. IntelliJ IDEA integrates with Node.js providing assistance in configuring, editing, running, debugging, testing, profiling, and maintaining your applications.

## Before you start

1. Download and install the [Node.js](#) runtime environment.
2. **Install** and **enable** the NodeJS plugin. The **NodeJS** plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Quick start with a Node.js application

**Tip** If you have only one Node.js on your machine and you followed the standard installation procedure, IntelliJ IDEA detects your Node.js automatically. Otherwise, choose the relevant interpreter from the drop-down list. Learn more from [Configuring Node.js Interpreters](#).

Here we will use a simple [Express application](#) as an example.

### To create an application

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose Node.js and NPM in the left-hand pane.
3. In the right-hand pane, choose Node.js Express App and click Next.
4. On the second page of the wizard, specify the project folder, the Node.js interpreter, and the version of [express-generator](#) to use. In the Options area, choose the template and the CSS to use.
5. When you click Finish, IntelliJ IDEA generates a **Node.js Express**-specific project with all the required configuration files.

## Configuring Node.js in a project

1. In the Settings/Preferences dialog ([Ctrl+Alt+S](#)), choose Node.js and NPM under Languages and Frameworks. The [Node.js and NPM](#) page opens.
2. In the Node Interpreter field, choose the interpreter from the drop-down list or from the dialog that opens when you click .
3. In the Coding Assistance area, click Enable to configure the **Node.js Core** module sources as a [JavaScript library](#) and associate it with your project. As a result, IntelliJ IDEA provides code completion, reference resolution, validation, and debugging capabilities for `fs`, `path`, `http`, and other core modules that are compiled into the Node.js binary. When the configuration is completed, IntelliJ IDEA displays information about the currently configured version, the notification Node.js Core Library is enabled, and adds the Disable and the Usage scope buttons.

### Optionally

Configure the scope in which the Node.js Core sources are treated as libraries:

1. Click Usage scope. The [Usage Scope](#) dialog opens.
2. Click the relevant directories, and for each of them select the newly configured Node.js Core library from the list.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

With IntelliJ IDEA, you can use local and remote Node.js interpreters. The term **local Node.js interpreter** denotes a Node.js installation on your computer. The term **remote Node.js interpreter** denotes a Node.js installation on a remote host or in a virtual environment set up in a **Vagrant** instance. Local interpreters are configured on the [Node.js and NPM](#) page as described below.

You can use a remote interpreter in four ways:

- Through SSH credentials to access the host where the Node.js interpreter is installed.
- Through access to the corresponding **Vagrant** instance.
- According to a [Server Access Configuration](#). This approach is also helpful if you are going to synchronize your project sources with the Web server on the target remote host.
- Through access to a **Docker Container** with Node.js.

Remote interpreters are configured in the [Configure Node.js Remote Interpreter Dialog](#) dialog that opens only from the [Run/Debug Configuration: Node.js](#) dialog. See [Configuring remote Node.js interpreters](#) for details.

## Configuring a local Node.js interpreter

1. In the Settings/Preferences dialog ([Ctrl+Alt+S](#)), choose Node.js and NPM under Languages and Frameworks. The [Node.js and NPM](#) page opens.
2. Click the  next to the Node Interpreter drop-down list.
3. In the [Node.js Interpreters Dialog](#) that opens with a list of all the currently configured interpreters, click **+** on the toolbar. In the dialog box that opens, choose Add Local on the context menu and choose the local installation of Node.js, then click OK. You return to the [Node.js Interpreters Dialog](#) where the Node interpreter read-only field shows the path to the chosen interpreter.
4. In the Npm package field, specify the Node package manager (npm) associated with the selected interpreter. Choose the relevant npm from the drop-down list or click  next to it and in the dialog box that opens choose the location of the npm to use.

Alternatively, you can specify the path to the [Yarn package manager](#) if you want to use it instead of npm.

The field is available only if the selected interpreter is of the type **local**.

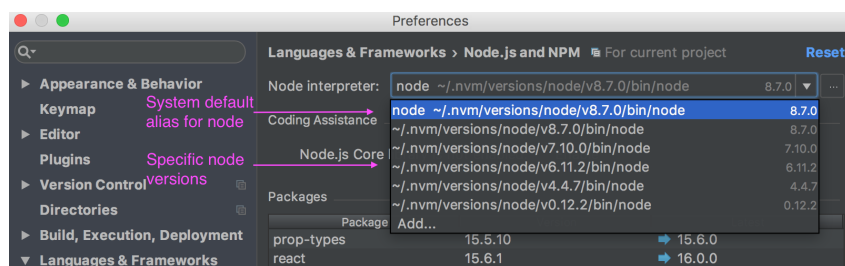

When you click OK, you return to the Node.js and NPM page where the Node interpreter field shows the new interpreter.

## Using a system Node.js version

**Tip** This functionality is especially helpful when you are using [nvm](#).

With IntelliJ IDEA, you can set the default system node alias as your project's Node.js version. This means that if you install a new node version and make it the default in your system, all the tools and run configurations in IntelliJ IDEA where this system alias is specified in the Node.js interpreter field will use this newer version.

1. In the Settings/Preferences dialog ([Ctrl+Alt+S](#)), choose Node.js and NPM under Languages and Frameworks. The [Node.js and NPM](#) page opens.
2. From the Node interpreter drop-down list, choose **node**.
3. Specify this new Node.js interpreter where applicable, e.g. in your run/debug configurations or settings of specific tools.

## Configuring a remote Node.js interpreter on a host accessible through SSH connection

Before you start:

1. Configure access to an **ssh** server on the target remote host and make sure this server is running.
2. Make sure the **Node.js Remote Interpreter** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

To configure a Node.js interpreter using SSH credentials:

1. On the main menu, choose Run | Edit Configurations. In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button **+**, and choose Node.js on the context menu. In the [Run/Debug Configuration: Node.js](#) dialog that opens, click  next to the Node interpreter field.
2. In the [Node.js Interpreters Dialog](#) that opens with a list of all the currently configured interpreters, click **+** on the toolbar. In

- the dialog box that opens, choose Add Remote on the context menu .
- In the [Configure Node.js Remote Interpreter Dialog](#) that opens, choose the SSH Credentials method.
  - Specify the name of the remote host and the port which the SSH server listens to. The default port number is 22.
  - Specify your credentials to access the remote host in accordance with the credentials received during the registration on the server. Type your user name and choose the authentication method:
    - To access the host through a password, choose Password from the Auth type drop-down list, specify the password, and select the Save password checkbox to have IntelliJ IDEA remember it.
    - To use [SSH authentication](#) via a key pair, choose Key pair (OpenSSH or PuTTY) . To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the [OpenSSH](#) utility. Specify the path to the file where your **private key** is stored and type the passphrase (if any) in the corresponding text boxes. To have IntelliJ IDEA remember the passphrase, select the Save passphrase checkbox.
    - If your SSH keys are managed by a credentials helper application (for example, [Pageant](#) on Windows or [ssh-agent](#) on Mac and Linux), choose Authentication agent (ssh-agent or Pageant) .
  - Specify the location of the **Node.js** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/node` folder for remote hosts and Vagrant instances and `node` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the Node.js home directory must be open for edit.
  - When you click OK , IntelliJ IDEA checks whether the Node.js executable is actually stored in the specified folder.
    - If no Node.js executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
    - If the Node.js executable is found, you return to the Node.js Interpreters where the installation folder and the detected version of the Node.js interpreter are displayed.

## Configuring a remote Node.js interpreter in a Vagrant environment instance

Before you start:

- Make sure that [Vagrant](#) and [Oracle's VirtualBox](#) are downloaded, installed, and configured on your computer as described in [Vagrant](#) .
- Make sure the [Vagrant](#) and [Node.js Remote Interpreter](#) plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
- Make sure the [Node.js Remote Interpreter](#) repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
- Make sure that the parent folders of the following executable files are added to the system **PATH** variable:
  - `vagrant.bat` or `vagrant` from your Vagrant installation. This should be done automatically by the Vagrant installer.
  - `VBoxManage.exe` or `VBoxManage` from your Oracle's VirtualBox installation.
- Configure the Node.js development environment in the **Vagrant instance** to be used. Learn more about using [Vagrant](#) with IntelliJ IDEA in [Vagrant](#) .

To configure a Node.js Interpreter in a Vagrant instance

- On the main menu, choose Run | Edit Configurations . In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button , and choose Node.js on the context menu. In the [Run/Debug Configuration: Node.js](#) dialog that opens, click  next to the Node interpreter field.
- In the [Node.js Interpreters Dialog](#) that opens with a list of all the currently configured interpreters, click  on the toolbar. In the dialog box that opens, choose Add Remote on the context menu .
- In the [Configure Node.js Remote Interpreter Dialog](#) that opens, choose the Vagrant method.
- Specify the Vagrant instance folder which points at the environment you are going to use. Technically, it is the folder where the **VagrantFile** configuration file for the desired environment is located. Based on this setting, IntelliJ IDEA detects the **Vagrant host** and shows it as a link in the Vagrant Host URL read-only field.
- Specify the location of the **Node.js** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/node` folder for remote hosts and Vagrant instances and `node` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the Node.js home directory must be open for edit.
- When you click OK , IntelliJ IDEA checks whether the Node.js executable is actually stored in the specified folder.
  - If no Node.js executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the Node.js executable is found, you return to the Node.js Interpreters where the installation folder and the detected version of the Node.js interpreter are displayed.

## Configuring a remote Node.js interpreter on a remote host accessible through SFTP

Before you start:

- Make sure a `ssh` server is running on the target remote host and you have configured access to it.
- Make sure the [Node.js Remote Interpreter](#) repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling](#)

[Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

3. Make sure the **Remote Hosts Access** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .
4. Make sure you have at least one IntelliJ IDEA-wide **server access configuration** of the SFTP type to establish access to the target host. To make a configuration available in all IntelliJ IDEA projects, clear the Visible only for this project checkbox in the [Deployment: Connection Tab](#) . See [Creating a Remote Server Configuration](#) for details.

To configure a remote Node.js interpreter based on an SFTP server access configuration

1. On the main menu, choose [Run | Edit Configurations](#) . In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button  , and choose Node.js on the context menu. In the [Run/Debug Configuration: Node.js](#) dialog that opens, click  next to the Node interpreter field.
2. In the [Node.js Interpreters Dialog](#) that opens with a list of all the currently configured interpreters, click  on the toolbar. In the dialog box that opens, choose Add Remote on the context menu .
3. In the [Configure Node.js Remote Interpreter Dialog](#) that opens, choose the Deployment Configuration method.
4. From the Deployment Configuration drop-down list, choose the **server access configuration** of the SFTP type according to which you want IntelliJ IDEA to connect to the target host. If the settings specified in the chosen configuration ensure successful connection, IntelliJ IDEA displays the URL address of the target host as a link in the Deployment Host URL field.

To use an interpreter configuration, you need **path mappings** that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. By default, IntelliJ IDEA retrieves path mappings from the chosen server access (deployment) configuration. If the configuration does not contain path mappings, IntelliJ IDEA displays the corresponding error message.

To fix the problem, open the [Deployment](#) page under the Build, Execution, Deployment node, select the relevant server access configuration, switch to the Mappings tab, and map the local folders to the folders on the server as described in [Creating a Remote Server Configuration](#) section.

5. Specify the location of the **Node.js** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/node` folder for remote hosts and Vagrant instances and `node` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the Node.js home directory must be open for edit.
6. When you click OK , IntelliJ IDEA checks whether the Node.js executable is actually stored in the specified folder.
  - If no Node.js executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the Node.js executable is found, you return to the Node.js Interpreters where the installation folder and the detected version of the Node.js interpreter are displayed.

## Configuring a remote Node.js interpreter in a Docker container

You can quickly bootstrap your Node.js application with Docker, IntelliJ IDEA will take care of the initial configuration by automatically creating a new `Dockerfile` , keeping your source code up-to-date and installing `npm` dependencies in the container. Configuring a Node.js environment running in a Docker container as a Node.js remote interpreter lets you run, debug, and profile your Node.js application from IntelliJ IDEA.

Before you start:

1. Make sure the **Node.js** , **Node.js Remote Interpreter** , and **Docker Integration** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
2. Download, install, and configure **Docker** as described in [Docker](#) .

To configure a remote Node.js interpreter in a Docker container:

1. On the main menu, choose [Run | Edit Configurations](#) . In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button  , and choose Node.js on the context menu. In the [Run/Debug Configuration: Node.js](#) dialog that opens, click  next to the Node interpreter field.
2. In the [Node.js Interpreters Dialog](#) that opens with a list of all the currently configured interpreters, click  on the toolbar. In the dialog box that opens, choose Add Remote on the context menu .
3. In the [Configure Node.js Remote Interpreter Dialog](#) that opens, choose the Docker method.
4. In the Server field, specify the **Docker configuration** to use, see [Docker](#) . Choose a configuration from the drop-down list or click  next to it and create a new configuration in the [Docker](#) dialog box that opens.
5. In the Image name field, specify the base Docker image to use. Choose one of the previously downloaded or your custom images from the drop-down list or type the image name manually, for example, `node:argon` or `mhart/alpine-node` . When you later launch the run configuration, Docker will search for the specified image on your machine. If the search fails, the image will be downloaded from the image repository specified on the [Registry](#) page.
6. The Node.js interpreter path field shows the location of the default Node.js interpreter from the specified image.
7. When you click OK , IntelliJ IDEA closes the [Configure Node.js Remote Interpreter Dialog](#) and brings you to the [Node.js Interpreters Dialog](#) where the new interpreter configuration is added to the list. Click OK to return to the run configuration.

## Configuring mappings

When you debug an application with a remote Node.js interpreter, the debugger tells IntelliJ IDEA the name of the currently

processed file and the number of the line to be processed. IntelliJ IDEA opens the local copy of this file and indicates the line with the provided number. This behaviour is enabled by specifying correspondence between files and folders on the server and their local copies. This correspondence is called mapping, it is set in the debug configuration.

If you use an interpreter accessible through SFTP connection or located on a Vagrant instance, the mappings are automatically retrieved from the corresponding deployment configuration or `Vagrantfile`. To specify additional mappings:

1. On the main menu, choose Run | Edit Configurations. In the Edit Configuration dialog box that opens, click the Add New Configuration toolbar button , and choose Node.js on the context menu.
2. In the **Run/Debug Configuration: Node.js** dialog that opens, choose the required remote interpreter from the Node interpreter drop-down list.
3. Click  next to the Path Mappings field.
4. The **Edit Project Path Mappings Dialog** that opens, shows the path mappings retrieved from the deployment configuration or `Vagrantfile`. These mappings are read-only.
  - To add a custom mapping, click  and specify the path in the project and the corresponding path on the remote runtime environment in the Local Path and Remote Path fields respectively. Type the paths manually or click  and select the relevant files or folders in the dialog box that opens.
  - To remove a custom mapping, select it in the list and click .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA helps you run and debug your Node.js applications. You can debug applications that are started from IntelliJ IDEA as well as attach to already running applications.

## Before you start

Install and enable the NodeJS plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Running a Node.js application

IntelliJ IDEA runs Node.js applications according to a run configuration of the type **Node.js**. IntelliJ IDEA also uses this configuration for [debugging Node.js applications locally](#).

### To create a Node.js run/debug configuration

1. On the main menu, choose **Run | Edit Configuration**, then in the Edit Configurations dialog, click  on the toolbar and select Node.js from the pop-up list. The **Run/Debug Configuration: Node.js** dialog opens.
2. Choose Node.js interpreter to use from the drop-down list or configure a new one as described in [Configuring Node.js Interpreters](#).
3. In the JavaScript File field, specify the path to the main file of the application that starts it (for example, `bin/www` for [Node.js Express applications](#)).

### Optionally

- In the Node Parameters field, specify the flags that customize the start of Node.js. For example, to make your application accessible for remote debugging, type one of the debugging flags depending on your Node.js version: `--inspect=<debugger port>` for Node.js versions 6.5 and higher or `--debug=<debugger port>` for any Node.js version earlier than 8. The default debugger port is `5858`.
- In the Application parameters text box, specify the arguments to be passed to the application on start through the `process.argv` array.

### To run an application

Choose the newly created Node.js configuration in the Select run/debug configuration drop-down list on the toolbar and click  next to it. The application starts, and the **Run Tool Window** opens showing the application output.

## Debugging a Node.js application

IntelliJ IDEA makes it easier to debug Node.js applications. You can put breakpoints right in your JavaScript or TypeScript code so you no longer need any `debugger` and `console.log()` statements. You can do many things that will help you explore the code and understand where the bug is. In the Debug tool window, you can view the call stack and the variables in their current state, evaluate expressions in the editor, and step through the code.

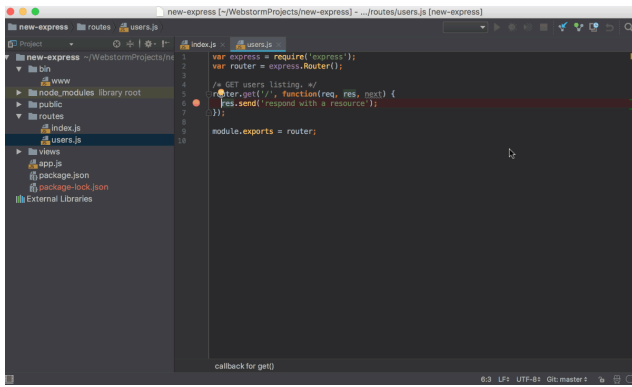

## Local and Remote debugging

IntelliJ IDEA supports two debugging modes:

- **Local debugging**: in this mode, your application is started from IntelliJ IDEA and is running locally on your computer. To debug it, use a Node.js configuration.
- **Debugging a remote application**: in this mode, your application is running in a remote environment in the [debug mode](#) and IntelliJ IDEA attaches to a running process. IntelliJ IDEA recognizes `--inspect` and `--debug` flags so you can make any application accessible for remote debugging. IntelliJ IDEA supports remote debugging with the [Chrome Debugging Protocol](#) and the [V8 Debugging Protocol](#) (also known as Legacy Protocol). In either case, a debugging session is initiated through a run/debug configuration of the type **Attach to Node.js/Chrome**.

## Debugging a Node.js application locally

1. Set the **breakpoints** in the Node.js code where necessary.
2. Create a Node.js run/debug configuration [as described above](#). If necessary, product% can generate a **JavaScript Debug** configuration and start it automatically together with the **Node.js** configuration as described in [Starting a JavaScript Debug configuration together with a Node.js configuration](#).
3. Choose the newly created Node.js configuration in the Select run/debug configuration drop-down list on the toolbar and click  next to it. The **Debug Tool Window** opens.
4. Perform the steps that will trigger the execution of the code with the breakpoints.
5. Switch to IntelliJ IDEA, where the controls of the Debug tool window are now enabled. Proceed with the debugging session — [step through the breakpoints](#), switch between frames, change values on-the-fly, [examine a suspended program](#), [evaluate expressions](#), and [set watches](#).

## Debugging a running Node.js application

With IntelliJ IDEA, you can debug an application that is running in a remote environment. IntelliJ IDEA supports remote debugging with the [Chrome Debugging Protocol](#) and the [V8 Debugging Protocol](#) (also known as Legacy Protocol). In either case, a debugging session is initiated through an **Attach to Node.js/Chrome** configuration.

When your application is running in a **remote environment**, you need to ensure that IntelliJ IDEA can connect to it. Please note that by default Node.js binds the debug port on the loopback interface. To listen on all network interfaces, start an application in a remote environment with `--inspect=0.0.0.0:<port>`, the default port is `9229`.

## Remote debugging with Chrome debugging protocol

Use this protocol to debug applications started with the `--inspect` flag. This flag is used with Node.js versions later than 6.3.

### To create an Attach to Node.js/Chrome run/debug configuration

1. Choose Run | Edit Configurations on the main menu, then click **+** in the Edit Configuration dialog box that opens, and choose Attach to Node.js/Chrome from the list. The **Run/Debug Configuration: Attach to Node.js/Chrome** dialog box opens.
2. Specify the host where the target application is running and the port passed to `--inspect` when starting the Node.js process to connect to. Copy the port number from the information message `Debugger listening <host>:<port>` in the **Run** tool window that controls the running application. The default port is 5858.
3. In the Attach to area, choose Chrome or Node.js > 6.3 started with `--inspect`.

### To start debugging

1. Set the breakpoints in the Node.js code as necessary.
2. Choose the newly created Attach to Node.js/Chrome configuration in the Select run/debug configuration drop-down list on the toolbar and click **🐞** next to it. The **Debug Tool Window** opens.
3. In the browser of your choice, open the starting page of your application. Control over the debugging session returns to IntelliJ IDEA.
4. Switch to IntelliJ IDEA. In the Debug tool window, [step through the breakpoints](#), switch between frames, change values on-the-fly, [examine a suspended program](#), [evaluate expressions](#), and [set watches](#).

## Remote debugging with V8 Debugging Protocol

Use this protocol to debug applications started with the `--debug` flag. This flag is used with Node.js versions earlier than 8.

### To create an Attach to Node.js/Chrome run/debug configuration

1. Choose Run | Edit Configurations on the main menu, then click **+** in the Edit Configuration dialog box that opens, and choose Attach to Node.js/Chrome from the list. The **Run/Debug Configuration: Attach to Node.js/Chrome** dialog box opens.
2. Specify the host where the target application is running and the port passed to `--debug` when starting the Node.js process to connect to. Copy the port number from the information message `Debugger listening <host>:<port>` in the **Run** tool window that controls the running application. The default port is 5858.
3. In the Attach to area, choose Node.js < 8 started with `--debug`.

### To start debugging

1. Make sure the application to debug has been launched in the remote environment with the following parameters: `--debug=<debugger port>` The default port is `5858`.
2. Set the breakpoints in the Node.js code as necessary.
3. Choose the newly created Attach to Node.js/Chrome configuration in the Select run/debug configuration drop-down list on the toolbar and click **🐞** next to it. The **Debug Tool Window** opens.
4. In the browser of your choice, open the starting page of your application. Control over the debugging session returns to IntelliJ IDEA.

5. Switch to IntelliJ IDEA, where the controls of the Debug tool window are now enabled. Proceed with the debugging session — [step through the breakpoints](#) , switch between frames, change values on-the-fly, [examine a suspended program](#) , [evaluate expressions](#) , and [set watches](#) .

## Starting a JavaScript Debug configuration together with a Node.js configuration

With IntelliJ IDEA, you can debug the server-side code and the client-side JavaScript code of your application in two modes:

- Separately, using single-run configurations.
- Simultaneously, using a complex Node.js with JavaScript Debug configuration. All you need is configure the behaviour of the browser and enable debugging the client-side code of the application. This functionality is provided through a `JavaScript Debug` run configuration, so technically, IntelliJ IDEA creates separate run configurations for the server-side and the client-side code, but you specify all your settings in one dedicated `Node.js` run configuration.

### To create a complex Node.js with JavaScript Debug configuration

1. Choose Run | Edit Configuration on the main menu.
2. From the list, choose the `Node.js` run configuration to start together with a `JavaScript Debug` configuration. In the dialog box that opens, switch to the Browser / Live Edit tab.
3. Select the After launch checkbox to start a browser automatically when you launch a debugging session.
4. In the text box below, type the URL address to open the application at.
5. Choose the browser to use from the drop-down list next to the After launch checkbox.
  - To use the system default browser, choose Default .
  - To use a custom browser, choose it from the list. Note that `Live Edit` is fully supported only in Chrome.
  - To configure browsers, click the Browse button  and adjust the settings in the Web Browsers dialog box that opens. For more information, see [Configuring Browsers](#) .
6. Select the With JavaScript debugger checkbox.

As for any other JavaScript debugging session, you can enable the Live Edit functionality as described in [Live Editing](#) .

### To enable Live Edit in a Node.js application

1. Make sure the `LiveEdit` repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
2. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Debugger under Build, Execution, Deployment , and then click Live Edit . The `Live Edit` page opens.
3. Select the Update Node.js application on changes checkbox. Set the elapsed time for applying the changes to a running application: accept the default value `300 ms` or specify a custom value using the spin box next to the corresponding field.

## Debugging a Node.js application running in a remote environment

With IntelliJ IDEA, you can attach to Node.js applications that are running in [Vagrant boxes](#) , in [Docker containers](#) , or on remote hosts accessible via [various transfer protocols](#) or via SSH.

## Debugging a Node.js application in a Docker container

**Tip** Find some examples at [Quick Tour of WebStorm and Docker](#).

**Tip** Even with automatic configuration, you still need to bind the port on which your application is running with the port of the container. Those exposed ports are available on the Docker host's IP address (by default 192.168.99.100). Such binding is required when you debug the client side of a `Node.js Express` application. In this case, you need to open the browser from your computer and access the application at the container host through the port specified in the application.

IntelliJ IDEA supports debugging of Node.js applications in Docker containers through run/debug configurations of the type `Node.js` .

### Before you start debugging a Node.js application on Docker

1. Make sure Docker is installed, configured, and running as described in [Downloading, installing, and starting Docker](#) and [Configuring Docker in IntelliJ IDEA](#) .

### To choose the Node.js interpreter on Docker

1. Create a Node.js run/debug configuration [as described above](#) .
2. Select one of the configured Node.js interpreters of the type Remote Interpreter - Docker from the drop-down list or configure a new one as described in [Configuring Node.js Interpreters](#) .

### To specify the Docker container settings

Click  next to the Edit Docker Container Settings field and specify the settings in the Edit Docker Container Settings dialog that opens.

Alternatively, select the Auto configure checkbox to do it automatically. Learn more about the Auto configure mode at [Quick Tour of WebStorm and Docker: What Happens On Each Run](#) .

#### To configure port bindings

1. Click  next to the Docker Container Settings field.
2. In the Edit Docker Container Settings dialog that opens, expand the Port bindings area.
3. Click  and in the Port bindings dialog that opens, map the ports as follows:
  - In the Container port text box, type the port specified in your application.
  - In the Host port text box, type the port through which you want to open the application in the browser from your computer.
  - In the Host IP text box, type the IP address of the Docker's host, the default IP is 192.168.99.100. The host is specified in the API URL field on the [Docker](#) page of the [Settings / Preferences Dialog](#) .
  - Click OK to return to the Edit Docker Container Settings dialog where the new port mapping is added to the list.
4. Click OK to return to the [Run/Debug Configuration: Node.js](#) dialog.

#### To start debugging

1. Set the breakpoints in the Node.js code as necessary.
2. Choose the newly created Node.js configuration in the Select run/debug configuration drop-down list on the toolbar and click  next to it.
3. Proceed as during a local debugging session, [as described above](#) .

### Node.js multiprocess debugging

IntelliJ IDEA supports debugging additional Node.js processes that are launched by the [child\\_process.fork\(\) method](#) or by the [cluster module](#) . Such processes are shown as **threads** in the **Frame** pane on the **Debugger tab** of the **Debug Tool Window** .

1. Set the breakpoints in the processes to debug.
2. Create a **Node.js** run/debug configuration.
3. Choose the newly created configuration in the Select run/debug configuration drop-down list on the tool bar and click the Debug toolbar button  .

The **Debug Tool Window** opens and the **Frames** drop-down list shows the additional processes as threads as soon as they are launched:

To examine the data (variables, watches, etc.) for a process, select its thread in the list and view its data in the **Variables** and **Watches** panes. When you select another process, the contents of the panes are updated accordingly.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

IntelliJ IDEA integrates with the [nodeunit](#) framework and makes it easier to test Node.js applications.

## Creating and running unit tests for Node.js applications

1. [Enable nodeunit support](#) .
2. [Write the unit tests](#) .
3. Mark the folder where the unit tests are stored as a test source folder, see [Configuring projects](#) .
4. [Create a run configuration](#) of the type **Nodeunit** .
5. [Launch unit tests](#) and [monitor test results](#) in the **Run** tool window.

### Before you start

1. Download, install, and enable the **Node.js** plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
2. Download and install the [Node.js](#) runtime environment.
3. Download and install the [nodeunit](#) testing framework.

### Creating Nodeunit tests

1. [Create a folder called](#) `test` at the same level as the `src` folder
2. Populate the `test` folder. For each production file, create a separate test file.
3. Mark the folder where the unit tests are stored as a test source folder, see [Configuring projects](#) .

### Creating a Nodeunit run configuration

1. Open the [Run/Debug Configuration](#) dialog box by choosing **Run | Edit Configurations** on the main menu.
2. Click the Add button **+** on the toolbar and select the Nodeunit configuration type.
3. In the dialog box that opens, specify the following:
  1. The name to identify the configuration.
  2. The path to the Node.js installation to use.  
If you have [appointed one of the installations as default](#) , the field displays the path to its executable file.
  3. The working directory. This can be the project root folder or the parent directory for the `test` folder.
  4. The scope of tests to run.
    - To have IntelliJ IDEA run all the test files in a folder, choose **All JavaScript test files** in the directory from the Run drop-down list. In the **Directory** field, provide the path to the test folder relative to the [working directory](#) .
    - To have a specific test executed, choose **JavaScript test file** from the Run drop-down list. In the **JavaScript test file** field, provide the path to the file relative to the [working directory](#) .
4. Apply the changes and close the dialog box.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

As you may know, [V8](#) is an open-source JavaScript engine developed by Google. It is used in Google [Chrome](#) , [Chromium](#) , [Node.js](#) , and [io.js](#) .

V8 has a sampling CPU profiler [V8 profiler](#) which is intended for capturing and analyzing CPU profiles and heap snapshots for your [Node.js](#) applications. With V8 CPU profiling you can get a better understanding of which parts of your code take up the most CPU time, and how your code is executed and optimized by the V8 JavaScript engine.

You can also open and explore profiles and snapshots captured in Google Chrome DevTools for your client-side code.

#### Why is profiling important

- A carefully designed algorithm can make your code faster and manage your memory consumption better, even more efficiently than the virtual machine can. Profiling is the way to look inside the execution of your code and prove your assumptions about your design decisions.
- Profiling is especially relevant for Javascript, which is a powerful language with advanced features like dynamic typing, closures, and even the ability to create code at runtime. Therefore the behavior of the JavaScript engine is quite sophisticated, and there are cases when you really need to go deep into the details of how the engine works. Some of the code patterns you use need being tweaked to allow the JavaScript optimizer to do its work.
- JavaScript is by no means a simple language to judge if your code manages memory well. Closure memory leaks are a good illustration of the fact that code that looks good and simple may still cause leaks.

### Before you start

1. Install the [Node.js](#) runtime environment version 0.11.0 or higher.
2. **Install** and **enable** the NodeJS plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. Restart IntelliJ IDEA for the changes to take effect.

### Preparing for V8 CPU and memory heap profiling

V8 CPU profiling is provided through the IntelliJ IDEA built-in functionality, you do not need to install any additional software.

V8 memory heap profiling is provided through the globally installed [v8-profiler](#) package.

**Tip** You can also install the [v8-profiler](#) package on the [Node.js](#) and [NPM](#) page as described in [NPM](#) .

#### To install v8-profiler globally

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install -g v8-profiler` at the command prompt.

### CPU profiling

With V8 CPU profiling you can get a better understanding of which parts of your code take up the most CPU time, and how your code is executed and optimized by the V8 JavaScript engine.

To identify the processes that consume most of your CPU, you can use two methods: [sampling](#) and [tracing](#) .

- When the [sampling](#) method is applied, you periodically record stack traces of your application. The periods between records are measured in conventional units referred to as [ticks](#) .  
This method does not guarantee very good accuracy or precision for the following reason: snapshots are taken at random moments therefore any function can happen to be recorded in a snapshot. However, sampling can give us a rough picture of where the most of time is spent.
- When the [tracing](#) method is used, we actively record tracing information by ourselves, directly in the code. It is obviously better to get exact measurements of how much time each method took, and also allows you to count how many times the traced method was called. The disadvantage of this method is that it comes with bigger [result distortion](#) compared to [sampling](#) .

**Result Distortion** . Both sampling and tracing introduce delays into execution and therefore influence the profiling results.

With sampling, delays can be estimated as some fixed amount of time for each sampling event and do not introduce greater distortion than the sampling method itself (i.e. the delay is much shorter than the sampling interval). With tracing, the profiling delay depends on the code and the places where we made tracing measurements. For instance, if a traced method is called inside other traced methods numerously, all inner delays will accumulate for the outer method. If so, it may be difficult to separate the execution time from tracing distortion.

Usually we use sampling and tracing methods together. We start with sampling to get an idea of which parts of our code take the most time, and then instrument the code with tracing calls to zero on the issues.

Measurements are made not only for the work of your code, but also activities performed by the engine itself, such as compilation, calls of system libraries, optimization, and garbage collection. The following time metrics are made for execution of functions themselves and for performing activities:

- **Total** : the number of ticks (the time) during which a function was executed or an activity was performed.
- **Total%** : the ratio of a function/activity execution time to the entire time when measurements were made.
- **Self** : the pure execution time of a function/activity itself, without the time spent on executing functions called by it.
- **Self%** : the ratio of the pure execution time of a function/activity to the entire time when the measurements were made.
- **Of Parent** : the ratio of the pure execution time of a function to the execution time of the function that called it ( **Parent** ).

## Configuring CPU profiling

To invoke V8 CPU profiling on application start, you need to specify additional settings in the Node.js run configuration according to which the application will be launched.

1. Choose Run | Edit Configuration on the main menu.
2. From the list, choose the **Node.js** run configuration to activate CPU Profiling in or create a new configuration as described in [Running and Debugging Node.js](#) .
3. Switch to the V8 Profiling pane and specify the following:
  1. Select the Record CPU profiling info checkbox.
  2. In the Log folder field, specify the folder to store recorded logs in. Profiling data are stored in V8 log files `isolate-  
<session number>` .

## Collecting CPU profiling information

1. Select the run configuration from the list on the main toolbar and then choose Run | Run <configuration name> on the main menu or click the Run toolbar button  .
2. When the scenario that you need to profile is executed, stop the process by clicking the Stop  toolbar button.

V8 log file will be processed by V8 scripts to calculate averaged call traces. IntelliJ IDEA opens the [V8 Profiling Tool Window](#) .

## Analyzing CPU profiling information

Analyzing the profiling logs is available after the process stops because currently stopping and restarting profiling during execution of an application is not supported.

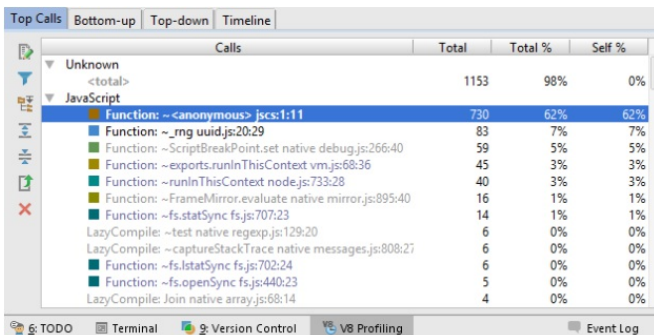

The collected profiling data is displayed in the [V8 Profiling Tool Window](#) which IntelliJ IDEA opens automatically when you stop your application. If the window is already opened and shows the profiling data for another session, a new tab is added. Tabs that were opened automatically are named after the run configurations that control execution of the applications and collecting the profiling data.

If you want to open and analyze some previously saved profiling data, choose V8 Profiling - Analyze V8 Profiling Log on the main menu and select the relevant V8 log file `isolate-  
<session number>` . IntelliJ IDEA creates a separate tab with the name of the log file.

## Exploring call Trees

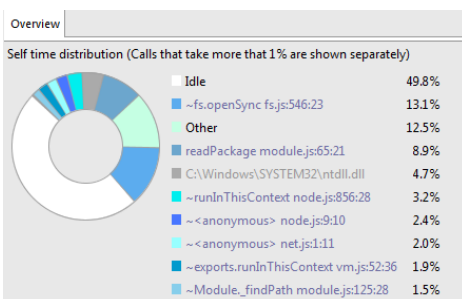

Based on the collected profiling data, IntelliJ IDEA builds three call trees and displays each of them in a separate pane. Having several call trees provides the possibility to analyze the application execution from two different points of view: on the one hand, which calls were time consuming ("heavy"), and on the other hand, "who called whom".

- The Top Calls pane shows a list of performed activities sorted in the descending order by the **Self** metrics. For each activity IntelliJ IDEA displays its **Total** , **Total%** , and **Self%** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined.

Calls	Total	Total %	Self %
Unknown <total>	1153	98%	0%
JavaScript			
Function: ~<anonymous> jscs:1:11	730	62%	62%
Function: ~rng uuid.js:20:29	83	7%	7%
Function: ~ScriptBreakPoint.set native debug.js:266:40	59	5%	5%
Function: ~exports.runInThisContext vm.js:68:36	45	3%	3%
Function: ~runInThisContext node.js:733:28	40	3%	3%
Function: ~FrameMirror.evaluate native mirror.js:895:40	16	1%	1%
Function: ~fs.statSync fs.js:707:23	14	1%	1%
LazyCompile: ~test native regexp.js:129:20	6	0%	0%
LazyCompile: ~captureStackTrace native messages.js:808:27	6	0%	0%
Function: ~fs.lstatSync fs.js:702:24	6	0%	0%
Function: ~fs.openSync fs.js:440:23	5	0%	0%
LazyCompile: Join native array.js:68:14	4	0%	0%

The diagram in the Overview pane shows distribution of self time for calls with the **Self%** metrics above 1%.

- The Bottom-up pane also shows the performed activities sorted in the descending order by the **Self** metrics. Unlike the Top Calls pane, the Bottom-up pane shows only the activities with the **Total%** metrics above 2 and the functions that called them. This is helpful if you encounter a **heavy** function and want to find out where it was called from. For each activity IntelliJ IDEA displays its execution time in **ticks** and the **Of Parent** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined.
- The Top-down pane shows the entire call hierarchy with the functions that are execution entry points at the top. For each activity IntelliJ IDEA displays its **Total**, **Total%**, **Self**, and **Self%** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined. Some of the functions may have been optimized by V8, see [Optimizing for V8](#) for details.
  - The functions that have been optimized are marked with an asterisk ( \* ) before the function name.
  - The functions that possibly require optimization but still have not been optimized are marked with a tilde ( ~ ) character before the function name. Though optimization may be delayed by the engine or skipped if the code is short-running, a tilde ( ~ ) points at a place where the code can be rewritten to achieve better performance.

Function	Total	Total %	Self	Self %
Function: listOnTimeout timers.js:94:23	1084	92%	0	0%
Function: ~Module.runMain module.js:488:26	1084	92%	0	0%
Function: Module.load module.js:268:24	1084	92%	0	0%
Function: ~Module.load module.js:339:33	1070	91%	0	0%
Function: ~Module.extensions.js module.js:4	1069	90%	0	0%
Function: ~Module.compile module.js:36	1069	90%	0	0%
Function: --<anonymous> js:1:11	1065	90%	730	62%
Function: ~require module.js:372:1	296	25%	0	0%
Function: ~Module.require mo	296	25%	0	0%
Function: Module.load mo	296	25%	0	0%
Function: ~Module.load	292	24%	0	0%
Function: ~Module.	291	24%	0	0%
Function: ~Modi	291	24%	0	0%
Function: ~<	273	23%	0	0%
Function:	273	23%	0	0%

## Working with call trees

- To navigate to the source code of a function, select the function in question in the tree and click on the toolbar or choose Jump to source on the context menu of the selection. The file with the source code of the selected function is opened in the editor with the cursor positioned at the function.
- When a tab for a profiling session is opened, by default the nodes with heaviest calls are expanded. While exploring the trees, you may like to fold some nodes or expand other ones. To restore the original tree presentation, click the Expand Heavy Traces button on the toolbar.
- To have IntelliJ IDEA display only the calls that indeed cause performance problems, filter out light calls:
  1. Click the Filter button on the toolbar.
  2. Using the slider, specify the minimum **Total%** or **Parent%** value for a call to be displayed and click Done .
- To expand or collapse all the nodes in the active pane, click or on the toolbar respectively.
- To expand or collapse a node, select it and choose Expand Node or Collapse Node on the context menu of the selection.
- Save and compare calls and lines:
  - To save a line with a function and its metrics, select the function and choose Copy on the context menu of the selection. This may be helpful if you want to compare the measurements for a function from two sessions, for example, after you make some improvements to the code.
  - To save only the function name and the name of the file where the function is defined, select the function and choose Copy Call on the context menu of the selection.
  - To compare an item with the contents of the Clipboard, select the item in question and choose Compare With Clipboard on the context menu of the selection. Compare the items in the **Difference Viewer** that opens.
- To save the call tree in the current pane to a text file, click on the toolbar and specify the target file in the dialog box that opens.

## Analyzing the Flame chart

Use the multicolor chart in the Flame Chart tab to find where the application paused and explore the calls that provoked these pauses. The chart consists of four areas:

- The upper area shows a timeline with two sliders to limit the beginning and the end of a fragment to investigate.
- The bottom area shows a stack of calls in the form of a multicolor chart. When called for the first time, each function is assigned a random color, whereupon every call of this function within the current session is shown in this color.
- The middle area shows a summary of calls from the **Garbage Collector**, the engine, the external calls, and the execution itself. The colors reserved for the **Garbage Collector**, the engine, the external calls, and the execution are listed on top of the area:

- The right-hand pane lists the calls within a selected fragment, for each call the list shows its duration, the name of the called function, and file where the function is defined.

## Selecting a Fragment in the Timeline

To explore the processes within a certain period of time, you need to select the fragment in question. You can do it in two ways:

- Use the sliders:

– Click the **window** between two sliders and drag it to the required fragment:

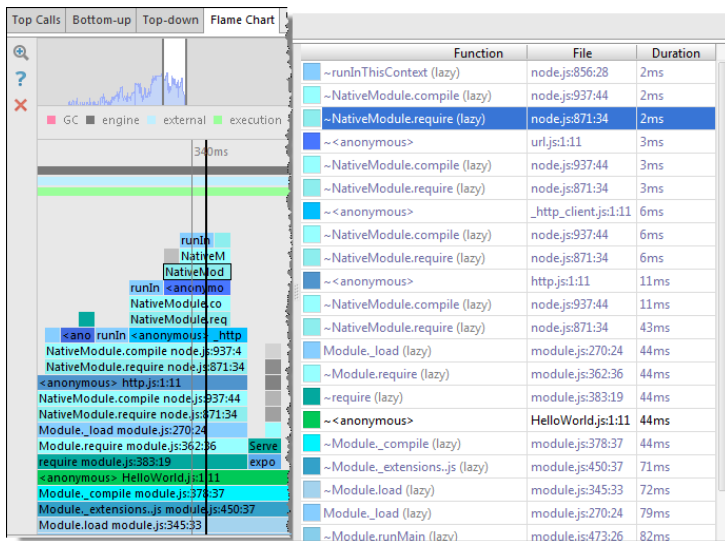

In either case, the multicolor chart below shows the stack of calls within the selected fragment.

To enlarge the chart, click the selected fragment and then click the Zoom button  on the toolbar. IntelliJ IDEA opens a new tab and shows the selected fragment enlarged to fit the tab width so you can examine the fragment with more details.

## Synchronization in the Flame chart

The bottom and the right-hand areas are synchronized: as you drag the slider in the bottom area through the timeline the focus in the right-hand pane moves to the call that was performed at each moment.

Moreover, if you click a call in the bottom area, the slider moves to it automatically and the focus in the right-hand pane switches to the corresponding function, if necessary the list scrolls automatically. And vice versa, if you click an item in the list, IntelliJ IDEA selects the corresponding call in the bottom area and drags the slider to it automatically:

IntelliJ IDEA supports navigation from the right-hand area to the source code of called functions, to the other panes of the tool window, and to areas in the flame chart with specific metrics.

– To jump to the source code of a called function, select the call in question and choose Jump to Source on the context menu of the selection.

– To switch to another pane, select the call in question, choose Navigate To on the context menu of the selection and then choose the destination:

- Navigate in Top Calls
- Navigate in Bottom-up
- Navigate in Top-down

IntelliJ IDEA switches to the selected pane and moves the focus to the call in question.

– To have the flame chart zoomed at the fragments with specific metrics of a call, select the call in question, choose Navigate To on the context menu of the selection, and then choose the metrics:

- Navigate to Longest Time
- Navigate to Typical Time
- Navigate to Longest Self Time
- Navigate to Typical Self Time

You can also navigate to the stacktrace of a call to view and analyze exceptions. To do that, select the call in question and choose Show As Stacktrace. IntelliJ IDEA opens the stacktrace in a separate tab, to return to the Flame Chart pane, click V8 CPU Profiling tool window button in the bottom tool window.

## Memory profiling

Though the V8 JavaScript engine does memory management for you, memory leaks or dynamic memory problems are still possible. Here are some examples of memory leaks or shortcomings reasons:

- Using global objects to store collections of data, with complicated free policies.
- Errors in usages of closures: closures keep references onto outside objects.
- Keeping detached DOM nodes in javascript variables.
- Too frequent memory allocation.

Memory management control is especially important for **Node.js** applications, because the server-side code tend to run long while memory inaccuracy is accumulated.

V8 heap snapshots are complicated by their nature; they include many “engine” objects; the inner structure of objects differs from what you expect while reading your code. Learn more at [Javascript Memory Profiling](#) .

## Configuring memory profiling

To allow taking memory snapshots, you need to specify additional settings in the Node.js run configuration according to which the application will be launched.

1. Choose Run | Edit Configuration on the main menu.
2. From the list, choose the **Node.js** run configuration to activate CPU Profiling in or create a new configuration as described in [Running and Debugging Node.js](#) .
3. Switch to the V8 Profiling pane and specify the following:
  1. Select the Allow taking heap snapshots checkbox.
  2. In the Log folder field, specify the folder to store recorded logs in. Profiling data are stored in V8 log files `isolate-  
<session number>` .
  3. Specify the **v8-profiler** package to use. Choose the relevant package from the v8-profiler package drop-down list or click the  button next to it and choose the package in the dialog box that opens.
  4. Specify the port through which IntelliJ IDEA communicates with the profiler, namely, sends a command to take a snapshot when you click the Take Heap Snapshot button  on the toolbar of the Run tool window.

To take memory snapshots of an application running on a Docker container, select the Auto configure checkbox and add **v8-profiler** to your `package.json` file, then switch to the V8 profiling tab and specify the path as `./node_modules/v8-profiler` .

## Collecting memory profiling information

1. Select the run configuration from the list on the main toolbar and then choose Run | Run <configuration name> on the main menu or click the Run toolbar button  .
2. At any time during the application execution, click the Take Heap Snapshot button  on the toolbar of the Run tool window.
3. In the dialog box that opens, choose the folder to store the taken snapshot in and specify the name to save the snapshot file with. To start analyzing the snapshot immediately, select the Open snapshot checkbox.
4. Click OK to save the snapshot.

## Analyzing memory profiling information

The collected profiling data is displayed in the [V8 Heap Tool Window](#) , which opens when you take a snapshot at choose to open it. If the window is already opened and shows the profiling data for another session, a new tab is added. Tabs that were opened automatically are named after the run configurations that control execution of the applications and collecting the profiling data.

If you want to open and analyze some previously saved memory profiling data, choose V8 Profiling - Analyze V8 Heap Snapshot on the main menu and select the relevant `.snapshot` file. IntelliJ IDEA creates a separate tab with the name of the selected file.

The tool window has three tabs that present the collected information from difference point of views.

- The Containment tab shows the objects in you application grouped under several top-level entries: **DOMWindow objects** , **Native browser objects** , and **GC Roots** , which are roots the **Garbage Collector** actually uses. See [Containment View](#) for details.

For each object, the tab shows its **distance from the GC root** , that is the shortest simple path of nodes between the object and the GC root, the [shallow size](#) of the object, and the [retained size](#) of the object. Besides the absolute values of the object's size, IntelliJ IDEA shows the percentage of memory the object occupies.

- The Biggest Objects tab shows the most memory-consuming objects sorted by their [retained sizes](#) . In this tab, you can spot memory leaks provoked by accumulating data in some global object.
- The Summary tab shows the objects in your application grouped by their types. The tab shows the number of objects of each type, their size, and the percentage of memory that they occupy. This information may be a clue to the memory state.

Each tab has a Details pane, which shows the path to the currently selected object from GC roots and the list of object's **retainers** , that is, the objects that keep links to the selected object. Every heap snapshot has many “back” references and loops, so there are always many retainers for each object.

## Navigating through a snapshot

- To help differentiate objects and move from one to another without losing the context, mark objects with text labels. To set a label to an object, select the object of interest and click  on the toolbar or choose Mark on the context menu of the selection. Then type the label to mark the object with in the dialog box that opens.
- To navigate to the function or variable that corresponds to an object, select the object of interest and click  on the toolbar or choose Edit Source on the context menu of the selection. If the button and the menu option are disabled, this means that IntelliJ IDEA has not found a function or a variable that corresponds to the selected object. If several functions or variables are found, they are shown in a pop-up suggestion list.
- To jump from an object in the Biggest Objects or Summary tab or Occurrences view to the same object in the Containment tab, select the object in question in the Biggest Objects or Summary tab and click  on the toolbar or choose Navigate in Main Tree on the context menu of the selection. This helps you investigate the object from the containment point of view and concentrate on the links between objects.

- To search through a snapshot:
  1. In the Containment tab, click  on the toolbar.
  2. In the [V8 Heap Search Dialog](#) that opens, specify the search pattern and the scope to search in. The available scopes are:
    - Everywhere: select this checkbox to search in all the scopes. When this checkbox is selected, all the other search types are disabled.
    - Link Names: select this checkbox to search among the object names that V8 creates when calling the **C++ runtime**, see <http://stackoverflow.com/questions/11202824/what-is-in-javascript>. In the [V8 Heap Tool Window](#), link names are marked with the `%` character (`%<link name>`).
    - Class Names: select this checkbox to search among functions-constructors.
    - Text Strings: select this checkbox to perform a textual search in the contents of the objects.
    - Snapshot Object IDs: select this checkbox to search among the unique identifiers of objects. V8 assigns such a unique identifier in the format to each object when the object is created and preserves it until the object is destroyed. This means that you can find and compare the same objects in several snapshots taken within the same session. In the [V8 Heap Tool Window](#), object IDs are marked with the `@` character (`@<object id>`).
    - Marks: select this checkbox to search among the labels you set to objects manually by clicking  on the toolbar of the Containment tab.

The search results are displayed in the Details pane, in a separate Occurrences of '<search pattern>' view. To have the search results shown grouped by the search scopes you specified, press the Group by Type toggle button on the toolbar.

When you open the dialog box next time, it will show the settings from the previous search.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js and Pug (ex-Jade) plugins are installed and enabled!

IntelliJ IDEA integrates with the [Pug \(Jade\)](#) template engine.

## Before you start

1. Install the [Node.js](#) runtime environment.
2. Make sure the **NodeJS** and **Pug (ex-Jade)** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

Also, if you need a file watcher, make sure that the **File Watchers** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

## Changes to the UI

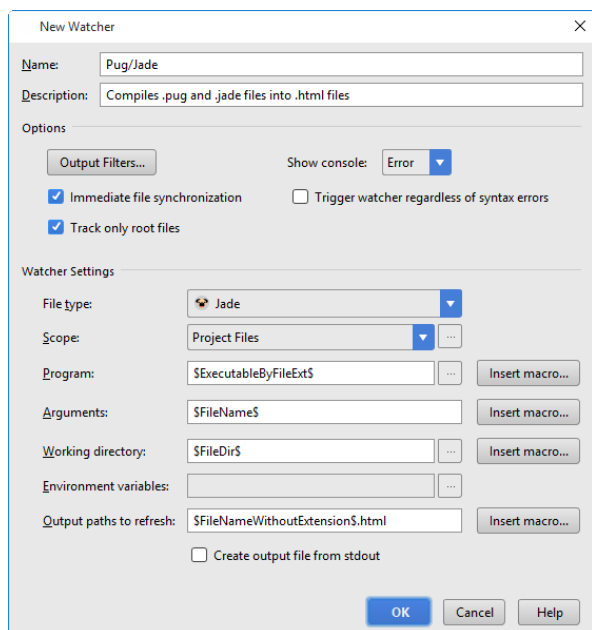

The **Pug (ex-Jade)** plugin introduces the following changes to the IntelliJ IDEA UI:

- The Jade file item is added to the New menu.
- The Pug files are marked with the icon  ; the Jade files are marked with the icon .
- Coding assistance is provided in the Pug (Jade)-specific and HTML context:
  - [Code formatting](#)
  - Syntax highlighting
  - [Code completion](#)
  - [Color schemes](#)

## Using Pug(Jade) templates in a Node.js application

At runtime, the Pug (Jade) files will be transformed into HTML pages.

1. Create a project from scratch, or around existing sources, or based on a **NodeExpress** template.
2. Create a **Pug (Jade)** file. Follow these steps:
  1. In the [Project Tool Window](#) , select the directory in which you want to create a new file. To do that, for example, choose `File | New` .
  2. On the context menu, choose Jade file and specify the file name in the dialog box that opens.
3. Create a File Watcher to transform files with the extension `.jade` or `.pug` into `.html` pages:
  1. Click the `Add Watcher` link in the upper right-hand corner of the editor.
  2. In the [New Watcher Dialog](#) , accept the default predefined settings.Note that if the executable is in the PATH, then you should not specify it explicitly. Depending on the file extension (`.jade` or `.pug` ), the corresponding executable is invoked.

4. As you edit a `.pug / .jade` file, IntelliJ IDEA invokes the file watcher which creates an `.html` file with the name of the processed `.pug / .jade` file and stores the generated `html` code in it.

See [Using File Watchers](#) for details.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

On this page:

- [Introduction](#)
- [Installing Node.js and Node Package Manager \(npm\)](#)
- [Installing an external tool globally](#)
- [Installing an external tool in a project](#)
- [Installing an external tool as a development dependency](#)
- [Running npm scripts](#)
  - [Before you start](#)
  - [Building a tree of scripts](#)
  - [Running npm scripts from the tree of scripts](#)
  - [Running tasks according to a run configuration](#)
  - [Running npm scripts automatically](#)
  - [Running a script as a as a before-launch task](#)

## Introduction

A number of tools are started through **Node.js**, for example, the **CoffeeScript**, **TypeScript**, and **Less** compilers, **YUI**, **UglifyJS**, and **Closure** compressors, **Karma** test runner, **Grunt** task runner, etc. The **Node Package Manager (npm)** is the easiest way to install these tools, the more so that you have to install **Node.js** anyway.

Depending on the desired location of the tool executable file, choose one of the following methods:

- Install the tool **globally** at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project.
- Install the tool in a specific project and thus restrict its use to this project.
- Install the tool in a project as a [development dependency](#).

In either installation mode, make sure that the parent folder of the tool is added to the `PATH` variable. This enables you to launch the tool from any folder.

## Installing Node.js and Node Package Manager (npm)

1. Download and install the [Node.js](#) runtime environment.

If you are going to use the command line mode, make sure the path to the parent folder of the **Node.js** executable file and the path to the `npm` folder are added to the `PATH` variable. This enables you to launch the tool and **npm** from any folder.

2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing an external tool globally

**Global** installation makes a tool available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project. Moreover, during installation the parent folder of the tool is automatically added to the `PATH` variable, which enables you to launch the tool from any folder.

- Run the installation from the command line in the **global** mode:

1. Open the embedded Terminal ( `View | Tool Windows | Terminal` ) and switch to the directory where **NPM** is stored or define a `PATH` variable for it so it is available from any folder, see [Installing NodeJs](#).
2. Type the following command at the command prompt:

```
npm install -g <tool name>
```

The `-g` key makes the tool run in the **global** mode. Because the installation is performed through **NPM**, the tool is installed in the `npm` folder. Make sure this parent folder is added to the `PATH` variable. This enables you to launch the tool from any folder.

For more details on the **NPM** operation modes, see [npm documentation](#). For more information about installing the tool, see <https://npmjs.org/package/>.

- Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`, and click **Node.js and NPM** under **Languages & Frameworks**.
2. On the **Node.js and NPM** page that opens, the **Packages** area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click `+`.
3. In the **Available Packages** dialog box that opens, select the required package to install.
4. Select the **Options** checkbox and type `-g` in the text box next to it.
5. Optionally specify the product version and click **Install Package** to start installation.

## Installing an external tool in a project

**Local** installation in a specific project restricts the use of a tool to this project.

– Run the installation from the command line:

1. Open the embedded Terminal ( View | Tool Windows | Terminal ) and switch to the project root folder.
2. At the command prompt, type `npm install <tool name>` .

– Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `(Ctrl+Alt+S)` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Node.js and NPM under Languages & Frameworks .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+** .
3. In the Available Packages dialog box that opens, select the required package.
4. Optionally specify the product version and click Install Package to start installation.

**Project level** installation is helpful and reliable in [template-based projects](#) of the type **Node Boilerplate** or **Node.js Express** , which already have the `node_modules` folder. The latter is important because **NPM** installs the tool in a `node_modules` folder. If your project already contains such folder, the tool is installed there.

Projects of other types or **empty** projects may not have a `node_modules` folder. In this case **npm** goes upwards in the folder tree and installs the tool in the first detected `node_modules` folder. Keep in mind that this detected `node_modules` folder may be **outside** your current project root.

Finally, if no `node_modules` folder is detected in the folder tree either, the folder is created right under the current project root and the tool is installed there.

In either case, make sure that the parent folder of the tool is added to the `PATH` variable. This enables you to launch the tool from any folder.

## Installing an external tool as a development dependency

If a tool is a documentation or a test framework, which are of no need for those who are going to re-use your application, it is helpful to have it excluded from download for the future. This is done by marking the tool as a [development dependency](#) , which actually means adding the tool in the `devDependencies` section of the `package.json` file.

With IntelliJ IDEA, you can have a tool marked as a **development dependency** right during installation. Do one of the following:

– Run the installation from the command line:

1. Launch the built-in Terminal ( View | Tool Windows | Terminal ).
2. Switch to the project root folder and at the command prompt type:

```
npm install --dev <tool name>
```

– Run **NPM** from IntelliJ IDEA using the Node.js and NPM page of the Settings dialog box.

1. Open the [Settings / Preferences Dialog](#) by pressing `(Ctrl+Alt+S)` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Node.js and NPM under Languages & Frameworks .
2. On the Node.js and NPM page that opens, the Packages area shows all the Node.js-dependent packages that are currently installed on your computer, both at the **global** and at the **project** level. Click **+** .
3. In the Available Packages dialog box that opens, select the package.
4. Select the Options checkbox and type `--dev` in the text box next to it.
5. Optionally specify the product version and click Install Package to start installation.

After installation, a tool is added to the `devDependencies` section of the `package.json` file.

## Running npm scripts

IntelliJ IDEA provides the interface for [running npm scripts](#) . IntelliJ IDEA parses `package.json` files, recognizing definitions of scripts, lets you build trees of scripts and navigate between a script in the tree and its definition in the `package.json` file, and supports running and debugging tasks as well as configuring the script execution mode and output.

## Before you start

1. Download and install [Node.js](#) which contains [npm](#) .
2. Install and enable the **NodeJS** plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. Create a `package.json` file with the `scripts` property containing the definitions of the scripts to run.
4. To enable debugging of a script, add the `$NODE_DEBUG_OPTION` to its definition in the `package.json` file, for example:

```

{
  "name": "application-name",
  "version": "0.0.1",
  "scripts": {
    "main": "node $NODE_DEBUG_OPTION ./app-compiled.js"
  }
}

```

Scripts are launched in the following ways:

- From a tree of scripts in the dedicated [NPM Tool Window](#) . The tool window opens when you invoke `npm` by choosing Show npm Scripts on the context menu of a `package.json` in the Project tool window or of a `package.json` opened in the editor.
- According to a dedicated run configuration, see [Run/Debug Configuration: NPM](#) .
- Automatically, as a start-up task.
- As a before-launch task, from another run configuration.

The result of executing a script is displayed in the [Run tool window](#) . The tool window shows the npm script output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed script is displayed on the title bar of the tool window.

## Building a tree of scripts

- If the npm tool window is not opened yet:

Select the required `package.json` file in the Project tool window or open it in the editor and choose Show npm Scripts on the context menu.

In either case, the npm tool window opens showing the scripts tree built according to the selected or opened `package.json` file.

- In the npm tool window, click  on the toolbar and choose the required `package.json` file from the list. IntelliJ IDEA adds a new node and builds a scripts tree under it. The title of the node shows the path to the `package.json` file according to which the tree is built.
- To re-build a tree, switch to the required node and click  on the toolbar.

### To sort the scripts in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name .

By default, a tree shows the scripts in the order in which they are defined in `package.json` (option Definition order ).

## Running npm scripts from the tree of scripts

### To run a script

Double click the required script. Alternatively select it in the tree and press  or choose Run <script name> on the context menu.

### To run several scripts

Use the multiselect mode: hold  (for adjacent items) or  (for non-adjacent items) keys and select the required scripts, then choose Run on the context menu of the selection.

## Running tasks according to a run configuration

Besides using **temporary** run configurations that IntelliJ IDEA creates automatically, you can create and launch your own **npm** run configurations.

### To create an npm run configuration

1. Choose Run | Edit Configuration on the main menu.
2. Click  on the toolbar and select npm from the pop-up list.
3. In the [Run/Debug Configuration: NPM](#) dialog box that opens, specify the name of the run configuration, the [npm command line command](#) to execute, the scripts to run (use blank spaces as separators), the location of the `package.json` file to retrieve the definitions of the scripts from, and the command line arguments to execute the script with.  
Specify the location of the Node executable file and the Node.js-specific options to be passed to this executable file, see [Node parameters](#) for details.

If applicable, specify the [environment variables](#) for the Node.js executable file.

To run a script according to a run configuration, select the run configuration from the list on the main tool bar and then choose Run | Run <configuration name> on the main menu or click the Run toolbar button  . The output is displayed in the [Run tool window](#) .

## Running npm scripts automatically

If you have some scripts that you run on a regular basis, you can add the corresponding run configurations to a list of **startup**

tasks . The tasks will be executed automatically on the project start-up.

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Startup Tasks under Tools .
2. On the [Startup Tasks page](#) that opens, click **+** on the toolbar.
3. From the drop-down list, choose the required **npm** run configuration. The configuration is added to the list.  
If no applicable configuration is available in the project, click **+** and choose Edit Configurations . Then define a configuration with the required settings in the [Run/Debug Configuration: NPM](#) page that opens. When you save the new configuration it is automatically added to the list of startup tasks.

## Running a script as a as a before-launch task

1. Open the [Run/Debug Configurations Dialog](#) dialog by choosing Run | Edit Configurations on the main menu, and select the required configuration from the list or create it anew by clicking **+** and choosing the relevant run configuration type.
2. In the dialog box that opens, click **+** in the Before launch area and choose Run npm script from the drop-down list.
3. In the NPM Script dialog box that opens, specify the `package.json` file where the required script is defined, select the script to execute, choose the command to apply to it, and specify the arguments to execute the script with.  
Specify the location of the Node.js interpreter and the parameters to pass to it.

This feature is only supported in the Ultimate edition.

In this section:

- OSGi and OSMORC
  - [Introduction](#)
  - [Prerequisite](#)
  - [Creating a project or module with OSGi support](#)
  - [Adding OSGi support to the existing module](#)
- [Importing a Project from Bnd/Bndtools Model](#)
- [Set Up a New Project](#)
- [Settings](#)
- [Run Configurations](#)

## Introduction

IntelliJ IDEA lets you create OSGi-based applications using Osmorc plugin. IntelliJ IDEA also lets you [import Bnd/Bndtools projects](#) . You can create a project with the OSGi support, add a module with the OSGi support to the existing project, or add the OSGi support to an existing module.

## Prerequisite

Before you start working with OSGi, make sure that the Osmorc plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#) .

## Creating a project or module with OSGi support

### To create a project or module with OSGi support

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java . In the right-hand part of the page, specify Project SDK and select OSGi from the list. In Libraries area specify OSGi library settings:
  - Use library - select this option to specify the existing OSGi library.
  - Download - select this option to download the library. You can click Configure to edit downloading options.
  - Set up library later - select this option to configure the library later in your project.

Click Next .
3. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click Finish .

## Adding OSGi support to the existing module

1. In the project tree right-click the module to which you want to add the OSGi support.
2. From the drop-down list select Add Framework Support .
3. In the dialog that opens, from the left-hand pane, select OSGi .
4. On the right side of the page, in the Libraries area, specify OSGi library settings.

The OSGi library settings are as follows:

- Use library - select this option to specify the existing OSGi library.
- Download - select this option to download the library. You can click Configure to edit downloading options.
- Set up library later - select this option to configure the library later in your project.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA lets you import Bnd/Bndtools projects.

Before import your project, make sure that [Osmorc](#) plugin is enabled in IntelliJ IDEA. The plugin is bundled with IntelliJ IDEA and activated by default. If the plugin is not enabled, [enable the plugin](#).

### To import an external Bnd/Bndtools model into IntelliJ IDEA, follow these steps

1. If no project is currently open in IntelliJ IDEA, click Import Project on the [Welcome screen](#). Otherwise, select File | New | Project from Existing Sources.
2. In the [dialog that opens](#), select the directory that contains the project to be imported, or a file that contains an appropriate project description. Click OK.
3. On the [first page](#) of the Import Project wizard, select Bnd/Bndtools, and click Next. (This page is not shown if IntelliJ IDEA has guessed what you are importing.)
4. On the next page of the wizard, specify [Bnd/Bndtools](#) projects you want to import and click Next.
5. On the next page of the wizard, specify [project SDK](#) and click Finish.

This feature is only supported in the Ultimate edition.

This topic describes how to set up a new project with Osmorc. Please take a look at [Importing an Eclipse Workspace](#) , if you want to import an existing Eclipse workspace into IntelliJ IDEA.

From this section you will learn how to activate Osmorc for a module. Nothing about the creation of projects and modules which will use Osmorc is Osmorc-specific. So create them just like you would create any other IntelliJ IDEA projects and modules.

Osmorc is activated in a module via the dedicated Osmorc [facet](#) .

## Adding the Osmorc facet to a module

– [Add the facet explicitly](#) .

1. In the root folder of your module, create a `META-INF` folder.
2. In the `META-INF` folder, create a manifest file `MANIFEST.MF` .
3. Add at least the following two headers to the `MANIFEST.MF` manifest file:
  - `Bundle-ManifestVersion`
  - `Bundle-SymbolicName`

IntelliJ IDEA will now recognize the Osmorc facet for the module and will propose to add it. Confirm the addition.

– [Have the facet detected](#) automatically.

Now you can start working on your OSGI application. Change your manifest files to export and import packages and Osmorc will create corresponding dependencies between the IntelliJ IDEA modules.

You may also want to take a look at the Settings-part of this documentation to learn how to define and use framework instances.

This feature is only supported in the Ultimate edition.

There are two places where Osmorc's settings can be changed:

- Project specific and application wide settings are managed on the [OSGi](#) page of the [Settings/Preferences](#) dialog box.
- Module specific settings are managed through the [Osmorc module facet settings](#) .

## Project and Application Settings

The [OSGi](#) page

### Facet Settings

In the facet settings you first have to decide whether you will edit the manifest files yourself or whether you want Osmorc to create it with bnd from the dependencies on other modules and libraries.

When you decide to maintain the manifest file manually, Osmorc creates dependencies on modules and the framework instance bundles in the module where the manifest file is changed. Here you take charge of the OSGi dependencies between your bundles and Osmorc tries to match them with corresponding module dependencies.

Letting Osmorc generate the manifest files for you is exactly the other way around. You develop your application as you would develop any other application in IntelliJ IDEA. You add dependencies on other modules and libraries and Osmorc tries to translate those dependencies into OSGi dependencies when running your bundles.

If you are maintaining the manifest file yourself, you have to tell Osmorc where it is to be found. You can change this location for each module or you can define a project default in the project settings and use it here.

Each time a module is compiled, Osmorc creates a bundle JAR for that module. This JAR is used when running an Osmorc run configuration. You can change how the JAR is named and where it is put, but for most cases the created default should be OK.

The created JAR contains the compilation output and the manifest file - either the manually maintained or the one created by Osmorc. Sometimes you will need to add some other files that need to be copied into the generated JAR . For Eclipse RCP bundles - or plugins as they are called there - you will need to add the `plugin.xml` . You can do this in the table listing additional JAR content. The first column takes the path to the source file relative to the content root of the module and the second column takes the path to the destination file. So since the plugin.xml of an Eclipse RCP plugin normally resides in the root of a plugin, you will type in `plugin.xml` for both columns of that entry. Future versions will provide a file chooser to choose the source file.

**Note** Currently the table for the additional JAR contents is very simple. It grows automatically as you type in new file definitions. There is always an empty row at the bottom that waits for new content. If you want to remove an entry, simply remove both the source and destination definition for it. It is then deleted automatically.

This feature is only supported in the Ultimate edition.

Project-specific Osmorc settings are managed in the Project Settings tab on the [OSGi](#) page of the [Settings](#) dialog box.

## To configure the project-specific Osmorc settings

1. From the Framework Instance drop-down list, select the desired framework instance.

The drop-down list contains all the framework instances defined for the currently running IntelliJ IDEA at the IDE level. If the framework instance you need is missing, switch to the [Framework Definitions](#) tab and define the required instance there.

The drop-down list shows the names of the framework instances followed by the name of the used framework integrator in parentheses. In case you are opening a project created with another installation of IntelliJ IDEA which does not yet have the framework instance used by the project, `undefined` will be shown where normally the name of the framework integrator appears. If that is the case, switch to the Framework Definitions tab and define the framework instance.

2. To have the specified framework instance created for the module, select the Create and maintain the module Framework Instance checkbox.
3. Specify the default manifest file `MANIFEST.MF` location.

This feature is only supported in the Ultimate edition.

The OSGi specification has a number of implementations. Each implementation has a different set of base bundles, different ways to start them, and require different layout for the folder containing the binary bundles and their sources.

To cope with this diversity, Osmorc uses the notion of framework integrators and framework instances .

A framework integrator is used to integrate an instance of a specific framework implementation. Osmorc contains framework integrators for [Eclipse Equinox](#) , [Knopflerfish](#) , and [Apache Felix](#) . An extension point for framework integrators is also available. So integrators for framework implementations that are not directly supported by Osmorc can be developed by third parties.

A framework instance is a concrete installation of a framework implementation. As framework instances are normally not installed in the folder structure of a project, a framework instance with a specific name can be installed in different locations under different installations of IntelliJ IDEA. A project only knows the name of the framework instance it uses. Osmorc creates the connection to the framework instance if it exists as soon as the project is opened.

The framework definitions known by the currently used IntelliJ IDEA installation are listed on the [OSGi](#) page of the [Settings](#) dialog box.

Framework definitions are added, edited, and removed in the [Framework Definitions](#) tab of the OSGi page.

## To define a new framework instance

1. [Open the Settings dialog box](#) , click the Osmorc node, and switch to the Framework Definitions tab.
2. Click the Add button.
3. In the Create New Framework Instance dialog box that opens select the type of framework integrator, specify a unique name and the base folder for the framework instance.

**Tip** Please, refer to the descriptions of various framework integrators to find out what requirements this folder should meet.

This feature is only supported in the Ultimate edition.

The Equinox framework integrator provides integration for Eclipse Equinox and its derivatives, such as Eclipse RCP DSK .

The base directory for Equinox framework instances is the `eclipse` folder of the installation or the folder containing the `plugins` folder, if the installation doesn't contain an `eclipse` folder.

This feature is only supported in the Ultimate edition.

The Knopflerfish framework integrator provides integration for Knopflerfish .

The base directory for Knopflerfish framework instances is the installation folder of Knopflerfish. This installation folder should contain a `knopflerfish.org` folder, which in its turn should contain an `osgi` folder.

The integrator searches for bundles in the JARs in the child folder and for the matching sources in bundles.

This feature is only supported in the Ultimate edition.

The Felix framework integrator provides integration for Apache Felix .

As there is no single downloadable package containing both sources and binary bundles, you need to download all the items separately and specify their location.

## To provide all the items the integrator expects to find, perform the following general steps

1. Download the binary ZIP or tar archive of Apache Felix and unpack its `felix-<version>` subfolder to the desired location.

**Note** At the time of this writing the current version of Apache Felix is 1.0.3, so the downloadable binary ZIP or tar contains a folder `felix-1.0.3` .

2. Specify the location of `felix-<version>` as the base folder for the integrator. The integrator loads the bundle JARs from the `bin` and `bundle` subfolders.

## To enable access to the sources of the bundles in IntelliJ IDEA

1. In the base folder, create an `src` folder with the `bin` and `bundle` subfolders.
2. Copy all source ZIP archives for `felix.jar` into the `src/bin` folder. `main-1.0.3.zip` and `framework-1.0.3.zip` should be put here.

**Tip** Unfortunately, sources for some classes in `felix.jar` are missing in the archives and you'll have to additionally download some files, such as `org.osgi.core-1.0.0.zip` , and put them here to get the sources for all classes.

3. Store the source ZIP archives for the other bundles in the `src/bundle` folder.

**Warning!** Do not change the source ZIP of any of the bundles. The integrator expects to find the Felix specific folder structure inside them. A source ZIP named `mybundle-1.00.zip` will contain the sources in the folder `mybundle-1.00/src/main/java` .

This feature is only supported in the Ultimate edition.

Osmorc provides the following run configuration types for running OSGi -based applications:

- [OSGi Bundles](#)

This feature is only supported in the Ultimate edition.

The OSGi Bundles run configuration allows running bundles that don't have any dependencies on a specific OSGi framework implementation on any of the installed framework instances.

Currently there are limitations for this run configuration type:

- Only the core framework bundle will be loaded.
- Your bundles cannot depend on any other bundles of the framework.

### **To create an OSGi Bundles run configuration, perform the following general steps**

- [Open the Run/Debug Configurations](#) dialog box, click the Add button , and choose OSGi Bundles .
- In the dialog box that opens choose a framework instance to run your bundles on and specify the bundle to start with.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

PHP support includes:

- Possibility to [create PHP files and classes from templates](#) .
- Full [PHP 5.6.x](#) syntax support.
- Partial support for [PHP 7](#) return type hints.
- Syntax and error highlighting.
- [Basic on-the-fly code completion](#) .
- Resolution of `include` statements and file references, including references to `PHAR` archives.  
All the `PHAR` files from the current project and the specified include path are shown in the [project](#) tool window under the Project View/Libraries/PHAR node and available for browsing right there.
- [Class Completion](#) .
- [Intention actions and quick fixes](#) .
- [Surrounding](#) with code constructs `Ctrl+Alt+J` and `Ctrl+Alt+T` .
- [Code inspections](#) .
- [Jump to declaration](#) (`Ctrl+B`) .
- [Refactoring](#) :
  - [Rename](#) (`Shift+F6`) .
  - [Move](#) (`F6`) .
  - [Copy](#) (`F5`) .

PHP development support is provided through the `PHP` plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

This part describes some procedures that are specific for developing PHP applications and some preliminary steps that are required to configure PHP development environment.

## To develop an application using PHP

Follow these general steps:

1. [Configure the PHP development environment](#) .
2. Configure PHP interpreters as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#) .
3. Start [creating a project from scratch](#) . On the first page of the [New Project wizard](#) , choose PHP in the left-hand pane, then choose PHP Empty Project in the right-hand pane.

**Tip** To run and debug your application on a local Web server, create the project root below the Web server document root. Thus your application sources will be "visible" for the local Web server.

4. Create and configure the required data sources (see [Managing data sources](#)) .
5. [Populate the application](#) using provided coding assistance.
6. [Deploy](#) the application.

**Tip** With IntelliJ IDEA you can flexibly configure deployment of PHP applications. For example, you can set up your PHP project on a local Web server from the very beginning, or develop and test an application locally and then upload it to a remote Web server, etc.

7. [Run](#) the application. You can do it in several ways:
  - From IntelliJ IDEA using a [run configuration](#) of the type [PHP Web Application](#) to view application output in a browser.
  - From IntelliJ IDEA using a [PHP Console](#) run configuration to view the application output in the Run tool window.
  - From IntelliJ IDEA, using a [built-in Web server](#) . This approach saves your time and effort because you do not need to deploy the application sources.

The following optional steps may be helpful:

- [Set up unit testing](#) in your project.
- Install and configure a debugging engine and specify the debugger options, see [Configuring a Debugging Engine](#) and [Configuring Debugger Options](#) for details.
- [Debug](#) the application.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Configuring PHP Development Environment](#)
  - [Prerequisites](#)
  - [Configuring PHP development environment](#)
- [Installing an AMP Package](#)
- [Installing Components Separately](#)
- [Built-In Web Server](#)
- [Configuring Remote PHP Interpreters](#)
- [Configuring Local PHP Interpreters](#)
- [Using Distributed Configuration Files \(.htaccess\)](#)
- [Configuring Include Paths](#)
- [Configuring PHP Namespaces in a Project](#)
- [Composer Dependency Manager](#)

## Prerequisites

**Warning!** This topic gives general guidelines in configuring environment for developing and testing PHP applications locally. These instructions by no means apply to configuring production environment, which is outside the scope of this Help.

PHP development requires the following software installed and configured:

- A Web server and a PHP engine are mandatory.  
Starting with version 5.4, PHP interpreters contain a built-in Web server. The server is by no means intended for production but for development and testing purposes only.
- A database server, if your application will use a database.
- A debugging tool, if you are going to debug your application.
- A command line tool, if you are going to run PHP commands from the command line.

## Configuring PHP development environment

### To set up the PHP development environment, follow these general steps:

1. Download, install, and configure the Web server, the PHP engine, and the MySQL server. Do one of the following:
  - Download, install, and configure the desired [AMP package](#) ( A pache, M ySQL, P HP).
  - Install and configure [each component separately](#) , then [check your installation](#) .
2. Optionally, perform these steps:
  - Install and configure a [debugging engine](#) .
  - Install and enable the [PHPUnit tool](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

AMP packages are operating system-specific. The most common ones are:

– [XAMPP](#) for Windows.

**Tip** It is recommended that you use version 1.7.1 or later.

– The LAMP package compatible with the Linux distribution used.

– [MAMP](#) for macOS.

The installation procedure may differ depending on the operating system used, follow the installation instructions provided.

**Warning!** If you are using Windows Vista, avoid installing the package in the `Program Files` folder. This folder is write-protected by default, which means that no files can be placed on the server and further processed by the PHP engine.

## To install and configure an AMP package

1. Download and install the desired AMP package.

2. Use the AMP control pane to start the components.

If the server does not start, most likely a port conflict takes place. By default, the Apache HTTP server listens to port 80. This port can be already used by other services, for example, Skype. To solve the issue, update the server configuration file as follows:

– Locate the line `Listen 80` and change it to, e.g., `Listen 8080` .

– Locate the line `ServerName localhost:80` and change it accordingly, in this example to `ServerName localhost:8080` .

Save the configuration file and restart the Web server.

3. To check your installation, open your browser and type the following URL address: `http://localhost:<port number>` . The AMP welcome page appears.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

The installation procedure for PHP environment components may differ depending on the operating system used, follow the installation instructions provided.

In this section:

- [Installing and configuring the components separately](#)
- [Checking the Web server installation](#)
- [Checking the PHP engine installation](#)

## To install and configure each component separately

1. Download and install a [Web server](#) . The most common choice is the [Apache HTTP server](#) .
2. Download and install the [PHP engine](#) . During the installation, specify the Web server you are going to use and its home directory.

**Tip** To enable the use of the MySQL database server, select the Complete installation option or select the MySQL and MySQLi items in the Extensions list on the corresponding page of the installation wizard.

3. Download, install, and configure a [database server](#) .

## To check the Web server installation

- To make sure that the Web server has been installed correctly, start the server, open your browser, and type the following URL address: `http://localhost`

The Test page for Apache installation should appear.

**Tip** If the server does not start, most likely a port conflict takes place. [Resolve the conflict](#) as during an AMP package installation.  
- If you have changed the default port 80, specify the port number explicitly: `http://localhost:<port number>`

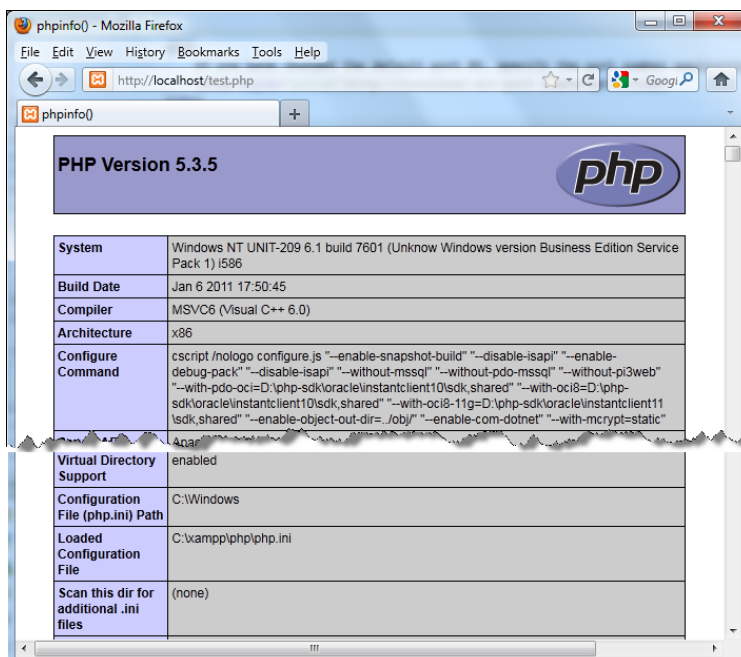

## To check the PHP engine installation

Finally, make sure that the PHP engine has been installed successfully and interacts with the Web server correctly.

1. Using a text processor of your choice, create a file `test.php` and type the following text:

```
<?php
    echo phpinfo();
?>
```

2. Save the file on the Web server, in the folder the PHP engine looks at.
3. Run the browser and enter the following URL address: `http://localhost:<port number>/test.php` . The page that opens should show detailed information on the version of PHP engine used, the location of the configuration files, etc.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Configuring the built-in web server](#)
- [Opening a file in the browser](#)

## Introduction

IntelliJ IDEA has a built-in web server that can be used to preview and debug your application. This server is always running and does not require any manual configuration. All the project files are served on the built-in server with the root URL

`http://localhost:<built-in server port>/<project root>`, with respect to the project structure.

The built-in server can only serve static content like HTML, JavaScript and CSS. To use it with PHP files, you need a [local PHP interpreter](#) specified for your project. When the interpreter is configured, IntelliJ IDEA will automatically start the [PHP Built-in Web Server](#) and redirect all PHP requests to it as soon as you run your PHP application. To run your PHP application, either [open a file in the browser](#) or [create a dedicated run/debug configuration](#) and [launch it](#).

Integration with the built-in Web server is supported in IntelliJ IDEA 11.1 and higher.

## Configuring the built-in web server

If necessary, you can customize the parameters of the built-in web server. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`, and click `Debugger` under `Build, Execution, Deployment`.

### ItemDescription

Port	Use this spin box to specify the port on which the built-in web server runs. By default this port is set to port <code>63343</code> through which IntelliJ IDEA accepts connections from services. You can set the port number to any other value starting with 1024 and higher.
------	--

Can accept external connections	If this checkbox is selected, then the files on the built-in server running on the specified port are accessible from another computer.  If this checkbox is cleared (by default), then the debugger listens only to local connections.
---------------------------------	---

Allow unsigned requests	For security reasons, any request to a page on the built-in server from outside IntelliJ IDEA is by default rejected and the following authorization pop-up window is displayed:
-------------------------	--

To access the requested page, click `Copy authorization URL to clipboard` and paste the generated token in the address bar of the browser.  
However this behaviour may be annoying, for example, it may block your debugging session if manual intervention is impossible. To suppress displaying the authorization pop-up window, select the `Allow unsigned requests` checkbox.

## Opening a file in the browser

Do one of the following:

- Choose `View | Open in Browser` on the main menu or press `Alt+F2`. Then select the desired browser from the pop-up menu.
- Hover your mouse pointer over the code to show the browser icons bar:  Click the icon that indicates the desired browser.

Note that if a `Deployment server` is defined for this project and marked as default, the file will be served from this server instead. If necessary, you can still open the page via the IntelliJ IDEA built-in web server. To do this, open the desired browser and type the URL of the file with respect to the project structure, using `http://localhost:<built-in server port>/<project root>` as the root URL.

**Note** For more details on working with deployment servers, refer to the [Working with Web Servers: Copying Files](#) section.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Prerequisite](#)
- [Important notes](#)
- [Configuring a remote PHP interpreter on a host accessible through SSH connection](#)
- [Configuring a remote PHP interpreter in a Vagrant environment instance](#)
- [Configuring a remote PHP interpreter on a remote host accessible through SFTP](#)
- [Configuring a remote PHP interpreter in a Docker container](#)
- [Configuring custom mappings](#)

## Prerequisite

Before you start working with remote interpreters, make sure that the SSH Remote Run plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#) .

## Important notes

The term **remote PHP interpreter** denotes a PHP engine installed on a remote host or in a virtual environment. The term **remote PHP interpreter** is used as the opposite of **local PHP interpreters** that are installed on your computer, see [Configuring Local PHP Interpreters](#) .

You can access a remote PHP interpreter in the following ways:

- Using SSH credentials to access the host where the PHP interpreter is installed.
- Through access to the corresponding [Vagrant](#) instance.
- According to a [Server Access Configuration](#) . This approach is also helpful if you are going to synchronize your project sources with the Web server on the target remote host.

## Configuring a remote PHP interpreter on a host accessible through SSH connection

Before you start:

1. Configure access to an `ssh` server on the target remote host and make sure this server is running.
2. Make sure the **PHP Remote Interpreter** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

To configure a PHP interpreter using SSH credentials:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the PHP page that opens, click the  button next to the CLI Interpreter drop-down list in the Development environment section.
3. In the [CLI Interpreters](#) dialog box that opens, click the Add toolbar button  in the left-hand pane, then choose Remote on the context menu.
4. In the Configure Remote PHP Interpreter dialog box that opens, choose the SSH Credentials method.
5. Specify the name of the remote host and the port which the SSH server listens to. The default port number is 22.
6. Specify your credentials to access the remote host in accordance with the credentials received during the registration on the server. Type your user name and choose the authentication method:
  - To access the host through a password, choose Password from the Auth type drop-down list, specify the password, and select the Save password checkbox to have IntelliJ IDEA remember it.
  - To use [SSH authentication](#) via a key pair, choose Key pair (OpenSSH or PuTTY) . To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the [OpenSSH](#) utility.  
Specify the path to the file where your **private key** is stored and type the passphrase (if any) in the corresponding text boxes. To have IntelliJ IDEA remember the passphrase, select the Save passphrase checkbox.
  - If your SSH keys are managed by a credentials helper application (for example, [Pageant](#) on Windows or [ssh-agent](#) on Mac and Linux), choose Authentication agent (ssh-agent or Pageant) .

To use an interpreter configuration, you need **path mappings** that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. IntelliJ IDEA first attempts to retrieve path mappings itself by processing all the available application-level configurations. If IntelliJ IDEA finds the configurations with the same host as the one specified above, in the Host field, the mappings from these configurations are merged automatically. If no configurations with this host are found, IntelliJ IDEA displays an error message informing you that path mappings are not configured.

To fix the problem, open the [Deployment](#) page under the Build, Execution, Deployment node, select the server access configuration in question, switch to the Mappings tab, and map local folders to folders on the server as described in [Creating a Remote Server Configuration](#) , section Mapping Local Folders to Folders on the Server and the URL Addresses to Access Them .

- Specify the location of the **PHP** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/php` folder for remote hosts and Vagrant instances and `php` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the PHP home directory must be open for edit.
- When you click OK, IntelliJ IDEA checks whether the PHP executable is actually stored in the specified folder.
  - If no PHP executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the PHP executable is found, you return to the Interpreters where the installation folder and the detected version of the PHP interpreter are displayed.
- Optionally, customize the configuration settings of the installation in the Additional area. In the Debugger extension text box, specify the path to Xdebug. This enables IntelliJ IDEA to activate Xdebug when it is necessary if you have disabled it in the `php.ini` file, see [Configuring Xdebug for Using in the On-Demand Mode](#).
  - In the Configuration options field, compose a string of configuration directives to be passed through the `-d` [command line option](#) and thus add new entries to the `php.ini` file. The directives specified in this field override the default directives generated by IntelliJ IDEA, such as `-dxdebug.remote_enable=1`, `-dxdebug.remote_host=127.0.0.1`, `-dxdebug.remote_port=9001`, `-dxdebug.remote_mode=req`. For example, if you specify the `-dxdebug.remote_mode=jit` directive it will override the default `-dxdebug.remote_mode=req` directive and thus switch Xdebug to the **Just-In-Time (JIT)** mode, see [Debugging in the Just-In-Time Mode](#) for details.

To do that, click the Browse button  next to the Configuration options field, and then create a list of entries in the Configuration Options dialog box, that opens.

  - To add a new entry, click the Add button . In the new line, that is added to the list, specify the name of the new entry and its value in the Name and Value text boxes respectively. You can add as many entries as you need, just keep in mind that they will be transformed into a command line with its length limited to 256 characters.
  - To delete an entry, select it in the list and click the Remove button .
  - To change the order of entries, use the Up  and Down  buttons.

Upon clicking OK, you return to the CLI Interpreters dialog box, where the entries are transformed into a command line.

## Configuring a remote PHP interpreter in a Vagrant environment instance

Before you start

- Make sure that [Vagrant](#) and [Oracle's VirtualBox](#) are downloaded, installed, and configured on your computer as described in [Vagrant](#).
- Make sure the **Vagrant** and **PHP Remote Interpreter** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
- Make sure that the parent folders of the following executable files are added to the system **PATH** variable:
  - `vagrant.bat` or `vagrant` from your Vagrant installation. This should be done automatically by the Vagrant installer.
  - `VBoxManage.exe` or `VBoxManage` from your Oracle's VirtualBox installation.
- Configure the PHP development environment in the **Vagrant instance** to be used.

Learn more about using **Vagrant** with IntelliJ IDEA in [Vagrant](#).

To configure a PHP interpreter in a Vagrant instance:

- Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
- On the PHP page that opens, click the  button next to the CLI Interpreter drop-down list in the Development environment section.
- In the [CLI Interpreters](#) dialog box that opens, click the Add toolbar button  in the left-hand pane, then choose Remote on the context menu.
- In the Configure Remote PHP Interpreter dialog box that opens, choose the Vagrant method.
- Specify the Vagrant instance folder which points at the environment you are going to use. Technically, it is the folder where the **VagrantFile** configuration file for the desired environment is located. Based on this setting, IntelliJ IDEA detects the **Vagrant host** and shows it as a link in the Vagrant Host URL read-only field. To use an interpreter configuration, you need **path mappings** that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. IntelliJ IDEA evaluates path mappings from the `VagrantFile` configuration file.
- Specify the location of the **PHP** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/php` folder for remote hosts and Vagrant instances and `php` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the PHP home directory must be open for edit.
- When you click OK, IntelliJ IDEA checks whether the PHP executable is actually stored in the specified folder.
  - If no PHP executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the PHP executable is found, you return to the Interpreters where the installation folder and the detected version of the

PHP interpreter are displayed.

8. Optionally, customize the configuration settings of the installation in the Additional area. In the Debugger extension text box, specify the path to Xdebug. This enables IntelliJ IDEA to activate Xdebug when it is necessary if you have disabled it in the `php.ini` file, see [Configuring Xdebug for Using in the On-Demand Mode](#) .
  - In the Configuration options field, compose a string of configuration directives to be passed through the `-d` [command line option](#) and thus add new entries to the `php.ini` file. The directives specified in this field override the default directives generated by IntelliJ IDEA, such as `-dxdebug.remote_enable=1` , `-dxdebug.remote_host=127.0.0.1` , `-dxdebug.remote_port=9001` , `-dxdebug.remote_mode=req` .  
For example, if you specify the `-dxdebug.remote_mode=jit` directive it will override the default `-dxdebug.remote_mode=req` directive and thus switch Xdebug to the **Just-in-Time (JIT)** mode, see [Debugging in the Just-in-Time Mode](#) for details.

To do that, click the Browse button  next to the Configuration options field, and then create a list of entries in the Configuration Options dialog box, that opens.

- To add a new entry, click the Add button  . In the new line, that is added to the list, specify the name of the new entry and its value in the Name and Value text boxes respectively.  
You can add as many entries as you need, just keep in mind that they will be transformed into a command line with its length limited to 256 characters.
- To delete an entry, select it in the list and click the Remove button  .
- To change the order of entries, use the Up  and Down  buttons.

Upon clicking OK , you return to the CLI Interpreters dialog box, where the entries are transformed into a command line.

## Configuring a remote PHP interpreter on a remote host accessible through SFTP

Before you start:

1. Make sure that an `ssh` server is running on the target remote host and you have configured access to it.
2. Make sure the **PHP Remote Interpreter** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. Make sure the **Remote Hosts Access** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .
4. Make sure you have at least one IntelliJ IDEA-wide **server access configuration** of the SFTP type to establish access to the target host. To make a configuration available in all IntelliJ IDEA projects, clear the Visible only for this project checkbox in the [Deployment: Connection Tab](#) . See [Creating a Remote Server Configuration](#) for details.

To configure a remote PHP interpreter based on an SFTP server access configuration:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the PHP page that opens, click the  button next to the CLI Interpreter drop-down list in the Development environment section.
3. In the [CLI Interpreters](#) dialog box that opens, click the Add toolbar button  in the left-hand pane, then choose Remote on the context menu.
4. In the Configure Remote PHP Interpreter dialog box that opens, choose the Deployment Configuration method.
5. From the Deployment Configuration drop-down list, choose the **server access configuration** of the SFTP type according to which you want IntelliJ IDEA to connect to the target host. If the settings specified in the chosen configuration ensure successful connection, IntelliJ IDEA displays the URL address of the target host as a link in the Deployment Host URL field.

To use an interpreter configuration, you need **path mappings** that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. By default, IntelliJ IDEA retrieves path mappings from the chosen server access (deployment) configuration. If the configuration does not contain path mappings, IntelliJ IDEA displays the corresponding error message.

To fix the problem, open the [Deployment](#) page under the Build, Execution, Deployment node, select the relevant server access configuration, switch to the Mappings tab, and map the local folders to the folders on the server as described in [Creating a Remote Server Configuration](#) section.

6. Specify the location of the **PHP** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/php` folder for remote hosts and Vagrant instances and `php` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the PHP home directory must be open for edit.
7. When you click OK , IntelliJ IDEA checks whether the PHP executable is actually stored in the specified folder.
  - If no PHP executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the PHP executable is found, you return to the Interpreters where the installation folder and the detected version of the PHP interpreter are displayed.
8. Optionally, customize the configuration settings of the installation in the Additional area. In the Debugger extension text box, specify the path to Xdebug. This enables IntelliJ IDEA to activate Xdebug when it is necessary if you have disabled it in the `php.ini` file, see [Configuring Xdebug for Using in the On-Demand Mode](#) .
  - In the Configuration options field, compose a string of configuration directives to be passed through the `-d` [command](#)

[line option](#) and thus add new entries to the `php.ini` file. The directives specified in this field override the default directives generated by IntelliJ IDEA, such as `-dxdebug.remote_enable=1` , `-dxdebug.remote_host=127.0.0.1` , `-dxdebug.remote_port=9001` , `-dxdebug.remote_mode=req` .

For example, if you specify the `-dxdebug.remote_mode=jit` directive it will override the default `-dxdebug.remote_mode=req` directive and thus switch Xdebug to the **Just-In-Time (JIT)** mode, see [Debugging in the Just-In-Time Mode](#) for details.

To do that, click the Browse button  next to the Configuration options field, and then create a list of entries in the Configuration Options dialog box, that opens.

- To add a new entry, click the Add button  . In the new line, that is added to the list, specify the name of the new entry and its value in the Name and Value text boxes respectively.
- You can add as many entries as you need, just keep in mind that they will be transformed into a command line with its length limited to 256 characters.
- To delete an entry, select it in the list and click the Remove button  .
- To change the order of entries, use the Up  and Down  buttons.

Upon clicking OK , you return to the CLI Interpreters dialog box, where the entries are transformed into a command line.

9. Click the Show phpinfo button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the [CLI Interpreters](#) dialog box are not listed.

## Configuring a remote PHP interpreter in a Docker container

Before you start:

1. Make sure that [Docker](#) is downloaded, installed, and configured on your computer as described in [Docker](#) .
2. Make sure the [Docker Integration](#) , [PHP Docker](#) , and [PHP Remote Interpreter](#) plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
3. Configure the PHP development environment in the [Docker container](#) to be used.

Learn more about using [Docker](#) with IntelliJ IDEA in [Docker](#) .

To configure a PHP interpreter in a Docker container:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the PHP page that opens, click the  button next to the CLI Interpreter drop-down list in the Development environment section.
3. In the [CLI Interpreters](#) dialog box that opens, click the Add toolbar button  in the left-hand pane, then choose Remote on the context menu.
4. In the Configure Remote PHP Interpreter dialog box that opens, choose the Docker method.
5. In the Server field, specify the [Docker configuration](#) to use, see [Docker](#) . Choose a configuration from the drop-down list or click  next to it and create a new configuration in the [Docker](#) dialog box that opens.
6. In the Image name field, specify the base Docker image to use. Choose one of the previously downloaded or your custom images from the drop-down list or type the image name manually, for example, `php:latest` or `php:7.0-cli` . When you later launch the run configuration, Docker will search for the specified image on your machine. If the search fails, the image will be downloaded from the image repository specified on the [Registry](#) page.
7. Specify the location of the PHP executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/php` folder for remote hosts and Vagrant instances and `php` for Docker containers. To specify a different folder, click the Browse button  and choose the relevant folder in the dialog box that opens. Note that the PHP home directory must be open for edit.
8. When you click OK , IntelliJ IDEA checks whether the PHP executable is actually stored in the specified folder.
  - If no PHP executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
  - If the PHP executable is found, you return to the Interpreters where the installation folder and the detected version of the PHP interpreter are displayed.
9. Optionally, customize the configuration settings of the installation in the Additional area. In the Debugger extension text box, specify the path to Xdebug. This enables IntelliJ IDEA to activate Xdebug when it is necessary if you have disabled it in the `php.ini` file, see [Configuring Xdebug for Using in the On-Demand Mode](#) .
  - In the Configuration options field, compose a string of configuration directives to be passed through the [-d command line option](#) and thus add new entries to the `php.ini` file. The directives specified in this field override the default directives generated by IntelliJ IDEA, such as `-dxdebug.remote_enable=1` , `-dxdebug.remote_host=127.0.0.1` , `-dxdebug.remote_port=9001` , `-dxdebug.remote_mode=req` .
  - For example, if you specify the `-dxdebug.remote_mode=jit` directive it will override the default `-dxdebug.remote_mode=req` directive and thus switch Xdebug to the **Just-In-Time (JIT)** mode, see [Debugging in the Just-In-Time Mode](#) for details.

To do that, click the Browse button  next to the Configuration options field, and then create a list of entries in the Configuration Options dialog box, that opens.

To add a new entry, click the Add button  . In the new line, that is added to the list, specify the name of the new entry

To add a new entry, click the Add button . In the new line, that is added to the list, specify the name of the new entry and its value in the Name and Value text boxes respectively.

You can add as many entries as you need, just keep in mind that they will be transformed into a command line with its length limited to 256 characters.

- To delete an entry, select it in the list and click the Remove button .
- To change the order of entries, use the Up  and Down  buttons.

Upon clicking OK, you return to the CLI Interpreters dialog box, where the entries are transformed into a command line.

0. Click the Show phpinfo button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the [CLI Interpreters](#) dialog box are not listed.

## Configuring custom mappings

If you use an interpreter accessible through SFTP connection or located on a Vagrant instance, the mappings are automatically retrieved from the corresponding deployment configuration or `Vagrantfile`. To specify additional mappings:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. From the Interpreter drop-down list, choose the remote interpreter for which you want to customize the mappings. The Path Mappings read-only field shows the path mappings retrieved from the corresponding deployment configuration or `Vagrantfile`, see the chapters above. To specify the custom mappings, click  next to the Path Mappings field.
3. The [Edit Project Path Mappings Dialog](#) that opens, shows the path mappings retrieved from the deployment configuration or `Vagrantfile`. These mappings are read-only.
  - To add a custom mapping, click  and specify the path in the project and the corresponding path on the remote runtime environment in the Local Path and Remote Path fields respectively. Type the paths manually or click  and select the relevant files or folders in the dialog box that opens.
  - To remove a custom mapping, select it in the list and click .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

A **local PHP interpreter** is a PHP engine installed on your computer opposite to a **remote PHP interpreters** that can be installed on a remote host or in a virtual environment set up in a **Vagrant** instance .

1. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing **File | Settings for Windows and Linux** or **IntelliJ IDEA | Preferences for macOS**, and click **PHP** under **Languages & Frameworks** .
2. On the **PHP** page that opens, click the  button next to the **CLI Interpreter** drop-down list in the **Development environment** section.
3. In the **CLI Interpreters** dialog box that opens, click the **Add** toolbar button  in the left-hand pane, then choose **Local** on the context menu. If you already have a local interpreter configured in IntelliJ IDEA, it is also shown on the menu and the menu item changes to **Other Local** .
4. In the right-hand pane of the dialog box, specify the PHP interpreter's settings.

1. In the **Name** text box, type the identifier to distinguish the interpreter from others, for example,

```
php_installation_<version> .
```

2. Specify the PHP engine installation directory in the **PHP Home** field. Type the path manually or click the **Browse** button  and choose the location in the **Choose PHP Home** dialog box, that opens.

IntelliJ IDEA displays the version of the PHP engine detected in the specified folder and the debugger associated with this PHP engine in the `php.ini` file.

5. Optionally, customize the configuration settings of the installation in the **Additional** area. In the **Debugger extension** text box, specify the path to Xdebug. This enables IntelliJ IDEA to activate Xdebug when it is necessary if you have disabled it in the `php.ini` file, see [Configuring Xdebug for Using in the On-Demand Mode](#) .

- In the **Configuration options** field, compose a string of configuration directives to be passed through the **-d command line option** and thus add new entries to the `php.ini` file. The directives specified in this field override the default directives generated by IntelliJ IDEA, such as `-dxdebug.remote_enable=1` , `-dxdebug.remote_host=127.0.0.1` , `-dxdebug.remote_port=9001` , `-dxdebug.remote_mode=req` .

For example, if you specify the `-dxdebug.remote_mode=jit` directive it will override the default `-`

`dxdebug.remote_mode=req` directive and thus switch **Xdebug** to the **Just-In-Time (JIT)** mode, see [Debugging in the Just-In-Time Mode](#) for details.

To do that, click the **Browse** button  next to the **Configuration options** field, and then create a list of entries in the **Configuration Options** dialog box, that opens.

- To add a new entry, click the **Add** button  . In the new line, that is added to the list, specify the name of the new entry and its value in the **Name** and **Value** text boxes respectively.

You can add as many entries as you need, just keep in mind that they will be transformed into a command line with its length limited to 256 characters.

- To delete an entry, select it in the list and click the **Remove** button  .

- To change the order of entries, use the **Up**  and **Down**  buttons.

Upon clicking **OK** , you return to the **CLI Interpreters** dialog box, where the entries are transformed into a command line.

6. Click the **Show phpinfo** button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the **Configuration Options** field of the **CLI Interpreters** dialog box are not listed.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Associating a name pattern with the distributed configuration file type](#)
- [Important notes](#)

## Introduction

IntelliJ IDEA provides syntax highlighting, formatting, [code completion](#) and [documentation lookup](#) while editing [distributed configuration files](#) .

Distributed configuration files are used to make directory-based changes to the [HTTP Apache Server](#) configuration and usually have the name `.htaccess` .

If you are using a file with the name `.htaccess` , IntelliJ IDEA recognizes it as distributed configuration file and provides full coding assistance for it, so no additional steps are required from your side.

If you want to use a file with another name, you need to associate this full name or the corresponding pattern with the distributed configuration [file type](#) . After that, IntelliJ IDEA will treat any file with the name matching the specified pattern as a distributed configuration file and process it accordingly.

## Associating a name pattern with the distributed configuration file type

### To associate a name pattern with the distributed configuration file type

1. [Open the Settings/Preferences](#) and click File Types .
2. In the [File Types](#) page that opens, select Apache config files from the Recognized File Types list.
3. In the Registered Patterns area, click [+](#) .
4. In the Add wildcard dialog box that opens, specify the pattern that defines the extensions of your distributed configuration files.
5. Click OK . IntelliJ IDEA returns you to the File Types page where the specified pattern is added to the Registered Patterns list.

## Important notes

Please note the following:

- By default, the Registered Patterns list contains one item `htaccess` .
- To discard a pattern, select it in the list and click the Remove button.
- To change a pattern, select it in the list, click the Edit button, and update the pattern as necessary in the Add wildcard dialog box that opens.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

**Include paths** are used for code completion and reference resolution in some functions/methods that use file paths as arguments, for example, `require()` or `include()` .

To configure include paths:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the [PHP](#) page that opens, configure the list of include paths in the Include path area:
  - Use the `+` and `-` buttons to add and remove paths.
  - Use the `↑` and `↓` buttons to change the order of items in the list.
  - Press the `↓a` toggle button to have the paths sorted alphabetically in the ascending order.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Detecting namespace roots automatically](#)

## Introduction

IntelliJ IDEA comes with a configurable convention which specifies that the project root folder is also the root for the packages and namespaces. In other words: the project root folder is by default marked as **Source** and every directory created under it is considered a separate namespace. This complies with the [PSR-0](#), also known as the **Autoloading Standard**, which prescribes that classes and namespaces in PHP should match the directory and file structure, and vice-versa.

According to [PSR-4](#), any directory can be explicitly assigned a namespace prefix. With this project structure, autoloaders in different PHP frameworks become interoperable.

## Detecting namespace roots automatically

When you open a project that contains at least one file with a namespace, IntelliJ IDEA displays a message with a proposition to set the namespace root.

Accordingly, when no namespace root has been configured yet and you create a class, IntelliJ IDEA proposes to configure the namespace root.

You can also trigger namespace root detection by choosing Code | Detect PSR-0 Namespace Roots on the main menu. The Directories dialog box that opens, shows the folders under the project root folder with the project root folder marked as **Source**, which means that it is the root for all the namespaces in it. Accept the settings by clicking OK or configure the namespace root manually as described below.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA integrates with the [Composer Dependency Manager](#) so you can install PHP-related frameworks right from the IDE.

IntelliJ IDEA provides a dedicated interface for [initializing](#) a project and [adding dependencies](#). Note that in this mode, you can use Composer only in the current project.

To run any Composer command in any IntelliJ IDEA project, use the tool in the command-line mode, see [How do I run Composer from the command line in IntelliJ IDEA?](#) below.

Check [Composer Support in PhpStorm](#) for step-by-step guidance and examples.

## Where do I get Composer from?

### Option 1: Download Composer

Download `composer.phar` from the [Composer Official website](#).

### Option 2: Update Composer to the latest version

On the main menu, choose *Tools | Composer | Self-Update*. Learn more from the [Composer Official website](#).

## How do I initialize Composer in a IntelliJ IDEA project?

### 1. Run Init Composer

On the main menu, choose *Tools | Composer | Init Composer*. The [Composer Settings Dialog](#) opens.

### 2. Specify the PHP interpreter to use

Choose one of the configured local PHP interpreters from the list in the Execution area. See [Configuring Local PHP Interpreters](#) for details.

### 3. Specify the composer.phar to use

In the Execution area, specify the path to `composer.phar`. If you have not downloaded it yet, click the *Download* link and specify the folder to store `composer.phar` in.

### 4. Complete the generated composer.json

When you click OK, the *Composer Settings* dialog is closed, IntelliJ IDEA creates a stub of the `composer.json` file and opens it in the editor. Complete the code or accept the default values. For more details, see [Composer.json: Project Setup](#).

**Tip** Composer initialization in a project results in creating a `composer.json` file. Note that you can have several `composer.json` files in one IntelliJ IDEA project. For each `composer.json`, actions are invoked from its context menu in the editor or in the Project view.

## How do I set up an external Composer project in IntelliJ IDEA?

### 1. Open your project

Click *Open* on the Welcome screen or choose *File | Open* on the main menu, then choose the folder where your Composer project is stored. IntelliJ IDEA shows a notification:

```
Event Log
6/6/2017
2:46 PM Composer: Composer configuration file found. Initialize Composer settings? Do not ask again.
```

### 2. Initialize Composer

Click *Initialize*. IntelliJ IDEA shows the *Composer* dialog where you need to specify the location of `composer.json`. If IntelliJ IDEA detects a configuration file, the *Path to composer.json* field is already filled in:

### 3. Complete configuration for executing Composer commands

Open the *Composer* page (*File | Settings | Languages and Frameworks | PHP | Composer* for Windows and Linux or *IntelliJ IDEA | Preferences | Languages and Frameworks | PHP | Composer* for macOS).

Alternatively, if you have one `composer.json` in your project, choose *Tools | Composer | Install* on the main menu. IntelliJ IDEA shows the following dialog:

In either case, specify the PHP interpreter and the `composer.phar` to use. See [How do I initialize Composer in a IntelliJ IDEA project?](#) above.

#### 4. Install the dependencies

- If you have only one `composer.json` in your project, choose *Tools | Composer | Install* on the main menu. See also [How do I appoint the default composer.json in a IntelliJ IDEA project?](#) .
- If you have several `composer.json` files, choose *Composer | Install* from the context menu of the relevant one.

## How do I appoint a default composer.json in a IntelliJ IDEA project?

You can have several `composer.json` files in one IntelliJ IDEA project. For each `composer.json` , actions are invoked from its context menu in the editor or in the Project view. You can also appoint the **default composer.json** for your IntelliJ IDEA project. Composer actions for it are invoked from *Tools | Composer* on the main menu.

To appoint a default composer.json

#### 1. Open the Composer page

Choose *File | Settings | Languages and Frameworks | PHP | Composer* for Windows and Linux or *IntelliJ IDEA | Preferences | Languages and Frameworks | PHP | Composer* for macOS.

#### 2. Specify the location of the default composer.json

If you have only one Composer configuration file in your IntelliJ IDEA project, the *Path to composer.json* field is filled in automatically.

#### 3. Configure the open-for-edit status of Composer packages

To protect packages under `vendor/**/*` against editing, leave the *Add packages as libraries* checkbox selected (this is the default setting).

If you want to edit Composer packages under `vendor/**/*` , clear the *Add packages as libraries* checkbox.

#### 4. Enable settings synchronization

Make sure the *Synchronize IDE settings with composer.json* checkbox is selected to automatically detect the PHP language level and configure project Source and Test roots based on the configuration from `composer.json` .

IntelliJ IDEA is aware of PSR-0/PSR-4 source roots and of their namespace prefixes declared in the `autoload` and `autoload-dev` sections in `composer.json` . IntelliJ IDEA also detects the PHP language level based on the `php` setting in the `require` section.

Because `composer.json` contains the most up-to-date information about the project configuration, this automatic synchronization ensures that the Source and Test folder exactly match the project structure and the correct PHP language level is set automatically. Learn more about PSR and autoload from the [Composer official website](#) . For examples and details in synchronizing settings, see [PhpStorm blog](#) .

**Tip** By default, all packages under `vendor/**/*` are excluded from the project and added as write-protected libraries.

## How do I install dependencies?

You can install specific packages one-by-one, IntelliJ IDEA will update your `composer.json` automatically. Alternatively, you can list the packages you need in the `require` and `require-dev` sections and then install them all at once.

Learn more about adding dependencies from the [Composer Official website](#) .

#### Option 1: Install packages one-by-one

##### 1. Open the Manage Composer Dependencies dialog

On the context menu of `composer.json` , choose *Composer | Manage Dependencies* .

##### 2. Choose the package to add

Select the required package from the *Available Packages* list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick.

Choose the relevant version from the *Version to install* list.

##### 3. Optionally, customize the package installation

Expand the *Settings* hidden area and specify the advanced installation options. In the *Command line parameters* text box, type the additional command line parameters. For example, to have a dependency added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.

Click *Install* to start installation. To leave the dialog, click *Close*.

When the installation is completed, IntelliJ IDEA creates a new subfolder under *vendor*, stores the new package in this subfolder, and adds the new package to the `require` or `require-dev` section of `composer.json`.

**Tip** To install packages from the default `composer.json`, choose *Tools | Composer | Manage Dependencies* on the main menu.

#### Option 2: Install all dependencies at once

On the context menu of `composer.json`, choose *Composer | Install*. IntelliJ IDEA installs all the packages listed in the `require` and `require-dev` sections.

## How do I update dependencies?

You can update specific packages to the latest version one-by-one, IntelliJ IDEA will update your `composer.json` automatically. Alternatively, you can update all the packages listed in the `require` and `require-dev` sections at once.

#### Option 1: Update packages one-by-one

##### 1. Open the Manage Composer Dependencies dialog

On the context menu of `composer.json`, choose *Composer | Manage Dependencies*.

##### 2. Choose the package to update

Select the required package from the *Available Packages* list among the packages marked with a tick and click *Update*.

#### Option 2: Update all dependencies at once

On the context menu of `composer.json`, choose *Composer | Update*. IntelliJ IDEA updates all the packages listed in the `require` and `require-dev` sections.

**Tip** To update packages from the default `composer.json`, choose *Tools | Composer | Manage Dependencies* on the main menu.

## How do I uninstall a dependency?

##### 1. Open the Manage Composer Dependencies dialog

On the context menu of `composer.json`, choose *Composer | Manage Dependencies*.

##### 2. Choose the package to uninstall

In the *Available Packages* list, select the package to uninstall among the packages marked with a tick and click *Remove*.

When the uninstallation is completed, IntelliJ IDEA updates the `require` or `require-dev` section of `composer.json` automatically.

**Tip** To remove packages from the default `composer.json`, choose *Tools | Composer | Manage Dependencies* on the main menu.

## How do I generate a Composer project stub?

##### 1. Open the New Project dialog

Choose *File | New | Project* or click *Create NewProject* on the Welcome screen.

##### 2. Choose the project type and location

In the left-hand pane, click *PHP* from the list, then choose *Composer Project* in the right-hand pane, and then click *Next*.

On the second page of the wizard, specify the project name and the folder where it will be created.

##### 3. Choose composer.phar to use

– To use commands from a previously downloaded `composer.phar`, choose *Use existing composer.phar* and specify its location in the text box.

– To download a new instance of Composer, choose *Download composer.phar from getcomposer.org*. The `composer.phar` file will be saved under the project root folder specified in the *Location* text box.

##### 4. Specify PHP interpreter to use

Choose one of the configured local PHP interpreters from the list, see [Configuring Local PHP Interpreters](#) for details.

## 5. Specify the package to install during the project creation

Select the package to add from the *Available Packages* list, possibly using the search field, and choose the relevant version from the *Version to install* list.

## 6. Optionally

In the *Command line parameters* text box, type the additional command line parameters. For example, to have a package added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.

When you click *Finish*, the `create-project` command is invoked with the selected package. This results in creating a Composer project whose configuration and structure depends on the selected package, see <https://getcomposer.org/doc/03-cli.md> for details. After that a IntelliJ IDEA project opens.

## How do I run Composer from the command line in IntelliJ IDEA?

In the command-line mode the full range of Composer command is at your disposal. To use Composer in this mode, you need to configure it as an external command-line tool.

**Tip** Make sure the Command Line Tool Support repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA but it can be installed from the JetBrains plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

### Step 1: Integrate Composer with IntelliJ IDEA as an external command-line tool

#### 1. Open the Composer dialog

Choose *File | Settings | Tools | Command Line Tool Support for Windows and Linux or IntelliJ IDEA | Preferences | Tools | Command Line Tool Support for macOS*. On the [Command Line Tool Support](#) page that opens, click **+** and choose *Composer* from the list.

#### 2. Specify how you want to launch Composer

Choose one of the options *composer.phar* or *php script* or *composer executable*. Depending on your choice, specify the paths to PHP installation folder and `composer.phar` or to `composer` executable file.

IntelliJ IDEA parses the contents of the specified `.phar` archive or executable file for Composer commands. When the file analysis is completed, IntelliJ IDEA returns to the *Command Line Tools Support* page where the specified file is added to the list of command line tools available in IntelliJ IDEA.

#### 3. Complete Composer configuration

On the *Command Line Tools Support* page where Composer is added to the list of tools, select the *Enable* checkbox, specify the alias to use in calls, customize the command set if necessary, and choose where to show the input pane for running commands. See [How do I customize a tool?](#) and [Input pane location](#) for details.

**Tip** You can have several instances of Composer configured and switch between them from one project to another by specifying the relevant one during [Composer initialization](#).

**Tip** If you choose *composer executable*, IntelliJ IDEA does not provide coding assistance and you cannot execute scripts because no PHP interpreter is appointed.

### Step 2: Initialize a Composer project

Open the Input pane (*Tools | Run Command*), type `c init` at the command prompt, and answer the questions of the wizard. Learn more from the [Composer Official website](#).

**Tip** If you have specified a custom alias for Composer instead of the default `c`, type `<tool alias> init`.

### Step 3: Run Composer commands

Open the Input pane (*Tools | Run Command*) and type `<alias>` (`c` by default) and press `Ctrl+Space` to invoke completion. The result of command execution is shown in the *Output* tab with the name of the command. Learn more from [How do I run a command?](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

On this page:

- [Basics](#)
- [Enabling documentation comments](#)
- [Generating a PHPDoc block for a method or a function](#)
- [Creating tags in a PHPDoc comment block](#)
- [Inspecting PHPDoc comments](#)
- [Configuring formatting inside PHPDoc comments](#)
- [Viewing PHPDoc comments](#)

## Basics

IntelliJ IDEA creates stubs of [PHPDoc blocks](#) on typing the opening tag `/**` and pressing `Enter` or pressing `Alt+Insert` and appointing the method/function to document.

If this feature is [applied to a method or a function](#), `@param`, `@throws`, `@return`, and `@var` tags are created. In any other places IntelliJ IDEA adds an empty documentation stub.

If you need [additional PHP-specific tags](#), IntelliJ IDEA provides code completion that suggests tag names that are relevant in the current context. If a certain tag has multiple values, the same code completion provides a list of available values.

In PHPDoc comments, IntelliJ IDEA supports formatting options in compliance with ZEND, PEAR, and other standards.

PHPDoc comments in your source code are available for the [Quick Documentation Lookup](#) feature and open for review on pressing `Ctrl+Q`.

## Enabling documentation comments

1. Open the Editor | General | Smart Keys page of IntelliJ IDEA settings (`Ctrl+Alt+S`).
2. In the Enter section, select or clear Insert documentation comment stub check box.

3. **Warning!** The following is only valid when Python Plugin is installed and enabled!

For Python, scroll to the Insert type placeholders in the documentation comment stub option and select or clear the check box as required. Refer to [the option description](#) for details.

## Generating a PHPDoc block for a method or a function

1. To invoke PHPDoc block generation, do one of the following:
  - Place the caret before the method or function declaration, type the opening block comment `/**`, and press `Enter`.
  - On the context menu anywhere in the editor, choose Generate, then choose Generate PHPDoc blocks, and choose the method or function to generate comments for.
  - Press `Alt+Insert`, then choose Generate PHPDoc blocks, and choose the method or function to generate comments for.

IntelliJ IDEA analyzes the appointed method or function, where possible extracts the data for method parameters, return values, variables, etc., and on this basis generates a stub of a documentation block.

2. Describe the listed parameters and return values where necessary. IntelliJ IDEA checks and treats syntax in comments according to the [PHP Inspections](#) settings.

## Creating tags in a PHPDoc comment block

IntelliJ IDEA analyzes the appointed method or function, where possible extracts the data for method parameters, return values, variables, etc., and on this basis generates a stub of a documentation block. If necessary, you can fill in the missing information.

1. In a PHPDoc block, select the desired empty line and press `Ctrl+Space`.
2. Select the relevant tag from the suggestion list.
3. If the entered tag has several values, press `Ctrl+Space` and select the desired value from the suggestion list.

## Inspecting PHPDoc comments

IntelliJ IDEA provides a set of predefined code inspections targeted at PHPDoc blocks. These inspections check whether classes, methods, functions, variables, and constants are supplied with a PHPDoc comment and whether the tags in the comment match the documented item.

- To enable or disable an inspection:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Inspections under Editor.
  2. On the [Inspections](#) page that opens, expand the PHPDoc node under the PHP node. The list of predefined inspections is displayed.

3. To enable or disable an inspection, select or clear the checkbox next to it.
- To have IntelliJ IDEA check that PHPDoc comments are provided for all code constructs of a certain type:
1. Select the checkbox next to the **Missing PHPDoc Comment** inspection.
  2. In the Options area, select the checkboxes next to the required code construct type: class, method, function, variable, or constant.
  3. To suppress reporting a **Missing PHPDoc Comment** error if a method or function does not contain any parameters and/or return values, select the Skip if empty .

## Configuring formatting inside PHPDoc comments

You can configure the appearance of PHPDoc comments and the presentation of class names in the Settings dialog box, on the PHPDoc tab of the [Code Style. PHP](#) under the Code Style node. Note that the tag for properties is no longer configurable, the default `@var` tag is inserted automatically. See <https://github.com/phpDocumentor/fig-standards/pull/55> for details.

1. [Open the Settings dialog box](#) , click Code Style , then click PHP , and switch to the PHPDoc tab.
2. Configure the alignment by selecting or clearing the checkboxes in the tab.
3. Specify how you want IntelliJ IDEA to present class names for properties, function parameters, **return** and **throws** values, etc. by selecting or clearing the Use fully-qualified class names checkbox.

## Viewing PHPDoc comments

[Quick Documentation Lookup](#) helps you get quick information for any symbol that is supplied with Documentation comments in the applicable format. IntelliJ IDEA recognizes inline documentation created in accordance with the [PHP Documentation](#) format and shows it in the [Documentation Tool Window](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this part:

- [Configuring a Debugging Engine](#)
- [PHP Debugging Session](#)
- [Multiuser Debugging via Xdebug Proxies](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

This section describes how to configure two most popular tools used in PHP debugging:

- [Xdebug](#)
- [Zend Debugger](#)

These tools cannot be used simultaneously because they block each other. To avoid this problem, you need to update the corresponding sections in the `php.ini` file. To open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the [PHP](#) page that opens, click  next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor .

In this part:

- [Configuring Xdebug](#)
- [Configuring Zend Debugger](#)
- [Validating the Configuration of a Debugging Engine](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Downloading and installing Xdebug](#)
- [Enabling Xdebug integration with the PHP interpreter](#)
- [Configuring Xdebug in IntelliJ IDEA](#)
- [Configuring Xdebug for using in the On-Demand mode](#)
- [Configuring Xdebug for using in the Just-In-Time mode](#)
  - [Command-line scripts](#)
  - [Web server debugging](#)

## Downloading and installing Xdebug

Download the [Xdebug](#) extension compatible with your version of PHP and save it in the `php/` folder.

- The location of the `php/` folder is defined during the [installation of the PHP engine](#).
- If you are using an [AMP package](#), the Xdebug extension may be already installed. Follow the instructions in the `xdebug.txt`.

See [Xdebug Installation Guide](#) for detailed step-by-step instructions.

## Enabling Xdebug integration with the PHP interpreter

1. Open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, click `...` next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor.

2. To disable the [Zend Debugger](#) and [Zend Optimizer](#) tools, that blocks Xdebug, remove or comment the following lines in the `php.ini` file:

```
zend_extension=<path_to_zend_debugger>
zend_extension=<path_to_zend_optimizer>
```

3. To enable Xdebug, locate the `[Xdebug]` section in the `php.ini` file and update it as follows:

```
[Xdebug]
zend_extension="<path to php_xdebug.dll>"
xdebug.remote_enable=1
xdebug.remote_port="<the port for Xdebug to listen to>" (the default port is 9000)
xdebug.profiler_enable=1
xdebug.profiler_output_dir="<AMP home\tmp>"
```

4. To enable [multiuser debugging via Xdebug proxies](#), locate the `xdebug.idekey` setting and assign it a value of your choice. This value will be used to register your IDE on Xdebug proxy servers.

5. Save and close the `php.ini` file.

## Configuring Xdebug in IntelliJ IDEA

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.

2. Check the [Xdebug](#) installation associated with the selected PHP interpreter:

1. On the PHP page, choose the relevant PHP installation from the CLI Interpreter drop-down list and click the Browse button `...` next to the field. The list shows all the PHP installations available in IntelliJ IDEA, see [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#).
2. The CLI Interpreters dialog box that opens shows the following:
  - The version of the selected PHP installation.
  - The name and version of the debugging engine associated with the selected PHP installation (Xdebug or Zend Debugger). If no debugger is configured, IntelliJ IDEA shows `Debugger: Not installed`.

Alternatively, open the [Xdebug checker](#), paste the output of the `phpinfo()`, and click Analyze my phpinfo() output. Learn more about checking the [Xdebug](#) installation in [Validating the Configuration of a Debugging Engine](#).

3. Define the Xdebug behaviour. Click Debug under the PHP node. On the [Debug](#) page that opens, specify the following settings in the Xdebug area:

- In the Debug Port text box, appoint the port through which the tool will communicate with IntelliJ IDEA. This must be

exactly the same port number as specified in the `php.ini` file:

```
xdebug.remote_port = <port_number>
```

By default, Xdebug listens on port 9000.

- To have IntelliJ IDEA accept any incoming connections from Xdebug engines through the port specified in the Debug port text box, select the Can accept external connections checkbox.
  - Select the Force break at the first line when no path mapping is specified checkbox to have the debugger stop as soon as it reaches and opens a file that is not mapped to any file in the project on the [Servers](#) page. The debugger stops at the first line of this file and [Debug Tool Window. Variables](#) shows the following error message: **Cannot find a local copy of the file on server <path to the file on the server>** and a link [Click to set up mappings](#) . Click the link to open the Resolve Path Mappings Problem dialog box and map the problem file to its local copy.  
When this checkbox cleared, the debugger does not stop upon reaching and opening an unmapped file, the file is just processed, and no error messages are displayed.
  - Select the Force break at the first line when the script is outside the project checkbox to have the debugger stop at the first line as soon as it reaches and opens a file outside the current project. With this checkbox cleared, the debugger continues upon opening a file outside the current project.
4. In the External Connections area, specify how you want IntelliJ IDEA to treat connections received from hosts and through ports that are not registered as [deployment server configurations](#) .
- Ignore external connections through unregistered server configurations: Select this checkbox to have IntelliJ IDEA ignore connections received from hosts and through ports that are not registered as deployment server configurations. When this checkbox is selected, IntelliJ IDEA does not attempt to create a deployment server configuration automatically.
  - Break at first line in PHP scripts: Select this checkbox to have the debugger stop as soon as connection between it and IntelliJ IDEA is established (instead of running automatically until the first breakpoint is reached). Alternatively turn on the *Run | Break at first line in PHP scripts* option on the main menu.
  - Max. simultaneous connections: Use this spin box to limit the number of external connections that can be processed simultaneously.

## Configuring Xdebug for using in the On-Demand mode

Starting with version 2016.2, IntelliJ IDEA supports the **On-Demand** mode where you can disable Xdebug for your global PHP installation, and have it enabled automatically on demand only when you are debugging your command-line scripts or when you need code coverage reports. This lets your command line scripts (including Composer and unit tests) run much faster.

1. Disable Xdebug for command-line scripts:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. From the PHP executable drop-down list, choose the relevant PHP interpreter and click `...` next to it. In the [CLI Interpreters](#) dialog box that opens, click the Open in Editor link next to the Configuration file: `<path to php.ini>` file. Close all the dialog boxes and switch to the tab where the `php.ini` file is opened.
3. In the `php.ini` file, find the `[XDebug]` section and comment the following line in it by adding `;` in preposition:

```
;[XDebug]  
  
;zend_extension = "<full_path_to_xdebug>"
```

4. Open the [CLI Interpreters](#) dialog box and click `🔗` next to the PHP executable field. IntelliJ IDEA informs you that debugger is not installed:

2. To enable IntelliJ IDEA to activate Xdebug when it is necessary, specify the path to it in the Debugger extension text box, in the Additional area. Type the path manually or click `...` and select the location in the dialog box that opens.

## Configuring Xdebug for using in the Just-In-Time mode

IntelliJ IDEA supports the use of Xdebug in the **Just-In-Time (JIT)** mode so it is not attached to your code all the time but connects to IntelliJ IDEA only when an error occurs or an exception is thrown. The Xdebug operation mode is toggled through the `xdebug.remote_mode` setting, which is by default set to `req` . The mode is available both for debugging command-line scripts and for web server debugging.

Depending on whether you are going to debug command-line scripts or use a Web server, use one of the scenarios below.

## Command-line scripts

For debugging command-line scripts, specify the custom `-dxdebug.remote_mode=jit` directive as an **additional configuration option** :

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. From the PHP executable drop-down list, choose the relevant PHP interpreter and click `⋮` next to it.
3. In the [CLI Interpreters](#) dialog box that opens, click `⋮` next to the Configuration options text box in the Additional area.
4. In the Configuration options dialog that opens, click `+` to add a new entry, then type `-dxdebug.remote_mode` in the Configuration directive field and `jit` in the Value field.

When you click OK , you return to the CLI Interpreters dialog box where the Configuration options text box shows `-dxdebug.remote_mode=jit` .

## Web server debugging

1. On the main menu, choose [Run | Web Server Debug Validation](#) .
2. In the [Web Server Debug Validation Dialog](#) that opens, choose the Web server to validate the debugger on.
  - Choose Local Web Server or Shared Folder to check a debugger associated with a local Web server.
    - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. For Web servers of the type **Inplace** , the folder is under the project root. The folder must be accessible through [http](#) .
    - URL to Validation Script: In this text box, type the URL address of the folder where the validation script will be created. If the project root is mapped to a folder accessible through [http](#) , you can specify the project root or any other folder under it.
  - Choose Remote Web Server to check a debugger associated with a remote server.
    - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. The folder must be accessible through [http](#) .
    - Deployment Server: In this field, specify the server access configuration of the type [Local Server](#) or [Remote Server](#) to access the target environment. For details see [Configuring Synchronization with a Web Server](#) . Choose a configuration from the drop-down list or click the Browse button `⋮` in the [Deployment dialog](#) .
3. Click Validate to have IntelliJ IDEA create a validation script, deploy it to the target remote environment, and run it there.
4. Open the `php.ini` file which is reported as loaded and associated with Xdebug.
5. In the `php.ini` file, find the `[XDebug]` section and change the value of the `xdebug.remote_mode` from the default `req` to `jit` .

See also [Just-In-Time debugging and PHP Exception Breakpoints with PhpStorm and Xdebug](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Downloading and installing Zend Debugger](#)
- [Enabling Zend Debugger integration with the PHP interpreter](#)
- [Integrating Zend Debugger with IntelliJ IDEA](#)
- [Configuring Zend Debugger for using in the On-Demand mode](#)

## Downloading and installing Zend Debugger

1. Download the [Zend Debugger package](#) which corresponds to your operating system.
2. Locate the `ZendDebugger.so` (Unix) or `ZendDebugger.dll` (Windows) file in the directory which corresponds to your version of PHP (e.g. 4.3.x, 4.4.x, 5.0.x, 5.1.x, 5.2.x, 5.3.x, 5.4.x).
3. Copy the file to your Web server in a location that is accessible by the Web server.

## Enabling Zend Debugger integration with the PHP interpreter

1. Open the active `php.ini` file in the editor:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
  2. On the [PHP](#) page that opens, click `...` next to the CLI Interpreter field.
  3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor .
2. Locate or create the `[Zend]` section.
3. To load the Zend Debugger extension, add one of the following lines inside the `[Zend]` section depending on your operating system:
  - Linux and macOS :

```
zend_extension=<full_path_to_ZendDebugger.so>
```

– Windows :

```
zend_extension_ts=<full_path_to_ZendDebugger.dll>
```

– Windows non-thread safe :

```
zend_extension=<full_path_to_ZendDebugger.dll>
```

**Warning!** The Windows non-thread safe binary file is only used with Zend Core 2.0.

4. To enable access to Zend Debugger from IntelliJ IDEA, add the following lines:

```
zend_extension=<full_path_to_zend_debugger_extension>
zend_debugger.allow_hosts=127.0.0.1
zend_debugger.expose_remotely=allowed_host
zend_debugger.tunnel_min_port=<any integer value above 1024>
zend_debugger.tunnel_max_port=<any integer value below 65535>
```

The value of the `zend_debugger.allow_hosts` parameter is the IPs of your machine to connect to the server debugger. It could be a comma-separated list of IPs in the format `X.X.X.X` (for example, 192.168.0.6).

**Tip** For a thread-safe Windows binary use the `zend_extension_ts` parameter instead of `zend_extension` .

5. Restart your Web server.
6. To check that the Zend Debugger has been installed and configured correctly, create a file with the following contents:

```
<?php
    phpinfo();
?>
```

Open the page that corresponds to the file in the browser. The output should contain a Zend Debugger section.

## Integrating Zend Debugger with IntelliJ IDEA

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. Check the **Zend Debugger** installation associated with the selected PHP interpreter:
  1. On the PHP page, choose the relevant PHP installation from the CLI Interpreter drop-down list and click the Browse button  next to the field. The list shows all the PHP installations available in IntelliJ IDEA, see [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#) .
  2. The CLI Interpreters dialog box that opens shows the following:
    - The version of the selected PHP installation.
    - The name and version of the debugging engine associated with the selected PHP installation (Xdebug or Zend Debugger). If no debugger is configured, IntelliJ IDEA shows `Debugger: Not installed` .

Learn more about checking the **Zend Debugger** installation in [Validating the Configuration of a Debugging Engine](#) .

3. Define the Zend Debugger behaviour. Click Debug under the PHP node. On the [Debug](#) page that opens, specify the following settings in the Zend Debugger area:
  - In the Debug Port text box, appoint the port for IntelliJ IDEA to communicate with the tool through. Type the port number within the **tunnel** specified in the `php.ini` file through `zend_debugger.tunnel_min_port` and `zend_debugger.tunnel_max_port` . For details, see <http://files.zend.com/help/previous-version/Zend-Server-4-Community-Edition/zenddebugger.html>
  - To have IntelliJ IDEA accept any incoming connections from Zend Debugger engines through the port specified in the Debug port text box, select the Can accept external connections checkbox.
  - To use a debugger toolbar in the browser, specify the port through which the debugger settings are passed to the browser in the Settings broadcasting port text box.
  - Use the Automatically detect IDE IP checkbox to enable and disable autodetection of host IP addresses. When this checkbox is selected, IntelliJ IDEA detects all the host IP addresses to be sent to Zend Debugger through the `debug_host` parameter. All the detected IP addresses are listed in the text box to the right. Autodetection of IP address is helpful when you use [Vagrant](#) , or [VirtualBox](#) , or other virtualization tool.

Clear the checkbox to block autodetection of host IP addresses and specify the required ones explicitly in the text box.

4. In the External Connections area, specify how you want IntelliJ IDEA to treat connections received from hosts and through ports that are not registered as [deployment server configurations](#) .
  - Ignore external connections through unregistered server configurations: Select this checkbox to have IntelliJ IDEA ignore connections received from hosts and through ports that are not registered as deployment server configurations. When this checkbox is selected, IntelliJ IDEA does not attempt to create a deployment server configuration automatically.
  - Break at first line in PHP scripts: Select this checkbox to have the debugger stop as soon as connection between it and IntelliJ IDEA is established (instead of running automatically until the first breakpoint is reached). Alternatively turn on the *Run | Break at first line in PHP scripts* option on the main menu.
  - Max. simultaneous connections: Use this spin box to limit the number of external connections that can be processed simultaneously.
5. To block requests from the [Z-Ray system](#) if they annoy you by invoking the IntelliJ IDEA debugger too often, select the Ignore Z-Ray system requests checkbox.

## Configuring Zend Debugger for using in the On-Demand mode

Starting with version 2016.2, IntelliJ IDEA supports the **On-Demand** mode where you can disable Zend Debugger for your global PHP installation, and have it enabled automatically on demand only when you are debugging your command-line scripts or when you need code coverage reports. This lets your command line scripts (including Composer and unit tests) run much faster.

1. Disable Zend Debugger for command-line scripts:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
  2. From the PHP executable drop-down list, choose the relevant PHP interpreter and click  next to it. In the [CLI Interpreters](#) dialog box that opens, click the Open in Editor link next to the Configuration file: <path to php.ini> file. Close all the dialog boxes and switch to the tab where the `php.ini` file is opened.
  3. In the `php.ini` file, find the `[Zend]` section and comment the following lines in it by adding `;` in preposition: Linux and macOS :

```
zend_extension=<full_path_to_ZendDebugger.so>
```

Windows :

```
zend_extension_ts=<full_path_to_ZendDebugger.dll>
```

Windows non-thread safe :

```
zend_extension=<full_path_to_ZendDebugger.dll>
```

**Warning!** The Windows non-thread safe binary file is only used with Zend Core 2.0.

4. Open the [CLI Interpreters](#) dialog box and click  next to the PHP executable field. IntelliJ IDEA informs you that debugger is not installed:

2. To enable IntelliJ IDEA to activate Zend Debugger when it is necessary, specify the path to it in the Debugger extension text box, in the Additional area. Type the path manually or click  and select the location in the dialog box that opens.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA can validate your configuration of **Xdebug** or **Zend Debugger** and tell you if some setting is missing (for example, `xdebug.remote_enable` ) or inconsistent with other settings. When configuring the PHP interpreter for a project, IntelliJ IDEA informs you whether a debugger is installed in your local PHP development environment and reports on the **Xdebug** or **Zend Debugger** version used. For details, see [Configuring a Debugging Engine](#) , [Configuring Local PHP Interpreters](#) , and [Configuring Remote PHP Interpreters](#) .

You can also get more detailed information about the debugging engine on a local or remote Web server.

1. On the main menu, choose Run | Web Server Debug Validation .

2. In the [Web Server Debug Validation Dialog](#) that opens, choose the Web server to validate the debugger on.

- Choose Local Web Server or Shared Folder to check a debugger associated with a local Web server.
  - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. For Web servers of the type **Inplace** , the folder is under the project root. The folder must be accessible through **http** .
  - URL to Validation Script: In this text box, type the URL address of the folder where the validation script will be created. If the project root is mapped to a folder accessible through `http` , you can specify the project root or any other folder under it.
- Choose Remote Web Server to check a debugger associated with a remote server.
  - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. The folder must be accessible through **http** .
  - Deployment Server: In this field, specify the server access configuration of the type **Local Server** or **Remote Server** to access the target environment. For details see [Configuring Synchronization with a Web Server](#) .  
Choose a configuration from the drop-down list or click the Browse button  in the [Deployment dialog](#) .

3. Click Validate to have IntelliJ IDEA create a validation script, deploy it to the target remote environment, and run it there.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Before you start debugging, make sure that you have a debugging engine installed and configured properly. IntelliJ IDEA supports debugging with two most popular tools: [Xdebug](#) and [Zend Debugger](#). These tools cannot be used simultaneously because they block each other. To avoid this problem, you need to update the corresponding sections in the `php.ini` file as described in [Configuring Xdebug](#) and [Configuring Zend Debugger](#).

To open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, click `...` next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor.

With IntelliJ IDEA, a PHP debugging session can be initiated either through a debug configuration or without it. The latter approach is also called **Zero-configuration debugging**. IntelliJ IDEA supports three main ways to initiate a PHP debugging session:

- You create a [PHP Web Application debug configuration](#), and then IntelliJ IDEA uses its settings to launch the application, open the browser, and activate the debugging engine.
- You create a [PHP HTTP Request debug configuration](#), IntelliJ IDEA generates a request on its base, and then accesses a specific page through this request.
- **Zero-configuration debugging**, when no debug configuration is created at all. Instead, you open the starting page of your PHP application in the browser manually and then activate the debugging engine from the browser, while IntelliJ IDEA listens to incoming debugger connections.

No matter which method you choose, you can specify the scripts requests to which you want IntelliJ IDEA to ignore during debugging. This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the **skipped paths** list. You can also group such scripts into folders and add these folders to the "ignore list".

When using Xdebug, you can also [debug PHP applications in the multiuser mode](#) via Xdebug proxy servers.

In this part:

- [Creating a PHP Debug Server Configuration](#)
- [Debugging with a PHP Web Application Debug Configuration](#)
- [Zero-Configuration Debugging](#)
- [Debugging a PHP HTTP Request](#)
- [Debugging in the Just-In-Time Mode](#)
- [Debugging with PHP Exception Breakpoints](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

The term **PHP debug server configuration** denotes the settings that ensure HTTP access for debugging engines to interact with local and remote Web servers and set correspondence between files on the server and their local copies in the IntelliJ IDEA project. The settings from debug server configurations are used when debugging with run/debug configurations of the type **PHP Web Application** or **PHP Remote Debug** and during **Zero-Configuration Debugging** sessions.

You can create a debug server configuration manually from scratch or import some settings from a server access (deployment) configuration (see [Configuring Synchronization with a Web Server](#) for details).

On this page:

- [Defining a debug server configuration manually](#)
- [Importing settings from a server access \(deployment\) configuration](#)

## Defining a debug server configuration manually

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`. Expand the `Languages & Frameworks` node, and then click `Servers` under `PHP`.

Alternatively, click  next to the `Server` drop-down list in the [Run/Debug Configuration: PHP Web Application](#) dialog box.

In either case, the [Servers](#) page opens with the left-hand pane showing all the available debug server configurations. Click  on the toolbar and specify the debug server settings in the right-hand pane.

2. Specify the debug server configuration name.

3. Specify the host where the application is run and the port to access it.

4. From the `Debugger` drop-down list, choose the [debugging engine](#) to use.

5. Specify how IntelliJ IDEA will set up correspondence between files on the server and their local copies. Based on these mappings, IntelliJ IDEA will open local copies of currently processed files.

Path mappings in **PHP Debug Server** configurations look very similar to the path mappings in **server access (deployment)** configurations. Unfortunately, they cannot be reused, as **deployment** configurations uses relative paths while **PHP Debug Servers** configurations rely on absolute paths.

– Select the `Use path mappings` checkbox if you are working on a remote Web server, that is, when the Web server is on a physically remote host, or the Web server is installed on your machine but your project is outside the Web server document root. Also select the checkbox if you are using symlinks.

Map the absolute paths to the files and folders on the server with absolute paths to your project files in the local file system using the `Path on server` and `File/Directory` fields respectively.

– `File / Directory`: This read-only field displays the files and folders of the current project. Select a file or a folder to be used as the local copy.

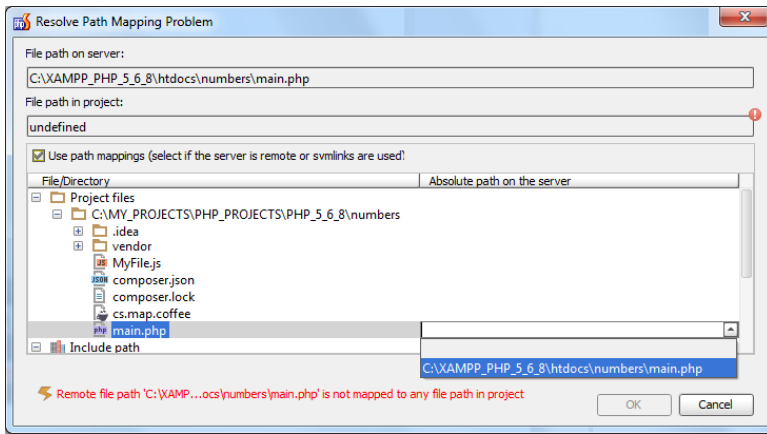

– `Path on server`: In this field, specify the absolute path to the file or folder on the target server to which the selected local file or folder corresponds. Type the path manually or select it from the drop-down list.

– Clear the `Use path mappings` checkbox if you are working right on your Web server so your project root is under the server document root. In this case the absolute paths to the files on the Web server and the absolute paths to the corresponding files in your project are the same.

If you do not specify any path mappings and start debugging an application that is not under the server document root, IntelliJ IDEA displays an error message:

The `Click to set up path mappings` link brings up the `Resolve Path Mappings Problem` dialog box, where you can define the path mappings:

When you click OK and leave the dialog box, IntelliJ IDEA selects the Use path mappings checkbox on the [Servers](#) page automatically.

6. Select the Shared checkbox to share the debug server configuration across a team. The host/port settings and the path mappings are stored in the `.idea/php.xml` file is available to all team members through a version control system. Note that mappings are shared only for directories inside the project.

## Importing settings from a server access (deployment) configuration

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Servers under PHP .

Alternatively, click  next to the Server drop-down list in the [Run/Debug Configuration: PHP Web Application](#) dialog box.

In either case, the [Servers](#) page opens with the left-hand pane showing all the available debug server configurations. Click  on the toolbar. The [Import from Deployment Configuration Dialog](#) dialog box opens.

2. From the Deployment drop-down list, choose the server access configuration (deployment configuration) to copy the server access settings from. The list contains all the available deployment configurations. To create a new configuration, click  and specify new settings in the [Deployment: Connection Tab](#) dialog box that opens.
3. Depending on the type of the server access configuration chosen from the Deployment drop-down list, specify one of the following:
  - For an **FTP** , **SFTP** , or **FTPS** server access configuration, specify the absolute path to the server deployment root. This path will be added as a prefix to the path from the Root Path text box on the [Deployment: Connection Tab](#) .  
If you are not sure about this absolute path, you can open the Remote Host tool window, choose the required deployment configuration, position the cursor at the root folder, and choose Copy Path on the context menu, see [Accessing Files on Web Servers](#) for details. Alternatively, contact your hosting provider.
  - For **Local or mounted folder** , type the absolute path to the **server root** as specified in the Folder field of the [Creating a PHP Debug Server Configuration](#) dialog box.
  - For **Inplace Server** configurations no mappings are required because the local and remote paths are the same in this case.
4. The Preview area shows the host/port and the path mappings retrieved from the chosen server access configuration (deployment configuration).

When you choose the deployment configuration to use, the Absolute path on the server field shows relative paths mapped to the project files and folders in the chosen configuration, that is, paths to files and folders relative to the deployment root. As you specify the absolute path to the deployment root (the server root for FTP/SFTP/FTPS or the mounted folder), the contents of the field are updated automatically and finally the field shows absolute paths on the server.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Preparing the debugging engine](#)
- [Setting breakpoints](#)
- [Creating a debug configuration of the type PHP Web Application](#)
- [Initiating a debugging session and examining the suspended program](#)
- [Specifying scripts to skip requests to](#)

## Introduction

In this debugging mode, IntelliJ IDEA fully controls the debugging process: it launches the application, opens the browser, and activates the debugging engine according to a [PHP Web Application debug configuration](#).

A PHP Web Application debug configuration tells IntelliJ IDEA the URL address to access the starting page of the application, the browser to open the starting page in, and the [debug server configuration](#) to use.

You can also specify the scripts requests to which you want IntelliJ IDEA to ignore during debugging. This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the [skipped paths](#) list. You can also group such scripts into folders and add these folders to the "ignore list".

## Preparing the debugging engine

Before you start debugging, make sure that you have a debugging engine installed and configured properly. IntelliJ IDEA supports debugging with two most popular tools: [Xdebug](#) and [Zend Debugger](#). These tools cannot be used simultaneously because they block each other. To avoid this problem, you need to update the corresponding sections in the `php.ini` file as described in [Configuring Xdebug](#) and [Configuring Zend Debugger](#).

To open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, click `...` next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor.

## Setting breakpoints

Breakpoints are source code markers used to trigger actions during a debugging session. Typically, the purpose behind setting a breakpoint is to suspend program execution to allow you to examine program data. However, IntelliJ IDEA can use breakpoints as triggers for a variety of different actions. Breakpoints can be set at any time during the debugging process. Your breakpoints don't affect your source files directly, but the breakpoints and their settings are saved with your IntelliJ IDEA project so you can reuse them across debugging sessions.

1. Place the caret on the desired line of the source code.

Breakpoints can be set in the PHP context inside `*.php`, `*.html`, and files of other types. Line breakpoints can be set only on executable lines, but not on comments, declarations, or empty lines.

2. Do one of the following:

- Click the left gutter area at a line where you want to toggle a breakpoint.
- On the main menu, choose *Run | Toggle Line Breakpoint*.
- Press `Ctrl+F8`.

## Creating a debug configuration of the type PHP Web Application

1. Open the [Run/Debug Configuration](#) dialog box by doing one of the following:

- On the main menu, choose Run | Edit Configurations.
- Press `Shift+Alt+F10`, then press `0` to display the Edit Configuration dialog box or select the configuration from the pop-up window and press `F4`.

2. Click `+` on the toolbar or press `Insert`. From the drop-down list, select the PHP Web Application configuration type.

The [PHP Web Application](#) dialog box opens.

3. Specify the configuration name.

4. Choose the applicable debug server configuration from the Server drop-down list or click the Browse button `...` and define a debug server configuration in the [Servers](#) dialog box that opens as described in [Creating a PHP Debug Server Configuration](#).

5. In the Start URL text box, type the server path to the file that implements the application starting page. Specify the path relative to the server configuration root (The [server configuration root](#) is the highest folder in the file tree on the local or remote server accessible through the server configuration. For in-place servers, it is the project root.). The read-only field below shows the URL address of the application starting page. The URL address is composed dynamically as you type.

- Specify the browser to open the application in. Choose a configured browser from the Browser drop-down list or click the Browse button  and [specify another browser](#) in the [Web Browsers](#) dialog box that opens.

## Initiating a debugging session and examining the suspended program

- To start debugging, click the Debug button  on the toolbar.
- As soon as the debugger suspends on reaching the first breakpoint, examine the application by analyzing **frames**. A **frame** corresponds to an active method or function call and stores the local variables of the called method or function, the arguments to it, and the code context that enables expression evaluation. All currently active frames are displayed on the Frames pane of the [Debug tool window](#), where you can switch between them and analyze the information stored therein in the Variables and Watches panes. For more details, see the section [Examining Suspended Program](#).
- Continue running the program and examine its frames as soon as it is suspended again.
  - To control the program execution manually, step through the code using the commands under the *Run* menu or toolbar buttons: *Step Into* () , *Step Out* () , *Step Over* () , and others. For more details, see [Stepping Through the Program](#).
  - To have the program run automatically up to the next breakpoint, resume the session by choosing *Run | Resume Program* or pressing () .

## Specifying scripts to skip requests to

This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the **skipped paths** list. You can also group such scripts into folders and add these folders to the "ignore list".

- Open the [Settings / Preferences Dialog](#) by pressing () or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the PHP node under Languages & Frameworks, and then click Skipped Paths under Debug.
- On the [Skipped Paths](#) page that opens, configure an "ignore list" of scripts and folders with scripts not to be invoked if IntelliJ IDEA receives incoming connections to them.
  - To add a new entry to the list, click the Add button  or press () . Then click the Browse button  and in the dialog box that opens choose the file or folder to skip connections to.
  - To remove an entry from the list, select it and click the Remove button  or press () . The script will be now executed upon receiving requests to it.
- To have IntelliJ IDEA inform you every time it receives a request to a script to be skipped, select the Notify about skipped paths checkbox.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Overview](#)
- [Preparing the debugging engine](#)
- [Setting the breakpoints](#)
- [Generating the Start Debugger/Stop Debugger bookmarks](#)
- [Initiating a debugging session and examining the suspended program](#)
- [Troubleshooting](#)
  - [No Path Mappings are Configured](#)

  - [A Script Is not Suspended](#)
- [Specifying the scripts to skip requests to](#)
- [Starting a debugging session from the command line](#)
  - [Starting a Script with Xdebug](#)
  - [Starting a script with Zend Debugger](#)
  - [Configuring path mappings](#)
  - [Troubleshooting](#)

## Overview

In case of **zero-configuration debugging**, you do not need to create any debug configuration. Instead, you open the starting page of your PHP application in the browser manually, and then activate the debugging engine from the browser, while IntelliJ IDEA listens to incoming debugger connections.

To enable starting and stopping the debugging engine from the browser manually, you need to set a special `GET / POST` or `COOKIE` parameter. You can do it manually in the `php.ini` configuration file or generate the **Start Debugger / Stop Debugger** bookmarks on the toolbar of your browser. These bookmarks provide control over the debugger cookie, through them you will activate and deactivate the debugger.

For more details about setting the parameters manually, see [Starting the Debugger](#) for Xdebug and [Zend Debugger GET Request Parameters](#) for Zend Debugger.

You can also specify the scripts requests to which you want IntelliJ IDEA to ignore during debugging. This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the **skipped paths** list. You can also group such scripts into folders and add these folders to the "ignore list".

## Preparing the debugging engine

Before you start debugging, make sure that you have a debugging engine installed and configured properly. IntelliJ IDEA supports debugging with two most popular tools: [Xdebug](#) and [Zend Debugger](#). These tools cannot be used simultaneously because they block each other. To avoid this problem, you need to update the corresponding sections in the `php.ini` file as described in [Configuring Xdebug](#) and [Configuring Zend Debugger](#).

To open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, click  next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor.

## Setting the breakpoints

Breakpoints are source code markers used to trigger actions during a debugging session. Typically, the purpose behind setting a breakpoint is to suspend program execution to allow you to examine program data. However, IntelliJ IDEA can use breakpoints as triggers for a variety of different actions. Breakpoints can be set at any time during the debugging process. Your breakpoints don't affect your source files directly, but the breakpoints and their settings are saved with your IntelliJ IDEA project so you can reuse them across debugging sessions.

1. Place the caret on the desired line of the source code.
  - Breakpoints can be set in the PHP context inside `*.php`, `*.html`, and files of other types. Line breakpoints can be set only on executable lines, but not on comments, declarations, or empty lines.
2. Do one of the following:
  - Click the left gutter area at a line where you want to toggle a breakpoint.
  - On the main menu, choose [Run | Toggle Line Breakpoint](#).
  - Press `Ctrl+F8`.

## Generating the Start Debugger/Stop Debugger bookmarklets

These bookmarklets will appear on the toolbar of your browser. They provide control over the debugger cookie, through them you will activate and deactivate the debugger.

1. Enable the **Bookmarks toolbar** in your browser by doing one of the following depending on the browser type:
  - In **Firefox**, choose *View | Toolbar | Bookmarks Toolbar*.
  - In **Chrome**, choose *Bookmarks | Showbookmarks bar*.
2. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing *File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS*. Expand the **Languages & Frameworks** node, and then click **Debug** under **PHP**.
3. On the **Debug** page, that opens, click the **Use debugger bookmarklets** to initiate debugger from your favorite browser link.
4. On the **Zend Debugger & Xdebug bookmarklets** page that opens, check the debugging engine settings and click **Generate**. The bookmarks for listed debugging-related actions are generated.
5. Drag the generated links to the bookmark toolbar in your browser.

## Initiating a debugging session and examining the suspended program

1. Generate the bookmarklets to toggle the debugger through. These bookmarklets will appear on the toolbar of your browser. They provide control over the debugger cookie, through them you will activate and deactivate the debugger.
  1. Enable the **Bookmarks toolbar** in your browser by doing one of the following depending on the browser type:
    - In **Firefox**, choose *View | Toolbar | Bookmarks Toolbar*.
    - In **Chrome**, choose *Bookmarks | Showbookmarks bar*.
  2. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing *File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS*. Expand the **Languages & Frameworks** node, and then click **Debug** under **PHP**.
  3. On the **Debug** page, that opens, click the **Use debugger bookmarklets** to initiate debugger from your favorite browser link.
  4. On the **Zend Debugger & Xdebug bookmarklets** page that opens, check the debugging engine settings and click **Generate**. The bookmarks for listed debugging-related actions are generated.
  5. Drag the generated links to the bookmark toolbar in your browser.
2. **Set the breakpoints** where necessary.
3. Toggle the **Start Listen PHP Debug Connections** button  so it changes to . After that IntelliJ IDEA starts listening to the port of the debugging engine used in the current project. Ports for debuggers are set at the IntelliJ IDEA level in the **Debug** dialog box (*File | Settings | PHP | Debug*).
4. Open the starting page of your application in the browser, choose the **Start debugger** bookmark to activate the debugging engine from the browser, re-load the current page (the starting page of the application), and then return to IntelliJ IDEA.
5. As soon as the debugger suspends on reaching the first breakpoint, examine the application by analyzing **frames**. A **frame** corresponds to an active method or function call and stores the local variables of the called method or function, the arguments to it, and the code context that enables expression evaluation. All currently active frames are displayed on the **Frames** pane of the **Debug tool window**, where you can switch between them and analyze the information stored therein in the **Variables** and **Watches** panes. For more details, see the section **Examining Suspended Program**.
6. Continue running the program and examine its frames as soon as it is suspended again.
  - To control the program execution manually, step through the code using the commands under the **Run** menu or toolbar buttons: **Step Into** (`F7`), **Step Out** (`Shift+F8`), **Step Over** (`F8`), and others. For more details, see **Stepping Through the Program**.
  - To have the program run automatically up to the next breakpoint, resume the session by choosing **Run | Resume Program** or pressing `F9`.

## Troubleshooting

During a debugging session you may encounter one of the following problems:

### No Path Mappings are Configured

In some cases you may get one of the following error messages: **Remote file path path/to/script/on/the/server.php is not mapped to any file path in project** or **The script path/to/script/on/the/server.php is outside the project**. This means that IntelliJ IDEA is not sure which local file corresponds to the specified remote file path because you have not specified the path mappings in the **Debug server configuration**.

Even if path mappings in a **Debug Server** configuration look very similar to path mappings in a **Deployment** configuration, they cannot be reused, because **Deployment** configurations require paths to be relative, and **Debug Server** configurations rely on absolute paths.

Click the link and configure path mappings in the dialog box that opens, as described in **Creating a PHP Debug Server Configuration**.

### No Debug Server is Configured

If you initiate a debugging session without having configured a **Debug server**, upon establishing connection IntelliJ IDEA displays the **Incoming Connection Dialog** where suggests importing mappings from a **server access configuration** (**deployment configuration**). If you choose **Import mappings from deployment**, IntelliJ IDEA tries to detect the most suitable deployment configuration, preselects it in the **Deployment** drop-down list, and the **Preview** area shows the absolute path to

the project file which corresponds to the currently executed script according to the mappings from the selected configuration.

If IntelliJ IDEA does not detect a relevant configuration:

1. Choose the most suitable configuration from the drop-down list or click  and create a new configuration in the **Deployment** dialog box that opens, whereupon the new configuration is added to the list.
2. In the Deployment root text box, type the absolute path to the server root folder.

You can also select the Manually choose local file or project option, in this case IntelliJ IDEA displays the project tree view where you can select a project file and map the currently executed script to it. You can also select and map the entire project.

To continue debugging with the imported or manually specified configuration settings, click **Accept**.

## A Script Is not Suspended

Establishing a **Zero-Configuration** debugging session may fail, with no breakpoints hit and therefore the script not suspended. This may happen if the path mappings are not configured or configured erroneously, or if you have not set any breakpoints. In the latter case, enabling selecting the **Break at First Line in PHP Scripts** checkbox in the **External Connections** area or turning the **Run | Break at First Line in PHP Scripts** option on the main menu may also help.

To have IntelliJ IDEA display a notification if the script is not suspended, select the **Notify if debug session was finished without being stopped** checkbox in the **Advanced Settings** area on the **Debug** page of the **Settings** dialog box.

## Specifying the scripts to skip requests to

This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the **skipped paths** list. You can also group such scripts into folders and add these folders to the "ignore list".

1. Open the **Settings / Preferences Dialog** by pressing **Ctrl+Alt+S** or by choosing **File | Settings for Windows and Linux** or **IntelliJ IDEA | Preferences for macOS**. Expand the **PHP** node under **Languages & Frameworks**, and then click **Skipped Paths** under **Debug**.
2. On the **Skipped Paths** page that opens, configure an "ignore list" of scripts and folders with scripts not to be invoked if IntelliJ IDEA receives incoming connections to them.
  - To add a new entry to the list, click the **Add** button  or press **Alt+Insert**. Then click the **Browse** button  and in the dialog box that opens choose the file or folder to skip connections to.
  - To remove an entry from the list, select it and click the **Remove** button  or press **Alt+Delete**. The script will be now executed upon receiving requests to it.
3. To have IntelliJ IDEA inform you every time it receives a request to a script to be skipped, select the **Notify about skipped paths** checkbox.

## Starting a debugging session from the command line

You can start debugging a PHP CLI script from the command line, having IntelliJ IDEA listen for incoming debugger connections.

1. **Set the breakpoints** where necessary.
2. On the toolbar, toggle the **Start Listening for PHP Debug Connections** button or choose **Run | Start Listening for PHP Debug Connections** on the main menu.
3. Start the script with debugger options depending on the debugging engine you are using - Xdebug or Zend Debugger.

## Starting a Script with Xdebug

Xdebug has various [configuration options](#) which can be used to let the PHP interpreter reach out to IntelliJ IDEA. These parameters have to be passed to the PHP interpreter using the `-d` command line switch. A more convenient is to set an environment variable you do not need to provide the `-d` switches all the time.

Do one of the following:

- Launch PHP with several switches:

```
php -dxdebug.remote_enable=1 -dxdebug.remote_mode=req -dxdebug.remote_port=9000 -dxdebug.remote_host=1
```

- Set an environment variable that configures Xdebug:

- `set XDEBUG_CONFIG="remote_enable=1 remote_mode=req remote_port=9000 remote_host=127.0.0.1 remote_connect_back=0"` for Windows
- `export XDEBUG_CONFIG="remote_enable=1 remote_mode=req remote_port=9000 remote_host=127.0.0.1 remote_connect_back=0"` for Linux and macOS

## Starting a script with Zend Debugger

Zend Debugger has various [configuration options](#) which can be used to let the PHP interpreter reach out to IntelliJ IDEA. These parameters have to be passed to the PHP interpreter using an environment variable:

- `set QUERY_STRING="start_debug=1&debug_host=127.0.0.1&no_remote=1&debug_port=10137&debug_stop=1"` for Windows
- `export QUERY_STRING="start_debug=1&debug_host=127.0.0.1&no_remote=1&debug_port=10137&debug_stop=1"` for Linux and macOS

## Configuring path mappings

To tell IntelliJ IDEA which path mapping configuration should be used for a connection from a certain machine, set the value of the `PHP_IDE_CONFIG` environment variable to `serverName=SomeName`, where `SomeName` is the name of the **debug server configuration** defined on the [Servers](#) page, see [Creating a PHP Debug Server Configuration](#). Depending on the operating system you are using, set the value in one of the following formats:

- `set PHP_IDE_CONFIG="serverName=SomeName"` for Windows
- `export PHP_IDE_CONFIG="serverName=SomeName"` for Linux and macOS

## Troubleshooting

- The **debug server configuration** is not specified through the `PHP_IDE_CONFIG` environment variable. In this case, IntelliJ IDEA detects the host and port from `$_SERVER['SSH_CONNECTION']` and suggests to create a new **debug server configuration** if it doesn't exist. This works for all connections through **ssh** even without a tunnel.
- The **debug server configuration** is not specified through the `PHP_IDE_CONFIG` environment variable and `$_SERVER['SSH_CONNECTION']` is not defined. In this case, a warning is displayed with a link to the instruction in specifying the **debug server configuration** through the `PHP_IDE_CONFIG` environment variable.
- The **debug server configuration** is specified through the `PHP_IDE_CONFIG` environment variable but a wrong format is used, IntelliJ IDEA displays an error message with the instructions.
- The `PHP_IDE_CONFIG` environment variable is configured properly, but the specified **debug server configuration** doesn't exist, IntelliJ IDEA displays a warning with a link to the [Servers](#) page.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Besides debugging the entire application, you can debug separate [HTTP Requests](#). This is helpful when you are actually interested in a specific page that is accessed in a number of steps, but for this or that reason you cannot specify this page as the start page for debugging, for example, because you need to "come" to this page with certain data.

Debugging PHP HTTP requests in IntelliJ IDEA is supported through the [PHP HTTP Request](#) run configuration. Based on the configuration settings, IntelliJ IDEA composes the request to run.

On this page:

- [Preparing the debugging engine](#)
- [Setting the breakpoints](#)
- [Creating a debug configuration of the type PHP HTTP Request](#)
- [Initiating a debugging session and examining the suspended program](#)

## Preparing the debugging engine

Before you start debugging, make sure that you have a debugging engine installed and configured properly. IntelliJ IDEA supports debugging with two most popular tools: [Xdebug](#) and [Zend Debugger](#). These tools cannot be used simultaneously because they block each other. To avoid this problem, you need to update the corresponding sections in the `php.ini` file as described in [Configuring Xdebug](#) and [Configuring Zend Debugger](#).

To open the active `php.ini` file in the editor:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, click `⋮` next to the CLI Interpreter field.
3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor.

## Setting the breakpoints

Breakpoints are source code markers used to trigger actions during a debugging session. Typically, the purpose behind setting a breakpoint is to suspend program execution to allow you to examine program data. However, IntelliJ IDEA can use breakpoints as triggers for a variety of different actions. Breakpoints can be set at any time during the debugging process. Your breakpoints don't affect your source files directly, but the breakpoints and their settings are saved with your IntelliJ IDEA project so you can reuse them across debugging sessions.

1. Place the caret on the desired line of the source code.  
Breakpoints can be set in the PHP context inside `*.php`, `*.html`, and files of other types. Line breakpoints can be set only on executable lines, but not on comments, declarations, or empty lines.
2. Do one of the following:
  - Click the left gutter area at a line where you want to toggle a breakpoint.
  - On the main menu, choose *Run | Toggle Line Breakpoint*.
  - Press `Ctrl+F8`.

## Creating a debug configuration of the type PHP HTTP Request

IntelliJ IDEA agglutinates the settings specified in this configuration into a PHP HTTP request.

1. Open the [Run/Debug Configuration](#) dialog box by doing one of the following:
  - On the main menu, choose *Run | Edit Configurations*.
  - Press `Shift+Alt+F10`, then press `0` to display the Edit Configuration dialog box or select the configuration from the pop-up window and press `F4`.
2. Click `+` on the toolbar or press `Insert`. From the drop-down list, select the PHP HTTP Request configuration type. The [PHP HTTP Request](#) dialog box opens.
3. Specify the configuration name.
4. In the Server drop-down list, specify the debug server configuration to interact with the Web server where the application is executed. Select one of the existing configurations or click the Browse button `⋮` and define a debug server configuration in the [Servers](#) dialog box that opens as described in [Creating a PHP Debug Server Configuration](#).
5. In the URL text box, complete the `host` element of the request to debug. Type the path relative to the host specified in the debug server configuration. As you type, IntelliJ IDEA composes the URL address on-the-fly and displays it below the text box.
6. Specify whether you want to bring any data to the target page. From the Request method drop-down list, choose the relevant request type:
  - To access the page without bringing any data, choose GET.
  - To access the page with some data saved in variables, choose POST and type the relevant variables in the Request body text box.  
By default, the [Project Encoding](#) is used in requests encoding if it is not specified explicitly, for example:

```
header('Content-type: text/html;charset=utf-8');
```

The **Project Encoding** is specified on the [File Encodings](#) page, under the **Editor** node of the [Settings / Preferences Dialog](#) .

7. In the Query text box, type the query string of the request. This string will be appended to the request after the  symbol.
8. Click OK , when ready.

## Initiating a debugging session and examining the suspended program

1. To start debugging, click the Debug button  on the toolbar.
2. As soon as the debugger suspends on reaching the first breakpoint, examine the application by analyzing **frames** . A **frame** corresponds to an active method or function call and stores the local variables of the called method or function, the arguments to it, and the code context that enables expression evaluation. All currently active frames are displayed on the Frames pane of the [Debug tool window](#) . where you can switch between them and analyze the information stored therein in the Variables and Watches panes. For more details, see the section [Examining Suspended Program](#) .
3. Continue running the program and examine its frames as soon as it is suspended again.
  - To control the program execution manually, step through the code using the commands under the *Run* menu or toolbar buttons: *Step Into* (), *Step Out* () , *Step Over* (), and others. For more details, see [Stepping Through the Program](#) .
  - To have the program run automatically up to the next breakpoint, resume the session by choosing *Run | Resume Program* or pressing 

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA supports the use of Xdebug in the **Just-In-Time (JIT)** mode so it is not attached to your code all the time but connects to IntelliJ IDEA only when an error occurs or an exception is thrown. The Xdebug operation mode is toggled through the `xdebug.remote_mode` setting, which is by default set to `req`. The mode is available both for debugging command-line scripts and for web server debugging.

In this section:

- [Configuring Xdebug for using in the Just-In-Time mode](#)
- [Command-line scripts](#)
- [Web server debugging](#)
- [Debugging session](#)

## Configuring Xdebug for using in the Just-In-Time mode

Depending on whether you are going to debug command-line scripts or use a Web server, use one of the scenarios below.

### Command-line scripts

For debugging command-line scripts, specify the custom `-dxdebug.remote_mode=jit` directive as an **additional configuration option**:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. From the PHP executable drop-down list, choose the relevant PHP interpreter and click  next to it.
3. In the [CLI Interpreters](#) dialog box that opens, click  next to the Configuration options text box in the Additional area.
4. In the Configuration options dialog that opens, click  to add a new entry, then type `-dxdebug.remote_mode` in the Configuration directive field and `jit` in the Value field.

When you click OK, you return to the CLI Interpreters dialog box where the Configuration options text box shows `-dxdebug.remote_mode=jit`.

### Web server debugging

1. On the main menu, choose *Run | Web Server Debug Validation*.
2. In the [Web Server Debug Validation Dialog](#) that opens, choose the Web server to validate the debugger on.
  - Choose Local Web Server or Shared Folder to check a debugger associated with a local Web server.
    - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. For Web servers of the type **Inplace**, the folder is under the project root. The folder must be accessible through `http`.
    - URL to Validation Script: In this text box, type the URL address of the folder where the validation script will be created. If the project root is mapped to a folder accessible through `http`, you can specify the project root or any other folder under it.
  - Choose Remote Web Server to check a debugger associated with a remote server.
    - Path to Create Validation Script: In this field, specify the absolute path to the folder under the server document root where the validation script will be created. The folder must be accessible through `http`.
    - Deployment Server: In this field, specify the server access configuration of the type [Local Server](#) or [Remote Server](#) to access the target environment. For details see [Configuring Synchronization with a Web Server](#). Choose a configuration from the drop-down list or click the Browse button  in the [Deployment dialog](#).
3. Click Validate to have IntelliJ IDEA create a validation script, deploy it to the target remote environment, and run it there.
4. Open the `php.ini` file which is reported as loaded and associated with Xdebug.
5. In the `php.ini` file, find the `[XDebug]` section and change the value of the `xdebug.remote_mode` from the default `req` to `jit`.

### Debugging session

Set the breakpoints and launch a debugging session, as described in [Initiating a Debugging Session](#) or [Debugging with a PHP Web Application Debug Configuration](#).

Xdebug connects to IntelliJ IDEA in the following two cases:

- When an error occurs. In this case, Xdebug stops on the line right after the error condition. The reason for that is that IntelliJ IDEA first has to run the erroneous code before it knows something is wrong.
- When an exception is thrown. If the exception is handled, Xdebug breaks at the first line of the `catch` block if there is one, or at the `finally` block.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Configuring PHP Exception breakpoints](#)
- [Examining the suspended program](#)

## Configuring PHP Exception breakpoints

1. On the main menu, choose Run | View Breakpoints , or press `Ctrl+Shift+F8` .
2. In the [Breakpoints](#) dialog box that opens, click `+` .
3. From the drop-down list, choose PHP Exception Breakpoint .

4. In the Add Exception Breakpoint dialog box that opens, specify the errors or exceptions on which you want the debugger to suspend.
  - To break on PHP error conditions, choose one of the standard types from the drop-down list, the available options are **Warning** , **Notice** , or **Deprecated** .
  - Alternatively, specify a **custom Exception type** . Note that `E_ERROR` , `E_PARSE` , and `E_COMPILE_ERROR` are not handled as they halt execution of the PHP engine.

Click OK when ready.

IntelliJ IDEA returns you to the Breakpoints dialog box.

5. Configure the new exception breakpoint as described in [Configuring Breakpoints](#) .

## Examining the suspended program

When the debugger breaks on an error or an exception, IntelliJ IDEA sets a **PHP Exception Breakpoint** .

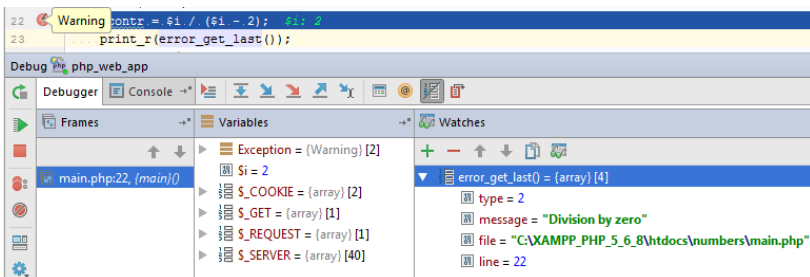

- To see the breakpoint type, hover the mouse pointer over the breakpoint. The type is displayed in a pop-up window:

- The Variables pane displays a fake **Exception** variable which shows the exception message and the exception code:

- To get more information on PHP errors, add a **watch** for the `error_get_last()` function, see [Adding, Editing and Removing Watches](#) . Then the details of errors will be displayed in the Watches pane:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

When using Xdebug, you can debug PHP applications in the multiuser mode via [Xdebug proxy](#) servers.

## To enable multiuser debugging via an Xdebug proxy server

1. Open the active `php.ini` file in the editor:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
  2. On the [PHP](#) page that opens, click  next to the CLI Interpreter field.
  3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor .
2. Locate the `xdebug.idekey` setting and assign it a value of your choice.
3. Configure access to the required Xdebug proxy server from your IDE:
  - To register your IDE to the server choose Tools | Xdebug Proxy | Register IDE on the main menu. In the [Xdebug Proxy](#) dialog box, that opens, specify the `xdebug.idekey` , the host on which the Xdebug proxy server resides, and the port which IntelliJ IDEA will listen to during a proxy debugging session. When you click OK , IntelliJ IDEA connects to the specified proxy server and sends the specified credentials. The server registers the credentials and sends a confirmation.
  - To update the credentials, choose Tools | Xdebug Proxy | Configuration on the main menu. In the [Xdebug Proxy](#) dialog box, that opens, edit the IDE key, the host, and the port settings.
  - To discard the current credentials, choose Tools | Xdebug Proxy | Cancel IDE Registration on the main menu.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Besides pure debugging, you can also profile the performance of your applications. IntelliJ IDEA provides visual representation of the profiling data collected by the debugging engine you are currently using.

In this section:

- [Profiling with Xdebug](#)
  - [Enabling Profiling with Xdebug](#)
  - [Analyzing Xdebug Profiling Data](#)
- [Profiling with Zend Debugger](#)
  - [Enabling Profiling with Zend Debugger](#)
  - [Analyzing Zend Debugger Profiling Data](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Besides [interactive debugging](#), IntelliJ IDEA integration with [Xdebug](#) also supports profiling. IntelliJ IDEA provides visual representation of profiling data generated by Xdebug. You can select several snapshots at a time and collect the aggregated profiling information.

Before profiling with Xdebug, download, install and configure the components of the [PHP development environment](#). Normally, these are a PHP engine, a web server, and the Xdebug tool.

In this part:

- [Enabling Profiling with Xdebug](#)
- [Analyzing Xdebug Profiling Data](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Xdebug profiler is incorporated in the Xdebug tool. Therefore you first need to download, install, and enable Xdebug itself and after that enable the profiling functionality within it.

To enable profiling with Xdebug, perform these general steps:

- [Configuring Xdebug](#)
- [Enabling the Xdebug profiler](#)
- [Configuring the way to toggle the profiler from the browser](#)
- [Specifying the location for storing accumulated profiling data](#)

## Configuring Xdebug

1. [Download and install](#) the Xdebug tool.
2. [Integrate Xdebug with the PHP engine](#) .
3. [Integrate Xdebug with IntelliJ IDEA](#) .

## Enabling the Xdebug profiler

1. Open the active `php.ini` file in the editor:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
  2. On the [PHP](#) page that opens, click `⋮` next to the CLI Interpreter field.
  3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor .
2. Set the [xdebug.profiler\\_enable](#) directive to 1:

```
xdebug.profiler_enable = 1;
```

3. To enable toggling the profiler from the browser through control over debugger cookies, set the [xdebug.profiler\\_enable\\_trigger](#) directive to 1:

```
xdebug.profiler_enable_trigger = 1;
```

## Configuring the way to toggle the profiler from the browser

To specify the GET/POST or COOKIE parameters, do one of the following:

- [Specify the values manually](#) .
- Generate the bookmarklets to toggle the debugger through. These bookmarklets will appear on the toolbar of your browser. They provide control over the debugger cookie, through them you will activate and deactivate the debugger.
  1. Enable the **Bookmarks toolbar** in your browser by doing one of the following depending on the browser type:
    - In **Firefox** , choose *View | Toolbar | Bookmarks Toolbar* .
    - In **Chrome** , choose *Bookmarks | Showbookmarks bar* .
  2. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Debug under PHP .
  3. On the [Debug](#) page, that opens, click the Use debugger bookmarklets to initiate debugger from your favorite browser link.
  4. On the [Zend Debugger & Xdebug bookmarklets](#) page that opens, check the debugging engine settings and click Generate . The bookmarks for listed debugging-related actions are generated.
  5. Drag the generated links to the bookmark toolbar in your browser.

## Specifying the location for storing accumulated profiling data

1. Open the active `php.ini` file in the editor:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
  2. On the [PHP](#) page that opens, click `⋮` next to the CLI Interpreter field.
  3. In the CLI Interpreters dialog box that opens, the Configuration File read-only field shows the path to the active `php.ini` file. Click Open in Editor .
2. Define location for accumulating profiling snapshots by specifying the [xdebug.profiler\\_output\\_dir](#) directive.

```
xdebug.profiler_output_dir = "<output folder name>"
```

3. Specify the name of the file to store snapshots in through the value of the `xdebug.profiler_output_name` directive. The default name is `cachegrind.out.%p`, where `%p` is the name format specifier. Accept the default name or define a custom one in compliance with the following standard:

1. The name should always be `cachegrind.out`.
2. Use the [supported format specifiers](#).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

When integration with [Xdebug profiler is enabled](#), IntelliJ IDEA provides visual representation of profiler snapshots. IntelliJ IDEA opens a separate editor tab with four views where the data are presented based on different criteria.

To have the profiling data collected and analyze it, perform these general steps:

- [Initiating an Xdebug debugging session](#)
- [Retrieving the data accumulated by the profiler](#)
- [Examining the profiling data](#)

## Initiating an Xdebug debugging session

To start an Xdebug session, do one of the following:

- To start debugging an entire application, create debug configuration of the type [PHP Web Application](#), and launch debugging by clicking the Debug toolbar button .  
See [Debugging with a PHP Web Application Debug Configuration](#) for details.
- To debug a specific PHP HTTP request, define a debug configuration of the type [PHP HTTP Request](#), and launch debugging by clicking the Debug toolbar button .  
See [Debugging a PHP HTTP Request](#) for details.
- To initiate a zero-configuration debugging session:
  1. Toggle the Start Listen PHP Debug Connections button  so it changes to . After that IntelliJ IDEA starts listening to the port of the debugging engine used in the current project. Ports for debuggers are set at the IntelliJ IDEA level in the [Debug](#) dialog box ( *File* | *Settings* | *PHP* | *Debug* ).
  2. Open the starting page of your application in the browser, choose the Start debugger bookmark to activate the debugging engine from the browser, re-load the current page (the starting page of the application), and then return to IntelliJ IDEA.

## Retrieving the data accumulated by the profiler

1. On the main menu, choose *Tools* | *Analyze Xdebug Profiler Snapshot*.
  2. In the *Select Xdebug profiler snapshot* dialog box, that opens, choose the [folder and the file where the profiling data is stored](#).
- IntelliJ IDEA presents the collected profiling data in a separate editor tab with the name of the selected profiler output file.

## Examining the profiling data

When you request on the accumulated profiling data, IntelliJ IDEA opens its visualized presentation in a separate editor tab. The tab is named after the selected [profiler output file](#) and consists of several views. Switch between the views to analyze the profiling data based on various criteria of analysis.

- In the *Execution Statistics* view, examine the summary information about execution metrics of every called function.
- In the *Call Tree* view, explore the execution paths of all called functions.
- To explore the execution paths of a specific function, select the function in question in the *Call Tree* view and view its callees in the *Callees* view.
- To explore all the paths that can result in calling a specific function, select the function in question in the *Call Tree* view and examine its possible callers in the *Callers* view.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Besides [interactive debugging](#) , IntelliJ IDEA integration with [Xdebug](#) also supports profiling. IntelliJ IDEA provides visual representation of profiling data generated by Zend Debugger.

Before profiling with Zend Debugger, download, install and configure the components of the [PHP development environment](#) . Normally, these are a PHP engine, a web server, and the Zend Debugger tool.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Xdebug profiler is incorporated in the Zend Debugger tool. Therefore you only need to download, install, and enable Xdebug itself.

To enable profiling with Zend Debugger, perform these general steps:

- [Configuring Zend Debugger](#)
- [Configuring the way to toggle the profiler from the browser](#)

## Configuring Zend Debugger

1. [Download and install](#) the Zend Debugger tool.
2. [Integrate Zend Debugger with the PHP engine](#) .
3. [Integrate Xdebug with IntelliJ IDEA](#) .

## Configuring the way to toggle the profiler from the browser

To specify the GET/POST or COOKIE parameters, do one of the following:

- Generate the bookmarklets to toggle the debugger through. These bookmarklets will appear on the toolbar of your browser. They provide control over the debugger cookie, through them you will activate and deactivate the debugger.
  1. Enable the **Bookmarks toolbar** in your browser by doing one of the following depending on the browser type:
    - In **Firefox** , choose *View | Toolbar | Bookmarks Toolbar* .
    - In **Chrome** , choose *Bookmarks | Showbookmarks bar* .
  2. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing *File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS*. Expand the *Languages & Frameworks* node, and then click *Debug* under *PHP* .
  3. On the [Debug](#) page, that opens, click the *Use debugger bookmarklets* to initiate debugger from your favorite browser link.
  4. On the [Zend Debugger & Xdebug bookmarklets](#) page that opens, check the debugging engine settings and click *Generate* . The bookmarks for listed debugging-related actions are generated.
  5. Drag the generated links to the bookmark toolbar in your browser.
- Specify the values manually.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

When integration with the [Zend Debugger profiler is enabled](#), IntelliJ IDEA provides visual representation of profiler snapshots. IntelliJ IDEA opens a separate editor tab with four views where the data are presented based on different criteria.

With Zend Debugger, profiling is supported within a [zero configuration debugging session](#).

To have the profiling data collected and analyze it, perform these general steps:

- [Initiating a zero configuration Zend Debugger session](#)
- [Examining the profiling data](#)

## Initiating a zero configuration Zend Debugger session

1. Generate the bookmarklets to toggle the debugger through. These bookmarklets will appear on the toolbar of your browser. They provide control over the debugger cookie, through them you will activate and deactivate the debugger.
  1. Enable the **Bookmarks toolbar** in your browser by doing one of the following depending on the browser type:
    - In **Firefox**, choose *View | Toolbar | Bookmarks Toolbar*.
    - In **Chrome**, choose *Bookmarks | Showbookmarks bar*.
  2. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing *File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS*. Expand the **Languages & Frameworks** node, and then click **Debug** under **PHP**.
  3. On the **Debug** page, that opens, click the **Use debugger bookmarklets** to initiate debugger from your favorite browser link.
  4. On the **Zend Debugger & Xdebug bookmarklets** page that opens, check the debugging engine settings and click **Generate**. The bookmarks for listed debugging-related actions are generated.
  5. Drag the generated links to the bookmark toolbar in your browser.
2. Toggle the **Start Listen PHP Debug Connections** button so it changes to . After that IntelliJ IDEA starts listening to the port of the debugging engine used in the current project. Ports for debuggers are set at the IntelliJ IDEA level in the **Debug** dialog box (*File | Settings | PHP | Debug*).
3. Open the starting page of your application in the browser, choose the **Start debugger** bookmark to activate the debugging engine from the browser, re-load the current page (the starting page of the application), and then return to IntelliJ IDEA. Establishing a **Zero-Configuration** debugging session may fail, with no breakpoints hit and therefore the script not suspended. This may happen if the path mappings are not configured or configured erroneously, or if you have not set any breakpoints. In the latter case, enabling selecting the **Break at First Line** in **PHP Scripts** checkbox in the **External Connections** area or turning the *Run | Break at First Line in PHP Scripts* option on the main menu may also help.

To have IntelliJ IDEA display a notification if the script is not suspended, select the **Notify if debug session was finished without being stopped** checkbox in the **Advanced Settings** area on the **Debug** page of the Settings dialog box.
4. In the dialog box, that opens, select the incoming connection to profile and click **Accept**. The **Incoming Connection** from Zend Debugger dialog box appears only once, when you accept connection from this host for the first time. IntelliJ IDEA presents the collected profiling data in a separate editor tab with the name of the selected profiler output file.

## Examining the profiling data

When you request on the accumulated profiling data, IntelliJ IDEA opens its visualized presentation in a separate editor tab. The tab is named after the file that implements the page you are currently profiling and consists of several views. Switch between the views to analyze the profiling data based on various criteria of analysis.

- In the **Execution Statistics** view, examine the summary information about execution metrics of every called function.
- In the **Call Tree** view, explore the execution paths of all called functions.
- To explore the execution paths of a specific function, select the function in question in the **Call Tree** view and view its callees in the **Callees** view.
- To explore all the paths that can result in calling a specific function, select the function in question in the **Call Tree** view and examine its possible callers in the **Callers** view.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

The topics in this part provide guidelines in PHP-specific unit testing procedures. For general information on testing in IntelliJ IDEA, see the section [Testing](#) .

IntelliJ IDEA supports unit testing of PHP applications through integration with the [PHPUnit](#) tool.

Generally, IntelliJ IDEA runs and debugs PHPUnit tests same way as other applications, by running the run/debug configurations [you have created](#) . When doing so, it passes the specified test class, file, or directory to the test runner. You can run unit testing locally and remotely depending on the chosen run configuration.

### **To create and run unit tests on PHP applications, perform the following general steps:**

- [Enable PHPUnit support](#) .
- Write the unit tests to run.
- [Group the test](#) to distinguish between testing in a production and in your development environment or to enable filtering tests by their authors.
- [Create a run configuration](#) :
  - To run unit tests locally, create a [PHPUnit](#) configuration.
  - To run unit tests on a remote server, create a [PHPUnit by HTTP](#) configuration.
- [Launch unit tests](#) by clicking the Run toolbar button  and [monitor test results](#) in the [Run tool window](#) .
- Launch unit tests with coverage by clicking the Run with coverage toolbar button  and analyze the test coverage in the [Coverage Tool Window](#) .
- Debug unit tests by setting breakpoints where necessary and clicking the Debug toolbar button  . For details, see [PHP Debugging Session](#) .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports unit testing of PHP applications through integration with the [PHPUnit](#) tool.

## Before you start

1. Make sure the **PHP** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).
2. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#), as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#).

## Where do I get PHPUnit from?

**Tip** Alternatively choose *Tools | Composer | Manage Dependencies* on the main menu.

**Tip** Before you start, make sure Composer is installed on your machine and initialized in the current project, see [Composer Dependency Manager](#).

### Option 1: Download phunit.phar

Download `phunit.phar` as described on [PHPUnit Official website](#) and save it on your computer:

- To get full coding assistance in addition to simply running PHPUnit tests, store `phunit.phar` under the root of the project where PHPUnit will be later used.
- If you only need to run PHPUnit tests and you do not need any coding assistance, you can save `phunit.phar` outside the project.

### Option 2: Use Composer

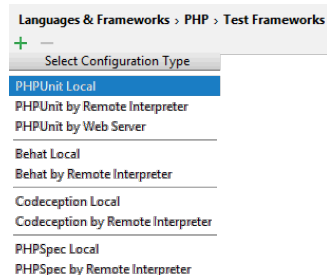

1. On the context menu of `composer.json`, choose *Composer | Manage Dependencies*.
2. In the [Manage Composer Dependencies Dialog](#) that opens, select the `phunit/phunit` package from the Available Packages list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick.  
Choose the relevant version from the *Version to install* list.
3. If necessary, expand the *Settings* hidden area and specify the advanced installation options. In the *Command line parameters* text box, type the additional command line parameters. For example, to have the package added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.
4. Click *Install*.

## How do I integrate PHPUnit with IntelliJ IDEA in a project?

### Step 1: Choose the type of configuration for PHPUnit

Open the [Settings / Preferences dialog](#) by pressing `Ctrl+Alt+S`, or alternatively choose *File | Settings* on Windows and Linux or *IntelliJ IDEA | Preferences* on macOS. Expand the *Languages and Frameworks* node and select *Test Frameworks* under *PHP*.

On the [Test Frameworks page](#) that opens, click `+` in the central pane and choose the configuration type from the list:

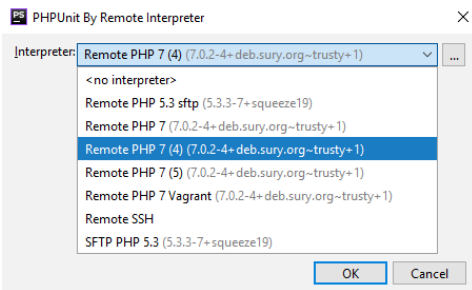

### Step 2: Choose the PHP interpreter or deployment server to use

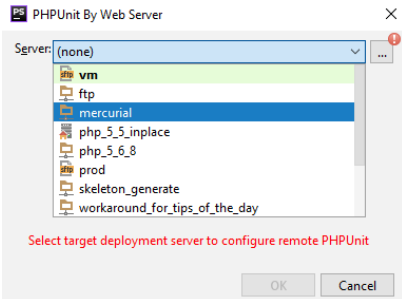

To use PHPUnit with a remote PHP interpreter or a web server, choose one of the configurations from the dialog box that opens.

- Choose a remote PHP interpreter:

– Choose a deployment configuration:

Step 3: Specify the PHPUnit installation type

In the right-hand pane, choose one of the methods:

– Option 1: Run PHPUnit downloaded via Composer

Specify the path to the `autoload.php` file in the `vendor` folder. See [PHPUnit Installation via Composer](#) and [Composer](#) for details.

– Option 2: Run PHPUnit from `phpunit.phar`

Download [phpunit.phar](#), save the archive in the project root folder, and specify the path to it. When you click , IntelliJ IDEA detects and displays the PHPUnit version.

– Option 3: Run PHPUnit from PEAR

Pear should be configured as an include path.

The PHPUnit installation procedure depends on the operating system you use and your system settings. Please, refer to the [PHPUnit installation instructions](#) for information on installing and configuring this tool.

Step 4 (optional): Specify the default configuration file

In the *Test Runner* area, appoint the configuration `xml` file to use for launching and executing scenarios.

By default, PHPUnit looks for a `phpunit.xml` configuration file in the project root folder or in the `config` folder. You can appoint a custom configuration file.

You can also type the path to a bootstrap file to have PHP script always executed before launching tests. In the text box, specify the location of the script. Type the path manually or click  and select the desired folder in the [dialog that opens](#).

**Tip** In local configurations the default project PHP interpreter is used, see [Default project CLI interpreters](#).

**Tip** Make sure Composer is set up in your project as described in [Composer Dependency Manager](#).

**Tip** For local configurations, you can download the archive by clicking the [Download](#) link. Just make sure a default PHP interpreter is defined in the current project.

## How do I generate a PHPUnit test for a class?

Step 1: Open the Generate PHPUnit Test dialog

In the Project view, select the PHP class to create unit tests for, e.g. `MyPHPClass` as shown in the image below, and choose *New | PHPUnit | PHPUnit Test* on the context menu of the selection.

## Step 2: Configure test generation

In the *Generate PHPUnit Test* dialog, specify the following:

1. The fully qualified name of the class to be tested, this name will be used to propose the *Test Class Name* . To use completion, press `Ctrl+Space` .
2. The name of the test class. IntelliJ IDEA automatically composes the name from the production class name as follows: `<production class>Test.php` . The test class name is displayed in the *Name* text box of the *Test Class* area.
3. The folder for the test class, by default the folder where the production class is stored. To specify another folder, click `...` next to the *Directory* text box and choose the relevant folder.
4. When the test is ready, navigate back to the production class by choosing *Navigate | Go to Test Subject* . For details, see [Navigating Between Test and Test Subject](#) .

## Step 3: Launch test generation

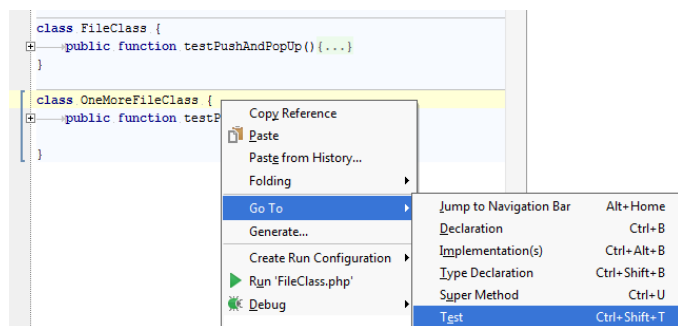

Check, accept, or update the predefined settings and click OK to initiate the test generation.

**Tip** By default, the Name text box displays the name of the class on which the test generation was invoked.

## How do I generate a test for a PHP class defined among others within a PHP file?

### Step 1: Open the Generate PHPUnit Test dialog

In the file, select the class to generate the test for and choose *Go To | Test* on the context menu, then choose *Create New Test* in the pop-up list.

### Step 2: Configure test generation

In the *Generate PHPUnit Test* dialog, proceed as described [above](#) : specify the name of the production class, the name of the test class, the name of the test file, and the folder for the test file.

Specify the namespace the test class will belong to. IntelliJ IDEA completes the namespace automatically based on the specified directory and displays the generated value in the *Namespace* text box.

When the test is ready, navigate back to the production class by choosing *Navigate | Go to Test Subject* . For details, see [Navigating Between Test and Test Subject](#) .

**Tip** Alternatively, choose *File | New | PHPUnit | PHPUnit Test* .

**Tip** When the directory is changed, the namespace is changed accordingly.

## How do I generate a PHPUnit test method?

1. Open the required test class in the editor, position the cursor anywhere inside the class definition, and choose *Generate* on the context menu, then choose *PHPUnit Test Method* from the *Generate* pop-up list.
2. Set up the test *fixture* , that is, have IntelliJ IDEA generate stubs for the code that emulates the required environment before test start and returns the original environment after the test is over:

On the context menu, choose *Generate | Override method* , then choose *SetUp* or *TearDown* in the *Choose methods to override* dialog that opens.

For more details, see [Fixtures on the PHPUnit Official website](#) .

## How do I run and debug PHPUnit tests?

You can run and debug single tests as well as tests from entire files and folders. IntelliJ IDEA creates a run/debug configuration with the default settings and launches the tests. You can later save this configuration for further re-use.

### Option 1: To run or debug a single test

Open the test file in the editor, right-click the call of the test and choose *Run '<test\_name>'* or *Debug '<test\_name>'* on the

context menu.

#### Option 2: To run or debug tests from a file

In the [Project view](#), select the file with the tests to run and choose *Run '<file\_name>'* or *Debug '<file\_name>'* on the context menu.

#### Option 3: To run or debug tests from a folder

In the Project view, select the folder with the tests to run and choose *Run '<folder\_name>'* or *Debug '<folder\_name>'* on the context menu.

#### Option 4: To save an automatically generated default configuration

After a test session is over, choose *Save <default\_test\_configuration\_name>* on the context menu of the test, test file, or folder.

#### Option 5: To run or debug tests through a previously saved run/debug configuration

Choose the required PHPUnit configuration from the list on the tool bar and click  or .

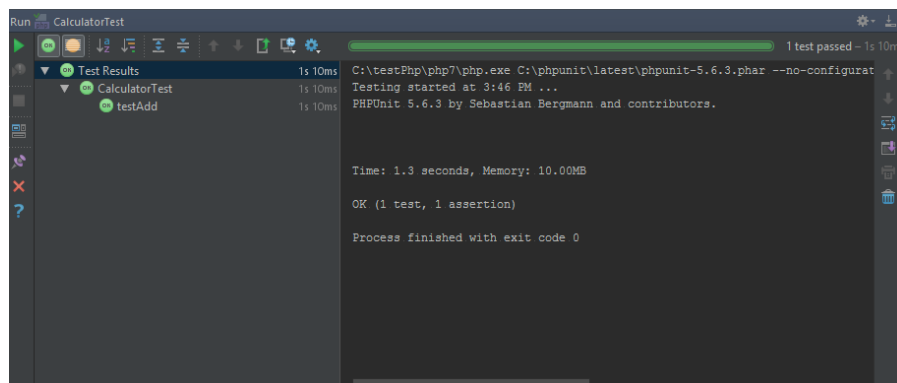

#### Option 6: To create a custom run/debug configuration

1. In the Project view, select the file or folder with the tests to run and choose *Create run configuration* on the context menu. Alternatively, choose *Run | Edit Configurations* on the main menu, then click  and choose *PHPUnit* from the list.
2. In the [Run/Debug Configuration: PHPUnit](#) dialog that opens, specify the test scope and (optionally) test runner options.

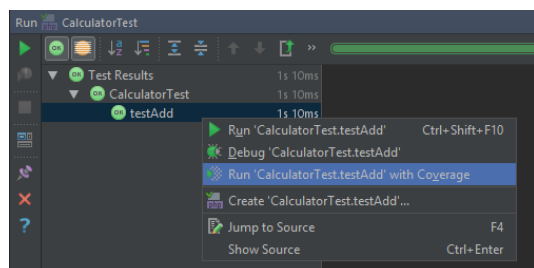

## How do I monitor test results?

IntelliJ IDEA shows the results of test execution in the [Test Runner](#) tab of the [Run Tool Window](#). The tab is divided in 2 main areas. In the left-hand area you can drill down through all unit tests to see which ones succeeded and which ones failed. In this area you can also filter tests and export results.

The right-hand area shows us the raw PHPUnit output:

Use the context menu in the left-hand area to run specific tests or navigate to the source code:

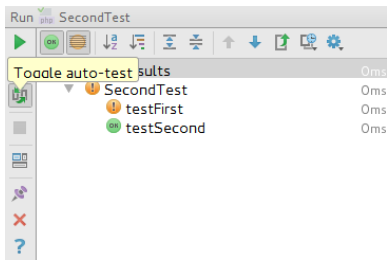

## How do I run PHPUnit tests automatically?

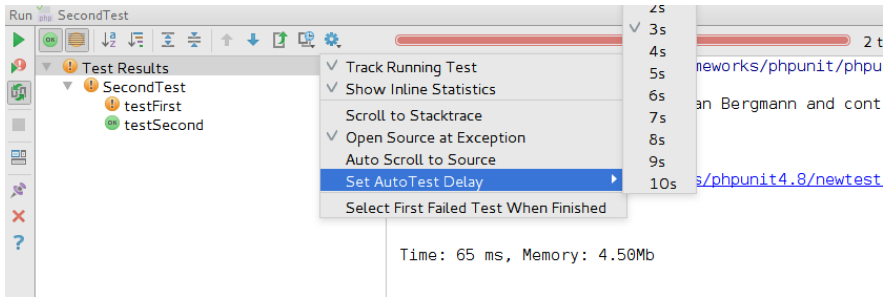

You can configure IntelliJ IDEA to re-run tests automatically when the affected code is changed. This option is configured per run/debug configuration and can be applied to a test, a test file, or a folder depending on the test scope specified in this run/debug configuration.

#### To configure re-running tests automatically

1. Run the tests.
2. In the *Test Runner* tab, press the  toggle button on the toolbar:

3. Optionally, set the time delay for launching the tests upon the changes in the code:

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you can practice behaviour-driven development by running **scenarios** using the **Behat** framework. Currently IntelliJ IDEA supports integration with [Behat 3](#) and [Behat 2](#) versions.

Native support of Behat in IntelliJ IDEA includes:

- Recognition of and coding assistance for `.feature` scenario files and `.php` scenario definition files.
- Support of [Gherkin](#) syntax in `.feature` files: `Feature`, `Scenario`, `Given`, `When`, `Then`, `And`, and `But` keywords.
- Recognition of `@given`, `@when`, and `@then` annotations in definition files.
- Setting correspondence between *scenarios* and their *definitions* through regular expressions in accordance with the [PCRE](#) standard for Behat 2.4 and PCRE+ for Behat 3.0. [Turnip expressions](#) are also welcome.

## Before you start

1. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#), as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#). Note that Behat 3 requires PHP 5.5 and higher.
2. Make sure the PHP and Behat plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

## Where do I get Behat from?

**Tip** Alternatively choose *Tools | Composer | Manage Dependencies* on the main menu.

**Tip** Before you start, make sure Composer is installed on your machine and initialized in the current project, see [Composer Dependency Manager](#).

### Option 1: Download behat.phar

1. Download `behat.phar` from the [Behat Downloads page](#).
2. Store `behat.phar` on your computer:
  - To get full coding assistance in addition to simply running Behat scenarios, store `behat.phar` under the root of the project where Behat will be later used. In this case, IntelliJ IDEA will include it in indexing, so references to Behat classes will be successfully resolved.
  - If you only need to run Behat scenarios and you do not need any coding assistance, you can save `behat.phar` outside the project.

### Option 2: Use Composer

1. On the context menu of `composer.json`, choose *Composer | Manage Dependencies*.
2. In the [Manage Composer Dependencies Dialog](#) that opens, select the `behat/behat` package from the Available Packages list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick.  
Choose the relevant version from the *Version to install* list.
3. If necessary, expand the *Settings* hidden area and specify the advanced installation options. In the *Command line parameters* text box, type the additional command line parameters. For example, to have the package added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.
4. Click *Install*.

Learn more about installing Behat from [Behat Official website](#).

## How do I integrate Behat with IntelliJ IDEA in a project?

**Tip** In local configurations the default project PHP interpreter is used, see [Default project CLI interpreters](#).

### Step 1: Choose how to use Behat

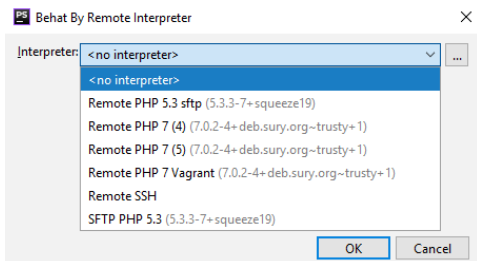

Open the [Settings / Preferences dialog](#) by pressing `Ctrl+Alt+S`, or alternatively choose *File | Settings* on Windows and Linux or *IntelliJ IDEA | Preferences* on macOS. Expand the *Languages and Frameworks* node and select *Test Frameworks* under *PHP*.

On the [Test Frameworks page](#) that opens, click `+` in the central pane and choose the configuration type from the list:

### Step 2: Choose the PHP interpreter to use

To use Behat with a remote PHP interpreter, choose one of the configurations from the dialog box that opens:

### Step 3: Specify the Behat library to use

In the *Behat Library* area, specify the location of the Behat executable file or `behat.phar` archive. Click  next to the *Path to Behat directory or phar file* text box. IntelliJ IDEA detects the version of Behat and displays it below the text box.

**Step 4: Specify the Behat configuration file to use** In the *Test Runner* area, appoint the configuration `.yaml` file to use for launching and executing scenarios.

By default, Behat looks for a `behat.yaml` configuration file in the project root folder or in the `config` folder. You can appoint a custom configuration file.

- Clear the *Default configuration file* checkbox to have Behat use the `behat.yaml` configuration file from the project root folder or from the `config` folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.
- Select the *Default configuration file* checkbox to specify your own `.yaml` configuration file. This file will be later used as default in all Behat run/debug configurations.
  - In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.

## How do I run and debug Behat tests?

For information about writing Behat features, see [http://docs.behat.org/en/latest/user\\_guide/writing\\_scenarios.html](http://docs.behat.org/en/latest/user_guide/writing_scenarios.html).

### Option 1: To run or debug Behat tests

In the Project tool window, select the feature file to run your tests from and choose *Run <feature\_name>* or *Debug <feature\_name>* on the context menu of the selection:

IntelliJ IDEA generates a default run configuration and starts a run/debug test session with it.

### Option 2: To save an automatically generated default configuration

After a test session is over, choose *Save <default\_test\_configuration\_name>* on the context menu of the feature file and choose *Save <default\_configuration\_name>* on the context menu.

### Option 3: To run or debug tests through a previously saved run/debug configuration

Choose the required Behat configuration from the list on the tool bar and click  or .

### Option 4: To create a custom run/debug configuration

1. In the Project view, select the file or folder with the tests to run and choose *Create run configuration* on the context menu. Alternatively, choose *Run | Edit Configurations* on the main menu, then click  and choose *Behat* from the list.

2. In the **Run/Debug Configuration: Behat** dialog that opens, specify the the scenarios to run and customize the behavior of the current **PHP interpreter** by specifying the options and arguments to be passed to the PHP executable file.

## How do I monitor test results?

IntelliJ IDEA shows the results of test execution in the **Test Runner** tab of the **Run Tool Window**. The tab is divided in 2 main areas. In the left-hand area you can drill down through all unit tests to see which ones succeeded and which ones failed. In this area you can also filter tests and export results.

The right-hand area shows us the raw Behat output:

Use the context menu in the left-hand area to run specific tests or navigate to the source code.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides support for running `unit`, `functional`, and `acceptance` tests with the [Codeception test framework](#), versions 2.2.0 and higher.

## Before you start

1. Make sure the `PHP` and `Codeception` plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
2. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#), as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#).

## Where do I get Codeception from?

**Tip** Alternatively choose `Tools | Composer | Manage Dependencies` on the main menu.

**Tip** Before you start, make sure Composer is installed on your machine and initialized in the current project, see [Composer Dependency Manager](#).

### Option 1: Download codeception.phar

1. Download `codeception.phar` at the [Codeception Installation page](#).
2. Save `codeception.phar` under the root of the project where Codeception will be later used. You can also save `codeception.phar` anywhere else and [configure it as an include path](#). In either case, IntelliJ IDEA will include `codeception.phar` in indexing, so IntelliJ IDEA will successfully resolve references to Codeception classes and thus provide you with full coding assistance.

### Option 2: Use Composer

1. On the context menu of `composer.json`, choose `Composer | Manage Dependencies`.
2. In the [Add Composer Dependency dialog](#) that opens, select the `codeception/codeception` package from the Available Packages list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick.  
Choose the relevant version from the `Version to install` list.
3. If necessary, expand the `Settings` hidden area and specify the advanced installation options. In the `Command line parameters` text box, type the additional command line parameters. For example, to have the package added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.
4. Click `Install`.

Learn more about installing Codeception from [Codeception Official website](#).

## How do I initialize Codeception in a project?

To generate a `codeception.yml` configuration file, open the built-in IntelliJ IDEA Terminal (`Alt+F12`) and at the command prompt type one of the following commands depending on the installation mode and your current operating system:

- If you installed `codeception.phar` in your project, type `php codecept.phar bootstrap` for Windows and macOS or `codecept bootstrap` for Linux.
- If you installed `Codeception` through `Composer`, type `codecept bootstrap` for all platforms.

## How do I integrate Codeception with IntelliJ IDEA in a project?

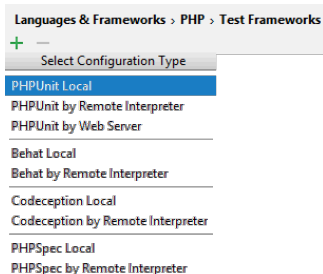

**Tip** In local configurations the default project PHP interpreter is used, see [Default project CLI interpreters](#).

### Step 1: Choose how to use Codeception

Open the [Settings / Preferences dialog](#) by pressing (`Ctrl+Alt+S`), or alternatively choose `File | Settings` on Windows and Linux or `IntelliJ IDEA | Preferences` on macOS. Expand the `Languages and Frameworks` node and select `Test Frameworks` under `PHP`.

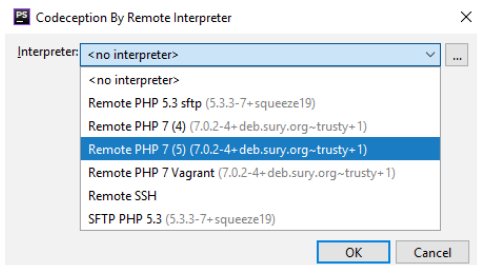

On the [Test Frameworks page](#) that opens, click `+` in the central pane and choose the configuration type from the list:

### Step 2: Choose the PHP interpreter to use

To use Codeception with a remote PHP interpreter, choose one of the configurations from the dialog box that opens:

### Step 3: Specify the Codeception library to use

In the *Codeception Library* area, specify the location of the Codeception executable file or `codeception.phar` archive in the target environment. For example, if you installed Codeception through Composer, the executable file is stored in `vendor/bin/codecept`. Click next to the *Path to Codeception directory or phar file* text box. IntelliJ IDEA detects the version of Codeception and displays it below the text box.

### Step 4: Specify the Codeception configuration file to use

In the Test Runner area, appoint the configuration `.yaml` file to use for launching and executing scenarios.

By default, Codeception looks for a `codeception.yaml` configuration file in the project root folder. You can appoint a custom configuration file.

- Clear the Default configuration file checkbox to have Codeception use the `codeception.yaml` configuration file from the project root folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.

- Select the Default configuration file checkbox to specify your own `.yaml` configuration file. This file will be later used as default in all Codeception run/debug configurations.

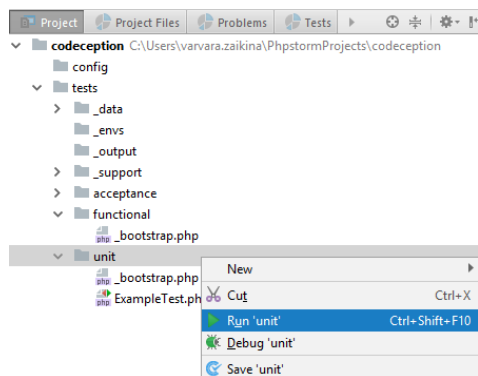

In the text box, specify the location of the configuration file to use. Type the path manually or click and choose the file in the dialog box that opens.

## How do I run and debug Codeception tests?

For information about writing Codeception tests, see [Unit Tests](#), [Acceptance Tests](#), and [Functional Tests](#). To run or debug your tests, do one of the following:

### Option 1: To run or debug Codeception tests

In the Project tool window, select the file or folder to run your tests from and choose *Run <file\_or\_folder\_name>* or *Debug <file\_or\_folder\_name>* on the context menu of the selection:

IntelliJ IDEA generates a default run configuration and starts a run/debug test session with it.

### Option 2: To save an automatically generated default configuration

After a test session is over, choose *Save <default\_test\_configuration\_name>* on the context menu of the file or folder and

choose *Save <default\_configuration\_name>* on the context menu.

Option 3: To run or debug tests through a previously saved run/debug configuration

Choose the required Codeception configuration from the list on the tool bar and click  or .

Option 4: To create a custom run/debug configuration

1. In the Project view, select the file or folder with the tests to run and choose *Create run configuration* on the context menu. Alternatively, choose *Run | Edit Configurations* on the main menu, then click  and choose *Codeception* from the list.
2. In the *Run/Debug Configuration: Codeception* dialog that opens, specify the the tests to run and customize the behavior of the current **PHP interpreter** by specifying the options and arguments to be passed to the PHP executable file.

## How do I monitor test results?

IntelliJ IDEA shows the results of test execution in the *Test Runner* tab of the *Run Tool Window*. The tab is divided in 2 main areas. In the left-hand area you can drill down through all unit tests to see which ones succeeded and which ones failed. In this area you can also filter tests and export results.

The right-hand area shows us the raw Codeception output:

Use the context menu in the left-hand area to run specific tests or navigate to the source code.

This feature is only supported in the Ultimate edition.

With IntelliJ IDEA, you can practice behaviour-driven development by running **specifications** using the **PHPSpec** toolset.

## Before you start

1. Make sure the **PHP** and **PHPSpec** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
2. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#) , as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#) .

## How do I install PHPSpec using Composer in IntelliJ IDEA?

**Tip** Before you start, make sure Composer is installed on your machine and initialized in the current project, see [Composer Dependency Manager](#) .

**Tip** Alternatively choose **Tools | Composer | Manage Dependencies** on the main menu.

1. On the context menu of `composer.json` , choose **Composer | Manage Dependencies** .
2. In the **Manage Composer Dependencies Dialog** that opens, select the `phpspec/phpspec` package from the Available Packages list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick.  
Choose the relevant version from the *Version to install* list.
3. If necessary, expand the Settings hidden area and specify the advanced installation options. In the Command line parameters text box, type the additional command line parameters. For example, to have the package added to the `require-dev` section instead of the default `require` section, type `--dev` . For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md> .
4. Click **Install** .

Learn more about PHPSpec installation from [PHPSpec Official website](#) .

## How do I integrate PHPSpec with IntelliJ IDEA in a project?

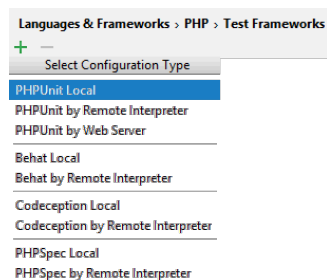

**Tip** In local configurations the default project PHP interpreter is used, see [Default project CLI interpreters](#) .

**Tip** If no path to PHPSpec is specified for a *Local* interpreter, IntelliJ IDEA does not provide full support of PHPSpec, for example, it does not show suggestion for code completion and does not resolve references.

### Step 1: Choose how to use Codeception

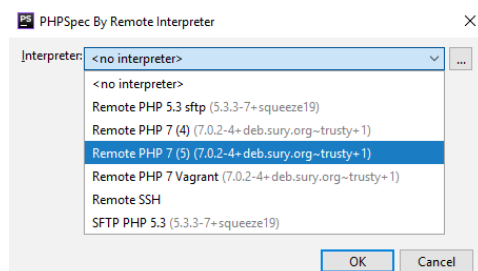

Open the **Settings / Preferences dialog** by pressing `Ctrl+Alt+S` , or alternatively choose **File | Settings** on Windows and Linux or **IntelliJ IDEA | Preferences** on macOS. Expand the **Languages and Frameworks** node and select **Test Frameworks** under **PHP** .

On the **Test Frameworks page** that opens, click **+** in the central pane and choose the configuration type from the list:

### Step 2: Choose the PHP interpreter to use

To use PHPSpec with a remote PHP interpreter, choose one of the configurations from the dialog box that opens:

### Step 3: Specify the PHPSpec library to use

In the *Path to PHPSpec executable* text box, specify the location of `phpspec`. PHPSpec does not necessarily have to be installed under the current project root. Click  next to the *Path to PHPSpec directory or phar file* text box. IntelliJ IDEA detects the version of PHPSpec and displays it below the text box.

### Specify the PHPSpec configuration file to use

In the Test Runner area, appoint the configuration `.yaml` file to use for launching and executing specifications.

By default, PHPSpec looks for a `phpspec.yaml` or a `phpspec.yaml.dist` configuration file in the project root folder. You can appoint a custom configuration file.

- Clear the Default configuration file checkbox to have PHPSpec use the `phpspec.yaml` or `phpspec.yaml.dist` configuration file from the project root folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.
- Select the Default configuration file checkbox to specify your own `.yaml` configuration file. This file will be later used as default in all PHPSpec run/debug configurations.

In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.

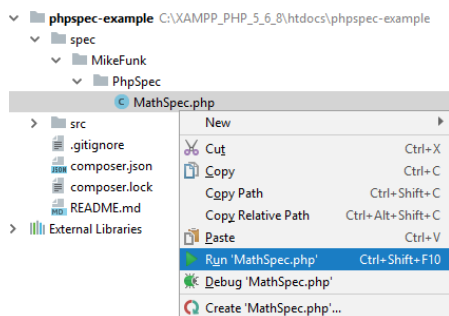

In local configurations, the *Prefix ('spec\_prefix')*: read-only field shows the namespace prefix for specifications. IntelliJ IDEA detects `spec_prefix` from the configuration file specified in the *Default Configuration File* field. The default value is `spec`. See [PHPSpec Configuration: PSR-4](#) and [PHPSpec Configuration: Spec and Source Location](#) for details.

## How do I run and debug PHPSpec tests?

For information about writing PHPSpec specifications, see <http://www.phpspec.net/en/stable/manual/getting-started.html#specifying-behaviour>. To run or debug your tests, do one of the following:

### Option 1: To run or debug PHPSpec tests

In the Project tool window, select the file or folder to run your tests from and choose *Run <file\_or\_folder\_name>* or *Debug <file\_or\_folder\_name>* on the context menu of the selection:

IntelliJ IDEA generates a default run configuration and starts a run/debug test session with it.

### Option 2: To save an automatically generated default configuration

After a test session is over, choose *Save <default\_test\_configuration\_name>* on the context menu of the file or folder and choose *Save <default\_configuration\_name>* on the context menu.

### Option 3: To run or debug tests through a previously saved run/debug configuration

Choose the required PHPSpec configuration from the list on the tool bar and click  or .

### Option 4: To create a custom run/debug configuration

1. In the Project view, select the file or folder with the tests to run and choose *Create run configuration* on the context menu. Alternatively, choose *Run | Edit Configurations* on the main menu, then click  and choose *PHPSpec* from the list.
2. In the *Run/Debug Configuration: PHPSpec* dialog that opens, specify the tests to run and customize the behavior of the current PHP interpreter by specifying the options and arguments to be passed to the PHP executable file.

## How do I monitor test results?

IntelliJ IDEA shows the results of test execution in the *Test Runner* tab of the *Run Tool Window*. The tab is divided in 2 main areas. In the left-hand area you can drill down through all unit tests to see which ones succeeded and which ones failed. In this area you can also filter tests and export results.

The right-hand area shows us the raw PHPSpec output: Use the context menu in the left-hand area to run specific tests or navigate to the source code.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

[Code Coverage](#) for [PHPUnit](#) shows you how much of your code is covered with tests and marks covered and uncovered lines visually right in the editor.

In this section:

- [Prerequisites](#)
- [Configuring code coverage](#)
- [Measuring code coverage](#)

## Prerequisites

1. The [PHPUnit](#) tool is [installed](#) on your machine and [enabled in IntelliJ IDEA](#) .
2. A [Xdebug](#) or [Zend Debugger](#) debugging engine is configured in the current PHP interpreter.

## To configure code coverage

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Build, Execution, Deployment | Coverage .
2. Specify coverage options on the [Coverage](#) page.

## To measure code coverage

1. Write the tests manually.
2. [Create a run configuration](#) of the type [PHPUnit](#) .
3. On the main toolbar, select the [PHPUnit](#) run configuration in the Run/Debug Configurations drop-down list and click the Run with Coverage button  .
4. [Monitor the code coverage](#) in the [Coverage](#) tool window.

In this section:

- [Blade](#)
- [PHP Command Line Tools](#)
- [Drupal](#)
- [Google App Engine for PHP](#)
- [Joomla!](#)
- [Phing](#)
- [PHP Code Sniffer](#)
- [PHP Mess Detector](#)
- [WordPress](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Overview](#)
- [Preparing to use Blade templates](#)
- [Adding, editing, and removing Blade directives](#)
- [Configuring Blade delimiters](#)

## Overview

IntelliJ IDEA provides full support of the [Laravel Blade template engine](#) up to version 5.1. This support involves:

- Highlighting of **Blade** syntax in template files.
- Code completion for all **Blade** directives, both predefined and custom, as well as for braces.
- In `@for` and `@foreach` directives, variable introduction is offered with autocompletion inside the code constructs.
- Expanding and folding sections defined through the `@section` directive. A block of code between a `@section` directive and a closing directive (for example, `@stop`) can be expanded or folded by clicking  or  in the gutter area.
- Dedicated **Blade**-specific code inspections, for example an inspection to check that a section opened with `@section` directive is closed with one of the corresponding directives.
- **Blade**-aware navigation with `Ctrl+B` includes links to templates in `@extends` and `@include` directives.
- **Finding usages** (`Alt+F7`) can be invoked on a file name or a symbol in the code to show all the usages of a template across your codebase. Currently this functionality is available only inside other templates, but not from views.
- Customizing predefined **Blade** directives and defining custom directives for **Blade** templates.

## Preparing to use Blade templates

Before you start, make sure the **PHP** and **Blade** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

## Adding, editing, and removing Blade directives

In IntelliJ IDEA, **Blade** directives are managed in the Directives tab of the [Blade Page](#). The tab lists all the currently available **Blade** directives, for those that have parameters, the prefixes and suffixes are also shown. When you start, the list contains only **predefined** directives. You can edit these directives as well as create custom ones.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Blade under PHP. On the [Blade](#) page that opens, switch to the Directives tab. The tab shows a list of all currently available directives.
2. Do one of the following:
  - To define a new directive, click the Add directive button  and then specify the directive's name in the Name text box. If the new directives requires a prefix and a suffix, select the Has parameter checkbox and type the prefix and suffix to use in the Prefix and Suffix text boxes respectively. IntelliJ IDEA will automatically enclose the prefix and suffix in opening and closing brackets and quotes and add a colon separator `:` so the parameters will look as follows: `("<prefix>:<suffix>")`.
  - To edit an existing directive, select it in the list and change the values in the text boxes below. To restore the original definition, click the Reset to defaults button .
  - To remove a directive from the list, select it and click the Remove directive button .

## Configuring Blade delimiters

IntelliJ IDEA recognizes **Blade** templates and provides error highlighting and code completion for them based on the **delimiters** you specify. These delimiters are managed in the Text Tags tab of the [Blade Page](#).

The fields in the tab show the opening and closing characters for [raw tags](#), [content tags](#), and [escaped tags](#).

The fields are filled in with the default values in compliance with [Blade Templates 5.1](#). If you are using an earlier version, you can specify the relevant custom delimiters and IntelliJ IDEA will provide coding assistance according to the new rules.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports running commands of popular third-party or user-defined PHP tools: [Symfony 1.1+](#) , [Symfony2](#) , [Zend Framework 1](#) , [Zend Framework 2 \(ZFTool\)](#) , [Yii](#) , [Composer](#) , [Drush 5.8+](#) , [Laravel](#) and [Doctrine](#) (Symfony console-based), [WordPress Command Line Interface](#) .

Check the [Command Line Tools Tutorial](#) for step-by-step guidance and examples of using command line tools with IntelliJ IDEA.

**Tip** Before you start, install and enable the PHP and Command Line Tool Support repository plugins on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) .

On this page:

- [How do I integrate an external PHP command line tool with IntelliJ IDEA?](#)
- [How do I run a command?](#)
- [How do I customize a tool?](#)
- [How do I define my own command line tool?](#)
- [How do I keep a tool descriptor consistent?](#)

## How do I integrate an external PHP command line tool with IntelliJ IDEA?

1. Download and install the tool
2. Choose the tool type and visibility

Open the [Command Line Tool Support](#) page ( *File | Settings | Tools | Command Line Tool Support* for Windows and Linux or *IntelliJ IDEA | Preferences | Tools | Command Line Tool Support* for macOS). Click  on the toolbar and in the *Command Line Tools* dialog choose the name of the tool from the list. In the *Visibility* area, specify whether you want to use the tool in the current project or globally, in any IntelliJ IDEA project, and click *OK* .

3. Specify the tool alias

In the *Alias* text box, accept the default alias to use in calls of tool commands or edit it, if necessary.

4. Optionally customize the command set

See [How do I customize a tool?](#) for details.

## How do I run a command?

1. Open the Input pane

On the main menu, choose *Tools | Run Command* . The pane opens as a pop-up window or as a text box at the bottom of the [Command Line Tools Console](#) tool window.

2. Invoke the command

Type the call of the command in the format `<tool alias> <command>` . The result of command execution is shown in the *Output* tab with the name of the command.

3. Save the command output

Click  on the toolbar of the *Output* tab. In the *Export Preview* dialog that opens, specify the text file to store the output in or click *Copy* to save the output in the clipboard.

4. To terminate a command

Click  on the toolbar. If the *Output* tab is already closed, kill the current thread from the progress bar.

**Tip** If the file with this name and location already exists, choose to overwrite its contents with the new data or to append the new data to the existing file.

## How do I customize a tool?

1. Open the tool definition file

On the [Command Line Tool Support](#) page, select the tool in the list and click  on the toolbar. The `.xml` tool descriptor opens in the editor.

2. Update the definitions of the commands

As you type, `.xml` tool descriptor is [checked for well-formedness](#) on the fly.

3. Reload the command definitions

On the [Command Line Tool Support](#) page, select the tool in the list and click  on the toolbar.

**Tip** Reloading commands is currently supported only for Symfony.

## How do I define my own command line tool?

1. Create a tool definition file
2. Create a custom IntelliJ IDEA tool

Open the [Command Line Tool Support](#) page ( *File | Settings | Tools | Command Line Tool Support* for Windows and Linux or *IntelliJ IDEA | Preferences | Tools | Command Line Tool Support* for macOS). Click **+** on the toolbar and in the *Command Line Tools* dialog box that opens, select *Custom tool* from the *Choose tool* list, and [specify the visibility level](#) for it (Project or Global).

3. Specify the tool definition file and alias

In the [Tool Settings](#) dialog, type the path to the tool definition file, the tool alias, and provide a brief description of the tool.

When you click *OK*, IntelliJ IDEA brings you to the [Command Line Tool Support](#) page, where the new tool is added to the list.

4. Choose where to show the Input pane

See [Choose the Input pane location](#) above.

5. Open the tool definition file

Select the newly created tool and click . The tool definition `.xml` file opens in the editor.

6. Define the tool commands.

## How do I keep a tool descriptor consistent?

### Option 1: On-the-fly validation

Every time you edit a command definition in the `.xml` tool descriptor, IntelliJ IDEA [checks it for well-formedness](#) on the fly.

### Option 2: Full validation

[Full validation](#) is performed every time you invoke a command. If any inconsistencies are detected, the tool is marked with the *Invalid description* icon  on the [Command Line Tool Support](#) page.

### To run full validation

1. Open the Input pane

On the main menu, choose *Tools | Run Command*. The pane opens as a pop-up window or as a text box at the bottom of the [Command Line Tools Console](#) tool window.

2. Invoke validation

Type the call of a command and in the *Tool definition file errors* tab, analyze the notifications on detected structure inconsistencies. Each notification shows a brief description of the problem, the file and the line number where the problem is detected.

By default, the tab is hidden and opens when you click *More* in the *Command Line Tool* pop-up window with an error notification. To close the tab, click the cross on its header. To re-open it, click *More* once again.

**Tip** The location of the pane depends on the *Show console in* setting on the [Command Line Tool Support](#) page, see [Choosing where to show the Input pane](#).

**Tip** The *Command Line Tool* pop-up window remains on the screen until you close it manually.

This feature is only supported in the Ultimate edition.

You can use IntelliJ IDEA as an IDE for [Drupal](#) development including modules, themes, and core. The supported versions are 6, 7, and 8.

IntelliJ IDEA provides integration between the Symfony2 and Drupal 8 while developing Drupal modules and core.

## Before you start

Install and enable the PHP and Drupal Support repository plugins on the [Plugins settings](#) page as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Where do I get Drupal from?

Download Drupal from the [Drupal Official website](#) and install it as described in the [Drupal installation instructions](#).

## How do I set up a Drupal project in IntelliJ IDEA?

### Option 1: Create a IntelliJ IDEA project with a Drupal module

You can create a IntelliJ IDEA project by a Drupal Module template, this project will be set up and configured in accordance with the Drupal requirements.

#### 1. Open the New Project dialog

Choose *File | New | Project* or click *Create NewProject* on the Welcome screen.

#### 2. Choose the project type and location

In the left-hand pane, click PHP from the list, then choose Drupal Module in the right-hand pane, and then click *Next*. On the second page of the wizard, specify the project name and the folder where it will be created.

#### 3. Choose Drupal installation to use

Specify the root folder of the Drupal installation and choose the version of Drupal to use, the supported versions are 6, 7, and 8.

#### 4. Configure Include paths

Select the *Set up PHP | Include paths* checkbox to have Drupal include paths automatically configured for the project.

After you leave the dialog box, the following paths will be added to the *Include Paths* list on the [PHP](#) page: `<drupal installation root>/includes`, `<drupal installation root>/modules`, and `<drupal installation root>/sites/all/modules`

**Tip** IntelliJ IDEA generates and configured a project stub in accordance with the selected Drupal version. For Drupal 8, a `module_name.info.yml` file is generated.

**Tip** Later you can change the Drupal installation and re-configure the include paths on the [Frameworks](#) page as described in [How do I change Drupal settings?](#)

### Option 2: Import an existing Drupal module

When you open an existing Drupal module, IntelliJ IDEA recognizes the Drupal-specific structure and suggests activating the Drupal support.

#### 1. Open your project

Click *Open* on the Welcome screen or choose *File | Open* on the main menu, then choose the folder where your Drupal module is stored. IntelliJ IDEA detects a Drupal-specific structure and shows a notification:

**Drupal Support**  
Looks like it's Drupal module. [Enable Drupal support?](#) Or [do not ask again?](#)

#### 2. Enable Drupal support

Click *Enable* in the notification. In the *Drupal Module* dialog box that opens, select the *Enable Drupal integration* checkbox and proceed as when creating a project with a Drupal module: specify the root folder of the Drupal installation, choose the version to use, and configure include paths.

Whether you enable the Drupal support in an existing IntelliJ IDEA project or create a new project with a Drupal module, IntelliJ IDEA checks if the development environment is configured properly for Drupal development.

Any detected inconsistency is reported in the *Event Log* tool window and as a pop-up. For each discrepancy IntelliJ IDEA suggests a fix. To apply a suggestion, click the link next to the reported event.

```

EventLog
12:44:19 PM Drupal Support: Drupal-style formatting can be set for this project. Set it?
12:44:19 PM Drupal Support
Changed PHP | Include paths.
Added:
C:/DRUPAL/drupal-7.23/includes
C:/DRUPAL/drupal-7.23/modules
C:/DRUPAL/drupal-7.23/sites/all/modules
12:44:19 PM Drupal Support: *.theme, *.profile, *.install, *.test files
are not associated with PHP file type. Fix?
12:44:19 PM Drupal Support: *.info files are not associated with Ini file type. Fix?

```

## How do I associate Drupal-specific files with the PHP file type?

IntelliJ IDEA recognizes and treats files as `php` files and provides code highlighting based on file type associations.

### Option 1: Use the Event log

In the *Event Log* tool window, click *Fix* next to the `Drupal support: <*.file extension> files are not associated with PHP file type` message.

### Option 2: Use the File Types page

Open the [File Types page](#) (*File | Settings | Editor | File Types* for Windows and Linux or *IntelliJ IDEA | Preferences | Editor | File Types* for macOS) and define file masks in the *Registered Patterns* area. See [Creating and Registering File Types](#) for details.

## How do I change the Drupal settings?

### Option 1: Enable or disable Drupal integration

On the [Frameworks page](#) (*File | Settings | Languages and Frameworks | PHP | Frameworks* for Windows and Linux or *IntelliJ IDEA | Preferences | Languages and Frameworks | PHP | Frameworks* for macOS), toggle the *Enable Drupal integration* checkbox to activate or deactivate Drupal in the current IntelliJ IDEA project.

To use another Drupal installation, type the path to the relevant installation folder. Change the version if necessary.

### Option 2: Update the include paths

On the [PHP page](#) (*File | Settings | Languages and Frameworks | PHP* for Windows and Linux or *IntelliJ IDEA | Preferences | Languages and Frameworks | PHP* for macOS), make the required changes in the *Include Paths* area.

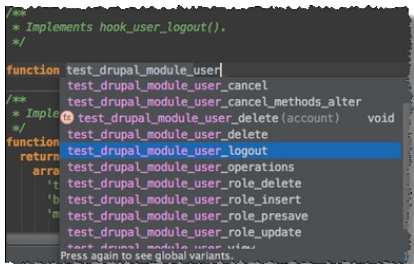

**Tip** If the Drupal integration is disabled, the paths are automatically excluded.

## How do I use Drupal hooks in IntelliJ IDEA?

IntelliJ IDEA provides full native support of [Drupal hooks](#) in `.module` files.

### Step 1: Use code completion for hoo declarations

IntelliJ IDEA indexes any hook invocation whereupon hook names become available in code completion for creating hook implementations. To complete a declaration, start typing the hook name and press `Ctrl+Space`.

### Step 2: Navigate to hook invocations

- To navigate to a hook invocation from the editor, click the icon in the gutter.
- In case of multiple invocations, IntelliJ IDEA displays a list of available hook invocations so you can choose which one to jump to.

You will be navigated to the line where the relevant hook is invoked with `module_invoke_all()`, `module_invoke()`, or `drupal_alter()`.

### Step 3: View hook documentation

Position the cursor at the name of the hook in question and choose *View | Quick Documentation Lookup* or press

`Ctrl+Q`.

**Tip** Documentation is taken from `.ap1.php` files provided by `core` and many other modules for reference purposes.

## How do I set up the Drupal code style in a IntelliJ IDEA project?

IntelliJ IDEA automatically offers to apply the pre-configured Drupal Coding Standards (code style) if a project is recognized as a Drupal Module, or if the Drupal integration is enabled in an existing project, or when you create a new project with a Drupal Module. However, you can at any time change or customize this setting on the *Code Style: PHP* page of the *Settings* dialog box.

### To use the pre-configured Drupal code style in a project

In the *Event Log* tool window, click *Set* next to the `Drupal-style formatting can be set for this project` message.

**Tip** You can also set the predefined code style on the *Code Style: PHP* page (*File | Settings | Editor | Code Style | PHP* for Windows and Linux or *IntelliJ IDEA | Preferences | Editor | Code Style | PHP* for macOS); click *Set from* and choose *Predefined | Drupal*.

If applicable, customize the code style using the controls on the page.

## How do I check my code against the Drupal coding standards?

With IntelliJ IDEA, you can use two tools that detect violations against the Drupal coding standard: *Coder* and *PHP Code Sniffer*. They ensure your code remains clean and consistent and help prevent some common semantic errors made by developers.

### Option 1: Use PHP Code Sniffer

1. Install PHP Code Sniffer as a PEAR package or using Composer. For detailed installation instructions, see [https://github.com/squizlabs/PHP\\_CodeSniffer](https://github.com/squizlabs/PHP_CodeSniffer).
2. Register PHP Code Sniffer in IntelliJ IDEA and configure it as a IntelliJ IDEA inspection as described in [PHP Code Sniffer](#).

### Option 2: Use Coder

1. Download the [Drupal Coder module](#) (7x-2.0 version is recommended).
2. Unpack the downloaded archive and find the `coder_sniffer/Drupal` subdirectory inside. This directory should contain the `ruleset.xml` file and some other subdirectories.
3. Move the contents of `coder_sniffer/Drupal` to `<php installation folder>/CodeSniffer/Standards/Drupal`.

## How do I view the Drupal API documentation from IntelliJ IDEA?

In the IntelliJ IDEA editor, select the symbol you are interested in and choose *Search in Drupal API* on the context menu. The [Drupal API Documentation](#) opens.

## How do I use the Drush command line tool from IntelliJ IDEA?

**Tip** IntelliJ IDEA integrates with the Drush command line shell and scripting interface, version 5.8 and higher.

### Step 1: Download and install Drush

Download and install Drush as described at <https://github.com/drush-ops/drush>.

### Step 2: Configure Drush as a command line tool

1. Open the *Command Line Tool Support* page

Choose *File | Settings | Tools | Command Line Tool Support* for Windows and Linux or *IntelliJ IDEA | Preferences | Tools | Command Line Tool Support* for macOS. The *Command Line Tool Support* page opens.

2. Specify the tool type and visibility

Click *Add* and choose *Drush* in the *Choose Tool to Add* dialog. Choose whether Drush will be available in the current project (*Project* visibility) or across all IntelliJ IDEA projects (*Global* visibility). When you click *OK*, the *Drush* dialog opens.

3. Specify the Drush executable

In the *Drush* dialog that opens, IntelliJ IDEA has automatically filled in the default executable location, which is usually `C:/ProgramData/Drush/drush.bat` on Windows and `/usr/bin/drush` on macOS or Linux. If you followed the standard installation procedure, the predefined path will be correct, just click *OK*.

In case of custom installation, type the path to the Drush executable file and click *OK*.

In either case, IntelliJ IDEA loads command definitions automatically and returns to the *Command Line Tool Support* page.

4. Specify the alias for Drush

In the *Alias* text box, specify the alias to use in calls of tool commands. Accept the default alias or edit it, if necessary.

## 5. Activate Drush

Select the *Enable* checkbox to activate the detected command set.

### Step 3: Run Drush commands

Open the Input pane ( *Tools | Run Command* ) and type `<alias>` ( `drush` by default) and press `Ctrl+Space` to invoke completion. The result of command execution is shown in the *Output* tab with the name of the command. Learn more from [How do I run a command?](#) .

## How do I use Drupal 8 with Symfony2?

IntelliJ IDEA provides close integration between Drupal, version 8, and Symfony2. Through this integration, Symfony2 components are connected with Drupal infrastructure. To take advantage of this integration:

### Step 1: Install the Drupal Symfony2 Bridge plugin

Open the [Plugins page](#) ( *File | Settings | Plugins* for Windows and Linux or *@product@ | Preferences | Plugins* for macOS), click *Browse Repositories* , select the plugins and click *Install* . For details, see [Installing, Updating and Uninstalling Repository Plugins](#) and in [Enabling and Disabling Plugins](#) .

**Tip** The Drupal Symfony2 Bridge plugin depends on the Symfony2 plugin, which will be installed automatically.

### Step 2: Enable annotations

To get advanced annotations support, install the [PHP Annotations plugin](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and in [Enabling and Disabling Plugins](#) .

### What coding assistance for Drupal 8 - Symfony2 integration do I get?

- Completion for major Drupal-specific parameters in `<module_name>.info.yml` files that contain information about Drupal modules.
- Strings suitable for use inside Drupal-specific `t() function` are indexed across your project and offered for completion.
- Completion for relevant `.yml` key values in `url()` and other Drupal API functions, which makes search for the right value easier.
- Navigation to the `.yml` file by pressing `Ctrl+B` or choosing *Navigate | Go To Declaration* .
- Full support for [service containers](#) described in `.yml` files, including completion and navigation with `Ctrl+B` .
- Support of the [Twig template engine](#) , which is now the default template engine for Drupal 8, including completion, navigation, and recognition of Drupal functions. See also [Twig in Drupal 8](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

With IntelliJ IDEA, you can develop a PHP application for running in the [Google PHP Runtime Environment](#). IntelliJ IDEA supports all the major **Google App Engine for PHP** development practices and provides the possibility to run and debug your applications locally before uploading them to the runtime environment.

In this section:

- [Preparing to Develop a Google App for PHP Application](#)
- [Running, Debugging, and Uploading an Application to Google App Engine for PHP](#)

## Google App Engine support in IntelliJ IDEA

- A dedicated **project type** with a specific directory structure and configuration file.
- A dedicated **App Engine for PHP** run/debug configuration for running and debugging applications on the [PHP Development Server](#) which comes bundled with the Google App Engine for PHP SDK.
- Uploading applications using the command of the Tools menu.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA takes care of creating the specific directory structure and settings. IntelliJ IDEA can either generate a **Google App Engine for PHP** -specific project stub or you can enable support of **Google App Engine for PHP** in an existing project.

- [Before you start](#)
- [Creating a project stub of a Google App Engine for PHP application](#)
- [Activating the Google App Engine support in an existing project](#)

## Before you start

1. Download and install [Python](#) , version 2.7.
2. Download and install the [Google App Engine for PHP](#) .
3. **Install** and **enable** the Google App Engine Support for PHP plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
4. Create a Google account at <http://www.google.com> .
5. Create an application on the [Create application](#) page of the Google App Engine and remember its application ID, you will have to specify it during the creation of a project.

## Creating a project stub of a Google App Engine for PHP application

1. Choose File | New | Project on the main menu or click the New Project button on the Welcome screen.
2. In the [Project Category and Options](#) dialog, which is the first page of the New Project wizard, choose PHP in the left-hand pane.
3. In the right-hand pane, choose App Engine Project and click Next .
4. On the second page of the wizard, specify the following:
  1. The name of the project and the folder to create it in.
  2. The version of the template to use.
  3. In the Application ID text box, type the identifier of your application as you specified it on the [Create application](#) page.
  4. In the SDK directory text box, specify the path to the folder where the [Google App Engine SDK for PHP](#) is installed.
  5. The location of the Python executable file. Type the path manually in the Python executable text box or click the Browse button  and choose the Python executable in the dialog box that opens.

Click Finish when ready.

IntelliJ IDEA creates a project with the `main.php` file and the `app.yaml` configuration file. The `app.yaml` file contains the generated settings for the `runtime` (should be `php55` ), the `api_version` , the `applicationID` , the `application version` (by default is 1), the `threadsafe` element with the value `true` to enable sending multiple, parallel requests, and the `Script handlers` `url` and `script` (with the value `main.php` ).

## Activating the Google App Engine support in an existing project

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Google App Engine for PHP under PHP .
2. On the [Google App Engine for PHP](#) page that opens, select the Enable Google App Engine for PHP support checkbox and specify the following:
