Smart tabs	<ul style="list-style-type: none"><li>- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li><li>- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Tab size	In this text box, specify the number of spaces included in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.

## Set from...

Click this link to reveal the list of languages to be used as the base for the current language code style. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.

This link appears in the upper-right corner of the language-specific code style page, when applicable.

Click Reset to discard changes and return to the initial set of code style settings.

Ctrl+Alt+S 

Use this page to configure formatting options for Gherkin files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"><li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li><li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"><li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li><li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click [Reset](#).

Ctrl+Alt+S 

Use this page to configure formatting options for Groovy files. View the result in the Preview pane on the right.

## Tabs and Indents

### ItemDescription

Use tab character	<ul style="list-style-type: none"> <li>- If this checkbox is selected, tab characters are used: <ul style="list-style-type: none"> <li>- On pressing the  key</li> <li>- For indentation</li> <li>- For code reformatting</li> </ul> </li> <li>- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<ul style="list-style-type: none"> <li>- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li> <li>- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Tab size	In this text box, specify the number of spaces included in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Keep indents on empty lines	<p>If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.</p> <p>If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.</p>
Label indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted at the next line before a label statement.
Absolute label indent	If this checkbox is selected, label indentation is counted as an absolute number of spaces. Otherwise, label indentation is counted relative to previous indent levels.

## Spaces

Use this tab to specify where you want spaces in your code. To have IntelliJ IDEA automatically insert a space at a location, select the checkbox next to this location in the list. The results are displayed in the Preview pane.

## Wrapping and braces

In this tab, customize the code style options, which IntelliJ IDEA will apply on [reformatting the source code](#) . The left-hand pane contains the list of exceptions ( Keep when reformatting ), and placement and alignment options for the various code constructs (lists, statements, operations, annotations, etc.) The right-hand pane shows preview.

Alignment takes precedence over indentation options.

## Right Margin (columns)

Use the Hard wrap at field to specify a margin space required on the right side of an element. If you select Default option then a value of the right margin from the [global settings](#) is used.

## Wrap on typing

Use the Wrap on typing settings to specify how the edited text is fitted in the specified Hard wrap at . You can select one the following options:

- Default - in this case IntelliJ IDEA uses the Wrap on typing option that is specified in the [global settings](#) .
- Yes - in this case IntelliJ IDEA uses the value specified in the Right Margin field.
- No - in this case this option is switched off and a line can exceed the value specified in the right margin.

## Visual guides

Use the Visual guides field to specify multiple right margins. You can leave a default value or enter the number of spaces for your margin. If you want to specify several margins, enter numbers separated by comma.

## Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the *Line breaks* checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks check box before you [reformat the source code](#) .

## Wrapping options

The wrapping style applies to the various code constructs, specified in the left-hand pane (for example, method call arguments, or assignment statements).

## ItemDescription

- Wrapping style From this drop-down list, select the desired wrapping style:
- Do not wrap - when this option is selected, no special wrapping style is applied. With this option selected, the nested alignment and braces settings are ignored.
  - Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.
  - Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.
  - Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.

## Alignment options

### ItemDescription

Align when multiline If this checkbox is selected, a code construct starts at the same column on each next line. Otherwise, the position of a code construct is determined by the current indentation level.

<character(s)> on next line Select this checkbox to have the specified character or characters moved to the next line when the lines are wrapped.

'else' on new line Use this checkbox to have the corresponding statements or characters moved to the next line.

New line after <character> Select this checkbox to have the code after the specified character moved to a new line.

Special else if treatment If this checkbox is selected, `else if` statements are located in the same line. Otherwise, `else if` statements are moved to the next line to the corresponding indent level.

Indent case branches If this checkbox is selected, the `case` statement is located at the corresponding indent level. Otherwise, `case` statement is placed at the same indent level with `switch`.

## Braces placement options

### ItemDescription

Braces placement style Use this drop-down list to specify the position of the opening brace in class declarations, method declarations, and other types of declarations. The available options are:

- End of line - select this option to have the opening brace placed at the declaration line end.
- Next line if wrapped - select this option to have the opening brace placed at the beginning of the line after the multiline declaration line.
- Next line - select this option to have the opening brace placed at the beginning of the line after the declaration line.
- Next line shifted - select this option to have the opening brace placed at the line after the declaration line being shifted to the corresponding indent level.
- Next line each shifted - select this option to have the opening brace placed at the line after the declaration line being shifted to the corresponding indent level, and have the next line shifted to the next indent level as well.

Force braces From this drop-down list, choose the braces introduction method for `if`, `for`, `while`, and `do () while` statements. The available options are:

## Blank lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. For each type of location, specify the number of blank lines to be inserted. The results are displayed in the Preview pane.

### ItemDescription

Keep Maximum Blank Lines In this area, specify the number of blank lines to be kept after reformatting in the specified locations.

Minimum Blank Lines In the text boxes in this area, specify the number of blank lines to be present in the specified locations.

**Warning!** These settings do not influence the number of blank lines before the first and after the last item.

## Imports

This table lists actions to be performed when [imports are optimized](#).

### ItemDescription

General In this area, configure general import options. Options:

- Use single class import : Select this checkbox to have IntelliJ IDEA import only a particular class from a package during code generation or [import optimization](#). Otherwise, a statement importing an entire package is inserted.
- Use fully qualified class names : Select this checkbox to have IntelliJ IDEA use the fully qualified name of the class to be imported during code generation or [import optimization](#). Otherwise, a normal import statement is inserted.
- Insert imports for inner classes : Select this checkbox to have IntelliJ IDEA create imports for the inner classes referenced in your code.
- Use fully qualified names in Javadoc : Select this checkbox to have IntelliJ IDEA use a fully qualified class name in Javadoc. Otherwise, a class is imported.
- Class count to use import with "\*" : In this text field, specify the number of classes to be imported from a single package until all statements importing a single class are substituted with a statement importing an entire package.
- Names count to use static import with "\*" : In this text box, specify the number of members to be imported from a

single class until all statements importing a single member are substituted with a statement importing an entire class.

---

**JSP Imports Layout** In this area, configure how JSP import statements should be organized in your code. The introduced changes are displayed in the Preview pane below.

Options:

- Prefer comma separated import list : Select this option to import statements organized in a comma separated list.
- Prefer one import statement per page directive : Select this option to have one import statement created per line.

---

**Packages to Use Import with ""** In this area, configure a list of packages and classes to be always imported completely.

Options:

- Static : Select this checkbox, if you want to declare static import for the selected class.
- Package : In the text fields of this column, specify the packages and classes to be always imported completely.
- With Subpackages : Select this checkbox to have all the subpackages of the selected package imported completely.
- Add Package : Click this button to add a new entry to the list of packages and classes.
- Add Blank : Click this button to add an empty separator to the list of packages and classes.
- Remove : Click this button to delete the selected package or class from the list.

---

**Import Layout** In this area, configure how import statements should be organized in your code. You can set up certain classes to be positioned first, or last, or one after another. Imported classes will be grouped as per their packages and sorted alphabetically within a package.

Options:

- Layout static imports separately : If this checkbox is selected, all static imports will be kept in a separate section. Otherwise, all import statements will be sorted according to the specified layout rules.
- Static : Select this checkbox, if you want to declare static import for the selected package.
- Package : In the text fields of this column, specify the packages to be imported.
- With Subpackages : Select this checkbox to have IntelliJ IDEA apply the layout rules to all the subpackages of the selected package.
- Add Package : Click this button to add a new entry to the list of packages.
- Add Blank : Click this button to have a blank line inserted after the selected entry, which indicates that a blank line should be inserted between the corresponding import statements.
- Move Up / Move Down : Click these buttons to move a package or a blank line up or down in the list thus defining the order of import statements.
- Remove : Click this button to delete the selected package from the list.

Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**TIP** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Other

### ItemDescription

Right Margin	Use these settings to specify a margin space required on the right side of an element. If you select Default option then a value of the right margin from the <a href="#">global settings</a> will be used.
Wrap on typing	<p>Use these settings settings to specify how the edited text is fitted in the specified Right margin . You can select one the following options:</p> <ul style="list-style-type: none"> <li>– Default - in this case IntelliJ IDEA uses the Wrap on typing option that is specified in the <a href="#">global settings</a> .</li> <li>– Yes - in this case the value in the specified right margin is used.</li> <li>– No - in this case this option is switched off and a line can exceed the number that is specified in the right margin.</li> </ul>
Keep line breaks	Select this checkbox to have IntelliJ IDEA honor line breaks when reviewing HTML files in the editor.
Keep line breaks in text	Select this checkbox to have IntelliJ IDEA honor line breaks in attributes (for example, lengthy descriptions) when reviewing HTML files in the editor.
Keep blank lines	In this text box, specify the minimum number of sequential blank lines to be retained after reformatting.
Wrap attributes	<p>Use this drop-down list to determine how attribute lines should be wrapped. The available options are:</p> <ul style="list-style-type: none"> <li>– Do not wrap - if this option is selected, no special wrapping style is applied to the code.</li> <li>– Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.</li> <li>– Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped to give one element per line with proper indentation.</li> <li>– Wrap always - select this option to have all elements in lists wrapped to give one element per line with proper indentation.</li> </ul>
Wrap text	Select this checkbox to have long lines wrapped according to the code style settings.
Align attributes	Select this checkbox to have attributes in sequential lines aligned.
Align text	Select this checkbox to have IntelliJ IDEA align the text that occupies several lines within a tag.
Keep white spaces	Select this checkbox to suppress replacing actual white spaces with tabs.
Spaces	<p>In this area, define the use of spaces for attributes and tag names.</p> <ul style="list-style-type: none"> <li>– Around "=" in attribute - select this checkbox to have spaces added around the "=" symbol in attributes.</li> <li>– After tag name - select this checkbox to have spaces added after tag names.</li> <li>– In empty tag - select this checkbox to have spaces added in empty tags.</li> </ul>
Insert new line before	This display field shows a list of tags before which a new line should be inserted. Use the button  next to the field or press <a href="#">Shift+Enter</a> to open the Insert New Line Before Tags dialog box, where you can edit the list of tags.
Remove new line before	This display field shows a list of tags before which a break line should be removed. Use the button  next to the field or press <a href="#">Shift+Enter</a> to open the Remove Line Breaks Before Tags dialog box, where you can edit the list of tags.

Do not indent children of	This display field shows a list of tags whose children should not be indented. Use the button  next to the field or press <code>Shift+Enter</code> to open the Do Not Indent Children Of dialog box, where you can edit the list of tags.
Or if tag size more than	In this text box, specify the minimum length of a tag in lines starting from which its children are not indented.
Inline elements	This display field shows a list of tags that are presented in the source code in the same line with the other tags. If a tag is removed from the list, the editor automatically moves it to a new line, when you add such tag to the source code. Use the button  next to the field or press <code>Shift+Enter</code> to open the Inline Elements dialog box, where you can edit the list of tags.
Keep white spaces inside	This display field shows a list of tags inside which you want the editor to preserve white spaces as is, without any changes. Use the button  next to the field or press <code>Shift+Enter</code> to open the Keep Whitespaces Inside dialog box, where you can edit the list of tags.
Don't break if inline content	This display field shows a list of tags that are not to be wrapped if their content is inlined. Use the button  next to the field or press <code>Shift+Enter</code> to open the Don't Wrap If Inline Content Only dialog box, where you can edit the list of tags.
Generated quote marks	Choose the style of the quote marks (double, single, or none) to be automatically inserted around HTML attributes on typing = . This is important when HTML is inserted dynamically using JavaScript or PHP and you want to consistently use double-quote pairs for JavaScript or PHP strings and single-quote pairs for HTML to prevent problems, for example, when copying and pasting.
Enforce on format	If this checkbox is selected, then on <a href="#">code reformatting</a> the previously generated quote marks will be replaced (for example, double quotes with single quotes).

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"> <li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.
Indent chained methods	<p>In declarations of functions, the second and further methods in a chain are displayed on a separate line.</p> <ul style="list-style-type: none"> <li>– When the checkbox is selected, the second and further methods in a chain are aligned with the first call.</li> <li>– When the checkbox is cleared, the second and further methods in a chain are aligned with the object on which they are invoked.</li> </ul>
Indent all chained calls in a group	The checkbox is available only when the Indent chained methods checkbox is selected.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Spaces

Use this tab to specify where you want IntelliJ IDEA to insert spaces automatically. Select the checkboxes next to the description of relevant locations and check the results in the Preview pane.

## Wrapping and Braces

In this tab, customize the exceptions, brace placement and alignment options that IntelliJ IDEA will apply to various code constructs on [reformatting the source code](#) . Check the results in the Preview pane.

**Tip** Alignment takes precedence over indentation options.

### Hard wrap at

In this field, specify the number of spaces required to the right of an element. If you accept the Default option then the value from the [global settings](#) is used.

### Wrap on typing

In this field, specify how the edited text is fitted in the specified Hard wrap at field.

- Default - choose this option to use the Wrap on typing value from the [global settings](#) .
- Yes - choose this option to use the value from the Right Margin field.
- No - if you choose this option a line can exceed the value specified in the right margin.

**Visual guides** In this field, specify multiple right margins. You can leave a default value or enter the number of spaces for your margin. If you want to specify several margins, enter numbers separated by comma.

## Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the Line breaks checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks checkbox before reformatting.

## Wrapping options

A wrapping style applies to various code constructs, specified in the left-hand pane (for example, method call arguments, or assignment statements).

Do not wrap	When this option is selected, no special wrapping style is applied, the nested alignment and braces settings are ignored.
Wrap if long	Select this option to wrap lines going beyond the right margin with proper indentation.
Wrap always	Select this option to wrap all elements in lists so that there is one element per line with proper indentation.
Chop down if long	Select this option to wrap elements in lists that go beyond the right margin so that there is one element per line with proper indentation.

## Alignment options

Align when multiline	If this checkbox is selected, a code construct starts at the same column on each next line. Otherwise, the position of a code construct is determined by the current indentation level.
<character(s)> on next line	Select this checkbox to move the specified character or characters to the next line when the lines are wrapped.
'else' on new line	Use this checkbox to move the corresponding statements or characters to the next line.
New line after <character>	Select this checkbox to move the code after the specified character to a new line.
Special else if treatment	If this checkbox is selected, <code>else if</code> statements are located in the same line. Otherwise, <code>else if</code> statements are moved to the next line to the corresponding indent level.
Objects	From the drop-down list, choose how to align objects: <ul style="list-style-type: none"><li>– Do not align - the attributes in sequential lines will be not aligned.</li><li>– On colon - the attributes in sequential lines will be aligned against the colon.</li><li>– On value - the attributes in sequential lines will be aligned against the value.</li></ul>
Variable declarations	Choose one of the following options to configure alignment for equality signs: <ul style="list-style-type: none"><li>– Do not align - the equality signs are not aligned.</li><li>– Align when multiline - the equality signs in multiline <code>var</code> statements are aligned by inserting additional spaces.</li><li>– Align when grouped - the equality signs in multiple <code>var</code> statements are aligned by inserting additional spaces.</li></ul>

## ES6 import/export

Align 'from' clauses: When this checkbox is selected, IntelliJ IDEA aligns `import` and `export` statements in [ECMAScript 6](#) code automatically making your code easier to read and maintain. Compare the appearance of a code fragment with alignment and without it in the Preview pane.

With this option on, IntelliJ IDEA will align the new code on the fly. Existing `import` and `export` statements will be aligned after you reformat the code by pressing `Ctrl+Alt+L`, see the [Reformat Source Code](#) section for details.

## Braces placement options

Braces placement style	Use this drop-down list to specify the position of the opening brace in class declarations, method declarations, function declarations, and other types of declarations. The available options are: <ul style="list-style-type: none"><li>– End of line - select this option to place the opening brace at the declaration line end.</li><li>– Next line if wrapped - select this option to place the opening brace at the beginning of the line after the multiline declaration line.</li><li>– Next line - select this option to place the opening brace at the beginning of the line after the declaration line.</li><li>– Next line shifted - select this option to place the opening brace at the line after the declaration line being shifted to the corresponding indent level.</li><li>– Next line each shifted - select this option to place the opening brace at the line after the declaration line being shifted to the corresponding indent level, and shift the next line to the next indent level as well.</li></ul>
------------------------	--

## Force braces

From this drop-down list, choose the braces introduction method for `if`, `for`, `while`, and `do () while` statements. The available options are:

- Do not force - select this option to suppress introducing braces automatically.
- When multiline - select this option to insert braces automatically if a statement occupies more than one line. Note that IntelliJ IDEA analyzes the number of lines in the entire statement but not only its condition.

- Always - when this checkbox is selected, IntelliJ IDEA always inserts braces automatically.

## Blank Lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. The results are displayed in the Preview pane.

---

**Keep Maximum Blank Lines** In this area, specify the number of extra blank lines to be kept after reformatting.

---

**Minimum Blank Lines** In this area, configure whether to have or not to have extra empty lines after the blocks of `import` statements and around classes, fields, methods, or functions.

In the text box next to each option, specify the minimum number of extra blank lines to be left.

**Tip** These settings do not affect the number of blank lines before the first and after the last item.

## Punctuation

Use the drop-down lists in this tab to form directives in automatic insertion of terminating semicolons, single and double quotes, and trailing commas.

---

**Semicolon to terminate statements**

- Use semicolon to terminate statements in new code
- Use semicolon to terminate statements always
- Don't use semicolon to terminate statements in new code
- Don't use semicolon to terminate statements always

---

**Quotes**

- Use double quotes in new code
- Use double quotes always
- Use single quotes in new code
- Use single quotes always

---

**Trailing comma** Use this drop-down list to configure whether you want to use [trailing commas](#) in objects, arrays, and for the parameters in method definitions and calls. The available options are:

- Keep
- Remove
- Add when multiline

## Code Generation

On this tab, configure the code style for generated code.

---

**Naming conventions** In this area, configure or accept default prefixes that will be added automatically to the names of generated fields and properties.

---

**Comment Code** In this area, configure code style for generated comments.

- Line comment at first column - select this checkbox to start line comments at the first column. When the checkbox is cleared, line comments are aligned in the code.
- Add a space at comment start - when this checkbox is selected, a space will be inserted between a line comment character and the first character of a commented line.

## Imports

---

**Merge imports for members from the same module**

- When this checkbox is selected, imported symbols from the same module are listed in one `import` statement with a comma as separator. The members are listed in the order in which they are imported. To arrange them alphabetically, select the Sort imported members checkbox and run Code | Optimize Imports .
- When this checkbox is cleared, for each imported symbol a separate `import` statement is generated.

---

**Use paths relative to the project, resource or sources roots** This option is applied during automatic generation of import statements in JavaScript code.

- When this checkbox is selected, IntelliJ IDEA suggests paths relative to the project root, resource root, or sources root.
- By default, this checkbox is cleared and IntelliJ IDEA suggests paths relative to the current file.

---

**Use directory import (Node-style module resolution)**

- When this checkbox is selected, `import` statements are generated in compliance with the [Node.js module resolution strategy](#) .
- When this checkbox is cleared, `import` statements are generated in compliance with the [JavaScript module resolution strategy](#) .

---

**Sort imported members**

- When this checkbox is selected, IntelliJ IDEA lists the imported members in merged `import` statements alphabetically. Note that the members are listed comma-separated in the order they are imported and re-sorted only when you run Code | Optimize Imports .
- When this checkbox is cleared, the members in merged `import` statements are always listed comma-separated in the order they are imported.

---

**Sort imports by modules**

- When this checkbox is selected, `import` statements are re-sorted alphabetically by the module names when you run Code | Optimize Imports .
- When this checkbox is cleared, `import` statements are always shown in the order they are generated and

this order is not changed after you run Code | Optimize Imports .

## Arrangement

In this tab, define a set of rules to rearrange your JavaScript code according to your preferences.

---

Grouping Rules	Use this area to set the grouping rules. <ul style="list-style-type: none"><li>- Group property field with corresponding getter/setter</li></ul>
Matching rules	Use this area to define elements order as a list of rules, where every rule has a set of matches such as modifier or type. <ul style="list-style-type: none"><li>-  - use this button to add a rule. The empty rule area opens.</li><li>-  - use this button to remove the rule from the list.</li><li>-  - use this button to edit an existing rule. To see this button, navigate to the rule that you want to edit and click on the button. In pop-up window that opens, modify the rule fields.</li><li>-  - use these buttons to move the selected rule up or down.</li></ul>
Empty rule	Use this area to create a new matching rule or edit an existing one. You can select from the following filters: <ul style="list-style-type: none"><li>- Type - use this filter to choose classes or methods for your rule.<p>Note that clicking a type keyword twice negates the condition.</p></li><li>- Modifier - use this filter to select the types of modifiers for the rule.<p>Note that clicking a modifier keyword twice negates the condition.</p></li><li>- Name - use this field to specify entry names in the rule. This filter matches only entry names, such as field names, method names, class names, etc. The filter supports regular expressions and uses a <a href="#">standard syntax</a>. The match is performed against the entire name.</li><li>- Order - use this drop-down list to select the sorting order for the rule. This option is useful when more than one element uses the same matching rule. In this case, selecting Keep order will keep the same order as was set before the rearrangement and selecting Order by Name will sort the elements with the same matching rule by their names.</li><li>- Aliases - this option displays aliases that were defined in the Rules Alias Definition dialog. You can remove the ones you do not need.</li></ul> <hr/>  This icon appears when you select Order by Name from the Order list. The icon indicates that the items in this rule are sorted alphabetically.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click Reset .

Ctrl+Alt+S 

Use this page to configure formatting options for JSON files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"> <li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Spaces

Use this tab to specify where you want IntelliJ IDEA to insert spaces automatically. Select the checkboxes next to the description of relevant locations and check the results in the Preview pane.

## Wrapping and braces

In this tab, customize the exceptions, brace placement and alignment options that IntelliJ IDEA will apply to various code constructs on [reformatting the source code](#). Check the results in the Preview pane.

**Tip** Alignment takes precedence over indentation options.

### Hard wrap at

In this field, specify the number of spaces required to the right of an element. If you accept the Default option then the value from the [global settings](#) is used.

### Wrap on typing

In this field, specify how the edited text is fitted in the specified Hard wrap at field.

- Default - choose this option to use the Wrap on typing value from the [global settings](#).
- Yes - choose this option to use the value from the Right Margin field.
- No - if you choose this option a line can exceed the value specified in the right margin.

**Visual guides** In this field, specify multiple right margins. You can leave a default value or enter the number of spaces for your margin. If you want to specify several margins, enter numbers separated by comma.

### Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the Line breaks checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks checkbox before reformatting.

### Wrapping options

A wrapping style applies to various code constructs, specified in the left-hand pane (for example, method call arguments, or assignment statements).

Do not wrap	When this option is selected, no special wrapping style is applied, the nested alignment and braces settings are ignored.
Wrap if long	Select this option to wrap lines going beyond the right margin with proper indentation.
Wrap always	Select this option to wrap all elements in lists so that there is one element per line with proper indentation.

Chop down if long      Select this option to wrap elements in lists that go beyond the right margin so that there is one element per line with proper indentation.

---

Ensure right margin is not exceeded      If this checkbox is selected, the formatter will do its best to avoid having document lines exceeding the right margin. This option takes precedence over the Do not wrap wrapping style.

---

### Alignment options

---

Objects      From the drop-down list, choose how to align objects:

- Do not align - the attributes in sequential lines will be not aligned.
- On colon - the attributes in sequential lines will be aligned against the colon.
- On value - the attributes in sequential lines will be aligned against the value.

## Blank Lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. The results are displayed in the Preview pane.

---

Keep Maximum Blank Lines      In this area, specify the number of extra blank lines to be kept after reformatting.

**Tip** These settings do not affect the number of blank lines before the first and after the last item.

Ctrl+Alt+S 

Use this page to configure formatting options for JSP files. View the result in the Preview pane on the right.

## Tabs and Indents

### ItemDescription

Use tab character	<ul style="list-style-type: none"><li>- If this checkbox is selected, tab characters are used:<ul style="list-style-type: none"><li>- On pressing the  key</li><li>- For indentation</li><li>- For code reformatting</li></ul></li><li>- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<ul style="list-style-type: none"><li>- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li><li>- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Tab size	In this text box, specify the number of spaces included in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.

## Wrapping

Use this tab to configure wrapping options.

### ItemDescription

Right Margin	Use these settings to specify a margin space required on the right side of an element. If you select Default option then a value of the right margin from the <a href="#">global settings</a> will be used.
Wrap on typing	Use these settings to specify how the edited text is fitted in the specified Right margin . You can select one the following options: <ul style="list-style-type: none"><li>- Default - in this case IntelliJ IDEA uses the Wrap on typing option that is specified in the <a href="#">global settings</a> .</li><li>- Yes - in this case the value in the specified right margin is used.</li><li>- No - in this case this option is switched off and a line can exceed the number that is specified in the right margin.</li></ul>

## Set from...

## Tabs and Indents

### ItemDescription

Use tab character	<ul style="list-style-type: none"> <li>- If this checkbox is selected, tab characters are used: <ul style="list-style-type: none"> <li>- On pressing the <code>Tab</code> key</li> <li>- For indentation</li> <li>- For code reformatting</li> </ul> </li> <li>- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<ul style="list-style-type: none"> <li>- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li> <li>- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Tab size	In this text box, specify the number of spaces included in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.
Keep indents on empty lines	<p>If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.</p> <p>If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.</p>

## Spaces

Use this tab to specify where you want spaces in your code. To have IntelliJ IDEA automatically insert a space at a location, select the checkbox next to this location in the list. The results are displayed in the Preview pane.

## Wrapping and braces

In this tab, customize the code style options, which IntelliJ IDEA will apply on [reformatting the source code](#). The left-hand pane contains the list of exceptions (Keep when reformatting), and placement and alignment options for the various code constructs (lists, statements, operations, annotations, etc.) The right-hand pane shows preview.

Alignment takes precedence over indentation options.

## Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the *Line breaks* checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks check box before you [reformat the source code](#).

## Wrapping options

The wrapping style applies to the various code constructs, specified in the left-hand pane (for example, method call arguments, or assignment statements).

### ItemDescription

Wrapping style	<p>From this drop-down list, select the desired wrapping style:</p> <ul style="list-style-type: none"> <li>- Do not wrap - when this option is selected, no special wrapping style is applied. With this option selected, the nested alignment and braces settings are ignored.</li> <li>- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.</li> <li>- Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.</li> <li>- Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.</li> </ul>
----------------	--

## Alignment options

### ItemDescription

Align when multiline	If this checkbox is selected, a code construct starts at the same column on each next line. Otherwise, the position of a code construct is determined by the current indentation level.
----------------------	---

## Imports

### ItemDescription

Top-level Symbols Use this area to define how the top-level symbols are imported. The possible options are:

- **Use single name import** : if this option is selected, only a particular declaration from a package during code generation or import optimization is imported.
- **Use import with "\*"** : if this option is selected, a statement importing an entire package is inserted.
- **Use import with "\*" if at least <n> names used** : if this option is selected, specify the number of declarations to be imported from a single package, until all the statements importing a single declaration are substituted with a statement importing an entire package.

---

Java Statics and Enum Members Use this area to define how Java statics and enums are imported.

Other Use this area to define how the other symbols are imported.

**Insert imports for nested classes** :

- If this checkbox is selected, IntelliJ IDEA creates imports for the nested classes referenced in your code.
- If this option is not selected, IntelliJ IDEA generates import for the top-level class and qualifies the name of the nested class with the name of its top-level class.

---

Packages to Use Import with "\*" Use the table as follows:

- **Package** : In the text fields of this column, specify the packages to be imported.
- **With Subpackages** : Select this checkbox to have IntelliJ IDEA import all the subpackages of the selected package.

## Set from...

Click this link to reveal the list of languages to be used as the base for the current language code style. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.

This link appears in the upper-right corner of the language-specific code style page, when applicable.

Click Reset to discard changes and return to the initial set of code style settings.

Ctrl+Alt+S 

Use this page to configure formatting options for Less files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"><li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li><li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"><li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li><li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click [Reset](#).

Ctrl+Alt+S 

Use this page to configure formatting options for PHP files. View the result in the Preview pane on the right.

## Set from...

Click this link to choose the base for the current language default code style from the pop-up list, that appears. The list contains two options:

- Language: choose this option to inherit the coding style settings from another language. Select the source language from the list, that opens. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.
- Predefined code style: choose this option to use the coding standards defined for a specific framework. Select one of the following frameworks from the list:
  - [PEAR](#)
  - [Zend](#)
  - [Symfony2](#) . IntelliJ IDEA supports the official Symfony2 code style for [Twig](#) and automatically inserts one space **after** an opening pair of curly braces and **before** a closing pair of curly braces in Twig templates: `{{ some_variable }}` .
  - [PSR1 /PSR2](#)
  - [WordPress](#)
  - [Drupal](#)
  - [Joomla!](#)
  - [JavaScript Standard Style](#)
  - [Google JavaScript Style Guide](#)

This link appears in the upper-right corner of the language-specific code style page, when applicable.

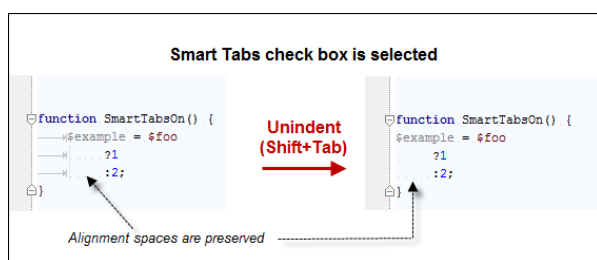

Click Reset to discard changes and return to the initial set of code style settings.

## Tabs and Indents

### ItemDescription

- Use tab character
- If this checkbox is selected, tab characters are used:
    - On pressing the  key
    - For indentation
    - For code reformatting
  - When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.

- Smart tabs
- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.

- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.

The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

Tab size In this text box, specify the number of spaces included in a tab.

Indent In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.

Continuation indent In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.

- Keep indents on empty lines If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.
- If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.

## PHP-specific formatting settings for Spaces

Select or clear the checkboxes to have spaces inserted, not inserted, or removed in the following PHP contexts:

### ItemDescription

- Before Parentheses - Array initializer parentheses  
Select this checkbox to have a space inserted before the opening parenthesis in array declarations, such as:

```
$array = array (0 => "zero", 1 => "one");
```

If the checkbox is cleared, no space is inserted and the code looks as follows:

```
$array = array(0 => "zero", 1 => "one");
```

- Around Operators - Concatenation  
Select this checkbox to have spaces inserted before and after the concatenation operator ( . ) so the code looks as follows:

```
echo "The result is " . $i;
```

When the checkbox is cleared, no spaces are inserted around the concatenation operator so the code looks as follows:

```
echo "The result is ".$i;
```

- Before Left Brace - Class left brace  
Select this checkbox to have a space inserted between the class name and the opening brace in class declarations:

```
class Class1 {
    function Foo()
}
```

When the checkbox is cleared, no space is inserted:

```
class Class1{
    function Foo()
}
```

Selecting or clearing the checkbox is relevant only when Braces placement in class declarations is set to End of line on the Wrapping and Braces tab.

- In Ternary Operator ( ?: ) - Select the checkboxes in this section to have spaces automatically inserted before and after ? , before and after : , and between ? and : in [ternary \(conditional\) operators](#) .

- Other - Select the checkboxes in this section to have spaces automatically inserted before and after commas, semicolons, unary NOT operators ( ! ), and after type casts.

- After type cast

When this checkbox is selected, IntelliJ IDEA automatically inserts a space after the closing parentheses of a `cast` :

```
$fst = (string) $foo;
```

If the checkbox is cleared, no spaces is inserted and the casted variable sticks to the cast: `$fst = (string)$foo;`

## PHP-specific formatting settings for Wrapping and Braces

### ItemDescription

- Braces placement In this section, choose the position for opening braces in declarations of namespaces, classes, and functions, in loops, and in other constructions. Choose the required position from the drop-down list, the available options are:
  - End of line - select this option to have the opening brace placed at the declaration line end.
  - Next line if wrapped - select this option to have the opening brace placed at the beginning of the line after the multiline declaration line.
  - Next line - select this option to have the opening brace placed at the beginning of the line after the declaration line.
  - Next line shifted - select this option to have the opening brace placed at the line after the declaration line being shifted to the corresponding indent level.
  - Next line each shifted - select this option to have the opening brace placed at the line after the declaration line being shifted to the corresponding indent level, and have the next line shifted to the next indent level as well.

- Extends/implements list In this section, configure wrapping and subsequent alignment of `extend` and `implements` lists:

- Do not wrap - when this option is selected, no special wrapping style is applied.
- With this option selected, the nested alignment and braces settings are ignored.
- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.

- Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.
- Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.
- Align when multiline  
When this checkbox is selected, each item in an **extends** or an **implements** list, which after wrapping starts on a new line, are aligned by the first item, which remains unwrapped:

```
abstract class Foo extends
  Class1 implements
  Class2,
  Class8 {
}
```

When the checkbox is cleared, the position of each item in a wrapped list is determined by the chosen indentation level.

The status of the checkbox affects the formatting only if you have chosen to wrap lists, if the Do not wrap option is chosen, selecting or clearing the checkbox has no effect.

**Extends/implements keyword** In this section, configure wrapping for the **extends** and **implements** keywords in class declarations. If you choose the Do not wrap option, no wrapping will be applied, if you choose Wrap if long or Wrap always, each keyword and each item in an **extends** or **implements** list will be displayed on a new line:

```
abstract class Foo
  extends
  Class1
  implements
  Class2,
  Class8 {
}
```

**Function declaration parameters** In this area, configure formatting in declarations of functions and methods.

- Keep ')' and '{' on one line  
When this checkbox is cleared, the opening curly brace is moved to the next line:

```
function Foo()
{
}
```

When the checkbox is selected, the opening curly brace is displayed on the same line as the function parameters:

```
function Foo() {
}
```

**Chained method calls** In this section, configure wrapping and subsequent alignment of chained calls.

- Do not wrap - when this option is selected, no special wrapping style is applied. With this option selected, the nested alignment and braces settings are ignored.
- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.
- Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.
- Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.
- Align when multiline  
When the checkbox is selected, each called method, which after wrapping is positioned on a new line, is aligned by the first one, which remains unwrapped:

```
$x = $x->one( "a", "b" )
      ->two( "c", "d", "e" )
      ->three( "fg" )
      ->four;
```

When the checkbox is cleared, the position of each item in a wrapped list is determined by the chosen indentation level.

The status of the checkbox affects the formatting only if you have chosen to wrap lists, if the Do not wrap option is chosen, selecting or clearing the checkbox has no effect.

- Place ';' on new line  
When the checkbox is cleared, the semicolon ( ; ) is displayed after the last item in a chained call. If the checkbox is selected, the semicolon is moved to a new line:

```
$x = $x->one( "a", "b" )
      ->two( "c", "d", "e" )
      ->three( "fg" )
      ->four
;
```

**Assignment statement** In this section, configure wrapping and subsequent alignment in assignment statements.

- Do not wrap - when this option is selected, no special wrapping style is applied.

With this option selected, the nested alignment and braces settings are ignored.

- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.
- Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.
- Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.
- Assignment sign on new line
- Align consecutive assignments

When this checkbox is selected, the assignment signs in consecutive assignment statements are aligned by the rightmost one:

```
$y           = foo( $x );
$intermediate = foo( $intermediate );
$result      = $result . $y . $intermediate;
```

When this checkbox is cleared, no alignment is applied:

```
$y = foo( $x );
$intermediate = foo( $intermediate );
$result = $result . $y . $intermediate;
```

#### Class field/constant groups

In this section, configure wrapping and subsequent alignment within lists of [class properties \(fields\)](#) or [class constants](#).

- Align fields in columns
- Align constants

#### Array initializer

In this section, configure wrapping and subsequent alignment in array declarations.

- Do not wrap - when this option is selected, no special wrapping style is applied.
- With this option selected, the nested alignment and braces settings are ignored.
- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.
  - Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.
  - Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.
  - Align when multiline
- When the checkbox is selected and the New line after '(' checkbox is cleared, each element, which after wrapping is positioned on a new line, is aligned by the first one, which remains unwrapped:

```
$colours = array( "blue",
                  "red",
                  "white",
                  "green",
                  "yellow" );
```

When both the Align when multiline and the New line after '(' checkboxes are selected, all the elements are aligned according to the indentation settings:

```
$colours = array(
    "blue",
    "red",
    "white",
    "green",
    "yellow" );
```

Selecting or clearing the Align when multiline and the New line after '(' checkboxes affects the formatting only if you have chosen to wrap lists, if the Do not wrap option is chosen, the status of the checkboxes has no effect.

- New line after '('

When this checkbox is selected, the first element of the array is displayed on a new line and all the elements of the array are aligned according to the indentation settings, regardless of the status of the Align when multiline checkbox.

When this checkbox is cleared, the first element of the array remains on the same line, and the other elements are aligned according to the indentation settings.

- Place ')' on new line

#### Modifier list

- Wrap after modifier list

When this checkbox is selected, the code is wrapped after a list of visibility modifiers:

```
protected
function Foo() {
}
```

When the checkbox is cleared, no wrapping is performed:

```
protected function Foo() {
}
```

#### Blank lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. For each type of location, specify the number of blank lines to be inserted. The results are displayed in the Preview pane.

#### ItemDescription

Keep Maximum Blank Lines In this area, specify the number of blank lines to be kept after reformatting in the specified locations.

Minimum Blank Lines In the text boxes in this area, specify the number of blank lines to be present in the specified locations.

**Warning!** These settings do not influence the number of blank lines before the first and after the last item.

## PHPDoc

In this tab, configure the code style to be applied inside [PHPDoc](#) comments. Learn more about documenting PHP code at [PHPDoc Comments](#).

#### ItemDescription

Align parameter names Select this checkbox to have the `<paramname>` elements aligned.

Keep blank lines Select this checkbox to suppress removing blank lines automatically.

Blank lines around parameters Select this checkbox to have a blank line inserted above and below the section with `@param` tags.

Blank line before the first tag Select this checkbox to have a blank line inserted above the first PHPDoc tag.

Align tag comments Select this checkbox to have the `description` elements aligned.

Wrap long lines Select this checkbox to have the text that exceeds the right margin wrapped to the next line.

Generated Doc Blocks In this area, configure the code style to be applied within generated PHP documentation blocks, see [PHPDoc Comments](#).

- Use fully-qualified class names: select this checkbox to have IntelliJ IDEA specify fully qualified class names for properties, function parameters, `return` and `throws` values, etc.

`@throws` Tag Analysis

- Call tree analysis depth : specify the depth of analysis. IntelliJ IDEA can analyze exceptions up to 3 levels deep.
- Ignore Runtime exceptions : If this checkbox is selected, the exceptions which can only be found at runtime (either based on `RuntimeException` or any of its subclasses), are ignored.
- Ignore Logic exceptions : If this checkbox is selected, exceptions caused by the error in the program logic (either based on `LogicException` or any of its subclasses), are ignored.

## Other

#### ItemDescription

Indent code in PHP tags Select this checkbox to have the code enclosed in `<?php>` tags indented against the opening `<?php` tag.

Convert True/False constants to upper case Select this checkbox to have the `true` and `false` constants displayed in the upper case.

Convert Null constant to upper case Select this checkbox to have the `null` constant displayed in the upper case.

Blank line before return statement Select this checkbox to have IntelliJ IDEA automatically insert a blank line before each `return` statement.

Spaces around variables/expressions in brackets

- Select this checkbox to have IntelliJ IDEA insert spaces inside brackets during reformatting only if the brackets enclose a variable or an expression. This setting affects reformatting only if you have not configured force insertion of spaces inside brackets by selecting the Brackets checkbox under the Within node in the Spaces tab. This option helps you keep your code in accordance with the [WordPress PHP Coding Standards](#).
- If this checkbox is cleared, the spaces insertion policy depends on the settings under the Within node in the Spaces tab regardless of the type of content inside brackets:
  - if the Brackets checkbox is selected, spaces are always inserted
  - if the Brackets checkbox is cleared, spaces are never inserted.

Code Commenting In this area, configure the code style options to be applied to comments.

- Line comment at first column : select this checkbox to have line comments start at the first column, without any indentation. Note that no extra blank spaces are added after the line comment characters. The checkbox is by default selected. When the checkbox is cleared, the line comments start from the minimum indentation within the selected code block to be commented.

Array declaration style

- Force short declaration style: select this checkbox to have IntelliJ IDEA replace the `array()` constructs with `[]` in array declarations during reformatting. When the checkbox is cleared, the traditional literal style in array declarations is preserved after reformatting.
- Align key-value pairs: select this checkbox to have the `=>` separators in key-value assignments aligned.

- Add a comma after last element in multiline array: select this checkbox to have IntelliJ IDEA automatically insert a comma after the last item in declarations of multiline arrays to meet the required coding standard, for example, the [Symfony coding standards](#) .

See [Arrays. Syntax](#) for details.

## Arrangement

In this tab, define a set of rules to rearrange your PHP code according to your preferences.

### ItemDescription

---

**Grouping** Use this area to set the grouping rules.

**Rules**

- Keep getters and setters together  
Select this checkbox to keep getter and setter methods together. By default, this checkbox is selected.
- Keep overridden methods together  
Select this checkbox to group the overridden methods together by class and interface. In order: list, select keep or by name options.
- Keep dependent methods together  
Select this checkbox to group the dependent methods together. In order: list, select depth-first or breadth-first options.

---

**Matching rules** Use this area to define elements order as a list of rules, where every rule has a set of matches such as modifier or type.

-  - use this button to add a rule. The empty rule area opens.
-  - use this button to remove the rule from the list.
-  - use this button to edit an existing rule. To see this button, navigate to the rule that you want to edit and click on the button. In pop-up window that opens, modify the rule fields.
-  - use these buttons to move the selected rule up or down.

---

**Empty rule** Use this area to create a new matching rule or edit an existing one. You can select from the following filters:

- Type - use this filter to choose classes or methods for your rule.

Note that clicking a type keyword twice negates the condition.

- Name - use this field to specify entry names in the rule. This filter matches only entry names, such as field names, method names, class names, etc. The filter supports regular expressions and uses a [standard syntax](#) . The match is performed against the entire name.
- Order - use this drop-down list to select the sorting order for the rule. This option is useful when more than one element uses the same matching rule. In this case, selecting Keep order will keep the same order as was set before the rearrangement and selecting Order by Name will sort the elements with the same matching rule by their names.
- Aliases - this option displays aliases that were defined in the Rules Alias Definition dialog. You can remove the ones you do not need.

---

 This icon appears when you select Order by Name from the Order list. The icon indicates that the items in this rule are sorted alphabetically.

Ctrl+Alt+S 

---

Use this page to configure formatting options for Properties files. View the result in the Preview pane on the right.

## Controls

### ItemDescription

---

Align properties in columns	Select this checkbox to align properties and their values.
Insert space around key-value delimiter	Select this checkbox to insert whitespace symbols around the key-value delimiters.
Key-value delimiter	Select the desired key-value delimiter from the drop-down list.
Keep blank lines	Select this checkbox to preserve blank lines as is.

Ctrl+Alt+S 

Use this page to configure formatting options for Python files. View the result in the Preview pane on the right.

## Prerequisites

Before you start working with Python, make sure that Python plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Python SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Python](#)
- [Django](#)

**Tip** When a piece of code is selected in the editor, IntelliJ IDEA suggests the quick fix [Adjust code style settings](#) .

- You can change the maximum line length for Python sources in Code Style | Python | Wrapping and Braces | Right margin of the editor settings.

## Tabs and Indents

### Item Description

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used:               <ul style="list-style-type: none"> <li>– On pressing the  key</li> <li>– For indentation</li> <li>– For code reformatting</li> </ul> </li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<ul style="list-style-type: none"> <li>– If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Tab size	In this text box, specify the number of spaces included in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.
Keep indents on empty lines	<p>If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.</p> <p>If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.</p>

## Spaces

Use this tab to specify where you want spaces in your code. To have IntelliJ IDEA automatically insert a space at a location, select the checkbox next to this location in the list. The results are displayed in the Preview pane.

## Wrapping and braces

In this tab, customize the code style options, which IntelliJ IDEA will apply on [reformatting the source code](#) . The left-hand pane contains the list of exceptions ( Keep when reformatting ), and placement and alignment options for the various code constructs (lists, statements, operations, annotations, etc.) The right-hand pane shows preview.

Alignment takes precedence over indentation options.

## Right Margin (columns)

Use the Hard wrap at field to specify a margin space required on the right side of an element. If you select Default option then a value of the right margin from the [global settings](#) is used.

## Wrap on typing

Use the Wrap on typing settings to specify how the edited text is fitted in the specified Hard wrap at . You can select one the following options:

- Default - in this case IntelliJ IDEA uses the Wrap on typing option that is specified in the [global settings](#) .
- Yes - in this case IntelliJ IDEA uses the value specified in the Right Margin field.
- No - in this case this option is switched off and a line can exceed the value specified in the right margin.

## Visual guides

Use the Visual guides field to specify multiple right margins. You can leave a default value or enter the number of spaces for your margin. If you want to specify several margins, enter numbers separated by comma.

## Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the *Line breaks* checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks check box before you [reformat the source code](#).

## Blank lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. For each type of location, specify the number of blank lines to be inserted. The results are displayed in the Preview pane.

### ItemDescription

**Keep Maximum Blank Lines** In this area, specify the number of blank lines to be kept after reformatting in the specified locations.

**Minimum Blank Lines** In the text boxes in this area, specify the number of blank lines to be present in the specified locations.

**Warning!** These settings do not influence the number of blank lines before the first and after the last item.

## Imports

This table lists actions to be performed when [imports are optimized](#).

### ItemDescription

**General** In this area, configure general import options.  
Options:

- Use single class import : Select this checkbox to have IntelliJ IDEA import only a particular class from a package during code generation or [import optimization](#). Otherwise, a statement importing an entire package is inserted.
- Use fully qualified class names : Select this checkbox to have IntelliJ IDEA use the fully qualified name of the class to be imported during code generation or [import optimization](#). Otherwise, a normal import statement is inserted.
- Insert imports for inner classes : Select this checkbox to have IntelliJ IDEA create imports for the inner classes referenced in your code.
- Use fully qualified names in Javadoc : Select this checkbox to have IntelliJ IDEA use a fully qualified class name in Javadoc. Otherwise, a class is imported.
- Class count to use import with "\*" : In this text field, specify the number of classes to be imported from a single package until all statements importing a single class are substituted with a statement importing an entire package.
- Names count to use static import with "\*" : In this text box, specify the number of members to be imported from a single class until all statements importing a single member are substituted with a statement importing an entire class.

**JSP Imports Layout** In this area, configure how JSP import statements should be organized in your code. The introduced changes are displayed in the Preview pane below.  
Options:

- Prefer comma separated import list : Select this option to import statements organized in a comma separated list.
- Prefer one import statement per page directive : Select this option to have one import statement created per line.

**Packages to Use Import with ""** In this area, configure a list of packages and classes to be always imported completely.  
Options:

- Static : Select this checkbox, if you want to declare static import for the selected class.
- Package : In the text fields of this column, specify the packages and classes to be always imported completely.
- With Subpackages : Select this checkbox to have all the subpackages of the selected package imported completely.
- Add Package : Click this button to add a new entry to the list of packages and classes.
- Add Blank : Click this button to add an empty separator to the list of packages and classes.
- Remove : Click this button to delete the selected package or class from the list.

**Import Layout** In this area, configure how import statements should be organized in your code. You can set up certain classes to be positioned first, or last, or one after another. Imported classes will be grouped as per their packages and sorted alphabetically within a package.  
Options:

- Layout static imports separately : If this checkbox is selected, all static imports will be kept in a separate section. Otherwise, all import statements will be sorted according to the specified layout rules.
- Static : Select this checkbox, if you want to declare static import for the selected package.
- Package : In the text fields of this column, specify the packages to be imported.
- With Subpackages : Select this checkbox to have IntelliJ IDEA apply the layout rules to all the subpackages of the selected package.
- Add Package : Click this button to add a new entry to the list of packages.
- Add Blank : Click this button to have a blank line inserted after the selected entry, which indicates that a blank line should be inserted between the corresponding import statements.
- Move Up / Move Down : Click these buttons to move a package or a blank line up or down in the list thus defining the order of import statements.
- Remove : Click this button to delete the selected package from the list.

## Other

### ItemDescription

---

Dict alignment      From the drop-down list, select the type of `dict` alignment:

- Do not align : the `dict`'s elements in sequential lines will be not aligned.
- Align on colon : the `dict`'s elements in sequential lines will be aligned against the colon.
- Align on value : the `dict`'s elements in sequential lines will be aligned against the value.

---

Add line feed at the end of file      Select this checkbox to add line feed character at the end of file.

---

Use continuation indent for arguments      Select this checkbox to use continuation indent (defined in the Tabs and Indents tab) for list of arguments. If this checkbox is not selected, then the indent value is used.

---

## Set from...

Click this link to reveal the list of languages to be used as the base for the current language code style. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.

This link appears in the upper-right corner of the language-specific code style page, when applicable.

Click Reset to discard changes and return to the initial set of code style settings.

Use this page to configure formatting options for Sass files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"><li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li><li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"><li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li><li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click [Reset](#).

Use this page to configure formatting options for SCSS files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"><li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li><li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"><li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li><li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click Reset .

Ctrl+Alt+S 

Use this page to configure formatting options for SQL files. View the result in the Preview pane on the right.

## General

Use this tab to specify certain formatting behaviors in your code. The results are displayed in the Preview pane.

### ItemDescription

**Word Case** In this node, specify whether the keywords, identifiers, or quoted identifiers case should change automatically. Click the right-hand column, and check the desired behavior on the menu to turn it on.  
The possible options are:

- To upper : the elements are automatically converted to the upper case.
- To lower : The elements are automatically converted to lower case.
- Do not change : The case of elements is left as is.

**Identifier quotations** Click the right-hand column, and check the desired behavior on the menu to turn it on.  
The possible options are:

- Quote : the identifiers are automatically quoted.
- Unquote : The identifiers are automatically unquoted.
- Do not change : The identifiers are left as is.

**New line before/after** Use these nodes to define how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. For each type of SQL element, select or clear the checkbox to the right. The results are highlighted in the Preview pane.

**New line around semicolon** Use this checkbox to manage line delimiters around a semicolon.

**Alignment** Select the checkboxes next to the desired elements of source code to have them automatically aligned.

## Tabs and Indents

### ItemDescription

**Use tab character**

- If this checkbox is selected, tab characters are used:
  - On pressing the `Tab` key
  - For indentation
  - For code reformatting
- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.

**Smart tabs**

- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.
- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.

The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

**Tab size** In this text box, specify the number of spaces included in a tab.

**Indent** In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.

**Continuation indent** In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.

**Keep indents on empty lines** If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.

If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.

## Spaces

Use this tab to specify where you want spaces in your code. To have IntelliJ IDEA automatically insert a space at a location, select the checkbox next to this location in the list. The results are displayed in the Preview pane.

## Wrapping and Braces

In this tab, customize the code style options, which IntelliJ IDEA will apply when [reformatting the source code](#). The left-hand pane contains the list of exceptions (Keep when reformatting), and placement and alignment options for the various code constructs (lists, statements, operations, annotations, etc.). The right-hand pane shows preview.

Alignment takes precedence over [indentation options](#).

### ItemDescription

**Keep When** Use the checkboxes in this node to configure exceptions that IntelliJ IDEA will make when reformatting the source

Reformatting	code. For example, by default, the <i>Line brakes</i> checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the <i>Line brakes</i> check box before you <a href="#">reformat the source code</a> .
Wrap inside	Use this node to define wrapping style for the lengthy elements.  You can use different <a href="#">wrapping style options</a> that are available from the drop-down list in the left-hand pane.
Values expression	Use this option to define wrapping style for values expressions. You can use different <a href="#">wrapping style options</a> that are available from the drop-down list in the left-hand pane.
Wrapping Style Options	The wrapping style applies to the various code constructs, specified in the left-hand pane (for example, expressions, or assignment statements).

From the drop-down list, select the desired wrapping style:

- Do not wrap - when this option is selected, no special wrapping style is applied.

**Note** If this option is selected, the nested alignment and braces settings are ignored.

- Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.
- Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped so that there is one element per line with proper indentation.
- Wrap always - select this option to have all elements in lists wrapped so that there is one element per line with proper indentation.

## Blank Lines

Use this tab to insert blank lines into your code.

### ItemDescription

Keep Maximum Blank Lines      Use this area to specify blank lines in your code.

Use In code field to enter the number of lines you want to insert. The default number is 2.

## Code Generation

The tab contains templates for the names of primary and foreign key constraints, and indexes. These templates are used to generate default names for the constraints and indexes when you create them in the Create Table or the Modify Table dialog.

The templates can contain variables (e.g. `{table}` ) and text. When generating a name, the specified text is reproduced literally.

To get the info about the variables and how you should use them, place the cursor into the field of interest and press

`Ctrl+Q` .

`{columns}` and `{ref_columns}` , depending on the situation, are the name of the column, or a list where the column names are separated with the underscore ( \_ ).

`{unique?u:}` checks if the index is unique ( `unique?` ), and, if it is, inserts the sequence of characters specified between `?` and `:` (in this example, it's `u` ). If the index is not unique, the sequence between `:` and `}` is inserted (in this example, it's nothing).

Example. Using the template `{table}_{columns}_{unique?u:index}` , you are creating an index on the columns

`FirstName` and `LastName` in the table `persons` . If the index is unique, its name, by default, will be

`persons_FirstName_LastName_uindex` . If the index is not unique, its name will be `persons_FirstName_LastName_index` .

## Set from...

Click this link to reveal the list of languages to be used as the base for the current language code style. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.

This link appears in the upper-right corner of the language-specific code style page, when applicable.

Click Reset to discard changes and return to the initial set of code style settings.

Ctrl+Alt+S 

Use this page to configure formatting options for Stylus files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"><li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li><li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"><li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li><li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**TIP** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"> <li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.
Indent chained methods	<p>In declarations of functions, the second and further methods in a chain are displayed on a separate line.</p> <ul style="list-style-type: none"> <li>– When the checkbox is selected, the second and further methods in a chain are aligned with the first call.</li> <li>– When the checkbox is cleared, the second and further methods in a chain are aligned with the object on which they are invoked.</li> </ul>
Indent all chained calls in a group	The checkbox is available only when the Indent chained methods checkbox is selected.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Spaces

Use this tab to specify where you want IntelliJ IDEA to insert spaces automatically. Select the checkboxes next to the description of relevant locations and check the results in the Preview pane.

## Wrapping and braces

In this tab, customize the exceptions, brace placement and alignment options that IntelliJ IDEA will apply to various code constructs on [reformatting the source code](#) . Check the results in the Preview pane.

**Tip** Alignment takes precedence over indentation options.

### Hard wrap at

In this field, specify the number of spaces required to the right of an element. If you accept the Default option then the value from the [global settings](#) is used.

### Wrap on typing

In this field, specify how the edited text is fitted in the specified Hard wrap at field.

- Default - choose this option to use the Wrap on typing value from the [global settings](#) .
- Yes - choose this option to use the value from the Right Margin field.
- No - if you choose this option a line can exceed the value specified in the right margin.

**Visual guides** In this field, specify multiple right margins. You can leave a default value or enter the number of spaces for your margin. If you want to specify several margins, enter numbers separated by comma.

## Keep when reformatting

Use the checkboxes to configure exceptions that IntelliJ IDEA will make when reformatting the source code. For example, by default, the Line breaks checkbox is selected. If your code contains lines that are shorter than a standard convention, you can convert them by disabling the Line breaks checkbox before reformatting.

## Wrapping options

A wrapping style applies to various code constructs, specified in the left-hand pane (for example, method call arguments, or assignment statements).

Do not wrap	When this option is selected, no special wrapping style is applied, the nested alignment and braces settings are ignored.
Wrap if long	Select this option to wrap lines going beyond the right margin with proper indentation.
Wrap always	Select this option to wrap all elements in lists so that there is one element per line with proper indentation.
Chop down if long	Select this option to wrap elements in lists that go beyond the right margin so that there is one element per line with proper indentation.

## Alignment options

Align when multiline	If this checkbox is selected, a code construct starts at the same column on each next line. Otherwise, the position of a code construct is determined by the current indentation level.
<character(s)> on next line	Select this checkbox to move the specified character or characters to the next line when the lines are wrapped.
'else' on new line	Use this checkbox to move the corresponding statements or characters to the next line.
New line after <character>	Select this checkbox to move the code after the specified character to a new line.
Special else if treatment	If this checkbox is selected, <code>else if</code> statements are located in the same line. Otherwise, <code>else if</code> statements are moved to the next line to the corresponding indent level.
Indent case branches	If this checkbox is selected, the <code>case</code> statement is located at the corresponding indent level. Otherwise, <code>case</code> statement is placed at the same indent level with <code>switch</code> .
Objects	From the drop-down list, choose how to align objects: <ul style="list-style-type: none"><li>– Do not align - the attributes in sequential lines will be not aligned.</li><li>– On colon - the attributes in sequential lines will be aligned against the colon.</li><li>– On value - the attributes in sequential lines will be aligned against the value.</li></ul>
Variable declarations	Choose one of the following options to configure alignment for equality signs: <ul style="list-style-type: none"><li>– Do not align - the equality signs are not aligned.</li><li>– Align when multiline - the equality signs in multiline <code>var</code> statements are aligned by inserting additional spaces.</li><li>– Align when grouped - the equality signs in multiple <code>var</code> statements are aligned by inserting additional spaces.</li></ul>

**ES6 import/export** Align 'from' clauses: When this checkbox is selected, IntelliJ IDEA aligns `import` and `export` statements in [ECMAScript 6](#) code automatically making your code easier to read and maintain. Compare the appearance of a code fragment with alignment and without it in the Preview pane.

With this option on, IntelliJ IDEA will align the new code on the fly. Existing `import` and `export` statements will be aligned after you reformat the code by pressing `Ctrl+Alt+L`, see the [Reformat Source Code](#) section for details.

## Braces placement options

Braces placement style Use this drop-down list to specify the position of the opening brace in class declarations, method declarations, function declarations, and other types of declarations. The available options are:

- End of line - select this option to place the opening brace at the declaration line end.
- Next line if wrapped - select this option to place the opening brace at the beginning of the line after the multiline declaration line.
- Next line - select this option to place the opening brace at the beginning of the line after the declaration line.
- Next line shifted - select this option to place the opening brace at the line after the declaration line being shifted to the corresponding indent level.
- Next line each shifted - select this option to place the opening brace at the line after the declaration line being shifted to the corresponding indent level, and shift the next line to the next indent level as well.

**Force braces** From this drop-down list, choose the braces introduction method for `if`, `for`, `while`, and `do ()` `while` statements. The available options are:

- Do not force - select this option to suppress introducing braces automatically.
- When multiline - select this option to insert braces automatically if a statement occupies more than one line. Note that IntelliJ IDEA analyzes the number of lines in the entire statement but not only its condition.
- Always - when this checkbox is selected, IntelliJ IDEA always inserts braces automatically.

## Blank Lines

Use this tab to define where and how many blank lines you want IntelliJ IDEA to retain and insert in your code after reformatting. The results are displayed in the Preview pane.

Keep Maximum Blank Lines	In this area, specify the number of extra blank lines to be kept after reformatting.
Minimum Blank Lines	In this area, configure whether to have or not to have extra empty lines after the blocks of <code>import</code> statements and around classes, fields, methods, or functions.  In the text box next to each option, specify the minimum number of extra blank lines to be left.

**Tip** These settings do not affect the number of blank lines before the first and after the last item.

## Punctuation

Use the drop-down lists in this tab to form directives in automatic insertion of terminating semicolons, single and double quotes, and trailing commas.

Semicolon to terminate statements	<ul style="list-style-type: none"> <li>- Use semicolon to terminate statements in new code</li> <li>- Use semicolon to terminate statements always</li> <li>- Don't use semicolon to terminate statements in new code</li> <li>- Don't use semicolon to terminate statements always</li> </ul>
Quotes	<ul style="list-style-type: none"> <li>- Use double quotes in new code</li> <li>- Use double quotes always</li> <li>- Use single quotes in new code</li> <li>- Use single quotes always</li> </ul>
Trailing comma	Use this drop-down list to configure whether you want to use <a href="#">trailing commas</a> in objects, arrays, and for the parameters in method definitions and calls. The available options are: <ul style="list-style-type: none"> <li>- Keep</li> <li>- Remove</li> <li>- Add when multiline</li> </ul>

## Code Generation

On this tab, configure the code style for generated code.

Use 'public' modifier	Use this checkbox to have the public access modifier inserted or omitted in the generated code.
-----------------------	---

For example, during generation of a public method from the following:

```
class Test {
  public test():void {
    var x = 1;
  }
}
```

- If the checkbox is selected, the public access modifier is automatically inserted in the generated code:

```
class Test {
  public test():void {
    this.extracted();
  }
  public extracted() {
    var x = 1;
  }
}
```

- If the checkbox is cleared, the public access modifier is omitted during code generation:

```
class Test {
  public test():void {
    this.extracted();
  }
  extracted() {
    var x = 1;
  }
}
```

See [TypeScript Language Handbook](#), chapter Private/Public Modifiers .

Naming conventions	In this area, configure or accept default prefixes that will be added automatically to the names of generated fields and properties.
Comment Code	In this area, configure code style for generated comments. <ul style="list-style-type: none"> <li>- Line comment at first column - select this checkbox to start line comments at the first column. When the checkbox is cleared, line comments are aligned in the code.</li> </ul>

- Add a space at comment start - when this checkbox is selected, a space will be inserted between a line comment character and the first character of a commented line.

**Tip** The Add a space at comment start checkbox is unavailable when Line comment at first column is selected.

## Imports

- Merge imports for members from the same module
- When this checkbox is selected, imported symbols from the same module are listed in one `import` statement with a comma as separator. The members are listed in the order in which they are imported. To arrange them alphabetically, select the Sort imported members checkbox and run Code | Optimize Imports .
  - When this checkbox is cleared, for each imported symbol a separate `import` statement is generated.

- Use paths relative to `tsconfig.json`
- When this checkbox is selected, IntelliJ IDEA calculates import paths using the `tsconfig.json` file as the root. When this checkbox is cleared, IntelliJ IDEA calculates import paths relative to the project root. For example, if your project is structured as follows:

```

▼ ts_import_example
  ▼ directory_1
    file_1.ts
  ▼ directory_2
    file_2.ts
    tsconfig.json
  
```

With the checkbox selected, IntelliJ IDEA generates the following import statement:

```
import {ClassName} from 'directory_2/file_2'
```

If the checkbox is cleared, the following import statement is generated:

```
import {ClassName} from '../directory_2/file_2'
```

- Use directory import (Node-style module resolution)
- When this checkbox is selected, `import` statements are generated in compliance with the [Node.js module resolution strategy](#) .
  - When this checkbox is cleared, `import` statements are generated in compliance with the [TypeScript classic module resolution strategy](#) .

- Do not import exactly from
- In this field, specify the exact paths that IntelliJ IDEA should skip during automatic import of a symbol. Instead, IntelliJ IDEA will look for alternative paths to import the symbol. This is particularly useful for modules that allow importing their submodules instead of the entire module. For example, to prefer imports like `import {Observable} from 'rxjs/Observable'` to a more general `import {Observable} from 'rxjs'` , add `rxjs` to the list.

To manage the list of modules to skip:

1. Click  to the right of the field.
2. In the Change modules dialog box that opens, click  and specify the module name in the Add module dialog box. To remove a module from the list, select it and click  .

- Sort imported members
- When this checkbox is selected, IntelliJ IDEA lists the imported members in merged `import` statements alphabetically. Note that the members are listed comma-separated in the order they are imported and re-sorted only when you run Code | Optimize Imports .
  - When this checkbox is cleared, the members in merged `import` statements are always listed comma-separated in the order they are imported.

- Sort imports by modules
- When this checkbox is selected, `import` statements are re-sorted alphabetically by the module names when you run Code | Optimize Imports .
  - When this checkbox is cleared, `import` statements are always shown in the order they are generated and this order is not changed after you run Code | Optimize Imports .

## Arrangement

In this tab, define a set of rules to rearrange your TypeScript code according to your preferences.

- Grouping Rules
- Use this area to set the grouping rules.
- Group property field with corresponding getter/setter

- Matching rules
- Use this area to define elements order as a list of rules, where every rule has a set of matches such as modifier or type.
-  - use this button to add a rule. The empty rule area opens.
  -  - use this button to remove the rule from the list.
  -  - use this button to edit an existing rule. To see this button, navigate to the rule that you want to edit and click on the button. In pop-up window that opens, modify the rule fields.
  -   - use these buttons to move the selected rule up or down.

- Empty rule
- Use this area to create a new matching rule or edit an existing one. You can select from the following filters:
- Type - use this filter to choose classes or methods for your rule.
- Note that clicking a type keyword twice negates the condition.
- Modifier - use this filter to select the types of modifiers for the rule.

Note that clicking a modifier keyword twice negates the condition.

- Name - use this field to specify entry names in the rule. This filter matches only entry names, such as field names, method names, class names, etc. The filter supports regular expressions and uses a [standard syntax](#). The match is performed against the entire name.
- Order - use this drop-down list to select the sorting order for the rule. This option is useful when more than one element uses the same matching rule. In this case, selecting Keep order will keep the same order as was set before the rearrangement and selecting Order by Name will sort the elements with the same matching rule by their names.
- Aliases - this option displays aliases that were defined in the Rules Alias Definition dialog. You can remove the ones you do not need.

This icon appears when you select Order by Name from the Order list. The icon indicates that the items in this rule are sorted alphabetically.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click Reset .

Ctrl+Alt+S 

Use this page to configure formatting options for Velocity files. View the result in the Preview pane on the right.

## Tabs and Indents

### ItemDescription

Use tab character	<ul style="list-style-type: none"><li>- If this checkbox is selected, tab characters are used:<ul style="list-style-type: none"><li>- On pressing the  key</li><li>- For indentation</li><li>- For code reformatting</li></ul></li><li>- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li></ul>
Smart tabs	<ul style="list-style-type: none"><li>- If this checkbox is selected, the part of indentation defined by the nesting of code blocks, is made of the tabs and (if necessary) spaces, while the part of indentation defined by the alignment is made only of spaces.</li><li>- If this checkbox is cleared, only tabs are used. This means that a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li></ul> <p>The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.</p>
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations and method calls.
Keep indents on empty lines	<p>If this checkbox is selected, then IntelliJ IDEA will keep indents on the empty lines as if they contained some code.</p> <p>If this checkbox is not selected, IntelliJ IDEA will delete the tab characters and spaces.</p>

## Set from...

Click this link to reveal the list of languages to be used as the base for the current language code style. So doing, only the settings that are applicable to the current language are taken. All the other settings are not affected.

This link appears in the upper-right corner of the language-specific code style page, when applicable.

Click Reset to discard changes and return to the initial set of code style settings.

Ctrl+Alt+S 

Use this page to configure formatting options for XML files. View the result in the Preview pane on the right.

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"> <li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.
Continuation indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted between the elements of an array, in expressions, method declarations, and method calls.
Keep indents on empty lines	If this checkbox is selected, IntelliJ IDEA retains indents on empty lines as if they contained some code. If the checkbox is cleared, IntelliJ IDEA deletes the tab characters and spaces on empty lines.

**TIP** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Other

### ItemDescription

Right Margin	Use these settings to specify a margin space required on the right side of an element. If you select Default option then a value of the right margin from the <a href="#">global settings</a> will be used.
Wrap on typing	Use these settings settings to specify how the edited text is fitted in the specified Right margin . You can select one the following options: <ul style="list-style-type: none"> <li>– Default - in this case IntelliJ IDEA uses the Wrap on typing option that is specified in the <a href="#">global settings</a> .</li> <li>– Yes - in this case the value in the specified right margin is used.</li> <li>– No - in this case this option is switched off and a line can exceed the number that is specified in the right margin.</li> </ul>
Keep line breaks	Select this checkbox to have IntelliJ IDEA honor line breaks when reviewing XML files in the editor.
Keep line breaks in text	Select this checkbox to have IntelliJ IDEA honor line breaks in attributes (for example, lengthy descriptions) when reviewing XML files in the editor.
Keep blank lines	In this text box, specify the minimum number of sequential blank lines to be retained after reformatting.
Wrap attributes	Use this drop-down list to determine how attribute lines should be wrapped. The available options are: <ul style="list-style-type: none"> <li>– Do not wrap - if this option is selected, no special wrapping style is applied to the code.</li> <li>– Wrap if long - select this option to have lines going beyond the right margin wrapped with proper indentation.</li> <li>– Chop down if long - select this option to have elements in lists that go beyond the right margin wrapped to give one element per line with proper indentation.</li> <li>– Wrap always - select this option to have all elements in lists wrapped to give one element per line with proper indentation.</li> </ul>
Wrap text	Select this checkbox to have long lines wrapped according to the code style settings.
Align attributes	Select this checkbox to have attributes in sequential lines aligned.
Keep white spaces	When this checkbox is selected, the editor preserves all whitespaces within tags. The same refers also to the indents, and line breaks.
Spaces	In this area, define the usage of spaces for attributes and tag names. <ul style="list-style-type: none"> <li>– Around "=" in attribute : select this checkbox to have spaces added around the "=" symbol in attributes.</li> <li>– After tag name : select this checkbox to have spaces added after tag names.</li> <li>– In empty tag : select this checkbox to have spaces added in empty tags.</li> </ul>
CDATA	In this area, define the usage of whitespaces around and inside CDATA sections in MXML files: <ul style="list-style-type: none"> <li>– Whitespaces around : from the drop-down list, choose how whitespaces around <code>CDATA[</code> will be treated. <ul style="list-style-type: none"> <li>– Preserve : all whitespaces will be left intact after reformatting.</li> <li>– Remove (keep with tags) : all whitespaces around <code>CDATA[</code> will be removed, and tags will be kept on the same lines.</li> <li>– New lines : new lines will be added before and after <code>CDATA[</code> .</li> </ul> </li> <li>– Keep whitespaces inside : If this checkbox is selected, whitespaces will be preserved after <code>CDATA[</code> and before <code>]]</code> .</li> </ul>

## Arrangement

This tab lets you define a set of rules that rearranges your code according to your preferences.

### ItemDescription

**Matching rules** Use this area to define elements order as a list of rules, where every rule has a set of matches such as modifier or type.

-  - use this button to add a rule. The empty rule area opens.
-  - use this button to remove the rule from the list.
-  - use this button to edit an existing rule. To see this button, navigate to the rule that you want to edit and click on the button. In pop-up window that opens, modify the rule fields.
-  - use these buttons to move the selected rule up or down.

**Empty rule** Use this area to create a new matching rule or edit an existing one. You can select from the following filters:

- **Type** - use this filter to choose classes or methods for your rule.

Note that clicking a type keyword twice negates the condition.

- **Name** - use this field to specify entry names in the rule. This filter matches only entry names, such as field names, method names, class names, etc. The filter supports regular expressions and uses a [standard syntax](#). The match is performed against the entire name.
- **Namespace** - use this field to specify the namespace in the rule. It lets you specify a rule that controls a namespace attribute position.
- **Order** - use this drop-down list to select the sorting order for the rule. This option is useful when more than one element uses the same matching rule. In this case, selecting **Keep order** will keep the same order as was set before the rearrangement and selecting **Order by Name** will sort the elements with the same matching rule by their names.
- **Aliases** - this option displays aliases that were defined in the Rules Alias Definition dialog. You can remove the ones you do not need.

 This icon appears when you select **Order by Name** from the **Order** list. The icon indicates that the items in this rule are sorted alphabetically.

**Additional Settings** Use this area to set additional arrangement options. The **Force rearrange** drop-down list lets you select options that affect the **Rearrange entries** checkbox in the **Reformat Code** dialog.

You can select from the following options:

- **Use current mode** (toggled in the **Reformat Code** dialog) - In this case the **Rearrange entries** checkbox stays active and you can modify it in the **Reformat Code** dialog.
- **Always** - In this case the **Rearrange entries** checkbox is selected and becomes read-only.
- **Never** - In this case the **Rearrange entries** checkbox is cleared and becomes read-only.

## Android

### ItemDescription

**Use custom formatting settings for Android XML files** Use this checkbox to set a custom formatting for the Android XML files. This might be helpful if you need to format Android files differently from other XML files or need to use specific Android formatting options.

If this checkbox is not selected, the default XML files formatting is applied.

**AndroidManifest.xml** Use this area to set the following formatting for **AndroidManifest.xml**:

- **Wrap attributes** - use this drop-down list to determine how attribute lines should be wrapped. See the [available options](#).
- **Insert line break before first attribute** - select this checkbox to insert a line before the first attribute.
- **Insert line break after last attribute** - select this checkbox to insert a line after the last attribute.
- **Group tags with the same name** - select this checkbox to group tags with the same name.

**Layout Files** Use this area to set the following formatting for the layout files:

- **Wrap attributes** - use this drop-down list to determine how the attribute lines should be wrapped. See the [available options](#).
- **Insert line break before first attribute** - select this checkbox to insert a line break before the first attribute.
- **Insert line break after last attribute** - select this checkbox to insert a line after the last attribute.
- **Insert blank line before tag** - select this checkbox to insert a blank line before the tag.

**Value Resources Files and Selectors** Use this area to set the following formatting for value resource files and selectors:

- **Wrap attributes** - use this drop-down list to determine how attribute lines should be wrapped. See the [available options](#).
- **Insert line breaks around style declaration** - select this checkbox to insert line breaks around a style declaration.

**Other XML resource files** Use this area to set **Wrap attributes** for other XML resource files. See the [available options](#).

- **Insert line break before first attribute** - select this checkbox to insert line breaks before the first attribute. This option is selected by default.
- **Insert line break after last attribute** - select this checkbox to insert line breaks after the last attribute.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click **Reset**.

Ctrl+Alt+S 

---

Use this page to configure formatting options for YAML files. View the result in the Preview pane on the right.

## Tabs and Indents

---

**Use tab character**

- If this checkbox is selected, tab characters are used for indentation and for code reformatting.
- When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.

---

**Indent**                      In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

## Set from

The link appears in the upper-right corner of the page, when applicable. Click this link and choose the language to be used as the base for the current language code style.

To return to the initial set of code style settings and discard the changes, click [Reset](#) .

Ctrl+Alt+S 

On this page:

- [Scheme](#)
- [Tabs and Indents](#)

## Scheme

In this area, choose the code style scheme and change it as required. Code style scheme settings are automatically applied every time IntelliJ IDEA generates, refactors, or reformats your code.

Code styles are defined at the project level and at the IDE level (global).

– At the **Project** level, settings are grouped under the Project scheme, which is predefined and is marked in bold. The **Project** style scheme is applied to the current project only.

You can copy the Project scheme to the IDE level, using the Copy to IDE... command.

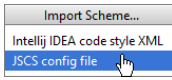

– At the **IDE** level, settings are grouped under the predefined Default scheme (marked in bold), and any other scheme created by the user by the Duplicate command (marked as plain text). Global settings are used when the user doesn't want to keep code style settings with the project and share them.

You can copy the IDE scheme to the current project, using the Copy to Project... command.

### ItemDescription

**Scheme** From this drop-down list, select the scheme to be used. The **predefined** schemes are shown bold. The **custom** schemes, ones created as copies of the predefined schemes, are in plain text. The location where the scheme is stored is written next to each scheme, for example, the Default scheme is stored in the IDE, the Project scheme is stored in the project.

 Click this button to invoke the drop-down list of commands to manage the schemes:

ItemDescriptionAvailable for		
Copy to IDE...	Choose this command to copy the scheme settings to the IDE.	Project
Export...	Choose this command to export the selected scheme to an <code>.xml</code> file in the selected location:	Project and IDE
		
Import Scheme...	Choose this command to import the scheme of the selected type from the specified location:	Project and IDE
		
Copy to Project...	Choose this command to copy the scheme settings to be stored with a project.	IDE
Duplicate...	Choose this command to create a copy of the selected scheme.	IDE
Reset	Choose this command to reset the default or bundled color scheme to the initial defaults shipped with IntelliJ IDEA. This command becomes available only if some changes have been done.	IDE
Rename	Choose this command to change the name of the selected custom scheme. Press <code>Enter</code> to save changes, or <code>Escape</code> to cancel.	Custom schemes

## Tabs and Indents

Use tab character	<ul style="list-style-type: none"> <li>– If this checkbox is selected, tab characters are used for indentation and for code reformatting.</li> <li>– When the checkbox is cleared, IntelliJ IDEA uses spaces instead of tabs.</li> </ul>
Smart tabs	<p>An indentation consists of two parts. One part results from nesting code blocks and the other part is determined by alignment.</p> <ul style="list-style-type: none"> <li>– If this checkbox is selected, the part that results from nesting contains both tabs and spaces (if necessary), while the part defined by alignment consists only of spaces.</li> <li>– If this checkbox is cleared, only tabs are used. This means that after reformatting a group of spaces that fits the specified tab size is automatically replaced with a tab, which may result in breaking fine alignment.</li> </ul>
Tab size	In this text box, specify the number of spaces that fits in a tab.
Indent	In this text box, specify the number of spaces (or tabs if the Use Tab Character checkbox is selected) to be inserted for each indent level.

**Tip** The Smart Tabs checkbox is available if the Use Tab Character checkbox is selected.

Ctrl+Alt+S

Use this page to [customize inspection profiles](#) , [configure inspection severities](#) , [disable and enable inspections](#) , and [configure inspections for different scopes](#) . The page is divided into the following areas:

- [Profile management](#)
- [Toolbar](#)
- [Inspection severity and scopes](#)
- [Options](#)

## Profile management

### ItemDescription

Profile	From this drop-down list, select the name of the profile to configure. All modified inspections are highlighted. Note that the selected profile is automatically used for project highlighting after clicking Apply .
*-	Click this button to reveal the following submenu:
Copy to IDE/Copy to Project	Choose the command Copy as IDE to move the selected profile to the global level. Choose the command Copy to Project to create the project level duplicate of the selected profile.
Duplicate	Choose this command to create a copy, <a href="#">based on the current profile</a> .
Rename	Choose this command to change the name of the current profile in the Profile field.
Delete	Choose this command to delete the current profile. The pre-defined profiles cannot be deleted, so this command is only available for the user-defined profiles.
Add description	If this command is selected, a text field appears on the right of the Profile field, enabling you to type in the description of the current profile. Press <b>Enter</b> to save the entered description, or <b>Escape</b> to cancel typing.
Export	Choose this command to export the selected profile as an <code>xml</code> file.
Import Profile	Choose this command to import a profile from an <code>xml</code> file.

**Note** Inspections that differ from the default profile are highlighted in blue.

## Toolbar

### Item Tooltip and Shortcut

Q in

Use this text box to search through the list of inspections. In the search field, start typing the desired inspection name, or any characters contained in the inspection name or description. IntelliJ IDEA shows the list of matching occurrences.

As you type a search string, the matching inspections are highlighted. To finalize the search, press **Enter** . The used search strings are memorized in the history list.

- : Click this button to reveal the history list.
- : Click this button to clear the search history.

Filter Inspections

Click this button to show the list of available filters:

Reset Filter
Show Only Enabled
Show Only Disabled
Show Only Modified Inspections
Error
Warning
Weak Warning
Server Problem
Typo
No highlighting, only fix
Filter by Language
Show Only "Available only for Analyze   Inspect Code"
Show Only Cleanup Inspections

Click the desired filters to reduce the list. The command Reset Filters becomes available, if some of the filters are checked.

	<p><b>Expand All/Collapse All</b> Click these buttons to have all inspection nodes expanded/collapsed.</p> <p>Ctrl+NumPad Plus</p> <p>Ctrl+NumPad -</p>
	<p><b>Reset to Empty</b> Click this button to have all the checkboxes of the profile cleared and thus disable all the profile inspections.</p>
	<p><b>Advanced Settings</b> Click this button to show the menu with the following check commands:</p> <ul style="list-style-type: none"> <li>- Disable new inspections by default : select this checkbox, if you don't want the new inspections that appear after IntelliJ IDEA update, to become available.</li> <li>- Reset to Default settings : select this checkbox to discard all changes.</li> </ul>

## Inspection severity and scopes

### ItemDescription

Description	This read-only field shows the description of the selected inspection.
Inspection severity	From this drop-down list, select the desired severity to assign to the current inspection. Refer to the section <a href="#">Configuring Inspection Severities</a> for details.
Scopes	Click this drop-down list to reveal the list of available scopes:

Clicking a scope in the list results in showing the scopes toolbar:

	Click this button to specify the scope for the selected inspection.
	Click this button to delete the selected scope for the current inspection.

Choosing the option Edit Scopes Order results in showing the Scopes Order dialog box, where one can change the order of scopes using the up and down arrows (↑ ↓) or keyboard shortcuts ((Alt+Up) / (Alt+Down)).

It is possible to select several inspections and add/remove scopes for the entire selection.

## Options

This area is only available for some types of inspections, provided that an inspection of this type is enabled (the checkbox next to it is selected). Use the controls in this area to re-configure the default inspection settings.

Ctrl+Alt+S 

Files can be created according to pre-defined templates (file templates). Use this page to view, edit, and create such templates.

Different groups of templates are located on different [tabs](#).

When you select a template, its contents and description are displayed in the right-hand part of the page.

- [Per-project vs default scheme](#)
- [Tabs](#)
- [Toolbar](#)
- [Template settings and contents](#)

## Per-project vs default scheme

### ItemDescription

Scheme	From this drop-down list, choose whether file and code template settings pertain to the entire workspace, or the current project: <ul style="list-style-type: none"> <li>– Default scheme is selected, when file and code templates are global.</li> <li>– Project scheme is selected, if you want to use the sharable project-specific file and code templates.</li> </ul>
--------	---

Refer to the section [Project and IDE Settings](#) for details.

## Tabs

### TabDescription

Files	This tab displays the available file templates. You can edit the existing templates, or create new ones.
-------	---

**Note** The templates shown in bold font cannot be deleted; their names and extensions cannot be edited.

Includes	This tab shows the templates for reusable fragments that can be included in file templates. You can edit the existing templates, or create new ones.
----------	---

Code	This tab displays built-in snippets, i.e. templates for code fragments that IntelliJ IDEA can generate in various typical situations, for example, for generating implemented or overridden method bodies. You can edit the existing snippets, but you cannot create new ones.
------	---

Other	This tab displays groups of templates related to various application servers and frameworks. You can edit the existing templates, but you cannot create new ones.
-------	--

## Toolbar

### ItemTooltipDescription

	<b>Create Template</b>	Click this button to create a new template in the currently opened tab. This option is only available in the Files and the Includes tabs. The location of the new template is defined by the Schema drop-down list.
	<b>Remove Template</b>	Click this button to delete the selected template. This option is only available for certain templates in the Files and the Includes tabs.
	<b>Copy Template</b>	Click this button to create a copy of the selected template. This option is only available in the Files and the Includes tabs.
	<b>Reset to Default</b>	Click this button to revert the selected template to its original state. This option is only available for the templates that have been modified (such templates are highlighted in blue).
NA	<b>Reset</b>	This link appears in the top-right corner of the page when you start editing a template. Clicking this link resets all unsaved changes to any template in any tab.

## Template settings and contents

### ItemDescription

Name	This text box appears when a new template is created. Specify the name of the new template.
Extension	In this text box, specify the extension. IntelliJ IDEA will apply this template when new files of this type are created.
Template text	Edit the template contents. You can use: <ul style="list-style-type: none"> <li>– Plain text.</li> <li>– <code>#parse</code> directives to work with <a href="#">template includes</a>.</li> <li>– Custom variables. Variables' names can be defined either directly in the template through the <code>#set</code> directive or during the file creation.</li> </ul>

Note that IntelliJ IDEA doesn't prompt for the values of Velocity variables defined with `#set`.

– Variables to be expanded into corresponding values in the `#{<variable_name>}` format.

The available predefined file template variables are:

- `#{PACKAGE_NAME}` - the name of the target package where the new class or interface will be created.
- `#{PROJECT_NAME}` - the name of the current project.
- `#{FILE_NAME}` - the name of the PHP file that will be created.
- `#{NAME}` - the name of the new file which you specify in the New File dialog box during the file creation.
- `#{USER}` - the login name of the current user.
- `#{DATE}` - the current system date.
- `#{YEAR}` - the current year.
- `#{MONTH}` - the current month.
- `#{DAY}` - the current day of the month.
- `#{TIME}` - the current system time.
- `#{HOUR}` - the current hour.
- `#{MINUTE}` - the current minute.
- `#{PRODUCT_NAME}` - the name of the IDE in which the file will be created.
- `#{MONTH_NAME_SHORT}` - the first 3 letters of the month name. Example: Jan, Feb, etc.
- `#{MONTH_NAME_FULL}` - full name of a month. Example: January, February, etc.

IntelliJ IDEA provides a set of additional variables for [PHP include templates](#). Include templates are used to define reusable pieces of code (namely, file headers and [PHPDoc comments](#)) to be inserted in file templates via the `#parse directive`.

The following variables are available in [PHP include templates](#):

- `#{NAME}` - the name of the class, field, or function (method) for which the PHPDoc comment will be generated.
- `#{NAMESPACE}` - the fully qualified name (without a leading slash) of the class or field namespace.
- `#{CLASS_NAME}` - the name of the class where the field to generate the PHPDoc comment for is defined.
- `#{STATIC}` - gets the value `static` if the function (method) or field to generate the comment for is `static`. Otherwise evaluates to an empty string.
- `#{TYPE_HINT}` - a prompt for the `return` value of the function (method) to generate the comment for. If the return type cannot be detected through the static analysis of the function (method), evaluates to `void`.
- `#{PARAM_DOC}` - a documentation comment for parameters. Evaluates to a set of lines `@param type name`. If the function to generate comments for does not contain any parameters, the variable evaluates to empty content.
- `#{THROWS_DOC}` - a documentation comment for exceptions. Evaluates to a set of lines `@throws type`. If the function to generate comments for does not throw any exceptions, the variable evaluates to empty content.
- `#{DS}` - a dollar character (`$`). The variable evaluates to a plain dollar character (`$`) and is used when you need to escape this symbol so it is not treated as a prefix of a variable.
- `#{CARET}` - indicated the position of the caret after generating and adding the comment.  
This `#{CARET}` variable is applied only when a PHPDoc comment is generated and inserted during file creation. When a PHPDoc comment is created through Code | Generate | PHPDoc block, multiple selection of functions or methods is available so documentation comments can be created to several classes, functions, methods, or fields. As a result, IntelliJ IDEA cannot "choose" the block to apply the `#{CARET}` variable in, therefore in this case the `#{CARET}` variable is ignored.
- `#{DATE}` - the current system date.
- `#{YEAR}` - the current year.
- `#{MONTH}` - the current month.
- `#{DAY}` - the current day of the month.

Treating dollar sign

– You can prevent treating dollar characters (`$`) in template variables as prefixes. If you need a dollar character (`$`) inserted as is, use the `#{DS}` file template variable instead. When the template is applied, this variable evaluates to a plain dollar character (`$`).

Examples:

- To use some version control keywords (such as `$Revision$`, `$Date$`, etc.) in your default class template, write `#{DS}` instead of the dollar prefix (`$`).
- The template code `#{DS}this` will be rendered as `$this`.

---

Reformat according to style	Select this checkbox, to have IntelliJ IDEA reformat generated stub files according to the style defined on the <a href="#">Code Style page</a> . This option is only available in the Files tab.
Enable Live Templates	Select this checkbox to use a live template inside a file template. So doing, one has to put the live template fragments into Velocity escape syntax. For example: <pre>#[[ \$MY_VARIABLES \$ENDS ]]</pre> Thus, one can specify the cursor position. Note that it is required to use the <a href="#">live template variables</a> here!
Description	This read-only field provides information about the template, its predefined variables, and the way they work. This field is not available in custom templates.

---

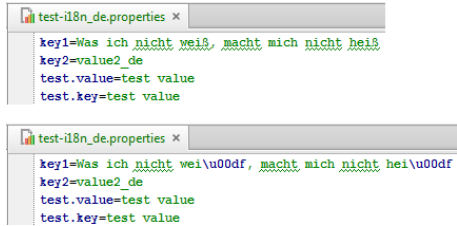

Ctrl+Alt+S 

Use this dialog to configure encoding options for a project and for the entire IDE.

The [file or directory encodings](#) take precedence over the [project encoding](#), which, in turn, takes precedence over the [IDE encoding](#).

If the file or directory encodings are not defined, then the project encoding is taken. If the project encoding cannot be taken (for example, if a project is not yet created), then the IDE encoding is taken.

#### ItemDescription

IDE Encoding	From this drop-down list, choose the encoding to be used when no project is currently opened. The encoding will be applied, for example, when you specify settings of a default project or check out sources from a version control storage. Choose System Default to have the default encoding of your operating system used or choose a specific encoding.
Project Encoding	From this drop-down box, choose the default encoding to use in the folders for which no encoding is appointed in the Default encoding field below. Choose System Default to have the default encoding of your operating system used or choose a specific encoding.
File/Directory	This column displays the project tree view.
Default encoding	This column displays encoding for a file or directory, if applicable. If encoding is defined within a file, it cannot be configured, and is shown in grey font. If encoding is configurable, click the Default Encoding column for a selected file or directory, and choose encoding from the drop-down list. Encoding information embedded in a file overrides the selected one; encoding information for the nested files or directories overrides that for the outer directories or the whole project.
Default encoding for properties files	Use this drop-down list to define encoding for the properties files in the project. According to the Java API, the <code>load(InputStream) / store(OutputStream, String)</code> methods of the <code>java.util.Properties</code> class, use ISO 8859-1 encoding for input/output stream. It is advisable to use this encoding unless you have special reasons to change it. In this case, you can select the desired encoding from the drop-down list; in particular, you can use encoding defined for the whole project.
Transparent native-to-ascii conversion	Select this option to show in properties files the national characters (non-ISO 8859-1), stored as escape sequences. For more details refer to <a href="#">Configuring Encoding for Properties Files</a> .  If this checkbox is not selected, the national characters will not be shown. Compare two representations of the national characters:
	
Create UTF-8 files	Use this drop-down list to select how you want to save the <a href="#">UTF-8</a> files: with <i>byte order mark</i> (BOM), without BOM, or BOM only for Windows. It might be helpful if you are working with the OS other than Windows and want more flexibility for the UTF-8 file encoding. Keep in mind that the UTF-8 with BOM option may cause problems with software which is not compatible with BOM or with scripts that need to be run by an interpreter.

Ctrl+Alt+S Use this page to [create, manage, and edit live templates](#) .

On this page:

- [List of available live templates](#)
- [Context menu of a live template](#)
- [Template editing area](#)
- [Side note about predefined template variables](#)
- [Predefined functions to be used in live template variables](#)

## List of available live templates

**Item** **Tooltip** **Description**  
and  
**shortcut**

By default expand with

Use this drop-down list to specify the default invocation key for all templates. Individual expansion keys for the particular templates are defined in the [editing area](#) . If the standard expansion keys (Tab, Enter, or Space) are not desirable, select the Custom option from this drop-down list.

When Custom is selected, the Change link appears next to the drop-down, leading you to the [Keymap](#) page.

Live Templates

This list shows all currently available template abbreviations supplied with their descriptions. The abbreviations are grouped below nodes and sorted alphabetically within each group. To activate a template or an entire group, select the checkbox to its left.

**Note** – Only active templates are displayed upon invoking live templates in the editor.  
– If a template is active, the editor is sensitive to its abbreviation. Otherwise, the abbreviation is considered merely a set of characters.

	Add	Click this button to have a new template item added to the current group of template. You can define the template abbreviation, description, text, variables, expansion key, and context in the editing area <a href="#">below</a> .
	Remove	Click this button to have the selected live template removed from the list.
	Duplicate	Click this button to create a new template based on the selected template. A new template item is added to the current node and the fields in the Template Text area show the definition of the selected template.
	Restore	Click this button to restore the deleted live templates. This button is only enabled when the changes are applied.

## Context menu of a live template

**Item****Description**

Move	Choose a group to move the selected template to.
Change context	Choose this command to modify the set of contexts where the current template is enabled. Upon choosing this command, a list of supported language contexts is displayed. To make IntelliJ IDEA consider a context sensitive to the template, select a checkbox next to the context name. The available context types depend on the enabled plugins.
Copy	Choose this command to create a <a href="#">serialized template XML</a> in the system clipboard.
Paste	Choose this command to paste an XML representation of the <a href="#">copied templates</a> to the selected <a href="#">group of templates</a> .
Restore defaults	This command only appears on the context menus of the modified templates, marked blue. Choose this command to restore the default template settings.

## Template editing area

The focus is moved to this area in the following cases:

- When you click the Add  or Copy  button.
- When you select a live template in the list.

– When you select a fragment of code in the editor and choose [Tools | Save as Live Template](#) .

Use controls of this area to create new [live templates](#) and edit the settings for the existing ones.

You can navigate through the Template Text Area using the hot keys that are marked in the field labels.

#### ItemDescription

**Abbreviation** In this text box, specify the [template abbreviation](#) , i.e a sequence of characters that identify the template in the editor.

**Description** In this text box, provide optional description of a template or an example of its usage.

**Template Text** In this text box, type the template body that may contain plain text and variables in the format `<variable name>$` .

When editing the live template variables, mind the following helpful hints:

- If you need a dollar sign ( `$` ) in the template text, escape it by duplicating this character ( `$$` ) .
- To change the variables in a template, click the Edit Variables button and [configure the variables](#) .

The Edit Variables button is enabled only if the template body contains at least one user-defined variable, that is, a variable different from `$$END$` or `$$SELECTION$` .

### Side note about predefined template variables

IntelliJ IDEA supports two predefined live template variables : `$$END$` and `$$SELECTION$` .

You cannot edit the predefined live template variables `$$END$` and `$$SELECTION$` .

- `$$END$` indicates the position of the cursor after the template is expanded. For example, the template `return` `$$END$`; will be expanded into

```
return ;
```

with the cursor positioned **right before** the semicolon.

- `$$SELECTION$` is used in surround templates and stands for the code fragment to be wrapped. After the template is expanded, the selected text is wrapped as specified in the template.

For example, if you select `EXAMPLE` in your code and invoke the `$$SELECTION$` template via the assigned abbreviation or by pressing `Ctrl+Alt+T` and selecting the desired template from the list, IntelliJ IDEA will wrap the selection in double quotes as follows:

```
"EXAMPLE"
```

**Applicable in:** This read-only field shows the languages and/or pieces of code where the editor should be sensitive to the template. Upon pressing `Ctrl+J` in such context, IntelliJ IDEA displays a list of templates that are valid for this context.

**Change** Click this link to modify the set of contexts where the current template is enabled. Upon clicking the link, a list of supported language contexts is displayed. To make IntelliJ IDEA consider a context sensitive to the template, select a checkbox next to the context name. The available context types depend on the enabled plugins.

**Edit Variables** Click this button to open the [Edit Template Variables](#) dialog box, where you can define how IntelliJ IDEA should process template variables upon template expansion. The Edit Variables button is enabled only if the template body contains at least one user-defined variable, that is, a variable different from `$$END$` or `$$SELECTION$` .

The Edit Template Variables dialog box contains a complete list of available functions. See the [list of predefined functions](#) below on this page.

**Options** In this area, define the behavior of the editor when a template is expanded.

- Expand with - from this drop-down list, choose the key to invoke the template.
- Reformat according to style - select this checkbox to have IntelliJ IDEA automatically reformat the expanded text according to the current style settings, defined on the [Code Style page](#) .
- Use static import if possible - select this checkbox to have IntelliJ IDEA add static import statements instead of inserting `Class.methodName()` .
- Shorten FQ names - select this checkbox to have IntelliJ IDEA truncate fully qualified names in the expanded template and add the corresponding import statements.

## Predefined functions to be used in live template variables

**Warning!** Note that the list of predefined functions in IntelliJ IDEA depends upon the installed and enabled plugins.

#### ItemDescription

`annotated("annotation qname")` Creates a symbol of type with an annotation that resides at the specified location. For an example, see [Live Templates in the iterations group](#).

`arrayVariable()` Suggests all array variables applicable in the current scope. For an example, see [Live Templates in the iterations group](#).

`anonymousSuper()` Suggests a supertype for a Kotlin object expression.

<code>camelCase(String)</code>	Returns the string passed as a parameter, converted to camel case. For example, <code>my-text-file</code> / <code>my text file</code> / <code>my_text_file</code> will be converted to <code>myTextFile</code> .
<code>capitalize(String)</code>	Capitalizes the first letter of the name passed as a parameter.
<code>capitalizeAndUnderscore(sCamelCaseName)</code>	Capitalizes the all letters of a CamelCase name passed as a parameter, and inserts an underscore between the parts. For example, if the string passed as a parameter is <code>FooBar</code> , then the function returns <code>FOO_BAR</code> .
<code>castToLeftSideType()</code>	Casts the right-side expression to the left-side expression type. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>className(sClassName)</code>	Returns the name of the current class (the class where the template is expanded).
<code>classNameComplete()</code>	This expression substitutes for the <a href="#">class name completion</a> at the variable position.
<code>clipboard()</code>	Returns the contents of the system clipboard.
<code>snakeCase(String)</code>	Returns CamelCase string out of snake_case string. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>complete()</code>	This expression substitutes for the code completion invocation at the variable position.
<code>completeSmart()</code>	This expression substitutes for the smart type completion invocation at the variable position.
<code>componentTypeOf (&lt;array variable or array type&gt;)</code>	Returns component type of an array. For example, see the <a href="#">Live Templates</a> in the iterations group in the other group.
<code>currentPackage()</code>	Returns the current package name.
<code>date(sDate)</code>	Returns the current system date in the specified format. By default, the current date is returned in the default system format. However, if you specify date format in double quotes, the date will be presented in this format:
	
<code>decapitalize(sName)</code>	Replaces the first letter of the name passed as a parameter with the corresponding lowercase letter.
<code>descendantClassEnum(&lt;String&gt;)</code>	Shows the children of the class entered as a string parameter.
<code>enum(sCompletionString1,sCompletionString2,...)</code>	List of comma-delimited strings suggested for completion at the template invocation.
<code>escapeString(sEscapeString)</code>	Escapes the specified string.
<code>expectedType()</code>	Returns the type which is expected as a result of the whole template. Makes sense if the template is expanded in the right part of an assignment, after return, etc.
<code>fileName(sFileName)</code>	Returns file name with extension.
<code>fileNameWithoutExtension()</code>	Returns file name without extension.
<code>firstWord(sFirstWord)</code>	Returns the first word of the string passed as a parameter.
<code>groovyScript("groovy code")</code>	Returns Groovy script with the specified code.  You can use <code>groovyScript</code> macro with multiple arguments. The first argument is a script text that is executed or a path to the file that contains a script. The next arguments are bound to <code>_1, _2, _3, ..._n</code> variables that are available inside your script.  Also, <code>_editor</code> variable is available inside the script. This variable is bound to the current editor.
<code>guessElementType (&lt;container&gt;)</code>	Makes a guess on the type of elements stored in a <code>java.util.Collection</code> . To make a guess, IntelliJ IDEA tries to find the places where the elements were added to or extracted from the container.
<code>iterableComponentType(&lt;ArrayOrIterable&gt;)</code>	Returns the type of an iterable component, such as an array or a collection.
<code>iterableVariable()</code>	Returns the name of a variable that can be iterated.
<code>lineNumber()</code>	Returns the current line number.
<code>lowercaseAndDash(String)</code>	Returns lower case separated by dashes, of the string passed as a parameter. For example, the string <code>MyExampleName</code> is converted to <code>my-example-name</code> .
<code>methodName()</code>	Returns the name of the embracing method (where the template is expanded).
<code>methodParameters()</code>	Returns the list of parameters of the embracing method (where the template is expanded).
<code>methodReturnType()</code>	Returns the type of the value returned by the current method (the method within which the template is expanded).

<code>qualifiedClassName()</code>	Returns the fully qualified name of the current class (the class where the template is expanded).
<div style="background-color: #ffff00; padding: 2px;"> <b>Tip</b> Clear the Shorten FQ names check box.         </div>	
<code>rightSideType()</code>	Declares the left-side variable with a type of the right-side expression. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>snakeCase(sCamelCaseText)</code>	Returns snake_case string out of CamelCase string passed as a parameter.
<code>spaceSeparated(String)</code>	Returns string separated with spaces out of CamelCase string passed as a parameter. For example, if the string passed as a parameter is <code>fooBar</code> , then the function returns <code>foo bar</code> .
<code>subtypes(sType)</code>	Returns the subtypes of the type passed as a parameter.
<code>suggestIndexName()</code>	Suggests the name of an index variable. Returns <code>i</code> if there is no such variable in scope, otherwise returns <code>j</code> if there is no such variable in scope, etc.
<code>suggestVariableName()</code>	Suggests the name for a variable based on the variable type and its initializer expression, according to your code style settings that refer to the variable naming rules.  For example, if it is a variable that holds an element within iteration, IntelliJ IDEA makes a guess on the most reasonable names, also taking into account the name of the container being iterated.
<code>suggestFirstVariableName(sFirstVariableName)</code>	Doesn't suggest <code>true</code> , <code>false</code> , <code>this</code> , <code>super</code> .
<code>time(sSystemTime)</code>	Returns the current system time.
<code>typeOfVariable(VAR)</code>	Returns the type of the variable passed as a parameter.
<code>underscoresToCamelCase(sCamelCaseText)</code>	Returns the string passed as a parameter with CamelHump letters substituting for underscores. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>underscoresToSpaces(sParameterWithSpaces)</code>	Returns the string passed as a parameter with spaces substituting for underscores.
<code>user()</code>	Returns the name of the current user.
<code>variableOfType(&lt;type&gt;)</code>	Suggests all variables that may be assigned to the type passed as a parameter, for example <code>variableOfType("java.util.Vector")</code> . If you pass an empty string ("") as a parameter, suggests all variables regardless of their types.
<code>jsArrayVariable</code>	Returns JavaScript array name.
<code>jsClassName()</code>	Returns the name of the current JavaScript class.
<code>jsComponentType</code>	Returns the JavaScript component type.
<code>jsMethodName()</code>	Returns the name of the current JavaScript method.
<code>jsQualifiedClassName</code>	Returns the complete name of the current JavaScript class.
<code>jsSuggestIndexName</code>	Returns a suggested name for an index.
<code>jsSuggestVariableName</code>	Returns a suggested name for a variable.

Ctrl+Alt+S

The dialog opens when you click the Edit Variables button in the [Template Text](#) area on the [Live Templates](#) page.

The Edit Variables button is enabled only if the template body contains at least one user-defined variable, that is, a variable different from `$END$` or `$SELECTION$`.

Use this dialog box to create and edit expressions for variables in the selected live template.

On this page:

- [Controls](#)
- [Predefined Functions to Use in Live Template Variables](#)

## Controls

### ItemDescription

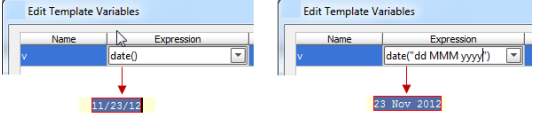

Name	In this text box, view or edit the variable name in the format <code>\$&lt;variable_name&gt;\$</code> .
Expression	<p>In this text box, specify the expression to have the value of the corresponding template input field calculated automatically.</p> <p>This expression may contain constructs of the following basic types:</p> <ul style="list-style-type: none"> <li>– String constants in double quotes.</li> <li>– The name of another variable defined in a live template.</li> <li>– Predefined functions with possible arguments.</li> </ul> <p>Type an expression manually or select a predefined function from the drop-down list. The list shows also the number and type of parameters, if any, for the selected function. The available functions are listed alphabetically in the <a href="#">Functions</a> table.</p>
Default value	<p>In this text box, specify the default string to be entered in the corresponding input field of the expanded template, if the expression does not give any result after calculation.</p> <p>Note that a default value of a variable is an expression that can refer to other live template variables. To define the default value as a literal, enclose it in quotation marks.</p>
Skip if defined	Select this checkbox to have IntelliJ IDEA proceed with the next input field, if the value of the current input field is defined.
Move Up / Move Down	Use these buttons to change the order of variables in the list. The order of variables in the table determines the order in which IntelliJ IDEA will switch between the corresponding input fields when the template is expanded.

## Predefined Functions to Use in Live Template Variables

### ItemDescription

<code>annotated("annotation qname")</code>	Creates a symbol of type with an annotation that resides at the specified location. For an example, see <a href="#">Live Templates</a> in the <a href="#">iterations</a> group.
<code>arrayVariable()</code>	Suggests all array variables applicable in the current scope. For an example, see <a href="#">Live Templates</a> in the <a href="#">iterations</a> group.
<code>anonymousSuper()</code>	Suggests a supertype for a Kotlin object expression.
<code>camelCase(String)</code>	Returns the string passed as a parameter, converted to camel case. For example, <code>my-text-file / my text file / my_text_file</code> will be converted to <code>myTextFile</code> .
<code>capitalize(String)</code>	Capitalizes the first letter of the name passed as a parameter.
<code>capitalizeAndUnderscore(sCamelCaseName)</code>	Capitalizes the all letters of a CamelCase name passed as a parameter, and inserts an underscore between the parts. For example, if the string passed as a parameter is <code>FooBar</code> , then the function returns <code>FOO_BAR</code> .
<code>castToLeftSideType()</code>	Casts the right-side expression to the left-side expression type. It is used in the <a href="#">iterations</a> group to have a single template for generating both raw-type and Generics Collections.
<code>className(sClassName)</code>	Returns the name of the current class (the class where the template is expanded).
<code>classNameComplete()</code>	This expression substitutes for the <a href="#">class name completion</a> at the variable position.
<code>clipboard()</code>	Returns the contents of the system clipboard.
<code>snakeCase(String)</code>	Returns CamelCase string out of snake_case string. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>complete()</code>	This expression substitutes for the code completion invocation at the variable position.
<code>completeSmart()</code>	This expression substitutes for the smart type completion invocation at the

	variable position.
<code>componentTypeOf (&lt;array variable or array type&gt;)</code>	Returns component type of an array. For example, see the <a href="#">Live Templates</a> in the iterations group in the other group.
<code>currentPackage()</code>	Returns the current package name.
<code>date(sDate)</code>	Returns the current system date in the specified format. By default, the current date is returned in the default system format. However, if you specify date format in double quotes, the date will be presented in this format:
	
<code>decapitalize(sName)</code>	Replaces the first letter of the name passed as a parameter with the corresponding lowercase letter.
<code>descendantClassEnum(&lt;String&gt;)</code>	Shows the children of the class entered as a string parameter.
<code>enum(sCompletionString1,sCompletionString2,...)</code>	List of comma-delimited strings suggested for completion at the template invocation.
<code>escapeString(sEscapeString)</code>	Escapes the specified string.
<code>expectedType()</code>	Returns the type which is expected as a result of the whole template. Makes sense if the template is expanded in the right part of an assignment, after return, etc.
<code>fileName(sFileName)</code>	Returns file name with extension.
<code>fileNameWithoutExtension()</code>	Returns file name without extension.
<code>firstWord(sFirstWord)</code>	Returns the first word of the string passed as a parameter.
<code>groovyScript("groovy code")</code>	Returns Groovy script with the specified code.  You can use <code>groovyScript</code> macro with multiple arguments. The first argument is a script text that is executed or a path to the file that contains a script. The next arguments are bound to <code>_1, _2, _3, ..._n</code> variables that are available inside your script.  Also, <code>_editor</code> variable is available inside the script. This variable is bound to the current editor.
<code>guessElementType (&lt;container&gt;)</code>	Makes a guess on the type of elements stored in a <code>java.util.Collection</code> . To make a guess, IntelliJ IDEA tries to find the places where the elements were added to or extracted from the container.
<code>iterableComponentType(&lt;ArrayOrIterable&gt;)</code>	Returns the type of an iterable component, such as an array or a collection.
<code>iterableVariable()</code>	Returns the name of a variable that can be iterated.
<code>lineNumber()</code>	Returns the current line number.
<code>lowercaseAndDash(String)</code>	Returns lower case separated by dashes, of the string passed as a parameter. For example, the string <code>MyExampleName</code> is converted to <code>my-example-name</code> .
<code>methodName()</code>	Returns the name of the embracing method (where the template is expanded).
<code>methodParameters()</code>	Returns the list of parameters of the embracing method (where the template is expanded).
<code>methodReturnType()</code>	Returns the type of the value returned by the current method (the method within which the template is expanded).
<code>qualifiedClassName()</code>	Returns the fully qualified name of the current class (the class where the template is expanded).
	<b>Tip</b> Clear the Shorten FQ names check box.
<code>rightSideType()</code>	Declares the left-side variable with a type of the right-side expression. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>snakeCase(sCamelCaseText)</code>	Returns snake_case string out of CamelCase string passed as a parameter.
<code>spaceSeparated(String)</code>	Returns string separated with spaces out of CamelCase string passed as a parameter. For example, if the string passed as a parameter is <code>fooBar</code> , then the function returns <code>foo bar</code> .
<code>subtypes(sType)</code>	Returns the subtypes of the type passed as a parameter.
<code>suggestIndexName()</code>	Suggests the name of an index variable. Returns <code>i</code> if there is no such variable in scope, otherwise returns <code>j</code> if there is no such variable in scope, etc.
<code>suggestVariableName()</code>	Suggests the name for a variable based on the variable type and its initializer expression, according to your code style settings that refer to the variable naming rules.  For example, if it is a variable that holds an element within iteration, IntelliJ IDEA makes a guess on the most reasonable names, also taking into account the name of the container being iterated.

<code>suggestFirstVariableName(sFirstVariableName)</code>	Doesn't suggest <code>true, false, this, super</code> .
<code>time(sSystemTime)</code>	Returns the current system time.
<code>typeOfVariable(VAR)</code>	Returns the type of the variable passed as a parameter.
<code>underscoresToCamelCase(sCamelCaseText)</code>	Returns the string passed as a parameter with CamelHump letters substituting for underscores. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>underscoresToSpaces(sParameterWithSpaces)</code>	Returns the string passed as a parameter with spaces substituting for underscores.
<code>user()</code>	Returns the name of the current user.
<code>variableOfType(&lt;type&gt;)</code>	Suggests all variables that may be assigned to the type passed as a parameter, for example <code>variableOfType("java.util.Vector")</code> . If you pass an empty string ("") as a parameter, suggests all variables regardless of their types.
<code>JsArrayVariable</code>	Returns JavaScript array name.
<code>jsClassName()</code>	Returns the name of the current JavaScript class.
<code>jsComponentType</code>	Returns the JavaScript component type.
<code>jsMethodName()</code>	Returns the name of the current JavaScript method.
<code>jsQualifiedClassName</code>	Returns the complete name of the current JavaScript class.
<code>jsSuggestIndexName</code>	Returns a suggested name for an index.
<code>jsSuggestVariableName</code>	Returns a suggested name for a variable.

Ctrl+Alt+S 

Use this page to manage the list of file types and extension patterns to be recognized by IntelliJ IDEA.

#### ItemKeyboardDescription Shortcut

Recognized file types	<p>This list box displays all the default and custom file types currently <a href="#">supported</a> by IntelliJ IDEA.</p> <p>Use the Add , Edit , and Remove buttons to manage the contents of the list box.</p> <div style="background-color: #ffff00; padding: 5px;"> <p><b>Tip</b> Default types cannot be edited or removed.</p> </div>	
		Click this button to open the <a href="#">New File Type dialog</a> and define a new custom file type there.
		Click this button to open the <a href="#">Edit File Type dialog</a> box and edit the selected file type there. This button is disabled when a default file type is selected.
		Click this button to delete the selected file type from the list. This button is disabled when a default file type is selected.
Registered Patterns	<p>Shown in this area are all the registered extensions associated with the file type selected in the Recognized file types list. Use  ,  and  to manage the corresponding patterns.</p>	
		Use this icon or shortcut to open the Add wildcard dialog box and specify a new pattern using wildcards there.
		Use this icon or shortcut to edit the selected pattern.
		Use this icon or shortcut to remove the selected pattern from the list.
Ignore files and folders	<p>In this text box, specify the files and folders, which you want to be ignored by IntelliJ IDEA. Such files and folders will be completely excluded from any kind of processing. By default the list includes temporary files, service files related to version control systems, etc. You can specify multiple names or wildcard masks, with semicolons ( ; ) as separators.</p> <p>Below is the default setting, in case you need to restore it:</p> <pre>CVS;SCCS;RCS;rcs;.DS_Store;.svn;.pyc;.pyo;*.pyc;*.pyo;.git;*.hprof;.svn;.hg;*.lib;*-;__pycache__;*.bundle;*.rbc;*\$py.class;</pre>	

Ctrl+Alt+S

The dialog box opens when you click the Add button or select a custom file type and click the Edit button on the [File Types page](#).

Use the dialog box to configure and re-configure presentation and highlighting of keywords, comments, numbers etc. in files of a specific custom file type. These settings make the basis for parsing files of this type in the editor.

#### ItemDescription

Name	In this text box, specify the name of the file type.
Description	In this text box, provide an optional description of the file type.
Syntax Highlighting	In this area, specify the character strings to indicate borders of comments, the numeric system used, and configure highlighting for brackets, braces, etc. syntax elements.
Line comment	In this text box, specify the character string to indicate the start of a single-line comment.
Only at line start	If this checkbox is selected, the character string that denotes the beginning of a line comment, is recognized as a comment if located in the first position of a line. This checkbox becomes available if at least one character is inserted in the Line comment field.
Block comment start	In this text box, specify the character string to indicate the start of a block comment.
Block comment end	In this text box, specify the character string to indicate the end of a block comment.
Hex prefix	In this text box, specify the character string to indicate that the subsequent value is a hexadecimal number. For example, <code>0x</code> .
Number postfixes	In this text box, specify the character string to indicate which numeric system or unit is used. A postfix is a trailing string of characters, for example, <code>e-3</code> , <code>kg</code> etc.
Support paired braces	Select this checkbox, to have paired braces highlighted.
Support paired brackets	Select this checkbox, to have paired brackets highlighted.
Support paired parens	Select this checkbox, to have paired parentheses highlighted.
Support string escapes	Select this checkbox, to have string escapes highlighted.
Ignore case	Select this checkbox to have IntelliJ IDEA ignore case when processing file type extensions.
Keywords	Use this area to flexibly configure highlighting of keywords by grouping them into sets and associating each set with its own <a href="#">highlighting scheme</a> . The area consists of 4 tabs. In each tab, create a set of keywords using the Add and Remove buttons. To associate a keyword set 1-4 with a highlighting scheme, edit the corresponding Keyword1 - Keyword4 property on the <a href="#">Custom</a> page of the Colors and Fonts dialog box.
	Click this button to open the Add a new keyword dialog box and define the new keyword there.
	Click this button to delete the selected keyword from the list.

Ctrl+Alt+S

Use this page to associate copyright profiles with the specific scopes within your project.

In this section:

- Copyright
  - [Copyright options](#)
- [Copyright Profiles](#)
- [Formatting](#)
  - [File Types](#)

## Copyright options

### Item Tooltip Description and shortcut

Default project copyright

Use this drop-down list to specify the default copyright profile at the project level. The default profile applies to those project files that do not belong to any defined scope. The default profile also applies when no specific profile-scope combinations have been created.

By default, IntelliJ IDEA suggests **No copyright**.

If **No copyright** value is selected, then, on an attempt to create a copyright notice in a file out of any defined scope, IntelliJ IDEA will show a dialog box asking you whether you want to edit the copyright settings.

Choosing OK results in opening this page, where you can select the default project profile from the existing ones, or create a new one; choosing Cancel generates no copyright notice at all.

The drop-down list contains the available copyright profiles defined in the [Copyright Profiles](#) page.

If only No copyright option is available, the scope-profile combinations area is disabled. With at least one copyright profile defined, the scope-profile combinations area below becomes enabled.

Scope-profile combinations area

Note that unless you have at least one [copyright profile](#) and [scope](#), the controls below are disabled.

Scope

Click an entry in this column to select the desired [shared scope](#) from the drop-down list. If the desired scope is not yet defined, click the link below to open the [Scopes](#) dialog box, where you can create a new scope or edit an existing one.

Copyright

Click an entry in this column to select a copyright profile from the drop-down list of available copyright profiles.

 **Add**  
 Use this icon or shortcut to add a new scope-profile combination.

 **Delete**  
 Use this icon or shortcut to remove the selected item from the list.

 **Up/Down**  
 Use these icons or shortcuts to move the selected item one line up or down in the list. The order of scope-profile combination is important, because if a file belongs to several scopes, these scopes are checked upside down. So doing, the first scope where this file belongs, is declared the proper one, and its copyright profile is used.

Select Scopes to add new scopes or modify existing ones

Click this link to open the [Scopes page](#), where you can create a new scope or edit an existing one.

Ctrl+Alt+S

Use this page to create, edit, and remove copyright profiles.

In this topic:

- [Profiles Toolbar](#)
- [Copyright Profile Page](#)

## Profiles Toolbar

Item	Tooltip and Shortcut	Description
		Click this button to add a new profile at the desired level. You can choose to create an empty profile or a profile based on the current default profile.
		Click this button to discard the selected profile.
		Click this button to open the Copy Copyright Profile dialog box, where you can create a copy of the selected profile.
	Import	Click this button to import a file that contains the desired copyright notice definition.

**Tip** You can perform the same actions using context menus of the profile nodes.

## Copyright Profile Page

Use this page to configure the selected profile: define the copyright notice to be generated and specify the keyword to detect copyright notices in comments.

### ItemDescription

Name	Description
Name	Use this text field to view or edit the name of the selected copyright profile.
Copyright text (may contain Velocity templates)	Use this text area to view or edit the copyright notice to be generated. A copyright profile can contain an explicit plain text of the copyright notice or its definition through a <a href="#">Velocity</a> template. Currently the following variables are available in the Velocity context:

#### Name Type Comment

Name	Type	Comment
<code>\$today</code>	<code>DateInfo</code>	The current date and time.
<code>\$file.fileName</code>	<code>String</code>	The name of the currently opened file where the notice is to be generated.
<code>\$file.pathName</code>	<code>String</code>	The complete path and name of the currently opened file where the notice is to be generated.
<code>\$file.className</code>	<code>String</code>	The name of the currently opened Java file where the notice is to be generated.
<code>\$file.qualifiedClassName</code>	<code>String</code>	The fully qualified name of the currently opened Java file where the notice is to be generated.
<code>\$file.lastModified</code>	<code>DateInfo</code>	The date and time when the current file was last changed.
<code>\$project.name</code>	<code>String</code>	The name of the current project.
<code>\$module.name</code>	<code>String</code>	The name of the current module.
<code>\$username</code>	<code>String</code>	The name of the current user.

`DateInfo` has the following properties:

Name	Type	Comment
<code>year</code>	<code>int</code>	The current year.
<code>month</code>	<code>int</code>	The current month (1-12).
<code>day</code>	<code>int</code>	The current date of month (1-31).
<code>hour</code>	<code>int</code>	The current hour (0-11).
<code>hour24</code>	<code>int</code>	The current hour (0-23).
<code>minute</code>	<code>int</code>	The current minute of the hour (0-59).
<code>second</code>	<code>int</code>	The current second of the minute (0-59).

---

`DateInfo` has the following method:

---

`format(String format)` `String` See `java.text.SimpleDateFormat` format options.

---

**Validate** Click this button to check that the Velocity template has been specified correctly.

---

**Regex to detect copyright in comments** Use this text box to type, view, or edit the [regular expression](#) that will be used to find copyright notices in comments. Note that this regular expression should match the above specified copyright notice. Otherwise instead of [updating](#) copyright notices, IntelliJ IDEA will insert new ones.

---

**Allow replacing copyright if old copyright matches** Use this text box to type or edit the regular expression pattern that will be recognized in the existing copyright notice and allow replacing it with the new one. For example, if you specify the following pattern for `year` indication: `20[0-1][0-6]`, updates will affect all the copyrights with the indications of years 2000-2006 and 2010-2016.

Ctrl+Alt+S

Use this page to configure common formatting options, regardless of the type of a particular file.

---

**Item****Description**

<b>Comment Type</b>	<p>In this area, specify the type of comment to enclose copyright notices in. The available options are:</p> <ul style="list-style-type: none"><li>- Use block comment - select this option to have copyright notices enclosed in block comments.</li><li>- Prefix each line - select this checkbox to have each line of a copyright notice prepended with the character defined in the Separator char text box. By default, an asterisk is used.</li><li>- Use line comment - select this option to have copyright notices represented as a sequence of line comments.</li></ul>
<b>Borders</b>	<p>In this area, define how to separate copyright notices from other comments.</p> <ul style="list-style-type: none"><li>- Separator before - select this checkbox have a copyright notice prepended with a line of characters defined in the Separator char text box. The number of characters in a separator line is defined in the Length text box.</li><li>- Separator char - in this text box, type the character that will be used in the separator strings and as a prefix or ending character in block comments.</li><li>- Box - select this checkbox to have each line of a copyright notice followed by a character defined in the Separator char text box.</li><li>- Add blank line after - select this checkbox to have a blank line inserted after a copyright notice.</li></ul>
<b>Relative Location</b>	<p>In this area, specify the location of a copyright notice relative to other comments in a file.</p> <ul style="list-style-type: none"><li>- Before other comments - when this option is selected, copyright notices are inserted above other comments.</li><li>- After other comments - when this option is selected, copyright notices are inserted below other comments.</li></ul>
<b>Preview</b>	<p>Use this area to view a sample copyright notice with the formatting you have defined.</p>

Ctrl+Alt+S

The page opens when you click a file type below the Formatting node. Use this page to define formatting of copyright notices depending on the target file type.

**ItemDescription**

No copyright	If this option is selected, the copyright notice will not be updated in the files of the selected type.
Use default settings	If this option is selected, the copyright notice will be updated according to the default project settings.
Use custom formatting options	If this option is selected, the copyright notice in the files of the selected type will be updated according to the custom settings defined below.
Comment Type	In this area, specify the type of comment to enclose copyright notices in. The available options are: <ul style="list-style-type: none"> <li>– Use block comment - select this option to have copyright notices enclosed in block comments.</li> <li>– Prefix each line - select this checkbox to have each line of a copyright notice prepended with the character defined in the Separator char text box. By default, an asterisk is used.</li> <li>– Use line comment - select this option to have copyright notices represented as a sequence of line comments.</li> </ul>
Borders	In this area, define how to separate copyright notices from other comments. <ul style="list-style-type: none"> <li>– Separator before - select this checkbox have a copyright notice prepended with a line of characters defined in the Separator char text box.</li> <li>– Separator after - select this checkbox have a copyright notice followed by a line of characters defined in the Separator char text box.</li> <li>– Separator char - in this text box, type the character that will be used in the separator strings and as a prefix or ending character in block comments.</li> <li>– Length - in this text box, type the number of characters in a spartor line.</li> <li>– Box - select this checkbox to have each line of a copyright notice followed by a character defined in the Separator char text box.</li> <li>– Add blank line after - select this checkbox to have a blank line inserted after a copyright notice.</li> </ul>
Relative Location	In this area, specify the location of a copyright notice relative to other comments. <ul style="list-style-type: none"> <li>– Before other comments - when this option is selected, copyright notices are inserted above other comments.</li> <li>– After other comments - when this option is selected, copyright notices are inserted below other comments.</li> </ul>
Preview	Use this area to view a sample copyright notice with the formatting you have defined.
Location in File	Use this area to specify the location of the copyright notice in a file. Depending on the file type, the available options are: <ul style="list-style-type: none"> <li>– JAVA <ul style="list-style-type: none"> <li>– Before the package statements</li> <li>– Before imports</li> <li>– Before the class declaration</li> </ul> </li> <li>– HTML , JSP , JSPX , XML <ul style="list-style-type: none"> <li>– Before the root tag</li> <li>– Before the Doctype statement</li> </ul> </li> <li>– For Properties , PHP , JavaScript , CSS , SCSS , and SASS file types no choice is available. Copyright notices are always inserted at the top of a file.</li> </ul>

Ctrl+Alt+S 

---

On the nested pages, enable IntelliJ IDEA to use Emmet in [HTML](#), [XML](#), [JavaScript \(JSX Harmony\)](#) files and [style sheets](#).

#### ItemDescription

---

Expand abbreviation with  Use this drop-down box to select the default key to expand Emmet selectors with. This key will also by default expand [Emmet live templates](#).

**Note** IntelliJ IDEA expands abbreviations only if their output does not exceed 15 KB.

Ctrl+Alt+S **ItemDescription**

Enable CSS Emmet	Select this checkbox to enable Emmet support for style sheets. If this checkbox is not selected, the complicated abbreviations, like <code>bdcin</code> expanding into <code>border-corner-image: none;</code> , will not work in the editor.
Enable fuzzy search among CSS abbreviations	When this checkbox is selected, every unknown abbreviation will be scored against available template names. The match with the best score will be used to resolve the template. For example, with this option enabled, the following abbreviations can be equal to: <ul style="list-style-type: none"> <li>- <code>ov:h</code></li> <li>- <code>ov-h</code></li> <li>- <code>o-h</code></li> <li>- <code>oh</code></li> </ul>
Enable expansion of unknown properties ('unknown' to 'unknown:;')	<ul style="list-style-type: none"> <li>- When this checkbox is selected, any entered word will be expanded into the same word followed with a colon and a semicolon;</li> <li>- When this checkbox is cleared, only known properties (for example, <code>color</code>) will be expanded this way (<code>color;</code>)</li> </ul>
Auto insert CSS vendor prefixes	If this checkbox is selected, the CSS properties listed in the table below are expanded into constructs that contain pre-pending vendor prefixes. Learn more at <a href="#">Vendor prefixes</a> . If this checkbox is cleared, the entire table of properties is disabled.
Properties and vendor prefixes	The table contains a list of CSS properties and vendor prefixes that correspond to various browsers. <ul style="list-style-type: none"> <li>- To enable or disable a property in a browser, select or clear the checkbox under the browser column.</li> <li>- To add a new property to the list, click the Add button  or press <code>Alt+Insert</code>. Then type the name of the property in the dialog box that opens and enable it in the relevant browsers.</li> <li>- To delete one or more properties from the list, select them and press Remove  or press <code>Alt+Delete</code>.</li> </ul>

Ctrl+Alt+S **ItemDescription**

**Enable XML/HTML Emmet** Select this checkbox to enable Emmet support for XML and HTML. If this checkbox is not selected, complicated abbreviations, such as `div.class>ul#list>.item$)` and similar, will not work in the editor.

**Enable abbreviation preview** Select this checkbox to have IntelliJ IDEA show a pop-up window with a preview of the entered abbreviation before actually expanding it.

```
table#users>tr.user>td
<table id="users"><tr class="user"><td></td></tr></table>
Ctrl+Down and Ctrl+Up will move caret down and up in the editor >>
```

**Enable automatic URL recognition while wrapping text with <a> tag**

- If this checkbox is cleared and you attempt to wrap an URL address with the `<a>` tag, IntelliJ IDEA simply encloses the URL address in `<a href=""></a>` and positions the cursor inside the double quotes in the `href` attribute. For example, wrapping `http://www.jetbrains.com` will result in `<a href=" " >http://www.jetbrains.com</a>` :

```
<a href=" " >http://www.jetbrains.com</a>
```

- If this checkbox is selected and you attempt to wrap an URL address with the `<a>` tag, IntelliJ IDEA inserts the URL address inside the double quotes as the value of the `href` attribute and encloses the URL in `<a href=" <wrapped URL >"></a>` . For example, wrapping `http://www.jetbrains.com` will result in `<a href="http://www.jetbrains.com">http://www.jetbrains.com</a>` . Moreover, IntelliJ IDEA highlights the wrapped URL green as a recognized URL:

```
<a href="http://www.jetbrains.com">http://www.jetbrains.com</a>
```

**Add edit point at the end of template** If this checkbox is selected, an editing position adds to the end of an HTML template (`$END$`);

if this checkbox is not selected, then the new edit point is not added.

Compare the following:

```
<tr>
  <td></td>
  <td></td>
</tr>
<tr>
  <td></td>
  <td></td>
</tr> $END$
```

**BEM** In this area, specify the BEM separators for the class names, modifiers and short elements. Refer to the [Emmet documentation](#) for details.

**Filters enabled by default** In this area, specify which **Emmet filters** you want to be applied to an expanded abbreviation before it is shown in the editor. Learn more about filters at <http://docs.emmet.io/filters/> . To have a filter always applied by default, select the checkbox next to it. The available options are:

- [XSL tuning](#)
- [Comment tags](#)
- [Escape](#)
- [Single line](#)
- [BEM](#)
- [Trim line markers](#)

File | Settings | Editor | Emmet | JSX for Windows and Linux

IntelliJ IDEA | Preferences | Editor | Emmet | JSX for macOS

Ctrl+Alt+S 

---

#### ItemDescription

---

Enable JSX Emmet      Select this checkbox to use Emmet within XML fragments in the [JSX Harmony](#) context if you have chosen the JSX language level on the [JavaScript](#) page of the Settings dialog box.

Ctrl+Alt+S

**ItemDescription**

Generate GUI into This option specifies what kind of output the GUI Designer generates for the visual forms you create. The available settings are:

- Binary class files . This is the default option. When selected, no Java source code is generated for GUI forms and components. When the project compiles, IntelliJ IDEA simply creates the necessary compiled runtime classes.
- Java source files .If this option is selected, the GUI Designer writes Java source code for the form and its components to the source file of the class to which the form is **bound** , on compiling, running or debugging. During compilation, two blocks of code are added to the form's class:
  - A private method `$$$setupUI$$$()` that contains the GUI initializer code for the bound form and its components.
  - A call to the `$$$setupUI$$$()` method.

**Warning!** Do not change the generated method, or call it from any other code. If you manually modify GUI initializer code, your UI will no longer be in sync with the `.form` file, and the next compilation will overwrite your changes.

Automatically copy form runtime classes to the output directory If this option is checked, the classes from the package `com.intellij.uiDesigner.core` package are copied to the configured output directory, when the project is compiled. These classes are used when working with the `GridLayoutManager(IntelliJ)`, or when there are components with `mnemonics` , specified by the `&` character.

Default Layout Manager Set the default layout manager for new components placed into forms. The selection here appears as the setting for the *Layout Manager* property whenever a new component is placed on a form.

- `BorderLayout`: Design-time behavior in forms emulates Java's *Border* layout manager.
- `CardLayout`: Design-time behavior in forms emulates Java's *Card* layout manager.
- `FlowLayout`: Design-time behavior in forms emulates Java's *Flow* layout manager.
- `FormLayout (JGoodies)`: Design-time behavior in forms emulates JGoodies Forms layout manager. (For more information, see <https://jgoodies.dev.java.net/> )
- `GridBagLayout`: Design-time behavior in forms emulates Java's *Grid Bag* layout manager.
- `GridLayoutManager (IntelliJ)`: Design-time behavior in forms is controlled by this custom layout manager. It's basically a simple grid layout scheme that's sufficient for many uses. It is the default layout manager in new IntelliJ IDEA installations.

Default accessibility for UI-bound fields Use this option, if you want to change the default accessibility for UI-bound fields from `private` to something else, like `public` .

Resize column and row headers with mouse This checkbox enables/disables resizing in captions.

If this checkbox is selected, IntelliJ IDEA allows you to resize column and rows using mouse. When pointing to a column or a row, the mouse pointer changes its shape to the double arrow.

Ctrl+Alt+S 

Specify how you want images to be shown in IntelliJ IDEA. Optionally, specify an external editor for working with images.

**ItemDescription**

Editor	Use this area to specify the settings according to which images should be displayed in IntelliJ IDEA.
Show Grid lines by default	<p>Select this checkbox to have a grid displayed when reviewing image files.</p> <p><b>Tip</b> When the checkbox is selected, the area below is enabled where you can define how to display a grid and its elements.</p>
Show Grid lines only when zoom factor equal or more than	Use this spin box to specify the minimum zoom factor to have a grid displayed.
Show Grid line after every (pixels)	Use this spin box to specify the number of pixels between a pair of grid lines.
Grid line color	From this palette, click the colour to display grid lines.
Show transparency chessboard by default	Select this checkbox to have transparent pieces of images shown as a chessboard.
Chessboard cell size	Use this spin box to specify the chessboard cell size.
Color of 'white' cell	From this palette, click the colour to display chessboard cells located at initially 'white' positions.
Color of 'black' cell	From this palette, click the colour to display chessboard cells located at initially 'black' positions.
Zoom image with mouse wheel (Ctrl+Mouse Wheel)	Select this checkbox to enable zooming the image through the Ctrl+Mouse wheel combination.
Enable smart zooming for small images	Select this checkbox to have small images opened with the zooming factor to the size specified below.
Preferred minimum width/height for smart zooming (pixels)	Use this spin box to set the minimum number of pixels to zoom the small images to.
External Editor	In this area, specify an external editor for working with images.
Executable path	In this text box, specify the path to the executable image editor file.

Ctrl+Alt+S

Use this page to enable and disable [intention actions](#) .

## Intention List

The list shows all intention actions currently available in IntelliJ IDEA.

The intention actions are grouped by languages. To enable an intention action, select the checkbox to its left.

## Toolbar and Controls

**Item** **Tooltip** **Description**  
and  
**shortcut**

	Ctrl+NumPad Plus	Expand all nodes in the intention list.
	Ctrl+NumPad -	Collapse all nodes in the intention list.
		Use this text box to search through the list of intention actions. As you type a search string, the intention actions that match the search pattern are displayed. To finalize the search, press  . The previously used search patterns are stored in the search history list.
		Click this button to clear the search history list.
Description		This read-only field shows the description of the selected intention action.
Usage examples		<p>This area illustrates the effect of applying the selected intention action through the following fields:</p> <ul style="list-style-type: none"> <li>– Before - this read-only field shows an example of source code before applying the selected intention action.</li> <li>– After - this read-only field shows the result of applying the selected intention action to the above example of source code.</li> </ul>

For the Language Injections page to be available, the IntelliLang [plugin](#) must be enabled. (This plugin is bundled with the IDE and enabled by default.)

Use this page to manage the list of available language injections and configure the language injection feature for text, attributes, and parameters.

See also, [Using Language Injections](#) .

## Injection entries

You can sort the information by any of the columns by clicking the cells in the header row. The current sorting status is shown by the corresponding sorting marker: ▲ for the ascending order or ▼ for the descending order.

### ItemDescription

**Checkboxes** Use the checkboxes to enable or disable the corresponding injections. You can also enable or disable a number of injections at once. To do that, select the required injections in the list and click Enable Selected Injections  or Disable Selected Injections  on the toolbar.

**Name** The language in which the injection is available, the injection name and, in parentheses, the package that contains the corresponding implementation.

**Language** The injected language.

**Scope** One of the following:

- Built-in. This is a category for pre-defined injections. In terms of the scope, those are the IDE-level injections.
- IDE. User-defined injections that are available in all of your projects.
- Project. User-defined injections that are available only in the current project.

You can move the user-defined injections between the IDE and the project levels by using  on the toolbar.

## Toolbar

### ItemDescription

 Create a new injection entry. Select the injection category and then specify the injection settings in the dialog that opens.

 Remove the selected entries from the list.

 Edit the settings for the selected injection.  
**IMPORTANT:** Don't edit the settings for built-in injections.

 Create a copy of the selected injection entry. Then edit the settings for that copy as necessary.

 Enable all the injections currently selected in the list.

 Disable all the injections currently selected in the list.

 Move the selected injections between the IDE and the project levels. See also, [Scope](#) .

 Import injection entries from another IntelliJ IDEA installation:

1. In the [Select Path dialog](#) , select the `IntelliLang.xml` file to import the info from. As a result, a dialog opens that shows the entries contained in the selected configuration file.
2. Remove the entries that you don't want to import using the Delete button. (This doesn't affect the contents of the source configuration file.)

This selective import feature makes it easy to share certain configurations in a team without losing any local entries as it happens when the settings are imported via the core [Importing Settings](#) feature.

 Export the selected injection entries to a file. In the Export Selected Injections to File dialog that opens:

- To add the entries to an existing file, select the destination file.
- To save the entries in a new file, specify the file name and choose the file type from the list.

- Language Injection Settings dialog: Generic Groovy
- Language Injection Settings dialog: Generic JavaScript
- Language Injection Settings dialog: Java Parameter
- Language Injection Settings dialog: Sql Type Injection
- Language Injection Settings dialog: XML Attribute Injection
- Language Injection Settings dialog: XML Tag Injection

Ctrl+Alt+S

The dialog opens when you click **+** on the [Language Injections](#) page, and choose Generic Groovy on the context menu, or select an entry and click .

IntelliJ IDEA comes with a set of predefined injection configurations which is quite sufficient to ensure high productivity and comfortable environment. Therefore it is **strongly recommended** that you use the predefined injection configurations and avoid creating new ones.

#### ItemDescription

Name	The name of the injection.
Language	<p>The language to be injected.</p> <ul style="list-style-type: none"> <li>– ID. The language ID or name.</li> <li>– Prefix. A sequence of characters to be added before the corresponding string value.</li> <li>– Suffix. A sequence of characters to be added after the corresponding string value.</li> </ul> <p>The prefix and suffix are optional. For more info, see <a href="#">Using language injection prefixes and suffixes</a>.</p>

Places Pattern In this text box, type the rules that define the context where you want IntelliJ IDEA recognize literals as injections.

**Note** The rules are built from [Program Structure Interface Patterns](#) and are actually chained calls of methods of an internal IntelliJ IDEA language. The [Program Structure Interface](#) shows the structure of a file as IntelliJ IDEA treats it.

**Warning!** These rules are IntelliJ IDEA internals, and it is strongly recommended that you use the predefined injection configurations and avoid creating new ones.

Advanced In this area, specify additional settings to narrow the context where the injection is applicable and thus to enable more fine-grained control over the injection process.

- Value pattern - in this text box, type a regular expression that determines the context to inject the language into. By using the first capturing group of the pattern as the target for injection, you can configure the procedure to have the language injected only into values that match a certain pattern or into multiple parts that match the pattern. For example, `^javascript:(.+)`  matches the `javascript` protocol that can be used in hyperlink-hrefs to execute JavaScript code.
- Single file - If the option is off, the fragments that match the value pattern are treated separately, as different "files" - e.g. from the fragment editor's viewpoint.

If the option is on, the corresponding fragments are all merged together to form a single unit, or "file".

Given the value pattern

```
xxx (.+) yyy (.+) zzz
```

and the fragment

```
xxx select * yyy from family zzz ,
```

`select *` and `from family` are treated as two independent fragments (or "files") if the option is off. If the option is on, `select * from family` is treated as a single unit or "file".

Ctrl+Alt+S

The dialog box opens when you click and choose Generic JS on the context menu, or select an entry and click .

#### ItemDescription

Name	The name of the injection.
Language	<p>The language to be injected.</p> <ul style="list-style-type: none"> <li>– ID. The language ID or name.</li> <li>– Prefix. A sequence of characters to be added before the corresponding string value.</li> <li>– Suffix. A sequence of characters to be added after the corresponding string value.</li> </ul> <p>The prefix and suffix are optional. For more info, see <a href="#">Using language injection prefixes and suffixes</a> .</p>

Places Pattern In this text box, type the rules that define the context where you want IntelliJ IDEA recognize literals as injections.

**Note** The rules are built from [Program Structure Interface Patterns](#) and are actually chained calls of methods of an internal IntelliJ IDEALanguage. The [Program Structure Interface](#) shows the structure of a file as IntelliJ IDEA treats it.

**Warning!** These rules are IntelliJ IDEA internals, and it is strongly recommended that you use the predefined injection configurations and avoid creating new ones.

Advanced In this area, specify additional settings to narrow the context where the injection is applicable and thus to enable more fine-grained control over the injection process.

- Value pattern - in this text box, type a regular expression that determines the context to inject the language into. By using the first capturing group of the pattern as the target for injection, you can configure the procedure to have the language injected only into values that match a certain pattern or into multiple parts that match the pattern. For example, `^javascript:(.*)` matches the `javascript` protocol that can be used in hyperlink-hrefs to execute JavaScript code.
- Single file - If the option is off, the fragments that match the value pattern are treated separately, as different "files" - e.g. from the fragment editor's viewpoint.

If the option is on, the corresponding fragments are all merged together to form a single unit, or "file".

Given the value pattern

```
xxx (.+) yyy (.+) zzz
```

and the fragment

```
xxx select * yyy from family zzz ,
```

`select *` and `from family` are treated as two independent fragments (or "files") if the option is off. If the option is on, `select * from family` is treated as a single unit or "file".

Ctrl+Alt+S

The dialog box opens when you click  on the [Language Injections](#) page, and choose Java Parameter on the context menu, or select an entry and click .

Use this dialog box to configure language injections for Java parameters. The dialog box provides the ability to make use of IntelliJLang's features, if, for any reason, the injection annotations cannot be used. This mainly applies to configuring third party/library methods as well as projects that still have to use Java 1.4.

#### ItemDescription

Language	<p>In this area, specify the language to inject and the injection context.</p> <ul style="list-style-type: none"> <li>– ID - from this drop-down list, select the ID of the language to inject.</li> <li>– Prefix - in this text box, specify a prefix to make up the injection context.</li> <li>– Suffix - in this text box, specify a suffix to make up the injection context.</li> </ul> <p>Note that the Prefix and Suffix fields are optional.</p>
Class Methods	<p>Click  and select the class of interest. As a result, the methods of the class along with their parameters are shown.</p> <p>Select the parameters for which you want to enable the injection.</p>
Advanced	<p>Specify additional settings.</p> <ul style="list-style-type: none"> <li>– Value pattern - type a regular expression for the injection context.</li> <li>– Single file - If the option is off, the fragments that match the value pattern are treated separately, as different "files" - e.g. from the fragment editor's viewpoint.</li> </ul> <p>If the option is on, the corresponding fragments are all merged together to form a single unit, or "file".</p> <p>Given the value pattern</p> <pre>xxx (.+) yyy (.+) zzz</pre> <p>and the fragment</p> <pre>xxx select * yyy from family zzz ,</pre> <p><code>select *</code> and <code>from family</code> are treated as two independent fragments (or "files") if the option is off. If the option is on, <code>select * from family</code> is treated as a single unit or "file".</p>

---

Specify a data type pattern and associated injection language. See also, [Using pattern-based injections for user-defined data types](#) .

---

#### ItemDescription

---

**Type pattern** A regular expression pattern for a data type in your SQL code. E.g. `(?i).*DATA` would be a case-insensitive pattern for data types ending in `data` .  
You can test your pattern: click  or press `Alt+Enter` , and select `Check RegExp` . Then type the text to be matched against the pattern in the `Sample` field.

---

**Language** The language to be injected into a string value of the corresponding type.

- ID. The language ID or name.
- Prefix. A sequence of characters to be added before the corresponding string value.
- Suffix. A sequence of characters to be added after the corresponding string value.

The prefix and suffix are optional. For more info, see [Using language injection prefixes and suffixes](#) .

**ItemDescription**

<b>Name</b>	The name of the injection.
<b>Language</b>	<p>The language to be injected.</p> <ul style="list-style-type: none"> <li>– ID. The language ID or name.</li> <li>– Prefix. A sequence of characters to be added before the corresponding string value.</li> <li>– Suffix. A sequence of characters to be added after the corresponding string value.</li> </ul> <p>The prefix and suffix are optional. For more info, see <a href="#">Using language injection prefixes and suffixes</a> .</p>
<b>XML Tag</b>	<p>In this area, specify the XML tags in which the attributes are impacted by the defined configuration.</p> <ul style="list-style-type: none"> <li>– Local name - in this text box, specify the tag name without a namespace prefix. Use regular expressions to specify multiple tag names ( <code>name1 name2</code> ), case-insensitive names ( <code>(?i)tagname</code> matches <i>tagname</i> as well as <i>TagName</i> ), etc.</li> </ul> <div style="background-color: #ffff00; padding: 2px;"> <p><b>Warning!</b> Space characters are not allowed as they affect the match result.</p> </div> <ul style="list-style-type: none"> <li>– Namespace - in this text box, specify the namespace URI of the XML tag.</li> </ul> <p>Both fields are optional. However, if the Local name text box is empty the configuration will apply to any attribute that matches the configured name, regardless of its containing XML tag.</p>
<b>XML Attribute</b>	<p>In this area, define the XML tag attribute which indicates that the text enclosed in a tag with such attribute should be treated as the selected language.</p> <ul style="list-style-type: none"> <li>– Local name - in this text box, specify the attribute name without a namespace prefix. Use regular expressions: For example, to match HTML event handler attributes, type <code>on.*</code> in the text box. The field is optional, unless the Local name text box in the XML Tag area is empty. If the attribute local name is not specified, the configuration applies to all attributes of the enclosing tag.</li> <li>– Namespace - in this text box, specify the namespace URI of the attribute.</li> </ul>
<b>Advanced</b>	<p>In this area, specify additional settings to enable more fine-grained control over the injection process.</p> <ul style="list-style-type: none"> <li>– Value pattern - in this text box, type a regular expression that determines the part of the attribute's value to inject the language into. By using the first capturing group of the pattern as the target for injection, you can configure the procedure to have the language injected only into values that match a certain pattern or into multiple parts that match the pattern.</li> <li>– Single file - If the option is off, the fragments that match the value pattern are treated separately, as different "files" - e.g. from the fragment editor's viewpoint.</li> </ul> <p>If the option is on, the corresponding fragments are all merged together to form a single unit, or "file".</p> <p>Given the value pattern</p> <pre>xxx (.+) yyy (.+) zzz</pre> <p>and the fragment</p> <pre>xxx select * yyy from family zzz ,</pre> <p><code>select *</code> and <code>from family</code> are treated as two independent fragments (or "files") if the option is off. If the option is on, <code>select * from family</code> is treated as a single unit or "file".</p> <ul style="list-style-type: none"> <li>– XPath condition - in this text box, specify an XPath expression to address the injection-target more precisely. The context in which the expression is evaluated is the attribute itself. For the field to be active, the XPathView + XSLT Support <a href="#">plugin</a> must be enabled.</li> </ul>

**ItemDescription**

<b>Name</b>	The name of the injection.
<b>Language</b>	<p>The language to be injected.</p> <ul style="list-style-type: none"> <li>– ID. The language ID or name.</li> <li>– Prefix. A sequence of characters to be added before the corresponding string value.</li> <li>– Suffix. A sequence of characters to be added after the corresponding string value.</li> </ul> <p>The prefix and suffix are optional. For more info, see <a href="#">Using language injection prefixes and suffixes</a> .</p>
<b>XML Tag</b>	<p>In this area, define the XML tag which indicates that the text enclosed in this tag should be treated as the selected language.</p> <ul style="list-style-type: none"> <li>– Local name - in this text box, specify the tag name without a namespace prefix. Use regular expressions to specify multiple tag names ( <code>name1 name2</code> ), case-insensitive names ( <code>(?i)tagname</code> matches <i>tagname</i> as well as <i>TagName</i> ), etc.</li> </ul> <p><b>Warning!</b> Be sure not to enter any space characters as they would be significant for the match.</p> <ul style="list-style-type: none"> <li>– Namespace - in this text box, specify the namespace URI of the XML tag. The field is optional.</li> </ul>
<b>Sub-tags</b>	Select this checkbox to include all the subtags recursively.
<b>Advanced</b>	<p>In this area, specify additional settings to enable more fine-grained control over the injection process.</p> <ul style="list-style-type: none"> <li>– Value pattern - in this text box, type a regular expression that determines the part of the XML text's value to inject the language into. By using the first capturing group of the pattern as the target for injection, you can configure the procedure to have the language injected only into values that match a certain pattern or into multiple parts that match the pattern.</li> </ul> <p>Examples:</p> <p><code>[\$#]\{(.*)\}</code> matches the pattern used by the JSP/JSF Expression Language.</p> <p><code>^javascript:(.*)</code> matches the <code>javascript</code> protocol that can be used in hyperlink-hrefs to execute JavaScript code.</p> <ul style="list-style-type: none"> <li>– Single file - If the option is off, the fragments that match the value pattern are treated separately, as different "files" - e.g. from the fragment editor's viewpoint.</li> </ul> <p>If the option is on, the corresponding fragments are all merged together to form a single unit, or "file".</p> <p>Given the value pattern</p> <pre>xxx (.+) yyy (.+) zzz</pre> <p>and the fragment</p> <pre>xxx select * yyy from family zzz ,</pre> <p><code>select *</code> and <code>from family</code> are treated as two independent fragments (or "files") if the option is off. If the option is on, <code>select * from family</code> is treated as a single unit or "file".</p> <ul style="list-style-type: none"> <li>– XPath condition - in this text box, specify an XPath expression to address the injection-target more precisely. The context in which the expression is evaluated is the surrounding XML tag. It is possible to use the XPath <a href="#">extension functions</a> that are provided by the <a href="#">Jaxen</a> XPath engine, e.g. <code>lower-case()</code> . Also, there are three additional functions that can be used to determine the current file's name, extension, and file type: <code>file-name()</code> , <code>file-ext()</code> and <code>file-type()</code> . Alternatively, a list of available functions can be retrieved through standard code completion.</li> </ul> <p>For the field to be active, the XPathView + XSLT Support <a href="#">plugin</a> must be enabled.</p> <p><b>Warning!</b> For performance reasons, it is recommended that you keep these expressions as simple as possible. Especially expressions that cause the whole document to be scanned, such as <code>//foo/bar</code> might cause performance problems with large files.</p>

Ctrl+Alt+S

Use this page to specify different names for the base-annotations to be used. This helps avoid any dependencies on foreign code where it is not desired or possible. The custom annotations should provide the same properties as the original ones, i.e. `value` for all of them and an optional (default = "") `prefix` and `suffix` for the `@Language` replacement.

Also configure the runtime checks to be generated for the `@Pattern` validation.

#### ItemDescription

**Annotation** In this area, specify the classes that implement [annotations](#) of the following types:

- Classes**
- Language annotations
  - Pattern annotations
  - Substitution annotations

Type the class names, possibly using code completion. If necessary, use the Browse button  to open the Select Class dialog box, where you can locate the desired class in the project tree view. Alternatively, switch to the Search by Name tab and start typing the class name. As you type, the list of available classes narrows down to match your entry.

**Runtime Pattern Validation** In this area, configure the runtime checks to be generated for the `@Pattern` validation. The available options are:

- No runtime instrumentation - if this option is selected, no checks will be inserted and any compiled class files will be affected.

- Instrument with assertions - if this option is selected, pattern-validation is controlled with the `-ea` JVM switch and throws `AssertionError`.

**Tip** Selecting this option is recommended due to the potentially negative impact on the performance for methods that are invoked very often.

- Instrument with `IllegalArgumentException` - select this option to have the same result as when the `@NotNull` instrumentation of IntelliJ IDEA is used.

**Performance** Click one of the radio buttons in this area to select the level of analysis and performance of the language injections resolution procedure.

- Do not analyze (fast) - if this option is selected, IntelliJ IDEA does not analyze injections.

**Tip** Selecting the Do not analyze option significantly improves performance.

- Analyze references - if this option is selected, IntelliJ IDEA attempts to recognize injections introduced through variables.
- Look for variable assignments - if this option is selected, IntelliJ IDEA does not perform the dataflow analysis to detect the substitution strings, but looks for variable assignments only.
- Use dataflow analysis (slow) - if this option box is selected, IntelliJ IDEA applies [dataflow analysis](#) to language injections.

**Convert undefined operands to text in concatenation** If this checkbox is selected, IntelliJ IDEA inserts an injected operand as a literal, if its type is not recognized.

**Add @Language annotation or comment if needed** This checkbox enables/disables adding annotations or comments.

Ctrl+Alt+S

Use this settings page to create your own spelling dictionaries and thus expand the basic spelling support provided by IntelliJ IDEA by default.

## Accepted Words Tab

Use this tab to configure the list of words that should be skipped by the **Typo** inspection.

### ItemTooltip and Shortcut

  Click this icon to open the Add New Word dialog box and specify a new entry there. **CamelCase** or **snake\_case** are not supported. If you try to add a word that is already included in one of the spelling dictionaries, IntelliJ IDEA displays an error message **The word <just typed word> is already in the dictionary .**

  Click this button to delete the selected item from the list.

## Dictionaries Tab

Use this tab to configure the dictionaries to be used for spellchecking.

### ItemDescription

**Dictionaries** This area in the bottom of the page shows a list of the dictionaries that can be used in spellchecking. The list contains the dictionaries that come bundled with IntelliJ IDEA by default and user-defined dictionaries detected in the folders from the Custom Dictionaries Folder area above.

- To have a default dictionary applied in the current project, select the check box next to it.
- To exclude a default dictionary from spellchecking within the scope of the current project, clear the check box next to it.

**Custom Dictionaries Folder** This area displays a list of directories that contain user-defined dictionary files (text files with the `dic` extension, containing words separated with a newline).

- To add a new folder to the list, click  and choose the required folder in the **Select Path Dialog** dialog that opens . The full path to the folder is added to the Custom Dictionaries Folder list, and all the `*.dic` files found in this folder are added to the Dictionaries list.
- To remove a folder from the list, select it and click  .

Ctrl+Alt+S

Use this page to import the [TextMate/SublimeText 2 bundles](#) , and to map color scheme of IntelliJ IDEA to that of TextMate.

This page appears in the Settings/Preferences dialog, when TextMate bundle support plugin is [installed and enabled](#) .

The plugin is not bundled with IntelliJ IDEA.

#### ItemDescription

##### TextMate Bundles

This table of added bundles consists of the following columns:

- Checkbox : If a checkbox to the left of the added bundle name is selected, the bundle provides highlighting in the files of the corresponding type.
- Name of the TextMate Bundle
- Bundle location : for each added TextMate bundle, its location is shown.

Click this button to locate the desired bundle using the [Select Path](#) dialog box. When added, the bundle appears in the table of TextMate Bundles.

Click this button to remove the selected bundle. The bundle in question is removed from the list, but is not physically deleted from the computer.

##### IDE Color Scheme - TextMate Color Scheme

Use this table to establish mapping between the various color schemes of IntelliJ IDEA and TextMate.

**Tip** If you want to use a custom TextMate color scheme, you can import a TextMate bundle with schemes, and it will become visible in the list of TextMate color schemes after clicking Apply:

Ctrl+Alt+S 

In this page, configure filters to maintain your lists of TODO items in the [TODO tool window](#) and define TODO patterns to be used in filters.

## Patterns

In this area, create and manage the list of available TODO patterns.

### ItemDescription

**Icon** This read-only field displays the icon that is assigned to the current pattern. (This icon appears in the TODO tool window as a marker for the corresponding TODO items.)

**Case sensitive** This read-only checkbox indicates whether the current pattern is case sensitive or not. The status is changed in the [Edit Pattern](#) dialog box.

**Pattern** This read-only field displays the regular expression that describes the TODO pattern. IntelliJ IDEA recognizes regular expressions in the source code against the specified patterns and displays them in the TODO tool window.

**+ or** Use this icon or shortcut to open the [Add Pattern](#) dialog box, where you can create a new ToDo pattern by specifying a regular expression.

 or 

** or** Use this icon or shortcut to open the [Edit Pattern](#) dialog box, where you can modify the selected pattern.

 or 

**- or** Use this icon or shortcut to remove the selected pattern from the list.

 or 

## Filters

In this area, manage the list of available filters.

### ItemDescription

**Name** This read-only field shows a list of filter names.

**Patterns** This read-only field shows the names of patterns included in the current filter. A filter can contain several patterns.

**+ or** Use this icon or shortcut to open the [Add Filter](#) dialog box, where you can define a new filter.

 or 

** or** Use this icon or shortcut to open the [Edit Filter](#) dialog box, where you can edit the settings for the selected filter.

 or 

**- or** Use this icon or shortcut to delete the selected filter.

 or 

Ctrl+Alt+S

Use this dialog box to define filters that help track TODO items in your source code.

**ItemDescription**

---

Name	In this text box, specify the name of the filter.
Patterns	From the list of available patterns, choose the ones to be included in the filter by selecting the checkboxes next to them.

Ctrl+Alt+S

Use this dialog box to define patterns that help track TODO items in your source code. Make sure the TODO items in the source code are inserted inside comments that are valid for the supported file types.

#### ItemDescription

Pattern	In this text box, type the <a href="#">regular expression</a> that describes the desired TODO pattern.
Icon	From this drop-down list, choose an icon for the pattern.
Case sensitive	Select this check-box to make the pattern case-sensitive.
Font type	Select the corresponding checkbox to have the icon text displayed in bold or italic.
Foreground	Select this checkbox to enable the palette and choose the foreground color.
Background	Select this checkbox to enable the palette and choose the background color.
Error Stripe Mark	Select this checkbox to enable the palette and choose the error stripe color.
Effects	Select this checkbox to enable effects (underscore, strikethrough, etc.) and choose the color for them from the palette.

Ctrl+Alt+S 

The Plugins page shows the list of installed [plugins](#) . Use the checkboxes next to plugin names to enable or disable them.

Other controls on this page let you sort and filter the plugin list, update and uninstall [repository plugins](#) , access [plugin repositories](#) , and also install the plugins available locally.

## Main controls

### ItemDescription

 Type the text to be found.  
As you type, the list of plugins changes: only the plugins whose names and descriptions contain the specified text are shown.

To bring the plugin list back to its initial state, delete the text in the search box or click  .

To access the list of memorized search strings, click  .

Show Use this list to specify which plugins should be shown:

- All plugins
- Enabled
- Disabled
- Bundled
- Custom (these are the plugins that are not bundled with the IDE).

If you want to add sorting by plugin status, click  and select Status . As a result, disabled plugins will be displayed at the end of the list.  
This option is also available from the context menu.

Install JetBrains plugin Click this button to open the Browse Repositories dialog to download and install plugins from the JetBrains repository.

Browse repositories Click this button to open the Browse Repositories dialog to work with plugin repositories (to download and install repository plugins, manage enterprise plugin repositories, etc.).

Install plugin from disk Click this button to install a plugin available locally. Select the file that implements the required plugin in the dialog that opens.

## Context menu commands

### CommandDescription

Reload List of Plugins Use this command to check if newer versions of installed plugins are available (see [Colors for plugin statuses](#) ).

Sort by | Status Use this command to sort plugins by their status.  
When this option is turned on, disabled plugins are shown at the end of the list, after the enabled plugins.

Update Plugin For repository plugins: use this command to download and install a newer version of the selected plugin (if available). See [Colors for plugin statuses](#) .

Uninstall For plugins that are not bundled with the IDE: use this command to uninstall the selected plugin.  
Alternatively, the Uninstall button in the plugin description area can be used.

## Colors for plugin statuses

The names of plugins are shown in different colors depending on their status.

### ColorPlugin status

Black "Normal" plugin status. For a repository plugin: the plugin version is up-to-date.

Red One of the following:

- The plugin is incompatible with the installed version of IntelliJ IDEA.
- The plugin depends on another plugin which is disabled.

Blue For a repository plugin: a newer version of the plugin is available.

Green For a repository plugin: the plugin has been downloaded and installed, but has not been activated yet (IntelliJ IDEA needs to be restarted).

Gray The plugin has been uninstalled, but the changes have not taken effect yet (IntelliJ IDEA needs to be restarted).

This dialog opens when you click the Install JetBrains plugin button on the [Plugins page](#) .

This dialog shows a list of the JetBrains [repository plugins](#) .

You can sort and filter the list, download and install plugins, and configure HTTP proxy settings.

– [Main controls](#)

Download and Install	Use this command to download and install the selected plugin.
----------------------	---

This dialog opens when you click the Manage repositories button in the [Browse Repositories dialog](#) .

Use this dialog to manage the list of [enterprise plugin repositories](#) . The repositories are identified by their [URLs](#) .

#### IconShortcutDescription

		Use this icon or shortcut to add a new repository to the list. Specify the URL of the repository in the dialog that opens. Use the Check Now button to make sure that the specified URL is correct: IntelliJ IDEA will try to connect to the repository.
		Use this icon or shortcut to edit the selected URL.
		Use this icon or shortcut to remove the selected URL from the list.

Ctrl+Alt+S 

The settings under this node allow configuring integration with different version control systems.

[Common settings](#) that are applied to the project files regardless of which version control system is used:

- [Confirmation](#)
- [Background](#)
- [Ignored Files](#)
- [Issue Navigation](#)
- [Changelist Conflicts](#)

The settings for configuring integration with a specific version control system are located under the following nodes:

- [GitHub](#)
- [CVS](#)
- [Git](#)
- [Mercurial](#)
- [Perforce](#)
- [Subversion](#)
- [TFS](#)

Specify which version control systems will be used for specific directories, or the entire project.

#### ItemDescription

Directory	<p>This field shows the path to project directories or the project root(s). For projects with Git or Mercurial integration enabled, IntelliJ IDEA scans project directories to check if there are Git/Mercurial repositories that are not controlled by the IDE. If such repositories are found, they are listed here under Unregistered roots and are marked grey. To add an unregistered root, select it in the list and click the Add button .</p> <p>IntelliJ IDEA also checks if registered roots are valid, i.e. that a Git/Mercurial repository exists at the specified path. If invalid repositories are detected, they are marked with red.</p>
VCS	<p>Select a version control system for the specified directory. The list only displays the version control systems for which the corresponding <a href="#">plugins</a> are enabled.</p>
	<p>Click this button to open the Version Control Configurations dialog and update the configuration settings for the selected VCS.</p>
+	<p>Click this button to add a directory mapping to the list. The Add VCS Directory Mapping dialog box opens where you can specify the required directory, select a VCS for it, and open the Version Control Configurations dialog box to configure the specified VCS, if necessary.</p>
	<p>Click this button to edit the selected directory mapping. The Edit VCS Directory Mapping dialog box opens where you can update the selected mapping and configure the specified VCS, if necessary.</p>
-	<p>Click this button to remove the selected directory mapping from the list.</p>
Limit history to	<p>Select this checkbox to specify the number of lines displayed for a file's history. If this checkbox is selected, the text box of history depth, and the spin box become enabled.</p>
Show directories with changed descendants	<p>If this checkbox is selected, the directories that contain changes, are color-marked. The colors are configurable in the <a href="#">Color Scheme</a> pages of the Editor settings (File Status - Have immediate changed children, Have changed descendants).</p>
Shelve base revisions of files under distributed version control systems.	<p>This option is relevant only for <a href="#">Git</a> and <a href="#">Mercurial</a>. Select this check box to automatically shelve base revisions of files that are under Git or Mercurial version control. By default, IntelliJ IDEA always "remembers" the last commit hash. However, this information is not sufficient if the history has been changed since the last commit as a result of running the <a href="#">rebase</a> operation. In this case, having a copy of the base revision may help.</p>
Show changed in last <number> days	<p>Select this checkbox to have <a href="#">color indication of file status</a> applied during <a href="#">stacktrace analysis</a> and <a href="#">debugging</a>. The names of the files that have been changed within a certain period will be highlighted accordingly. Specify the number of days.</p>
Filter Update Project information by scope	<p>If this option is enabled and a scope is selected, the files that belong to this scope will be marked in bold in the <a href="#">Update Project Info</a> tab of the <a href="#">Version Control Tool Window</a>. If you click the Filter button  in the toolbar in the <a href="#">Update Project Info</a> tab, the files will be filtered by scope, i.e. only the files that belong to the selected scope will be displayed. Click the Manage Scopes link to open the <a href="#">Scopes</a> settings dialog and configure a scope.</p>
Commit message right margin (columns)	<p>In this field, specify the number of symbols that can fit into the right margin of the <a href="#">Commit Changes</a> dialog. Select the Wrap when typing reaches right margin option if you want the text to be transferred to the next line when the maximum number of characters has been reached.</p>

Show unversioned files in Commit dialog      Select this option to see newly added files that have not been added to version control yet under the Unversioned Files node in the [Commit Changes dialog](#) .

---

Check commit message spelling      Select this checkbox if you want to automatically check spelling of your commit messages.

Ctrl+Alt+S 

In this page, enable performing specific version control related operations in the background without any activities from your side.

#### ItemDescription

---

Background Operations	<p>In this area, specify the version control related operations to be performed in the background. To enable running an operation in the background, select the relevant checkbox:</p> <ul style="list-style-type: none"><li>- Perform update from VCS in background</li><li>- Perform commit to VCS in background</li><li>- Perform checkout from VCS in background</li><li>- Perform Edit/Checkout in background</li><li>- Perform Add/Remove in background</li><li>- Perform revert in background</li></ul>
-----------------------	--

---

Changelists to cache initially	Use this spin box to specify the number of changelists to be stored in the cache.
--------------------------------	---

---

Refresh changes every ... minutes	<p>Use this spin box to specify how often the VCS should check for new changes and refresh the cache.</p> <p>The spin box is only enabled when the Enable background processes checkbox is selected.</p>
-----------------------------------	--

---

"Changed on server" conflicts	<p>In this area, specify whether you want IntelliJ IDEA to check whether a checked out files have been updated by someone else. To enable background synchronization with the server, select the Check every ... minutes . In the spin box, specify how often you want synchronization to take place.</p> <p>This area is only enabled when the Enable background processes checkbox is selected.</p>
-------------------------------	---

Ctrl+Alt+S 

Use this page to configure protection of files belonging to inactive changelists, from occasional conflicts.

### ItemDescription

Enable changelist conflict tracking	If this checkbox is selected, IntelliJ IDEA makes it possible to protect files in inactive changelists. Such protection can be performed on the various levels enabled by the options listed below.
Show conflict resolving dialog	If this checkbox is selected, IntelliJ IDEA shows Resolve Changelist Conflict dialog box on an attempt to modify a file.

You need to define the way to resolve a conflict, before you proceed with changes. The possible ways to resolve a conflict are as follows:

- [Shelve](#) changes.
- [Move](#) file to the active changelist.
- Switch changelists to make the current changelist active.
- Ignore conflict. In this case, the file in question will be added to the list of files with ignored conflicts.

Highlight files with conflicts	If this checkbox is selected, IntelliJ IDEA shows a yellow stripe on top of a file from an inactive changelist, when such file has been modified.
--------------------------------	---

In this stripe, you can choose one of the possible ways to resolve conflict:

- Move file to the active changelist.
- Switch changelists.
- Ignore conflict.

Names of the files belonging to inactive changelists are shown in red font in the editor tabs and in the Project view.

Highlight files from non-active changelists	If this checkbox is selected, names of the files belonging to inactive changelists are shown in light-blue font in the editor tabs and in the Project view.
---	---

Files with ignored conflicts	This area shows the list of files, for which Ignore option has been selected in the Resolve Changelist Conflict dialog box, or in the editor stripe.
------------------------------	--

Clear	Click this button to remove all files from the list of files with ignored conflicts.
-------	--

Ctrl+Alt+S 

In this page, specify whether you want IntelliJ IDEA to ask you for confirmation before performing specific version control related actions.

**ItemDescription**

When files are created	<p>In this section, specify whether and how to put a file created in IntelliJ IDEA under version control. The following options are available:</p> <ul style="list-style-type: none"> <li>– Show options before adding to version control : When this option is selected, newly created files are put under version control after you specify the version control options in the dialog box that opens.</li> <li>– Add silently : When this option is selected, newly created files are automatically put under version control without displaying any messages.</li> <li>– Do not add : When this option is selected, newly created files remain unversioned and you can put them under version control later.</li> </ul>
When files are deleted	<p>In this section, specify whether and how to remove a file from the version control system when the file is removed in IntelliJ IDEA. The following options are available:</p> <ul style="list-style-type: none"> <li>– Show options before removing from version control : When this option is selected, locally removed files are also removed from the specified VCS but first a dialog box for selecting version control options is displayed.</li> <li>– Remove silently : When this option is selected, all locally removed files are removed from the specified VCS without asking for confirmation.</li> <li>– Do not remove : When this option is selected, locally removed files remain under version control.</li> </ul>
When empty changelist becomes inactive	<p>In this section, specify IntelliJ IDEA behavior on deleting an empty changelist.</p> <ul style="list-style-type: none"> <li>– Show options before removing : When this option is selected, IntelliJ IDEA asks for confirmation before removing an empty changelist that has lost its active status:</li> </ul>
	
<p>If you choose to delete such a changelist, IntelliJ IDEA suggests to choose another changelist to be marked as active.</p>	
	
<ul style="list-style-type: none"> <li>– Remove silently : When this option is selected, IntelliJ IDEA automatically deletes empty changelists that become inactive, except for the Default changelist.</li> <li>– Do not remove : When this option is selected, empty changelist is not deleted on losing its active status.</li> </ul>	
Display Option dialogs when these commands are invoked	<p>In this area, specify whether you want IntelliJ IDEA to ask you for confirmation when invoking commands, specified below. To enable showing a prompt before performing an action, select the relevant checkboxes.</p>
<div style="background-color: #ffff00; padding: 5px;"> <p><b>Tip</b> – Availability of commands depends on the particular version control system.          – Use controls in this area to restore the original settings, if you have suppressed showing operation-specific option dialog boxes by selecting the Do not show this dialog in the future checkbox.</p> </div>	
Show Clear Read-Only Status dialog box	<p>Select this checkbox to have IntelliJ IDEA explicitly require cancellation of the read-only status when you open a file in the editor and try to modify it.</p> <p>The read-only status can be cleared in two ways:</p> <ul style="list-style-type: none"> <li>– Using the current VCS: the file is added to a <a href="#">changelist</a>.</li> <li>– Using a file system: the file is not added to the changelist.</li> </ul> <p>This option is relevant for those version control systems that separate check-out from opening for editing.</p>
Suggest to move uncommitted changes to another changelist	<p>When this option is selected, on committing a changelist to the repository with some files excluded from the commit, IntelliJ IDEA prompts to move these files to another changelist.</p>
Force non-empty check-in comments	<p>Select this checkbox to suppress committing changes without supplying them with corresponding comments.</p>
Clear initial commit message	<p>If this checkbox is selected, the previous check-in comment is cleared from the Comment area.</p>
Show patch in explorer after creation	<p>Use this drop-down list to define the IntelliJ IDEA behavior when a <a href="#">patch is created</a> . The available options are:</p>

- Yes : if this option is selected, native file manager always opens to show the patch file.
- No : if this option is selected, the native file manager will not open.
- Ask : if this option is selected, IntelliJ IDEA will display a dialog box informing about successful patch creation, and a suggestion to locate the patch file in the native file manager.

---

Create changelist on failed commit

Use this drop-down list to define the IntelliJ IDEA behavior in case of failed commits. The available options are:

- Yes : if this option is selected, the Failed commit changelist will be automatically created, and the respective files will be moved to this changelist.
- No : if this option is selected, the files that failed to commit will remain in their original changelist.
- Ask : if this option is selected, on failed commit IntelliJ IDEA will display a dialog box asking whether the files should be moved to another changelist, or remain in the original one.

See the section [Resolving Conflicts](#) .

Ctrl+Alt+S 

Use this page to specify your [GitHub](#) remote storage account credentials or create a GitHub account if you do not have one yet.

#### ItemDescription

Host	Specify the URL of your GitHub repository.
Auth Type	Use this drop-down list to select how you want to be authenticated on GitHub. The available options are: <ul style="list-style-type: none"><li>– Password . If this option is selected and you have <a href="#">two-factor authentication</a> enabled in your GitHub account settings, you will be asked to enter an authentication code each time IntelliJ IDEA requires you to log in to your GitHub account.</li><li>– Token (recommended by GitHub for authentication from third-party applications, as it does not require IntelliJ IDEA to remember your password).</li></ul>
Login	In this text box, type your GitHub logon name. This field is only available if Password is selected as authentication method above.
Password	In this text box, type your GitHub account password. This field is only available if Password is selected as authentication method above.
Test	Click this button to verify the credentials you have specified.
Token	Specify your personal access token. This field is only available if Token is selected as authentication method above.
Create API Token	Click this button if you do not have a personal API token yet. Specify your GitHub credentials in the Login to GitHub dialog that opens and click the Login button. The token will be generated automatically.
Sign up	Click this link to open the Sign up for GitHub page where you can create a GitHub account.
Connection timeout	Specify the time period to wait for connection to be established.

Ctrl+Alt+S 

Use this dialog to configure a list of files and directories that you do not want to put under version control. These can be file names associated with VCS administration, backup files, and any other artifacts that you want to remain unversioned. You can also specify patterns of files you want to ignore.

**Tip** You can only ignore unversioned files, i.e. files that have not yet been put under version control.

Item	Keyboard shortcut	Description
	Alt+Insert	Use this icon or shortcut to add an item to the list. The <a href="#">Ignore Unversioned Files</a> dialog box opens where you can type an exact path to a file or directory to be ignored or specify a pattern that defines the names of files and directories to be ignored.
	Enter	Use this icon or shortcut to edit the selected path or pattern in the <a href="#">Ignore Unversioned Files</a> dialog box.
	Alt+Delete	Use this icon or shortcut to remove the selected path or pattern from the list.

Two characters can be used as wildcards:

- \* : to replace any string.
- ? : to replace a single character.

For example, \*.iml will ignore all files with the iml extension; \*.?ml will ignore all files whose extension ends with ml .

Ctrl+Alt+S

The dialog box opens when you click the Add  or Edit  button on the [Ignored Files](#) page.

Use this dialog to configure rules that define which files and folders should be ignored by version control systems. The files you want to ignore can be appointed explicitly by their names or through name patterns with wildcards. To ignore a directory, you need to specify the full path to it relative to the project root.

**Tip** You can only ignore unversioned files, i.e. files that have not yet been put under version control.

Select the relevant option and fill in the text box next to it.

#### ItemDescription

**Ignore specified file** In this text box, specify the name of the file to be ignored. Do one of the following:

- Type the file name relative to the project root, for example, `my_folder/my_subfolder1/my_subfolder2/my_file` .
- Click the Browse button  and select the desired file in the Select File to Ignore dialog box.

**Ignore all files under** In this text box, specify the name of the directory to be ignored. Do one of the following:

- Type the directory name relative to the project root, for example, `my_folder/my_subfolder1/` .
- Click the Browse button  and select the desired folder in the Select Directory to Ignore dialog box.

The rule is applied recursively to all subdirectories of the specified directory. If a directory has several subdirectories and you want only one of them ignored, specify the required directory explicitly, for example, `my_folder/my_subfolder1/my_subfolder2/` .

**Ignore all files matching** In this text box, specify a pattern that defines the names of files to ignore. The rule is applied to all directories under the project root.

**Note** Using wildcards in combination with slashes ( `/` ) to restrict the scope to a certain directory is not supported.

Ctrl+Alt+S 

Use this dialog to create a list of the so-called **issue navigation patterns**. An **issue navigation pattern** maps an **issue ID pattern** in commit messages with the URL addresses of the referenced issues. This enables you to navigate from committed changes to issues related to these changes. As soon as IntelliJ IDEA encounters a match to the issue ID pattern in a commit message, the match is displayed as a link in the **Version Control tool window**. If you mention several issues, all of them will be displayed as links. Clicking such link opens the matching issue in the default browser.

#### ItemDescription

Issue	This read-only field shows the issue pattern.
Link	This read-only field shows the link to navigate from the issue pattern in the current row to the issue in the bug tracking system.
	Click this button to create a new issue navigation pattern and link. The <b>Add Issue Navigation Link</b> dialog box opens where you can specify: <ul style="list-style-type: none"> <li>– A regular expression to define the issue ID.</li> <li>– A regular expression to define the navigation link to the issue.</li> </ul>
<div style="background-color: #ffff00; padding: 5px;"> <b>Tip</b> Refer to <a href="#">Regular Expressions Syntax Reference</a> for details on using special characters in regular expressions. </div>	
	Click this button to create a new JIRA pattern. The <b>Create JIRA Issue Navigation Pattern</b> dialog box is opened where you can specify the URL to your JIRA installation. The regular expression that defines the pattern is added automatically.
	Click this button to create a new pattern for <a href="#">YouTrack</a> . In the dialog box that opens, specify the URL to your YouTrack installation. The regular expression that defines the pattern is added automatically.
	Click this button to update the selected issue navigation link.
	Click this button to remove the selected issue navigation link from the list.

## Example

The example below shows how IntelliJ IDEA applies the abovementioned rules to detect a reference to an issue in a commit message and compose a link to it in the issue tracking system.

Issue ID pattern	The regular expression that defines the format in which issues are referenced in commit messages.
	<pre>[A-Z]+\-\d+</pre> <p>This regular expressions matches all character strings that consist of two substrings separated by an n-dash character:</p> <ol style="list-style-type: none"> <li>1. Substring 1: An unlimited number of upper case alphabetic characters.</li> <li>2. Substring 2: An unlimited number of digital characters.</li> </ol>
Issue link pattern	A combination of the URL address of your issue tracking system and a regular expression that identifies issues in it.
	<pre>http://mytracker/issue/\$0</pre> <p>Here <code>\$0</code> indicates a back reference to the entire match. This means that as soon as IntelliJ IDEA detects a match in a commit message, it is added to the URL address of the tracker as is.</p>
Matching issue ID	IntelliJ IDEA detects the following reference to an issue in the commit message of interest:
	<pre>MYPROJECT-110</pre>
Composed issue link	In accordance with the above issue navigation pattern, the detected matching reference is added to the URL of the tracker as is, so the link to the referenced issue is composed as follows:

<http://mytracker/issue/MYPROJECT-110>

---

Use this dialog box to create an issue pattern and navigation link to a bug tracking system.

**ItemDescription**

---

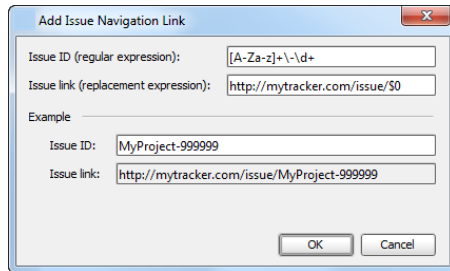

Issue ID (regular expression)      In this field, type a regular expression that will be converted to the a specific issue id.

---

Issue link (replacement expression)      In this field, type a regular expression that will be converted to a navigation link to the issue.

---

Example      In this section, type some specific issue id to make sure it matches the specified pattern:

Ctrl+Alt+S 

Use this page to specify the version control settings to be applied to the directories of your project that are under CVS control.

#### ItemDescription

---

**Updating** In this area, define the IntelliJ IDEA behavior when merge conflicts occur during update from the server.

- Show dialog - select this option to have IntelliJ IDEA display a dialog box where you can examine, analyze, and resolve possible conflicts before updating.
- Skip merging for all project or module files merged with conflicts - select this option to suppress updating files where conflicts occurred during merge.
- Get latest repository versions silently - select this option to have your local files in question automatically updated with their latest repository versions.

---

**Use read-only flag for not edited file** Select this checkbox to have the read-only status assigned to a file automatically after the check out, update, or commit operations.

---

**Show CVS server output** Select this checkbox to have the server output of CVS commands displayed in the CVS Output tool window.

---

**Default keyword substitution for text files** Use this drop-down list to specify the keyword expansion mode. CVS uses the keyword substitution mode of a file to differentiate binary files from ASCII files and to indicate what type of keyword substitution is applied when files are committed and checked out.

The available options are:

- keyword&value ( `-kkv` )
- keyword, value&locker ( `-kkv1` )
- keyword only ( `-kk` )
- original string ( `-ko` )
- binary ( `-kb` )
- value only ( `-kv` )

---

**Global Settings** Click this button to open the [Global CVS Settings](#) dialog box.

Ctrl+Alt+S

Use this dialog box to set up CVS options at the global level. The dialog is available for files and directories that are under CVS control.

#### ItemDescription

Charset	From this drop-down list, select the character set to be used.
Use gzip compression	Select this checkbox to apply <code>gzip</code> compression.
Password file	In this text box, specify the fully qualified path to the <code>.cvspass</code> file. Click  to select the file in the <a href="#">corresponding dialog</a> .
Connection timeout	In this text box, type the timeout value in seconds.
Send environment variable to server	Select this checkbox to have CVS-related environment variables sent to the server.
Log CVS client/server output	Select this checkbox to enable logging and have the <code>cvs.log</code> log file stored in the <code>log</code> directory of your IntelliJ IDEA installation.
to <code>cvs.log</code> file	

Ctrl+Alt+S 

Use this page to specify the version control settings that will be applied to the directories of your project that are under [Git](#) control.

**ItemDescription**

**Path to Git executable** In this text box, specify the path to the Git executable file. Type the path manually or click the Browse button  and specify the path in the dialog that opens.

**Test** Click this button to verify the path to the Git executable file.

**SSH executable** Use this drop-down list to specify the [SSH](#) version to be used with Git. The available options are:

- Built-in : select this option to use the implementation provided by IntelliJ IDEA.
- Native : select this option to use native implementation.

Note that on some platforms, the use of native ssh implementation may cause hang-up issues. You may need to configure a platform-specific `ssh-askpass` to receive prompts for passwords.

**Control repositories synchronously** This option only becomes available if you have a multirooted project, i.e. there are several Git repositories within a single project.

Select this option if you want branch operations (such as `checkout` , `merge` , etc.) to be applied synchronously to all repositories within your project.

**Commit automatically on cherry-pick** When you cherry pick a specific commit, the Commit Changes dialog is displayed. If the Commit automatically on cherry-pick option is selected, the selected commit is submitted silently on clicking the cherry-pick button  , without displaying the Commit Changes dialog.

**Warn if CRLF line separators are about to be committed** Select this option to enable smart handling of `LF` and `CRLF` line separators. IntelliJ IDEA will analyze your configuration, warn you if you are about to commit CRLF into the repository, and suggest changing the `core.autocrlf` setting to `true` or `input` depending on your operating system.

**Note** Note that this setting is not applied to files where you have set any related [Git attributes](#) . In this case, IntelliJ IDEA assumes that you clearly understand what you are doing and excludes such files from analysis.

If this option is deselected, you will have to fix issues with line endings manually using the [Difference Viewer dialog](#) .

**Warn when committing in detached HEAD or during rebase** Select this option if you want IntelliJ IDEA to display a warning when a commit is performed from a detached head or on rebase, as this may cause issues and code loss.

**Update method** Use this drop-down list to choose the strategy to synchronize your local repository with the remote storage. The selected method will be used when the `push` operation is rejected (if the [Auto-updated if push of the current branch was rejected](#) option is enabled), or when you invoke the Update Project operation. The following options are available:

- Merge: choose this option to have the [merge](#) strategy applied. The result is identical with that of running `git fetch ; git merge` or `git pull --no-rebase` .
- Rebase: choose this option to have the [rebase](#) strategy applied. The result is identical with that of running `git fetch ; git rebase` or `git pull --rebase` .
- Branch Default: choose this option to have the default command for the branch applied. The default command is specified in the `branch.<name>` section of the `.git/config` configuration file.

**Auto-update if push of the current branch was rejected** Select this checkbox if you want the current branch to be updated automatically if the `push` operation from the current branch to its tracked branch is rejected.

If this option is deselected, IntelliJ IDEA will display the Push Rejected dialog when [pushing a branch](#) is rejected because your local repository and the remote storage are not synchronized.

**Note** Note the following:

- If you have never seen the Push Rejected dialog box before and you are enabling the checkbox initially, IntelliJ IDEA will update the conflicting local branch silently by means of the `merge` operation.
- If you have already encountered the Push Rejected dialog box and selected the Remember the update method choice... option, IntelliJ IDEA saves your last choice ( `rebase` or `merge` ) and will apply it to update the conflicting local branch silently. Accordingly, to change the "remembered" setting, clear the checkbox, access the Push Rejected dialog box, select the Auto-update if push ... rejected option, and invoke another update strategy.

**Allow force push** If this checkbox is selected, the Force push option is added to the [Push Commits dialog](#) (as a drop-down option on the Push button).

**Protected branches** If you have selected the [Allow force push option](#) , but want to disable it for certain branches, list them here (this is a team-shared parameter that is stored in `.idea/vcs.xml` ).

You can list several branches separated by a colon, or supply branch patterns as the input is treated as a list of regular expressions.

Ctrl+Alt+S 

Use this page to specify the version control settings to be applied to the directories of your project that are under [Mercurial](#) control.

#### ItemDescription

Path to hg executable	<p>Specify the location of the Mercurial executable file. Enter the path manually, or click the Browse button  and select the path in the dialog that opens.</p> <p>If you followed the standard installation procedure, the default location is <code>/opt/local/bin</code> or <code>/usr/local/bin</code> for Linux and macOS and <code>/Program Files/TortoiseHG</code> for Windows.</p> <p>It is recommended that you add the path to the Mercurial executable file to the <code>PATH</code> <a href="#">variable</a> . In this case, you can specify only the executable name, the full path to the executable location is not required.</p>
Test	<p>Click this button to verify the path to the Mercurial executable.</p>
Control repositories synchronously	<p>This option only becomes available if you have a multirooted project, i.e. there are several Mercurial repositories within a single project.</p> <p>Select this option if you want branch operations (such as <code>checkout</code> , <code>merge</code> , etc.) to be applied synchronously to all repositories within your project.</p>
Check for incoming and outgoing changesets	<p>Select this option if you want IntelliJ IDEA to detect incoming and outgoing changes in the background mode. IntelliJ IDEA will automatically request the server for incoming and outgoing changesets every 5 minutes.</p>
Ignore whitespace differences in annotations	<p>Select this option if you want white spaces to be ignored when annotating, and, thus, get more meaningful annotations and cast out senseless ones.</p>

Ctrl+Alt+S 

Use this page to specify the version control settings to be applied to those directories of your project that are under Perforce control

**ItemDescription**

Perforce is online	Select this checkbox to work with Perforce in the online mode.
Switch to offline mode automatically if Perforce is unavailable	Select this checkbox to have IntelliJ IDEA automatically <a href="#">go offline</a> as soon as Perforce becomes unavailable and display the corresponding message.
Use P4CONFIG or default connection	If this option is selected, <code>P4CONFIG</code> or the default Perforce connection are used to connect to the Perforce server. Using <code>P4CONFIG</code> makes it trivial to switch between Perforce settings for different projects, when necessary.
Use connection parameters	If this option is selected, the connection credentials (port, client, user name, and charset) are specified manually.
Port	In this text box, type the server and the port which your Perforce client will listen to. For the default Perforce server configuration, it looks like <code>perforce:1666</code> .
Client	In this text box, type the name of your Perforce workspace name.
User	In this text box, type your user name to authenticate to the server.
Charset	From this drop-down list, select the character set to be used.
Dump Perforce commands to <path>	Select this checkbox to have IntelliJ IDEA create a file <code>P4.output</code> and store the output of Perforce commands in it.
Use login authentication	When this checkbox is selected, Perforce requires a login to authenticate a user.
Test Connection	Click this button to check whether the specified settings ensure establishing connection to the Perforce server.
Path to P4 executable	In this text box, specify the path to the Perforce Command Line Client's executable file <code>P4</code> . Click the Browse button  to open the Select Path - P4 Configuration dialog box and select the executable file in the directories tree.
Path to P4V executable	In this text box, specify the path to the Perforce Visual Client's executable file <code>P4V</code> . Click the Browse button  to open the Select Path - P4 Configuration dialog box and select the executable file in the directories tree.
Show branching history ...	Select this checkbox to enable displaying the branch history of a specified file, including all file branch points, edits, and merges.
Show integrated changelists in committed changes	Select this checkbox to have IntelliJ IDEA point at committed changes that are also integrated to other changelists and provide information on the target changelists that received the content in question.
Server timeout	In this text box, specify the time period in seconds after when the Perforce client cancels its attempts to establish connection to the server.
Enable Perforce Jobs Support	When this checkbox is selected, user interface for attaching and detaching Perforce jobs to change lists is provided in the <a href="#">Version Control</a> tool window and in the <a href="#">Commit Changes</a> dialog box.

Ctrl+Alt+S 

Use this page to specify the version control settings to be applied to those directories of your project that are under Visual SourceSafe control

**Item Description**

Path to VSS client (ss.exe)	In this text box, specify the location of the SourceSafe client executable file <code>ss.exe</code> .
	Click this button to access the Open dialog box for choosing the <code>ss.exe</code> file.
Path to VSS configuration file (srcsafe.ini)	In this text box, specify the location of the SourceSafe configuration file <code>srcsafe.ini</code> .
	Click this button to access the Open dialog box for choosing the <code>srcsafe.ini</code> file.
User name	In this text box, type your VSS user ID for accessing the repository.
Password	In this text box, type your VSS user password.

Ctrl+Alt+S 

Use this page to specify the settings to be applied to your project directories that are under Subversion control

**Item Description**

Use command line client	Select this option if you want to use the command line svn client. Enter the name of the executable file, or click the Browse button  and select the path in the dialog that opens.
Enable interactive mode	Select this option if you want IntelliJ IDEA to emulate the behavior when Subversion commands are executed directly from the terminal in the interactive mode (dialogs will pop up where you can input credentials). This is required to handle password/passphrase prompts for svn+ssh repositories, and trust invalid server certificates for https repositories.
Use custom configuration directory	Select this option if you do not want to store Subversion configuration files in the system default location, and specify the path to the custom directory.
Update administrative information only in changed subtrees	<p>This option only applies to working copies older than SVN 1.7 managed by SVNKit.</p> <p>During synchronization with the server (update), SVN locks your working copy one subtree after another by creating empty <code>lock</code> files in the corresponding administrative <code>.svn</code> directories. After that, SVN starts comparing file hashes to detect which local files need to be synchronized.</p> <p>When this option is selected, SVN first checks if any files from a subtree have been modified on the server, and locks this subtree (i.e. creates a <code>.svn/lock</code> file) only if such files are detected. This approach improves performance but may cause concurrency issues, for example, with antiviral software.</p>

## Presentation

Use this settings page to configure data presentation settings.

**Item Description**

Check svn:mergeinfo in target subtree when preparing for merge	Select this option if you want IntelliJ IDEA to check the merge tracking information for the target branch before merging to prevent duplicates.
Maximum number of revisions to look back in annotations	Select this option to limit the number of revisions to look back at when calculating annotations, and specify the number of revisions.
Show merge source in history and annotations	Select this option if you want merge sources to be visible in annotations and file history.
Ignore whitespace differences in annotations	Select this option if you want white spaces to be ignored when annotating, and, thus, get more meaningful annotations and cast out senseless ones.

## Network

Use this settings page to configure the connection settings.

**Item Description**

Use IntelliJ IDEA general proxy settings as default for Subversion	Select this option if you want Subversion to use the default IntelliJ IDEA proxy settings.
HTTP timeout	Specify the number of seconds to wait for HTTP connection to be established.
SSH connection timeout	Specify the number of seconds to wait for SSH connection to be established.
SSH read timeout	Specify the number of seconds to wait for response.
SSL protocols	In this area, select which SSL protocol you want to use. The available options are: <ul style="list-style-type: none"> <li>- All</li> <li>- SSLv3</li> <li>- TLSv1</li> </ul>
Edit Network Options	Click this button to change Subversion runtime configuration file in the <a href="#">Edit Subversion options related to the network layers dialog</a> .

## SSH

Use this settings page to configure the settings used to connect to an SVN server via a tunneling SSH protocol.

**ItemDescription**

SSH executable	Specify the path to the SSH client. Enter the name of the executable file, or click the Browse button  and select the path in the dialog that opens. If not specified, <code>'ssh'</code> is used by default. This field is only available if the Password or the Private key option is selected.
User name	Specify the user name for SSH connection. If the user name is explicitly specified in the repository URL, this value will be used and this setting will be ignored. This field is only available if the Password or the Private key option is selected.

Port	If your server is listening on a non-standard port (22 for svn+ssh://), modify the default value. This field is only available if the Password or the Private key option is selected.
Password	Select this option if you want to use a password for SSH authentication.
Private key	Select this option if you want to use a private key for SSH authentication.
Path	Specify the path to the private key. Enter the path manually, or click the Browse button  and select the path in the dialog that opens.
Subversion config	Select this option if you want to use the default settings stored in Subversion configuration for SSH connection.
SSH tunnel	This field displays the SSH tunnel settings stored in Subversion configuration. You can modify the value and click the Update button to write this value to the Subversion configuration.
Update	Click this button to check the Subversion configuration and update the value if necessary, or to write the value you have entered to the Subversion configuration.
SVN_SSH	This field displays the environment variable that can be used in the tunnel configuration (by default, <code>SVN_SSH</code> ) and is stored in Subversion configuration.

The dialog box opens when you click the Edit Network Options button on the [Subversion](#) page of the [Settings/Preferences](#) dialog box. In this dialog box, specify the Subversion network settings stored in the servers Subversion runtime configuration file.

The dialog box contains two tabs:

- System file - this tab displays the default network configuration settings specified by the system administrator.
- User file - in this tab, customize the default network configuration settings.

The dialog box consists of two panes:

- On the left-hand pane, add, edit, and remove configuration profiles. Network configuration settings are arranged into profiles of two types:
  - Group - settings from such profile apply to a specific group, defined by a glob pattern.
  - Global - settings from this profile are applied to all servers that do not match any glob pattern.
- On the right-hand pane, specify the settings for the selected configuration profile.

## Toolbar Options

**Item** **Tooltip** **Description**  
and  
**shortcut**

	Add	Click this button to have a new configuration profile added to the list.
		
	Delete	Click this button to remove the selected profile from the list.
		
	Copy	Click this button to have a copy of the selected profile created.
		

## HTTP Proxy Settings

**Item** **Description**

URL Patterns	In this text box, type the patterns that define the URL addresses of repositories to be accessed via proxy. Use commas to separate patterns.
Exceptions	In this text box, type the patterns that define the URL addresses of repositories to be accessed directly, without using proxy. Use commas to separate patterns.
Server	In this text box, specify the name or IP address of the proxy server to use.
Port	In this text box, specify the port number the proxy server listens to.
Connection timeout	In this text box, specify the time period in seconds after when the Subversion client cancels its attempts to establish connection to the server.
User	In this text box, type the user name or login to authenticate at the specified proxy server.
Password	In this text box, type the password that matches the specified login or user name.

## SSL Settings

**Item** **Description**

Comma separated paths	In this text box, specify the paths to files that contain certificates of the <a href="#">Certificate Authority (CAs)</a> files that are accepted by the Subversion client when accessing the repository.
to CAs certificate files	
SSL client certificate file	In this text box, specify the location of the SSL client certificate file. Type the path to the file manually or click the Browse button  and choose the location in the <a href="#">dialog that opens</a> .
SSL client certificate passphrase	In this text box, type the SSL client certificate passphrase to use.
Trust default CAs	Select this checkbox to have the Subversion integration trust the set of default <a href="#">Certificate Authority</a> files shipped with <a href="#">OpenSSL</a> .

## Repositories

**Item** **Description**

Repositories	This list displays the URL addresses of the previously accessed repositories.
--------------	---

Test connection Click this button to make sure that connection to the selected repository can be established successfully according to the settings specified in the dialog box.

**Tip** When you click this button, IntelliJ IDEA displays the **Authentication Required** dialog box.

Ctrl+Alt+S 

Use this page to specify the version control settings to be applied to those directories of your project that are under TFS control.

#### ItemDescription

---

**Servers and workspaces** In this area, configure access to workspaces and servers to use.

- **Manage** : click this button to open the [Manage TFS Servers and Workspaces](#) dialog box where you can create a list of servers and workspaces you need to have access to.
- Use IntelliJ IDEA HTTP Proxy settings for TFS: when this checkbox is selected, TFS servers are accessed through the Proxy server using the IntelliJ IDEA [default Proxy settings](#) .

---

**Passwords** In this area, handle the passwords for accessing TFS servers and workspaces.

- **Reset Saved Passwords**: click this button to discard the stored passwords.

---

**Check-in policies compatibility** A check-in policy is a rule that is executed before every check-in to ensure that the selected changeset is OK to commit. **Standard policies** are stored on the server and are executed on the client machines. **Custom policies** are implemented as custom plugins to IntelliJ IDEA. The IDs of these plugins are stored on the server, while the policies themselves are applied locally. Therefore, to enable the use of a policy in a team, all the team members should install the corresponding plugin.

Use the controls in this area to configure how IntelliJ IDEA should treat third party check-in policies. These settings are applied to all IntelliJ IDEA projects by default unless they are overridden for a specific project.

- **Evaluate Team Explorer policies**: select this checkbox to have the Microsoft Team Explorer policy definitions installed and executed on the client machine.
- **Evaluate Teamprise policies**: select this checkbox to have the Teamprise policy definitions installed and executed on the client machine.
- **Warn about not installed policies**: select this checkbox to have warnings displayed in case the specified policy definition is not installed.

Ctrl+Alt+S

The dialog box opens when you click the Manage servers and workspaces button in the [TFS](#) dialog box. Use this dialog box to handle the list of TFS servers and [workspaces](#) you have access to.

#### ItemDescription

Server/Workspace	This read-only field shows the URL addresses of TFS servers you have access to and workspaces available on these TFS servers.
Workspace comment	This read-only field shows the descriptions of workspaces on the servers you have access to.
Team Servers	Use the buttons in this area to manage the list of available servers and workspaces and configure access to them. <ul style="list-style-type: none"><li>– Add: click this button to open the <a href="#">Add Team Foundation Server</a> dialog box where you can specify the parameters for establishing connection to a TFS server. TFS uses <a href="#">NTLM authentication</a>, so native Windows applications (that is, <a href="#">Microsoft Team Explorer</a>) authenticate silently with system credentials. IntelliJ IDEA users must always specify their username and password because of limitations posed by Java Runtime.</li><li>– Remove: click this button to remove the selected server from the list.</li><li>– Reload workspaces: click this button to have the list of available workspaces refreshed.</li><li>– TFS Proxy: click this button to open the Set TFS proxy for server... dialog box where you can specify the parameters for accessing the selected server via Proxy.</li><li>– Check-in Policies: click this button to open the <a href="#">Edit Check-in Policies</a> dialog box where you can manage the list of check-in policies to be applied.</li></ul>
Workspaces	Use the buttons in this area manage the list of available workspaces and update the workspaces, when applicable. <ul style="list-style-type: none"><li>– Create: click this button to open the <a href="#">Create Workspace</a> dialog box for creating a new workspace.</li><li>– Edit: click this button to open the <a href="#">Edit Workspace</a> dialog box for editing the selected workspace.</li><li>– Delete: click this button to remove the selected workspace from the list.</li></ul>
Close	Click this button to save the settings, close the dialog box, and return to the <a href="#">TFS</a> dialog box.

Ctrl+Alt+S

The dialog box opens when you click the Add button in the [Manage TFS Servers and Workspaces](#) dialog box. Use this dialog box to specify and edit the parameters for establishing connection to TFS servers.

#### ItemDescription

Address	In this text box, type the URL address of the TFS server you want to connect to.
Auth	In this field, specify the authentication protocol to access the server. TFS uses <a href="#">NTLM authentication</a> , so native Windows applications (that is, <a href="#">Microsoft Team Explorer</a> ) authenticate silently with system credentials. IntelliJ IDEA users must always specify their username and password because of limitations posed by Java Runtime. To authenticate through OAuth ( <a href="#">Windows Live ID</a> ), choose Alternate from the Auth drop-down list.
User name	In this text box, type your TFS user name. The field is available for the NTLM) and Alternate authentication types.
Domain	In this text box, type the name of the network domain where the TFS server is located. The field is available for the NTLM) authentication type.
Password	In this text box, type your TFS password. The field is available for the NTLM) and Alternate authentication types.
Store password	Select this checkbox to have IntelliJ IDEA remember the specified password.

Ctrl+Alt+S

The dialog box opens when you select an entry in the Server/Workspace list and click the Check-in Policies button in the [Manage TFS Servers and Workspaces](#) dialog box.

A check-in policy is a rule that is executed before every check-in to ensure that the selected changeset is OK to commit. **Standard policies** are stored on the server and are executed on the client machines.

**Custom policies** are implemented as custom plugins to IntelliJ IDEA. The IDs of these plugins are stored on the server, while the policies themselves are applied locally. Therefore, to enable the use of a policy in a team, all the team members should install the corresponding plugin.

Use this dialog box to manage the list of the custom project policies to be applied when checking in to the selected workspace and to override the default IntelliJ IDEA-wide policies for the project, if necessary.

In this section:

- [Check-in Policies](#)
- [Compatibility](#)

## Check-in Policies

### ItemDescription

Team Project	From this drop-down list, select the name of the project to specify the policies for.
Policy Type	This read-only field shows the available policies.
Description	This read-only field shows brief descriptions of policies.
Enabled	When this checkbox is selected, the policy next to it is mandatory during check-in.
Add	Click this button to open the Add Check-in Policy dialog box where you can define a new check-in policy.
Edit	Click this button to open the Edit Check-in Policy dialog box where you can re-define the selected check-in policy.
Remove	Click this button to remove the selected check-in policy from the list.

## Compatibility

Use the controls in this area to suppress applying the default IntelliJ IDEA-wide check-in policy settings to the current project.

### ItemDescription

Override default settings for team project <project name>	<p>Select the checkbox to discard the default policy settings within the scope of the current project and re-define the settings by selecting or clearing the corresponding checkboxes below.</p> <ul style="list-style-type: none"><li>– Evaluate Team Explorer policies: select this checkbox to have the Microsoft Team Explorer policy definitions installed and executed on the client machine.</li><li>– Evaluate Teamprise policies: select this checkbox to have the Teamprise policy definitions installed and executed on the client machine.</li><li>– Warn about not installed policies: select this checkbox to have warnings displayed in case the specified policy definition is not installed.</li></ul>
---	--

Ctrl+Alt+S

The dialog box opens when you click the Create button or select a workspace and click the Edit button in the [Manage TFS Servers and Workspaces](#) dialog box.

Use this dialog box to define a new workspace or update the existing one by selecting the necessary folders on the TFS server and mapping them to local folders.

#### ItemDescription

Name	In this text box, specify the name of the new workspace.
Comment	In this text box, describe briefly what this workspace is intended for.
Server	This read-only field displays the URL address of the TFS server on which the new workspace will be created and which is selected in the <a href="#">Manage TFS Servers and Workspaces</a> dialog box.
Owner	This read-only field displays your TFS user name.
Computer	This read-only field displays the name of your computer in the network domain.

## Working Folders

In this area, define mappings between the necessary folders on the TFS server and local folders.

**Tip** You can map a folder including all its subfolders recursively or map each subfolder separately.

#### ItemDescription

Status	From this drop-down list, select the status of a new mapping.
Local path	In this text box, specify the path to the local folder. Use the  button, if necessary.
Server path	In this text box, specify the path to the corresponding folder on the server.
Add	Click this button to create a new mapping.
Remove	Click this button to remove the selected mapping from the list.

Ctrl+Alt+S 

---

When you select the Build, Execution, Deployment category in the left-hand pane, its main subcategories are listed in the right-hand part of the dialog.

- [Build Tools](#)
- [Compiler](#)
- [Debugger](#)
- [Deployment](#)
- [Arquillian Containers](#)
- [Application Servers](#)
- [Clouds](#)
- [Coverage](#)
- [Docker](#)
- [Instant Run](#)
- [Required Plugins](#)

Ctrl+Alt+S 

---

When you select the Build Tools category in the left-hand pane, its main subcategories are listed in the right-hand part of the dialog.

- [SBT](#)
- [Maven](#)
- [Gradle settings](#)
- [Gant settings](#)

Use this page to configure SBT project settings.

**ItemDescription**

---

Linked SBT projects	This area shows all linked projects.
Project-level settings	Use this area to configure the following options: <ul style="list-style-type: none"><li>- Use auto-import - select this checkbox to resolve all the changes made to the SBT project automatically every time you refresh your project.</li><li>- Create directories for empty content roots automatically - select this option to add the <code>src</code> directory to your project.</li><li>- Download sources and docs - select this checkbox to download sources and docs for project dependencies.</li><li>- Download SBT sources and docs - select this checkbox to download sources docs for SBT itself.</li></ul>
JVM	Use this area to configure the JVM settings. You can choose from the following options: <ul style="list-style-type: none"><li>- From project JDK - select this default option to use the project's JDK.</li><li>- Custom - select this option to use a custom JVM.</li></ul>
JVM Options	Use this area to configure additional JVM settings. You can choose from the following options: <ul style="list-style-type: none"><li>- Maximum heap size, MB - use this field to specify the maximum heap size available to the process that launches the compiler. The default 768 Mb is suitable for most of the purposes.</li><li>- VM parameters - use this field to type the string to be passed to the VM when IntelliJ IDEA launches the compiler. If you need more room to type, click <code>+</code> to open the VM parameters dialog where the text entry area is larger.</li></ul>
Launcher (sbt-launch.jar)	Use this area to configure settings for the sbt launcher. You can select from the following options: <ul style="list-style-type: none"><li>- Bundled - use this default option if you want the bundled launcher.</li><li>- Custom - use this option to specify a custom launcher.</li></ul>

**ItemDescription**

Work offline	If this checkbox is selected, Maven works in the offline mode and uses only the resources that are available locally. This option corresponds to the <code>--offline</code> command line option.
Use plugin registry	Select this checkbox to enable referring to the Maven's <a href="#">Plugin Registry</a> . This option corresponds to the <code>--no-plugin-registry</code> command line option.
Execute goals recursively	If this checkbox is selected, the build recurses into the nested projects. Clearing this checkbox corresponds to the <code>--non-recursive</code> command line option.
Print exception stack traces	If this option is checked, exception stack traces are generated. This option corresponds to the <code>--errors</code> command line option.
Always update snapshots	Select this checkbox, if you want IntelliJ IDEA to update snapshots on sync.
Output level	Select the desired level of the output log, which allows plugins to create messages at levels of <i>debug</i> , <i>info</i> , <i>warn</i> , and <i>error</i> , <i>fatal</i> , or disable output log.
Checksum policy	Select the desired level of checksum matching while downloading artifacts. You can opt to fails downloading, when checksums do not match ( <code>--strict-checksums</code> ), or issue a warning ( <code>--lax-checksums</code> ).
Multiproject build fail policy	Specify how to treat a failure in a multiproject build. You can opt to fail the build: <ul style="list-style-type: none"> <li>– At the very first failure, which corresponds to the command line option <code>--fail-fast</code>.</li> <li>– Fail at the end, which corresponds to the command line option <code>--fail-at-end</code>.</li> <li>– Ignore failures, which corresponds to the command line option <code>--fail-never</code>.</li> </ul>
Plugin update policy	Select plugin update policy from the drop-down list. You can opt to: <ul style="list-style-type: none"> <li>– Check for updates, which corresponds to the command line option <code>--check-plugin-updates</code>.</li> <li>– Suppress checking for updates, which corresponds to the command line option <code>--no-plugin-updates</code>.</li> </ul> <p>This option is ignored for Maven 3 and later versions.</p>
Threads (-T option)	Use this field to set the <code>-T</code> option for parallel builds. This option is available for Maven 3 and later versions. <p>For more information, see <a href="#">parallel builds in Maven 3</a> feature.</p>
Maven home directory	Use this drop-down list to select a bundled Maven version that is available (for Maven2, version 2.2.1 and for Maven3, version 3.0.5) or the result of resolved system variables such as <code>MAVEN_HOME</code> or <code>MAVEN2_HOME</code> . You can also specify your own Maven version that is installed on your machine. You can click <code>...</code> and select the necessary directory in the <a href="#">dialog that opens</a> .
User settings file	Specify the file that contains user-specific configuration for Maven in the text field. If you need to specify another file, check Override option, click ellipsis button and select the desired file in the Select Maven Settings File dialog.
Local repository	By default, the field shows the path to the local directory under the user home, that stores the downloads, and contains the temporary build artifacts that you have not yet released. If you need to specify another directory, check Override option, click ellipsis button and select the desired path in the Select Maven Local Repository dialog.

## ItemDescription

Keep projects files in	Select this checkbox to specify the location of your project's files after the import. For example, when you import a project and want to keep the <code>.iml</code> file and <code>.idea</code> directory files in a specific location instead of the default one. By default, IntelliJ IDEA places project's files next to your <code>pom.xml</code> .
Import Maven projects automatically	Select this checkbox, if you want IntelliJ IDEA to perform reimport automatically each time you change your <code>pom.xml</code> .
Create IntelliJ IDEA modules for aggregator projects (with 'pom' packaging)	If this checkbox is selected, IntelliJ IDEA <a href="#">Maven Modules</a> will be created for each module included in the <code>pom.xml</code> file of an aggregative project, provided that its packaging is set to 'pom'.
Create module groups for multi-module Maven projects	If this checkbox is selected, IntelliJ IDEA will create a module group from an aggregative Maven project, with the nested modules included in this group.
Keep source and test folders on reimport	If this checkbox is selected, all the source and test folders will be preserved on every import.  If this checkbox is cleared, all previously configured source and test folders will be removed on every import. By default, this checkbox is set as follows: <ul style="list-style-type: none"> <li>– For new projects : the checkbox is cleared.</li> <li>– For already imported projects : the checkbox is selected.</li> </ul>
Exclude build directory	Select this checkbox to exclude a build directory from the project. This might be useful, if you want to speed up the project's importing process . If this checkbox is cleared, IntelliJ IDEA will index files in the build directory every time you import a project which might take additional time.  ( <code>PROJECT_ROOT/target</code> )
Use Maven output directories	If this checkbox is not selected, the build will be created in the regular IntelliJ IDEA's output directory <code>USER_HOME\IdeaProjects\&lt;project&gt;\classes\Production\</code> .  If this checkbox is selected, the build is generated in the Maven's output directory, and the results of IntelliJ IDEA's compilation are reused. However, IntelliJ IDEA itself does not reuse Maven build results, and performs compilation <i>from scratch</i> .
Generated sources folders	Specify the directory of your source root when you reimport a project.  You can select one of the following options: <ul style="list-style-type: none"> <li>– Detect automatically This is a default option. When you select this option, IntelliJ IDEA automatically detects the location of the generated sources. IntelliJ IDEA also detects which directory to mark as a source root. However, IntelliJ IDEA searches for the generated sources only in <code>target/generated-sources</code> and <code>target/generated-sources/*</code> directories.</li> <li>– <code>target/generated-sources</code> This option enables you to mark the directory as source root manually.</li> <li>– subdirectories of "target/generated-sources" This option enables you to mark a subdirectory as a source root manually.</li> <li>– Don't detect This option lets you skip the detection process.</li> </ul>
Phase to be used for folders update	Select Maven phase to be used for folders update. This might be useful, if you adjust your plugins so that additional sources are loaded at some phase.
Automatically download	Select the corresponding checkboxes to automatically download sources ( Sources ) and documentation comments ( Documentation ) on opening Maven projects.
Dependency types	Use this field to specify dependency types that you want to include when you reimport your project.
VM options for importer	Use this field to specify VM options. The default option is <code>-Xmx512m</code> .  When you specify the options, follow the following rules: <ul style="list-style-type: none"> <li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li> <li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg or "some arg"</code> .</li> <li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="\quoted_value"</code> .</li> </ul>
JDK for importer	Use this drop-down list to specify which JDK to use when the maven project is imported.  You can choose one of the following options: <ul style="list-style-type: none"> <li>– Internal JRE - this is a default option that uses the installation directory for JRE.</li> <li>– JDK versions - this option uses your project's JDK.</li> <li>– Use JAVA_HOME - this option uses the value that is specified in the user's environment variable settings.</li> </ul>
Generate Flex compiler configuration files when importing Flexmojos projects	If this checkbox is selected, when importing Flexmojos projects, the Flex compiler configuration files are generated automatically.  The automatic generation of the configuration files is a rather time-consuming process, especially for large projects. Besides, for the reasons independent of IntelliJ IDEA, the automatic generation of the configuration files may sometimes be impossible or may lead to erroneous results.  In all such cases, you may want to turn this option off and generate the Flex compiler configuration files from the command line using this command:  <pre>mvn compile -DconfigurationReport=true</pre>

**Note** For this option to be available, the [Flash/Flex Support](#) enabled in IntelliJ IDEA. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

---

Create run configuration for Spring Boot application

Select this option if you want IntelliJ IDEA to automatically create a run/debug configuration for Spring Boot projects on Maven import.

Use this page to specify the `pom.xml` files or their paths of Maven modules which you want to exclude from the Maven project.

**ItemDescription**

---

Path patterns      Enter the comma-separated list of paths to be ignored during the build. Wildcards are honored.

---

Ignored files      Check the individual files to be ignored during the build.

Use this page to configure settings for the external Maven that will be used to run goals.

#### ItemDescription

Run in background	Check this option to perform run as a background task.
VM Options	Specify VM options that will be passed to the selected JRE. When specifying the options, follow these rules: <ul style="list-style-type: none"><li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li><li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg or "some arg"</code> .</li><li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="\quoted_value\"</code> .</li></ul>
JRE	Select the JRE that will be used to run the Maven goals.
Environment variables	This field lets you set custom environment variables on the project level for running maven goals. Click the Browse button  to open the Environment Variables dialog box, where you can create variables and specify their values.
Properties	Specify the properties and their values to be passed to Maven.
 or 	Use this icon or shortcut to define a new property as a name - value pair.
 or 	Use this icon or shortcut to change the selected property.
 or 	Use this icon or shortcut to remove the selected properties from the list.
Skip tests	Check this option to skip performing unit tests. This corresponds to the Maven option <code>-Dmaven.test.skip=true</code>

Use this page to configure settings for running JUnit tests using [Maven Surefire plugin](#) configuration.

The configuration parameters are activated by default.

You can use these settings for Maven 2 and Maven 3 versions.

---

**ItemDescription**

<code>argLine</code>	Select this checkbox to set arbitrary JVM options on the command line.
<code>systemPropertyVariables</code>	Select this checkbox to pass a list of System properties to the JUnit tests.
<code>environmentVariables</code>	Use this checkbox to set additional environment variables on the command line.

The table shows the list of [Maven repositories](#) , encountered in the current project, with their URLs, type (local or remote) and the date of the most recent update.

#### ItemDescription

---

Indexed Maven Repositories	<p>This area contains a list of Maven local repositories that are configured in the <code>pom.xml</code> file. The list is updated automatically.</p> <p>If you open a project that contains additional repositories specified, then the repositories are added to the Indexed Maven Repositories list and you can update the indices.</p>
Update	<p>Click this button to update indices of the selected repository. It might be helpful in case you expect to get information for newly deployed artifacts such as new versions of libraries that you use in the project. Also when you use maven dependencies completion in <code>pom.xml</code> or generation of maven dependencies using <a href="#">Maven Artifact Search</a> dialog.</p>

Use this page to configure Gradle project settings.

## ItemDescription

**Linked Gradle projects** This area contains the list of registered Gradle projects that are linked to your IntelliJ IDEA project.

**Project-level settings** This area contains settings for your Gradle project. You can select from the following options:

- Use auto-import - select this checkbox to resolve all the changes made to the Gradle project automatically every time you refresh your project.
- Create directories for empty content roots automatically - select this option to add a `src` directory to your project automatically when you import a project from Gradle model.
- Create separate module per source set - select this checkbox to use the [source set](#) feature in resolving your Gradle projects.
- Use default gradle wrapper (recommended) - select this checkbox to use [Gradle Wrapper](#). You can use this option when you have generated or checked out wrapper files in the default location.

```
gradle/wrapper/gradle-wrapper.jar (Wrapper JAR)
gradle/wrapper/gradle-wrapper.properties (Wrapper properties)
```

- Use gradle wrapper task configuration - select this checkbox to customize your [Gradle Wrapper](#). You can use this option if you do not have wrapper files on your disk yet or if you use a different location for them. In this case IntelliJ IDEA refers to the Gradle wrapper task definition and generates or updates the files based on the task configuration. This option can be useful when you don't want to check in binary wrapper files or reuse the same wrapper files for several projects.

```
task wrapper(type: Wrapper) {
    distributionUrl = "http://mycompanyserver/gradle-2.10-bin.zip"
    jarFile = "/mylocation/gradle/wrapper/gradle-wrapper.jar"
    scriptFile = "/mylocation/gradle/gradlew"
}
```

**Note** This option is supported for the Gradle version 1.7 or later.

- Use local gradle distribution - select this option to run local build scripts.
- Gradle home - in this text field, specify the fully qualified path to your Gradle installation. If Gradle location has been defined by the environment variables `GRADLE_HOME` or `PATH`, then IntelliJ IDEA deduces this location, and suggests this path as the default value.
 

If Gradle location has not been deduced from the environment variables, specify it manually, or click the [Browse](#) button, and select the desired directory in the [dialog that opens](#). Note that the value entered in this field takes preference over the environment variables.
- Gradle JVM - use this drop-down list to select a JVM for running Gradle projects. The default is set to your project JDK.

**Global Gradle settings** This area contains options for Gradle global settings. You can select from the following options:

- Offline work - use this checkbox to work with Gradle in the offline mode. In this case Gradle will use dependencies from the cache. Gradle will not attempt to access the network to perform dependency resolution. If required dependencies are not present in the dependencies' cache, a build execution will fail.
- Service directory path - use this field to override the default Gradle home location directory.
- Gradle VM options - use this field to specify VM options for your Gradle project.
 

When specifying the options, follow these rules:

  - Use spaces to separate individual options, for example, `-client -ea -Xmx1024m`.
  - If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, `some "arg" or "some arg"`.
  - If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, `-Dmy.prop="quoted_value"`.

IntelliJ IDEA lets you specify settings for running Gradle tests.

#### ItemDescription

---

Delegate IDE build/run actions to Gradle

Select this checkbox to delegate the following actions to Gradle:

- assemble and compile project files
- assemble `.war` or `.ear` artifacts
- run the application

---

Run tests using

Use this area to select one of the following test runner options:

- Platform Test Runner - select this option if you want to run your tests using the IntelliJ IDEA API.
- Gradle Test Runner - select this option if you want to run your tests using [Gradle tooling API](#).
- Let me choose per test - select this option if you want to choose the runner for the specific test. In this case IntelliJ IDEA prompts you to select the test runner the first time you try to execute your test.

This page appears when you have an Android project and work inside the Android environment.

**ItemDescription**

---

Allow Module selection on Project import	Select this checkbox to allow a partial import.
Skip source generation on Gradle sync if a Project has more than <number of modules> Modules	Select this checkbox to skip source generation if your project contains more than the specified number of modules. It might be helpful if you have a multi-module project.

Use this page to define Gant home directory, which is required to be able to run build scripts.

**ItemDescription**

---

Gant home    In this text field, specify the fully qualified path to your Gant installation, or click the ellipsis button, and select the desired directory in the [dialog that opens](#) .

Use this node to configure common options specified in the table below, as well as the specific options for compilers used in IntelliJ IDEA.

### ItemDescription

Resource Patterns	<p>In this field, specify the regular expression that describes the files that should be recognized as resources and, consequently, copied to the output directory. Use semicolons ( ; ) to separate individual patterns. Wildcards and negations are welcome. The following symbols are accepted:</p> <ul style="list-style-type: none"> <li>- * represents an unlimited number of any symbols, possibly none.</li> <li>- ? represents exactly one symbol.</li> <li>- . represents a delimiter.</li> <li>- ! negates the entire mask it is applied to. Consequently, any file with the name and extension that do not match the pattern will be recognized as a resource file.</li> <li>- / represents a path separator.</li> <li>- /**/ denotes any number of directories.</li> <li>- &lt;dir&gt;:&lt;pattern&gt; denotes any directory located under the source root &lt;dir&gt;; &lt;pattern&gt; is any pattern that meets the above-mentioned requirements.</li> </ul>
-------------------	---

The examples below illustrate the use of wildcards in the resource patterns:

- \*.xml - any XML file.
- !\*.xml - any file whose extension is not .xml .
- z\*.properties;z\*.gif;z\*.png;z\*.jpeg;z\*.xml - any .properties , .gif , .png , .jpeg , or .xml file with the name beginning with z .
- MyResources:\* - all files and folders within the directory MyResources .

**Tip** If you want to skip compilation of certain Groovy files in the modules with the Groovy support, include them in the list of the resource patterns.

Clear output directory on rebuild	Check this option to delete all files in the output directories. Do not check this option, if the output directory contains files IntelliJ IDEA is not aware of, like resources, etc. If there is any intersection of source and output paths, you will be prompted to resolve the issue by separating source and output directories, or ignore the issue.
Add runtime assertions for not-null annotated methods and parameters	If this option is checked, the assertions are added at runtime to all the methods and parameters, annotated with @NotNull annotations. The lists of annotations is <a href="#">configurable</a> (click the button Configure annotations... to the right).
Automatically show first error in editor	If this checkbox is selected, the file that contains the very first compilation error will be opened in the editor, with the highlighted line that contains the error.
Display notification on build completion	If this checkbox is selected, the notification balloon is shown, if the build process lasts longer than 1 minute. If this build process lasts less than a minute, or if the checkbox is not selected, the message is shown in the <a href="#">Event log</a> and in the <a href="#">Status bar</a> .
Make project automatically	Select this checkbox to automatically make (compile) the project each time project files change on your disk, for example, on save or autosave, or when you get the latest project revision from your version control system.
Compile independent modules in parallel	If this checkbox is selected, the modules without mutual dependencies are compiled simultaneously. This might require increased <a href="#">heap size</a> .
Rebuild modules on dependency change	Select this checkbox to have the modules with the changed dependencies fully rebuilt.
Build process heap size (Mbytes)	<p>In the text field, specify the heap size required for the build process.</p> <p><b>Note</b></p> <ul style="list-style-type: none"> <li>- If you are using a 64-bit JDK for compilation, the build process may require more memory.</li> <li>- The value is stored with the project settings. If you need to override this value, then in the field User-local build process VM options write %mem&lt;dir&gt; , where &lt;dir&gt; is the heap size value in megabytes. As soon as this value is recognized in the field User-local build process VM options , the field Build process heap size becomes read-only and is ignored.</li> </ul>
Shared build process VM options	These VM options will be added to the command line on launching the build process. The shared VM options are stored in the project settings and may be put <a href="#">under version control</a> .
User-local build process VM options (overrides Shared options)	These VM options will be added to the command line on launching the build process. The user-local VM options are stored in workspace.xml file and as such are visible to the author of these changes only. The user-local VM options has the priority over the shared VM options. It means that if anything is written in the field User-local build process VM options , then the field Shared build process VM options is ignored, and the values in the User-local build process VM options field are used instead.

This dialog box shows the lists of `@Nullable` and `@NotNull` annotations. To show this dialog box, click the button `Configure annotations...` in the [Compiler](#) page of the Settings/Preferences dialog.

#### ItemDescription

---

**Nullable annotations**      This list shows Nullable annotations defined in project. Use the following buttons:

-  . Click this button to add an annotations package to the list.
-  . Click this button to remove annotations from the list. This button becomes available for the custom annotations only.
-  . Click this button to select the annotations package used for code generation. The selected annotation is marked with the right arrow .

---

**NotNull annotations**      This list shows NotNull annotations defined in the project. Use the following buttons:

-  . Click this button to add an annotations package to the list.
-  . Click this button to remove annotations from the list. This button becomes available for the custom annotations only.
-  . Click this button to select the annotations package used for code generation. The selected annotation is marked with the right arrow .

Use this page to specify files and directories within your project that should not be passed to the compiler.

Item	Keyboard Shortcut	Description
Path		In this field, the path to a file or directory to be excluded from compilation is shown.
Recursively		For a directory; select this option to exclude from compilation all the corresponding subdirectories.
+	Alt+Insert	Use this icon or shortcut to add a file or directory to the list. Select the file or directory in the <a href="#">dialog that opens</a> .
-	Alt+Delete	Use this icon or shortcut to remove the selected item or items from the list.

**Note** The sources listed on this page, if they are used in the project parts to be compiled (e.g., if they are imported, extended or implemented), will nevertheless be compiled.

- Explicit compiler invocation on excluded directories will force their compilation.

On the Compiler > Java Compiler page, you can select the Java compiler to be used and specify associated options.

- [Compiler and bytecode versions](#)
- [Javac and Eclipse options](#)
- [Ajc options](#)
- [Groovy-Eclipse options](#)

## Compiler and bytecode versions

### ItemDescription

Use compiler	<p>Select the compiler to be used:</p> <ul style="list-style-type: none"> <li>– <a href="#">Javac</a> . This may be the compiler included in the IntelliJ IDEA distribution or a compiler from one of the project JDKs.</li> <li>– Eclipse (also known as Eclipse Compiler for Java or ECJ). IntelliJ IDEA comes bundled with the Eclipse compiler.</li> <li>– <a href="#">Groovy-Eclipse</a> . This compiler lets you perform joint compilation of Groovy and Java code using the Eclipse compiler.</li> <li>– <a href="#">Ajc</a> (the AspectJ compiler). This option is available only in the Ultimate Edition of IntelliJ IDEA. Besides, the AspectJ compiler is not included in IntelliJ IDEA distribution and should be downloaded separately. See also, <a href="#">Ajc options</a> , <a href="#">Using the AspectJ Compiler (ajc)</a> and <a href="#">Enabling AspectJ Support Plugins</a> .</li> </ul>
Project bytecode version	<p>Select the version of bytecode to be generated. (Roughly, this is the minimum target JVM version.) If no particular version is specified, the bytecode version is defined by the compiler.</p> <p>To specify different versions for particular modules, use the controls in the <a href="#">Per-module bytecode version area</a> .</p>
Per-module bytecode version	<p>If necessary, specify the target bytecode versions for individual modules (e.g. if they should differ from that <a href="#">set for the project</a> ).</p> <p>Click <a href="#">+</a> and select the modules of interest in the dialog that opens. Then, for each of the modules, click the corresponding Target bytecode version cell and select the version from the list.</p> <p>Use <a href="#">-</a> to remove the selected module or modules from the list.</p>

## Javac and Eclipse options

### ItemDescription

Use compiler from module target JDK when possible	<p>For the Javac compiler:</p> <p>When this option is on and the version of the JDK associated with a module is different from that of the <a href="#">build process JDK</a> , the compiler from the module JDK is used. The exception is when the version of the module JDK is earlier than 1.6. In such cases, the compiler from the build process JDK is used in the <a href="#">cross-compilation mode</a> against the classes of the module JDK.</p> <p>When the option is off, all the modules are compiled with the same compiler, the one from the build process JDK. When necessary, the cross-compilation mode is used.</p> <p>To start the build process, the latest of the available JDKs is used. This JDK is chosen from all the JDKs used in your modules, the default project JDK, and also the JDK bundled with IntelliJ IDEA.</p> <p>IMPORTANT! The choice of the compiler does not affect the source code language level, and also the bytecode target level and linking. That is, irrespective of which compiler is used, the bytecode is linked against the JDK associated with the module, and the resulting code levels are exactly the ones that are specified in your project settings.</p>
Generate debugging info	<p>If this checkbox is selected, the compiler generates the information necessary for running the compiled classes in the debugger.</p>
Report use of deprecated features	<p>If this checkbox is selected, the compiler displays warnings about the deprecated methods, classes, or fields encountered during compilation. (The corresponding warnings are shown in the compiler output window.)</p>
Generate no warnings	<p>If this checkbox is selected, the compiler omits the warnings about dubious usages of language constructs.</p>
Proceed on errors	<p>For the Eclipse compiler: If you select this checkbox, the compiler continues the compilation even when compilation errors occur.</p>
Additional command line parameters	<p>Specify the command-line parameters and options to be passed to the compiler at its start. Refer to the compiler documentation for the available options.</p> <p>If you need more room to type, click <a href="#">⌵</a> to open the Additional command line parameters dialog where the text entry area is larger.</p> <p>When specifying the parameters and options, follow these rules:</p> <ul style="list-style-type: none"> <li>– Use spaces to separate individual parameters and options, for example, <code>-client -ea -Xmx1024m</code> .</li> <li>– If a parameter or an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg Or "some arg"</code> .</li> <li>– If a parameter or an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li> </ul>

## Ajc options

The ajc options are available only in the Ultimate Edition of IntelliJ IDEA.

### ItemDescription

Path to Ajc compiler	Specify the path to <code>ajc</code> (the file <code>aspectjtools.jar</code> which is located in <code>&lt;AspectJ installation directory&gt;\lib</code> ). Type the path in the field, or click  and select the required file in the <a href="#">dialog that opens</a> .
Test	Click this button to check if the path and the command line parameters are correct. If all is well, the compiler version is displayed. Otherwise, an error message is shown. (Using the path and the parameters specified, IntelliJ IDEA tries to launch the compiler with the additional <code>-version</code> parameter.)
Command line parameters	<p>If necessary, specify the <a href="#">command-line options</a> to be passed to the compiler.</p> <p>You can type the parameters right in the field, or click  to open the Command line parameters dialog where the text entry area is larger.</p> <p>When specifying the options, follow these rules:</p> <ul style="list-style-type: none"><li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li><li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg</code> or <code>"some arg"</code> .</li><li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li></ul> <p>NOTE: The specified parameters are ignored when <code>ajc</code> is used for post-compile weaving.</p> <p>See also, <a href="#">Optimizing compilation performance: Using ajc in combination with javac</a> , <a href="#">Controlling the ajc aspectpath</a> and <a href="#">Fine-tuning the use of ajc at a module level</a> .</p>
Generate debug info	If this checkbox is selected, the compiler generates the information necessary for running the compiled classes in the debugger.
Delegate to Javac	<p>If this option is off, <code>ajc</code> is used in all cases.</p> <p>If this option is on, <code>javac</code> is used in addition to or instead of <code>ajc</code> . For example, <code>javac</code> will be used to compile the modules that contain no aspects. As a result, the compilation may become much faster.</p> <p>See also, <a href="#">Optimizing compilation performance: Using ajc in combination with javac</a> and <a href="#">Fine-tuning the use of ajc at a module level</a> .</p>

## Groovy-Eclipse options

### ItemDescription

Path to groovy-eclipse-batch jar	Specify a path to your groovy-eclipse-batch jar location. Click  to open <a href="#">Select Path dialog</a> , select the location of the <code>.jar</code> file and click OK .  Please note that it is necessary to enter the location of the groovy-eclipse-batch <code>.jar</code> file for the compiler to work correctly.
Additional command line parameters	<p>Specify the command-line parameters and options to be passed to the compiler at its start. Refer to the compiler documentation for the available options.</p> <p>If you need more room to type, click  to open the Additional command line parameters dialog where the text entry area is larger.</p> <p>When specifying the parameters and options, follow these rules:</p> <ul style="list-style-type: none"><li>– Use spaces to separate individual parameters and options, for example, <code>-client -ea -Xmx1024m</code> .</li><li>– If a parameter or an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg</code> or <code>"some arg"</code> .</li><li>– If a parameter or an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li></ul>
Generate debug info	If this checkbox is selected, the compiler generates the information necessary for running the compiled classes in the debugger.

## Annotation processing profiles

### ItemKeyboardDescription Shortcut

+		Click this button to <a href="#">create a new profile</a> .
-		Click this button to delete the selected profile from the list of existing profiles. All modules, associated with this profile, will be automatically moved to the default profile.
		Click this button to <a href="#">associate a module with a profile</a> . This button only becomes available, when a module in the list of modules under a certain profile gets the focus.

## Annotation processors settings

### ItemDescription

Enable annotation processing	<p>If you want annotation processors to be run during compilation, select this checkbox and specify associated options:</p> <ul style="list-style-type: none"><li>- Obtain processors from project classpath : Select this option, if you want IntelliJ IDEA to obtain the annotation processors from the project classpath. This is useful, for example, if you use a custom annotation processor as part of your project, or if the processor is stored in a <code>.jar</code> file attached to all the corresponding modules as a library.</li><li>- Processor path : Select this option and specify in the field to the right the path to the annotation processor, if it is not desirable to include the processor into the project or project libraries.</li><li>- Store generated sources relative to : Use the fields below to define where the sources, generated by the annotation processors, are stored, and to override the default behaviour for a profile.<ul style="list-style-type: none"><li>- Module output directory : By default, the sources generated by annotation processors are stored relative to the module output directory.</li><li>- Module content root : Choose this option to override the default behaviour for a profile.</li></ul></li></ul>
------------------------------	---

At a later time, if you want to use the generated classes as your own sources, you can mark the corresponding directories as source roots.

**Warning!** On rebuild, the directories in which the generated sources are stored will be cleaned up as ordinary output directories. So it is not recommended to store non-generated sources in such directories. Otherwise, the corresponding sources will be lost on rebuild.

Processor FQ Name	<p>Specify the processor fully qualified name.</p> <p>Use  () or  () to make up the list of annotation processors to be run.</p>
-------------------	--

Annotation processor options	<p>If necessary, specify the processor run options either as <code>-key=value</code> , or <code>key=value</code> . Use spaces to separate individual options.</p> <p>Use  () or  () to make up the list of options to be passed to the annotation processors.</p>
------------------------------	---

---

**ItemDescription**

---

**Enable RMI stubs generation** Use this item to analyze compiled classes, searching where the remote interface is implemented. If such classes are not found, IntelliJ IDEA generates stubs for these interfaces incrementally.

**Tip** Only the classes generated by IntelliJ IDEA are analyzed. Classes generated by the other tools are ignored.

---

**Generate IIOp stubs** If enabled, makes the compiler generate IIOp stubs.

---

**Generate debugging info** If enabled, makes the compiler include the information necessary to run this class in the debugger.

---

**Generate no warnings** If this option is enabled, the compiler omits warnings about dubious usages of language constructs.

---

**Additional command line parameters** Enter or edit any additional arguments to be passed to the compiler via the command line. Refer to the compiler documentation for valid options.

---

Use this page to configure the Groovy compiler-specific settings.

**ItemDescription**

---

Path to configscript Use this field to specify a path to the configuration script parameter to use in Groovy compilation. Type the path in the field, or click  and select the required file in the [dialog that opens](#) .

---

Invoke dynamic support Select this checkbox to activate compilation process that supports " `invokedynamic` " bytecode instruction.

---

Exclude from stub generation Use this section to make up a list of files and directories, for which the stub generation step should be omitted. Use  ( `Alt+Insert` ) to add files and directories to the list, and  ( `Alt+Delete` ) to delete the selected items.

Use the **Compiler > ActionScript and Flex Compiler** page to select the Flex compiler for your project and to specify the associated settings.

---

**ItemDescription**

---

Compile with	<p>Select which of the available Flex compilers should be used:</p> <ul style="list-style-type: none"> <li>- Built-in compiler shell. An IntelliJ IDEA compiler shell which uses the Flex SDK compiler API. This compiler shell can perform incremental compilations. As a multithreaded shell, it is capable of running a number of compilations simultaneously, in parallel.</li> <li>- Mxmlc/compc. The <code>mxmlc / compc</code> compiler available in Flex SDK. This compiler cannot compile incrementally. However, it can run several independent compilation processes simultaneously which significantly improves the compilation performance.</li> </ul> <p>Whichever of the compiler options you use, IntelliJ IDEA keeps track of the modules where nothing has changed since the previous compilation. Consequently, the SWF and SWC files that are up-to-date are not compiled.</p>
Prefer ActionScript Compiler 2.0 for pure ActionScript build configurations	<p>If this checkbox is selected, the ActionScript Compiler 2.0 (ASC 2.0) is used for <a href="#">pure ActionScript build configurations</a>.</p>
Parallel compilation with up to <this_many> threads or processes	<p>Specify the maximum number of compilation threads (for the built-in compiler shell) or processes (for the mxmlc/compc compiler) to run simultaneously.</p>
Compiler heap size	<p>Specify the maximum heap size available to the process that launches the compiler. The default 512 Mb is suitable for most of the purposes. However, the built-in compiler shell, as a single-process compiler, may require more memory for large projects.</p>
VM options	<p>If necessary, type the string to be passed to the VM when IntelliJ IDEA launches the compiler. If you need more room to type, click  next to the field to access the Flex Compiler VM options dialog where the text entry area is larger.</p> <p>When specifying the options, follow these rules:</p> <ul style="list-style-type: none"> <li>- Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code>.</li> <li>- If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg" OR "some arg"</code>.</li> <li>- If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code>.</li> </ul>

---

Use this page to specify the validation settings for your application.

**ItemDescription**

---

Validate on build	Select this checkbox, to have IntelliJ IDEA run the desired validators when building your project. The validation results will be shown in the <a href="#">Messages window</a> , and you will be able to easily navigate through the list of issues and jump directly to problematic code fragments.
-------------------	--

---

Validators	Select the validators you want to be run.
------------	---

---

Exclude from validation	Use <b>+</b> ( <code>Alt+Insert</code> ) and <b>-</b> ( <code>Alt+Delete</code> ) to form the list of files and directories that should be excluded from validation. For directories, use the <code>Recursively</code> checkbox to specify that the corresponding directory should be excluded from validation along with all the subdirectories contained therein.
-------------------------	---

Use this page to specify settings for compiling Android-Gradle projects.

**Item****Description**

---

Compile independent modules in parallel (may require larger heap size)	Select this checkbox if you need to compile independent modules in parallel. For more information, see <a href="#">decoupled projects</a> .
Command-line Options	Use this field to set Gradle command-line options. For more information, see the <a href="#">Gradle command-line options</a> page.
Make project automatically (only works while not running/debugging)	Select this checkbox to automatically make (compile) the project on every save or autosave.
Use in-process build	Select this checkbox to use the Gradle in-build process.
Configure on demand	This checkbox is selected by default. Configuration on demand mode attempts to configure only projects that are relevant for requested tasks. This way, the configuration time of a large multi-project build is greatly improved. For more information, refer to the <a href="#">Gradle configuration on demand</a> page.

Ctrl+Alt+S

Use this page to configure the behavior of the [Android dx tool](#) and the [ProGuard tool](#). This tool converts compiled `.class` files to executable `.dex` files in the [Dalvik](#) format for further execution in the Android environment.

On this page:

- [DEX](#)
- [ProGuard](#)

## DEX

In this area, configure the behaviour of the [Android dx tool](#) that converts the `.class` files to Dalvik byte code.

### ItemDescription

Maximum heap size	Use this spin box to control the size of the heap available to the process that launches the compiler. If you are compiling a particularly large or complex project, you may get out-of-memory errors and be required to increase the amount of memory allocated to the compiler.
Additional VM options	<p>In this text box, specify the string to be passed to the <a href="#">Dalvik Virtual Machine</a> for launching the Android application. If necessary, click  and type the desired string in the Android DX Compiler VM Options dialog.</p> <p>When specifying the options, follow these rules:</p> <ul style="list-style-type: none"> <li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code>.</li> <li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg Or "some arg"</code>.</li> <li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="quoted_value\"</code>.</li> </ul>
Optimize	<ul style="list-style-type: none"> <li>– Select this checkbox to have the <code>.dex</code> file converted into a <code>.odex</code> file (optimized). The optimized <code>.odex</code> version of a <code>.dex</code> file is stored <b>outside</b> the application package (<code>.apk</code>). During the booting of the Android operating system, <code>.odex</code> files make the basis for building a cache for the Dalvik virtual machine. As a result, the operating system in advance knows what applications will be loaded.</li> <li>– When this checkbox is cleared, the generated <code>.dex</code> file is not optimized. By default, the checkbox is selected.</li> </ul>
Force jumbo mode	Select this checkbox to increase the default number of strings allowed in <code>.dex</code> files. By default, the checkbox is cleared.
Add "--core-library" flag	<p>Select this checkbox to enable containing classes from certain packages as input files. The packages are as follows:</p> <pre>java , javax.accessibility , javax.crypto , javax.imageio , javax.management , javax.naming , javax.net , javax.print , javax.rmi , javax.security , javax.sound , javax.sql , javax.swing , javax.transaction , javax.xml .</pre>

## ProGuard

In this area, configure the behaviour of the [ProGuard tool](#).

### ItemDescription

VM options	In this text box, specify the additional options for running the ProGuard tool. For example, to increase the default ProGuard heap size, type <code>-Xmx&lt;required maximum heap size&gt;</code> .
------------	---

Use this page to configure Kotlin compiler-specific settings.

### ItemDescription

Generate no warning	If this checkbox is selected, the compiler won't generate warnings in course of compilation; only errors and info messages will be left.
Additional command line parameters	<p>Specify the command-line parameters and options to be passed to the compiler at its start. Refer to the compiler documentation for the available options.</p> <p>If you need more room to type, click  to open the Additional command line parameters dialog where the text entry area is larger.</p> <p>When specifying the parameters and options, follow these rules:</p> <ul style="list-style-type: none"> <li>– Use spaces to separate individual parameters and options, for example, <code>-client -ea -Xmx1024m</code> .</li> <li>– If a parameter or an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg"</code> Or <code>"some arg"</code> .</li> <li>– If a parameter or an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="\quoted_value\"</code> .</li> </ul>
Keep compiler process alive between invocations	If this checkbox is selected, the compiler process is always alive.
Kotlin to JVM	
Enable precise incremental compilation (experimental)	<p>If this checkbox is selected, the improved incremental compilation is turned on.</p> <p><b>Note</b> The incremental compilation is still experimental and may work incorrectly in some cases.</p>
Kotlin to JavaScript	
Generate source maps	If this checkbox is selected, the compiler generates <a href="#">source maps</a> that set the correspondence between lines in your Kotlin code and in the generated JavaScript code, otherwise your breakpoints will not be recognised and processed correctly.
Output file prefix	Specify the path to the file that will be added as is to the beginning of the generated code. You can enter the path manually, or click  and select the required file from the file chooser.
Output file postfix	Specify the path to the file that will be added as is to the end of the generated code. You can enter the path manually, or click  and select the required file from the file chooser.
Copy library runtime files	If this checkbox is selected, the JavaScript files from the libraries will be copied to the folder specified in the field Output directory for library runtime files .
Output directory for library runtime files	This field is only enabled, if the checkbox Copy library runtime files is selected. Specify here the target folder for the copied files.

Ctrl+Alt+S 

Use this page to configure behavior of the Debugger and customize its view.

## Common options

### ItemDescription

Focus application on breakpoint	If this checkbox is selected, on hitting a breakpoint, IntelliJ IDEA will show the location of this breakpoint in the editor and will attempt to bring its frame to the front.
Show debug window on breakpoint	If this checkbox is selected, IntelliJ IDEA activates the <a href="#">Debug Tool Window</a> on hitting a breakpoint.
Hide debug window on process termination	Automatically hide the <a href="#">Debug window</a> when the debugged program terminates.
Scroll execution point to center	If this checkbox is selected, the line with the current execution point will be kept in the middle of the screen.

## Java

### ItemDescription

Transport	Select transport for connection to the process. Available options are socket and shared memory , which is available for Windows systems only.
Force classic VM for JDK 1.3.x and earlier	Check this option to launch process to be debugged with classic VM. <b>Tip</b> For some Java SDKs this checkbox is disabled, because the <code>-cclassic</code> option should be forced automatically, or when no classic VM is available at all.
Disable JIT	With this option you can control whether the <code>-Djava.compiler=NONE</code> parameter is specified when the application is launched. This parameter affects JIT compiler, and if the option is turned on, JIT compiler will be disabled.
Show alternative source switcher	The alternative source switcher appears on top of the editor, if in project there is more than one class with the same fully qualified name.
Kill the debug process immediately	Select this checkbox, if you want to <a href="#">soft kill</a> the Java process.

## Built-in server

### ItemDescription

Port	Use this spin box to specify the port on which the built-in web server runs. By default this port is set to port <code>63343</code> through which IntelliJ IDEA accepts connections from services. You can set the port number to any other value starting with 1024 and higher.
Can accept external connections	If this checkbox is selected, then the files on the built-in server running on the specified port are accessible from another computer. If this checkbox is cleared (by default), then the debugger listens only to local connections.
Allow unsigned requests	For security reasons, any request to a page on the built-in server from outside IntelliJ IDEA is by default rejected and the following authorization pop-up window is displayed:

To access the requested page, click Copy authorization URL to clipboard and paste the generated token in the address bar of the browser.  
However this behaviour may be annoying, for example, it may block your debugging session if manual intervention is impossible. To suppress displaying the authorization pop-up window, select the Allow unsigned requests checkbox.

Ctrl+Alt+S 

Use this page to manage the way data is displayed in the debugger.

## Common debugger settings

### Item Description

Sort values alphabetically	Select this option to sort the values in the <a href="#">Variables pane</a> of the <a href="#">Debug Tool Window</a> .
Enable auto expressions in Variables view	<p>Select this option if you want the IntelliJ IDEA debugger to automatically evaluate expressions and show the corresponding values in the <a href="#">Variables pane</a> of the <a href="#">Debug Tool Window</a> .</p> <p>The debugger analyzes the context near the breakpoint (the current statement, one statement before, and one after). It does so to find various expressions in the source code (if available) such as, for example, <code>myvar.myfield</code> .</p> <p>If such expressions don't contain explicit method invocations, the debugger evaluates them and shows the corresponding values in the Variables view.</p>

**Note** In the languages such as Groovy, it is impossible to tell whether any methods are invoked when evaluating an expression, and such method invocations often cause unwanted side effects, so it is recommended to disable this option when debugging Groovy code.

## Editor

### ItemDescription

Show values inline	Select this option to enable the <a href="#">Inline Debugging</a> feature that allows viewing the values of variables right next to their usage in the editor.
Show value tooltip	<p>Select this option to enable automatic display of tooltips for values.</p> <p>A tooltip in this context is a pop-up that provides an alternative, sometimes a more convenient presentation of values in the <a href="#">Variables pane</a> of the <a href="#">Debug Tool Window</a> .</p> <p>To illustrate, let's assume that there is a statement like this in your code:</p>

```
String s =
  "Hello, World!
  \n
  Hello, World!";
```

When this statement is executed in the debugger, you'll see a line looking similar to this in the Variables pane:

```
s
= {java.lang.String@62}
  "Hello, World!
  \n
  Hello, World!"
```

with the line break shown as `\n` .

If the Show value tooltip option is on and you click this line and then hold the mouse pointer on it, you'll see a yellow area (the "tooltip") in which the value of `s` is shown as

```
Hello, World!
```

```
Hello, World!
```

with a real line break in place of `\n` .

If this option is disabled, press `Alt` to display a value.

Value tooltips delay (ms)	Specify the delay (in milliseconds) between the moment when the mouse pointer hovers over an object in the <a href="#">Variables pane</a> of the <a href="#">Debug Tool Window</a> , and the moment when a tooltip with the object's value is displayed.
Show value tooltip on code selection	Select this option to enable tooltips that <a href="#">show the expression value</a> when you select a code fragment in the editor.

Ctrl+Alt+S

Use this page to define the way data is displayed in the Java debugger.

**ItemDescription**

Autoscroll to new local variables	Select this option to automatically scroll to new variables that appear in the scope when stepping.
Show	<p>In this section, select which elements you want the Debugger to display:</p> <ul style="list-style-type: none"> <li>- Declared type</li> <li>- Synthetic fields</li> <li>- \$val fields as local variables</li> <li>- Fully qualified names</li> <li>- Object id</li> <li>- Static fields</li> <li>- Static final fields</li> </ul>
Show type for strings	Select this option if you want to show type for pure strings.
Show hex value for primitives	Select this option if you want numeric variables to be displayed in the hexadecimal format.
Hide null array elements	Select this option if you want null array elements to be omitted.
Enable alternative view for Collection classes	Select this option to display collections and maps in a more convenient format.
Enable <code>toString()</code> object view	<p>In this section, you can select classes if you need them and their descendants to be presented as a result of the <code>toString()</code> method call while debugging. Use the following controls:</p> <ul style="list-style-type: none"> <li>- For all classes that override <code>toString()</code> method : select this option to show all classes as <code>toString()</code> .</li> <li>- For classes from the list : populate the list of classes to be shown as <code>toString()</code> , using the  ,  and the  buttons. Use the checkboxes next to the class names to temporarily enable or disable particular filters.</li> <li>-  : click this button to add a class to the list using the Choose Class dialog.</li> <li>-  : click this button to add a custom class filter using the New Filter dialog. To define a filter, enter a string pattern, e.g. <code>*.Test</code> , <code>javax.swing.*</code> , etc.</li> <li>-  : click this button to remove a filter from the list.</li> </ul>

Ctrl+Alt+S

IntelliJ IDEA allows you to specify how different objects are displayed in the debugger on a class-by-class basis. You can assign the expressions to be displayed rather than rely on the object's String representation.

For example, if an object represents a user, you may want it to be represented by login names; or, for a cache entry object, its content may be appropriate. IntelliJ IDEA refers to these as **type renderers**.

All object types are supported (including primitive types and arrays).

If no rendering scheme is defined, this dialog does not show any controls. To start working with renderers, click **+**.

#### ItemDescription

	Click this icon to add a new rendering scheme to the list.
	Click this icon to remove the selected scheme from the list.
	Click this icon to create a copy of the selected scheme.
	Click these icons to move the selected item one line up or down in the list. Note that the order determines which renderer is used in case of ambiguity stemming of class inheritance.

**Renderer name** Specify the name of a new renderer, or edit an existing renderer name.

**Apply renderer to objects of type (fully-qualified name)** Specify the object type that will be represented by this renderer. Enter a fully qualified object name, or click the Browse button and choose the desired type from the list in the Renderer Reference Type dialog.

**When rendering a node** This option determines how an object is displayed in the debugger when nodes are collapsed:

- Show type and object id : if cleared, types are shown without class information or id.
- Use default renderer : select this option to display the node in the default way.
- Use following expression : enter the Java expression you want to use to identify an object. You can use object properties, constants, and even a string math as part of your renderer.  
Note that you can use code completion ( ) when defining expressions.

All method calls and member variable access are relative to the object you're rendering. Use `this` to refer to an instance to which the renderer applies.

**Note** – Using heavy expressions in renderers may slow down data rendering in views.  
– Method calls should be used with caution because of possible side-effects.

**When expanding a node** This option determines how an object is displayed in the debugger when nodes are expanded.  
Normally, expanding a node in the debugger lists the object's member variables (using the renderer appropriate for the corresponding object types). This option lets you override this behavior and select a single expression or a series of expressions to be displayed. You may use this to limit the amount of information displayed, or to be more precise in how the information is presented.

- Use default renderer : select this option to display the node children in the default way.
- Use following expression : enter the Java expression you want to use to identify an object.  
Test if a node can be expanded (optional) : enter a Boolean expression. If it is `true`, the renderer displays expandable nodes for the defined objects. Otherwise, no nodes are displayed.
- Use list of expressions : create a list of separate expressions to be calculated and presented as node children. Use:
  - ( ) to create a new expression.
  - ( ) to remove the selected expression from the list.
  - ( ) to move the selected expression one line up in the list.
  - ( ) to move the selected expression one line down in the list.

If you select the checkbox in the On-demand column next to a renderer, the evaluation of this expression will be done on demand. Simply click this expression when you need to evaluate it in the [Variables](#), [Watches](#) or other view instead of having it evaluated automatically.

**Tip** You can use code completion ( ) when defining expressions.

**Append default children** Select this checkbox to add default children to the list of expressions. This checkbox is only available when the checkbox Use list of expressions is selected.

Ctrl+Alt+S 

---

Use this page to configure JavaScript debug options.

#### ItemDescription

---

Show the following properties for an object node	Select this checkbox if you want IntelliJ IDEA to show certain object node properties and configure a list of the properties to display. For each object node in the Variables pane, IntelliJ IDEA will display a label with the values of the listed properties.  Use the <b>+</b> and <b>-</b> buttons to manage the list of properties.
--	---

Use this page to turn on or off showing the values of the delegated properties.

**ItemDescription**

---

Calculate values of delegated properties (may affect program execution)  If this checkbox is selected, the values of the delegated properties are shown in the list of an object's properties in the debugger.

Ctrl+Alt+S 

Use this page to improve the debug stepping speed and specify the elements to be skipped while stepping.

**Item Description**

## Groovy

Do not step into specific Groovy classes  Select this checkbox if you don't want to step into the `org.codehaus.groovy.*` and `groovy.*` Groovy classes while debugging.

## Java

Skip synthetic methods  Select this checkbox to suppress stepping into synthetic methods (methods generated by the compiler) while debugging.

Skip constructors  Select this checkbox to suppress stepping into constructors while debugging.

Skip class loaders  Select this checkbox to suppress stepping into class loaders while debugging.

Skip simple getters  Select this checkbox to suppress stepping into simple getter methods (i.e., methods designed just to return the necessary value) while debugging.

Do not step into the classes  Select this checkbox to suppress stepping into the specified classes while debugging. The list of classes contains entries of two types:

- Fully qualified class names.
- Regular expressions (either exact matches or patterns that begin or end with `***`, for example, `java.*`).

By default, the list contains some standard Java SDK class patterns so that you do not have to waste your time stepping into Java class libraries. Use the checkboxes in the list to disable/enable particular patterns temporarily.

Use the  ,  , and  buttons to manage the list.

Evaluate finally blocks on pop frame  Select whether you want to evaluate `finally` blocks on pop frame or not, or you want to be notified before they are evaluated.

Resume only the current thread  Select this checkbox, if you need to resume only the active thread when stepping.

## JavaScript

Do not step into library scripts  Select this checkbox to suppress stepping into library scripts while debugging.

Do not step into scripts  Select this checkbox to suppress stepping into certain scripts while debugging. Use the toolbar buttons to manage the list of scripts to be skipped.

**ItemShortcutDescription**

  Click this button to add a new script filter.

  Click this button to delete the selected filter from the list.

  Click this button to edit the selected filter.

 Use these buttons to arrange filters as required.

 Click this button to create a copy of the selected filter.

## Kotlin

Do not step into Kotlin runtime library implementation classes  Select this checkbox if you don't want to step into specific Kotlin classes while debugging.

## Python (these options are only available if the Python plugin is installed and enabled)

Do not step into library scripts  Select this checkbox to suppress stepping into library scripts while debugging.

Do not step into scripts  Select this checkbox to suppress stepping into certain scripts while debugging. Use the toolbar buttons to manage the list of scripts to be skipped.

**ItemShortcutDescription**

  Click this button to add a new script filter.

  Click this button to delete the selected filter from the list.

  Click this button to edit the selected filter.

 Use these buttons to arrange filters as required.

 Click this button to create a copy of the selected filter.

## Ruby (these options are only available if the Ruby plugin is installed and enabled)

Ignore non-project  
sources

Select this checkbox to suppress stepping into non-project sources while debugging.

**Warning!** This page only appears when Python Plugin is installed and enabled!

[File](#) | [Settings](#) | [Build, Execution, Deployment](#) | [Python Debugger for Windows and Linux](#)

[IntelliJ IDEA](#) | [Preferences](#) | [Build, Execution, Deployment](#) | [Python Debugger for macOS](#)

Ctrl+Alt+S

Use this page to configure Python debug options.

#### ItemDescription

Attach to subprocess automatically while debugging	If this checkbox is selected, IntelliJ IDEA will automatically attach all subprocesses of the process being debugged. Thus, if the parent process has subprocesses, their breakpoints will always work.
--	---

Collect run-time types information for code insight	If this checkbox is selected, the types of function calls are preserved during debugging, and passed to the type checker.
---	---

Clear caches	Click this button to remove information about the types of arguments, collected at run time.
--------------	--

Gevent compatible	If this checkbox is selected, the debugger will be compatible with the Gevent-monkeypatched code.
-------------------	---

**Note** This parameter works for Python >= 2.6, Python >= 3.3

PyQt compatible	<p>If PyQt is installed on the interpreter, but is not imported in the application code, some import errors may occur. Unchecking this option fixes these errors.</p> <p>If you have multiple PyQt backends, installed on your interpreter, you have to select the <b>PyQt backend</b> from the drop-down list. By default, the Auto option is enabled, which means that the backend first found will be used.</p>
-----------------	--

The page is available only when the LiveEdit plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Use this page to enable and disable **Live Edit** in HTML, CSS, and JavaScript and configure the appearance of the on-the-fly preview.

#### ItemDescription

Update Node.js application on change	Select this checkbox to enable reloading of JavaScript files that are executed by Node.js. Use the spin box to specify the elapsed time for upload, the default value is <code>300</code> .
Update application in Chrome	Select this checkbox to enable on-the-fly preview of HTML and CSS.
On change in	Select this checkbox to enable <b>Live Edit</b> in JavaScript in addition to HTML and CSS. Set the elapsed time for applying the changes to a running application: accept the default value <code>300 ms</code> or specify a custom value using the spin box next to the field. The default elapsed time is <code>300ms</code> .
Highlight current element in browser on caret change	When this checkbox is selected, the current element is highlighted when you move the cursor. Otherwise, during a debugging session, you have to hold <code>(Shift)</code> and click the element to highlight.
Restart if hotswap fails	Select this checkbox to have IntelliJ IDEA restart the server if automatic upload of changes to the client-side code fails.

With changes in HTML, CSS, and JavaScript on the client side, the contents of a Web page in the browser are updated without reloading. For **Node.js** or **Meteor** applications, IntelliJ IDEA first tries to update the application incorporating the changes without restarting the server.

- Select this checkbox to have IntelliJ IDEA try restarting the server if the changes cannot be applied automatically.  
If even with this option chosen automatic upload still fails, you will have to restart the server manually by clicking the Rerun `<run configuration name>` button .
- When the checkbox is cleared, IntelliJ IDEA just displays a pop-up window informing you about the failure and suggesting to restart the server manually.

Ctrl+Alt+S

Use this tab to manage the behavior of the [HotSwap](#) mechanism.

#### ItemDescription

In this section, specify the behavior of HotSwap for Java:

### Java

#### ItemDescription

**Make project before reloading classes** This option controls Run | Reload Changed Classes action behavior. If it's turned on, the make process is performed before searching and reloading changed classes.

**Enable "JVM will hang" warning** If this checkbox is selected, then, on an attempt to perform HotSwap while JVM is suspended, a warning about the possible hanging of this JVM will be displayed.

**Reload classes in background** Select here whether you want to reload classes in background mode. This means, all progress messages will be displayed in a status bar.

**Reload classes after compilation** Use the controls in this area to configure behavior of the HotSwap mechanism.  
– Always - select this option to have classes reloaded automatically.  
– Never - when this option is selected, classes are not reloaded at all because the HotSwap mechanism is inactive.  
– Ask - select this option to have IntelliJ IDEA ask you whether to reload altered classes or not.

In this section, specify the behavior of HotSwap for Groovy:

### Groovy

#### ItemDescription

**Enable hot-swap agent for Groovy code** If this checkbox is selected, then a special agent will be added to the debugged process in order to enable hot-swap for Groovy code.

If you don't want hot-swap, or this agent is getting in the way, clear this checkbox.

**Note** Enabling hot-swap agent may cause serialization problems in the debugged applications.

Use this page to configure capture points to facilitate debugging of asynchronous code.

A capture point is a place in your code where the debugger captures stacktraces to be used later when you reach a specific point in the code (the insertion point) and want to see how you got there. IntelliJ IDEA does this by substituting part of the call stack with a captured stack. For more information on asynchronous debugging refer to [Debugging Asynchronous flow](#).

Asynchronous stacktraces are enabled by default. To disable them, deselect the Instrumenting agent (requires debugger restart) option. The most common capture points are built-in, so no configuration is required.

If you need to use capture points that are not included in the default configuration, you can add them manually by using the following controls:

**Note** You can download some additional capture settings from the following repository: [IntelliJ IDEA debugger Capture Points](#)

#### ItemDescription

	<p>Click this icon to configure a new capture point. Fill in the following information:</p> <ul style="list-style-type: none"><li>– Capture class name : enter the name of the class at the top of the stack trace you want to capture.</li><li>– Capture method name : enter the name of the method at the top of the stack trace you want to capture.</li><li>– Capture key expression : enter the capture key expression. The capture key expression is evaluated and the value is used as the key.</li><li>– Insert class name : enter the name of the class where you want to insert the captured stack trace.</li><li>– Insert method name : enter the name of the method where you want to insert the captured stack trace.</li><li>– Insert key expression : enter the key expression that will be evaluated and this value will be matched with the key in the captured stack.</li></ul> <p>Use the checkbox next to each entry to enable/disable the selected capture point.</p>
	<p>Click this icon to remove the capture point from the list.</p>
	<p>Click these icons to move the selected item one line up or down in the list.</p>
	<p>Click these icons to enable/disable all selected capture points.</p>
	<p>Click this icon to duplicate the selected entry.</p>
	<p>Click this icon to import capture point settings from a file.</p>
	<p>Click this icon to export capture point settings to a file.</p>
Capture local variables	<p>Select this option if you also want to capture local variables (primitives and String values) together with the call stack. This may sufficiently slow down the debugging process. Note that this option is unavailable if the Instrumenting agent is enabled</p>

**Warning!** This page only appears when Python Plugin is installed and enabled!

[File](#) | [Settings](#) | [Build, Execution, Deployment](#) | [Console for Windows and Linux](#)

[IntelliJ IDEA](#) | [Preferences](#) | [Build, Execution, Deployment](#) | [Console for macOS](#)

Ctrl+Alt+S

Use this page to define console options for the Python console.

In this section:

- [Console](#)
  - [Console common options](#)
- [Python Console](#)

## Console common options

Item	Description
Always show debug console	If this checkbox is selected, the debug console will be shown by default in the Debug view.
Use IPython if available	When the checkbox is selected (by default): if IPython is installed, then IPython console will be launched.  If the checkbox is not selected, then, even with the installed IPython, a Python console will be launched.

**Warning!** This page only appears when Python Plugin is installed and enabled!

File | Settings | Build, Execution, Deployment | Console | Python Console for Windows and Linux

IntelliJ IDEA | Preferences | Build, Execution, Deployment | Console | Python Console for macOS

Ctrl+Alt+S

Use this page to define the Python interpreter, its options, starting script etc. for the Python console.

## ItemDescription

### Environment

Project	Click this drop-down list to select one of the projects, <a href="#">opened in the same IntelliJ IDEA window</a> , where this run/debug configuration should be used. If there is only one open project, this field is not displayed.
Environment variable	<p>This field shows the list of environment variables. If the list contains several variables, they are delimited with semicolons.</p> <p>To fill in the list, click the browse button, or press <code>Shift+Enter</code> and specify the desired set of environment variables in the Environment Variables dialog box.</p> <p>To create a new variable, click <code>+</code>, and type the desired name and value.</p>
Python Interpreter	From the drop-down list, select one of the pre-configured Python interpreters.
Interpreter options	In this field, specify the string to be passed to the interpreter. If necessary, click <code>+</code> , and type the string in the editor.
Working directory	Specify a directory to be used by the running console. When this field is left blank, the project directory will be used.
Configure interpreters	If the desired interpreter is missing in the drop-down list, click this link to open the <i>Python interpreters</i> page, and configure an interpreter or virtual environment.
Add content roots to PYTHONPATH	Select this checkbox to have the content roots added to the PYTHONPATH.
Add source roots to PYTHONPATH	Select this checkbox to have the source roots added to the PYTHONPATH.

**Starting script** In this editor area, type the script to be executed in the console after its start-up and initialization. Note that syntax highlighting, code completion, import assistance, documentation, inspections and quick fixes are available in this editor:

By default, this area contains the following script, which causes printing out a header information and extending the system paths:

```
import sys; print('Python %s on %s' % (sys.version, sys.platform))
sys.path.extend([WORKING_DIR_AND_PYTHON_PATHS])
```

If you want to omit such a printout, delete this script.

Ctrl+Alt+S 

## Basics

On this page, create, edit, and delete **server access configurations** that give you control over interaction between IntelliJ IDEA and servers. Anytime you are going to use a server, you need to define a **server access configurations**, no matter whether your server is on a remote host or on your computer.

Among numerous ways to configure your development and production environments the most frequent ones are as follows:

- The Web server is installed on your computer. The sources are under the server document root (for example, `/htdocs`), and you do your development right on the server.
- The Web server is installed on your computer but the sources are stored in another folder. You do your development, then copy the sources to the server.
- The Web server is on another computer (remote host). Files on the server are available through the FTP/SFTP/FTPS protocol, through a network share, or a mounted drive.

Note that IntelliJ IDEA assumes that all development, debugging, and testing is done on your computer and then the code is deployed to a production environment. For detailed reasoning of this approach, see [Deploying your application](#)

Let's define the terms and their meaning in the context of synchronization between IntelliJ IDEA and servers.

- An **in-place server** is a server whose **document root** is the parent of the project root, either immediate or not. In other words, the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.
- A **local server** is a server that is running in a local or a mounted folder and whose **document root** is **NOT** the parent of the project root.
- A **remote server** is a server on another computer (remote host).
- The **server configuration root** is the highest folder in the file tree on the **local** or **remote** server accessible through the server configuration. For **in-place** servers, it is the project root.
- A **local file/folder** is any file or folder under the project root.
- A **remote file/folder** is any file or folder on the server, either local or remote.  
Suppose you have a project `C:/Projects/My_Project/` with a folder `C:/Projects/My_Project/My_Folder` and a local server with the document root in `C:/xampp/htdocs`. You upload the entire project tree to `C:/xampp/htdocs/My_Project`. In the terms of IntelliJ IDEA, the folder `C:/Projects/My_Project/My_Folder` is referred to as **local** and the folder `C:/xampp/htdocs/My_Project/My_Folder` is referred to as **remote**.
- **Upload** is copying data from the project **TO** the server, either local or remote.
- **Download** is copying data **FROM** the server to the project.

Synchronization with servers, uploading, downloading, and managing files on them are provided via the Remote Hosts Access bundled plugin, which is by default enabled. If the plugin is disabled, activate it in the Plugins page of the Settings dialog box. For details, see [Enabling and Disabling Plugins](#). Note that the plugin is available only for the **Ultimate Edition** of IntelliJ IDEA.

## Toolbar and common options

Use the toolbar buttons to manage the list of configurations.

The left-hand pane shows a list of all the server access configurations available in IntelliJ IDEA. When you select a configuration, the right-hand pane shows the configuration details.

Item	Tooltip and shortcut	Description
	Add	Click this button to open the <a href="#">Add Server</a> dialog box and define a new configuration there. 
	Delete	Click this button to remove the selected configuration from the list. 
	Copy	Click this button to copy the settings of the selected configuration. 
	Use as Default	Click this button to have IntelliJ IDEA apply the settings of the selected configuration by default during automatic upload of changed files.

Item	Tooltip and shortcut	Description
	Add	Click this button to open the <a href="#">Add Server</a> dialog box and define a new configuration there. 
	Delete	Click this button to remove the selected configuration from the list. 
	Copy	Click this button to copy the settings of the selected configuration. 
	Use as Default	Click this button to have IntelliJ IDEA apply the settings of the selected configuration by default during automatic upload of changed files.

Use this tab to choose the [way to access the Web server](#) and specify the [connection settings](#) .

#### ItemDescription

Name	The text box shows the configuration name specified in the <a href="#">Add Server</a> dialog box. Edit the configuration name, if necessary.
Visible only for this project	<p>Use this checkbox to configure the visibility of the server access configuration (deployment configuration).</p> <ul style="list-style-type: none"> <li>– Select the checkbox to restrict the use of the configuration to the current project. Such configurations cannot be reused outside the current project, they do not appear in the list of available configurations in other projects. For example, if this checkbox is selected in an SFTP configuration, you cannot use your SSH credentials from it when you configure a remote interpreter.</li> <li>– When the checkbox is cleared, the configuration is visible in all IntelliJ IDEA projects and the settings from, including SSH credentials, can be reused.</li> </ul> <p>See <a href="#">Configuring Node.js Interpreters</a> and <a href="#">Configuring Remote PHP Interpreters</a> for details.</p>
Access type	<p>From this drop-down list, choose the way to access the server. Use the Up and Down keyboard keys to scroll through the list of server configuration types. The available options are:</p> <ul style="list-style-type: none"> <li>– FTP: choose this option to have IntelliJ IDEA access the server via the FTP <a href="#">file transfer protocol</a> .</li> <li>– SFTP: choose this option to have IntelliJ IDEA access the server via the <a href="#">SFTP</a> file transfer protocol.</li> <li>– FTPS: choose this option to have IntelliJ IDEA access the server via the FTP file transfer protocol over SSL (the <a href="#">FTPS</a> extension).</li> <li>– Local or mounted folder: choose this option if the Web server is running in a local or a <a href="#">mounted folder</a> and its document root is NOT the parent of the project root.</li> <li>– In-place: choose this option if the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.</li> </ul>

## Upload/Download Project Files

In this area, specify the settings for accessing the server to upload and download files to and from.

The set of controls in the area depends on the chosen server access type.

#### ItemDescriptionAvailable for

Folder	In this field, specify the <b>server configuration root</b> . The <b>server configuration root</b> is the highest folder in the file tree on the server that can be accessed through the server configuration. The easiest way is to use the <b>document root</b> of your Web server as defined in the Web server configuration file. However you can appoint any other existing folder under the <b>document root</b> .	Local or mounted folder
FTP/FTPS/SFTP host	In this text box, specify the host name of the FTP/SFTP server to upload the files to.	FTP, FTPS, SFTP
Port	In this text box, specify the port to use. The default values are: <ul style="list-style-type: none"> <li>– 21 for FTP and FTPS</li> <li>– 22 for SFTP</li> </ul>	FTP, FTPS, SFTP
Root Path	In this text box, specify the <b>server configuration root</b> relative to your <b>user home</b> which was defined when you registered your account. This folder will be the highest one in the folder structure accessible through the current server configuration. Do one of the following: <ul style="list-style-type: none"> <li>– Accept the default value <code>/</code> , which points at the <b>user home</b> folder on the server.</li> <li>– Type the path manually.</li> <li>– Click the Browse button  and select the desired folder in the Choose Root Path dialog box that opens.</li> <li>– Click the Autodetect button and have IntelliJ IDEA detect the user home folder settings on the FTP/SFTP server and set up the root path according to them. The button is only enabled when you have specified your user name and password.</li> </ul>	FTP, FTPS, SFTP
Autodetect	Click this button to have IntelliJ IDEA detect the user home folder settings on the FTP/SFTP server and set up the root path according to them.	FTP, FTPS, SFTP
User name	In this text box, type your user name for authentication to the server. <b>Note</b> The button is only enabled when you have specified your user credentials.	FTP, FTPS, SFTP
Log in as anonymous	Select this checkbox to enable <a href="#">anonymous access</a> to the server with your email address as password.	FTP, FTPS, SFTP
Auth type	From this drop-down list, select the client authentication method. The available options are: <ul style="list-style-type: none"> <li>– Password - select this option to use standard authentication through a password.</li> <li>– Key pair (OpenSSH or PuTTY) - select this option to use <a href="#">SSH authentication</a> via a key pair. To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the <a href="#">OpenSSH</a> utility.</li> <li>– Authentication agent (ssh-agent or Pageant) - select this option if your SSH keys are managed by a credentials helper application (for example, <a href="#">Pageant</a> on Windows or <a href="#">ssh-agent</a> on Mac and Linux).</li> </ul> <p>See the <a href="#">Generating a new SSH key and adding it to the ssh-agent</a> tutorial for details on working with SSH keys.</p>	SFTP
Password	In this text box, type your password for authentication to the server.	FTP, FTPS, SFTP
Private key file	In this text box, specify the location of your private key file.	SFTP

Passphrase	In this text box, specify your authentication passphrase.	SFTP
Save password	Select this checkbox to have IntelliJ IDEA remember the specified password.	FTP, FTPS, SFTP
Save passphrase	Select this checkbox to have IntelliJ IDEA remember the specified passphrase.	SFTP
Test FTP/FTPS/SFTP connection	Click this button to check that the specified settings ensure successful connection via FTP/SFTP.	FTP, FTPS, SFTP
Explicit	Choose this option to have the <a href="#">explicit (active) security</a> applied. Immediately after establishing connection, the FTP client on your machine sends a command to the server to establish secure control connection through the default FTP port.	FTPS
Implicit	Choose this option to have the <a href="#">implicit (passive) security</a> applied. In this case, security is provided automatically upon establishing connection to the server which appoints a separate port for secure connections.	FTPS
Advanced options	Click this button to specify additional uploading settings in the <a href="#">Advanced Options</a> dialog box that opens.	FTP, FTPS, SFTP
Web server root URL	In this text box, specify the URL address of the <a href="#">Web server root folder</a> . Both the HTTP and the HTTPS protocols are supported. To access a server through HTTPS , you need to acquire a certificate file <code>&lt;certificate_name&gt;.cert</code> signed by a recognized authority and import this certificate in the <a href="#">truststore/keystore</a> of the Oracle JRE (Java Runtime Environment) on which IntelliJ IDEA runs. Note that self-signed certificates are rejected as unsafe.	All

### To import a certificate in Oracle JRE:

1. Open the embedded Terminal and type the following command:

```
<jre_home>/bin/keytool.exe -importcert -keystore <path to jre truststore/keystore> -file <full_path_to_<cert_name>.cert>
```

If you are using the Oracle JRE bundled with IntelliJ IDEA, the default path to the truststore/keystore is

```
<%product_installation_folder>/jre/jre/lib/security/jssecacerts or
```

```
<%product_installation_folder>/jre/jre/lib/security/cacerts .
```

Otherwise it is `<jre_home>/jre/lib/security/jssecacerts` or `<jre_home>/jre/lib/security/cacerts` .

2. When asked to enter a password for the truststore/keystore, specify the default one `changeit` .
3. Open the `IntelliJ IDEA.exe.vmoptions` file in the `<IntelliJ IDEA installation folder>/bin` and add the following line to it:

```
-Djavax.net.ssl.keyStore=<path to keystore>
```

4. Restart IntelliJ IDEA.

Learn more at [Java6](#) and [Java7](#) .

Open	Click this button to make sure that the specified server root URL address is accessible and points at the correct Web page.	All
------	---	-----

In this tab, configure **mappings**, that is, set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. The easiest way is to map the entire project root folder to a folder on the server, whereupon the project folder structure will be repeated on the server, provided that you have selected the Create Empty directories checkbox in the [Options dialog box](#). For more details, see [Customizing Upload/Download](#). Below are definitions of terms used in this topic in the context of synchronization between IntelliJ IDEA and servers.

- A **local server** is a server that is running in a local or a mounted folder and whose **document root** is **NOT** the parent of the project root.
- A **remote server** is a server on another computer (remote host).
- The **server configuration root** is the highest folder in the file tree on the **local** or **remote** server accessible through the server configuration. For **in-place** servers, it is the project root.
- A **local file/folder** is any file or folder under the project root.
- A **remote file/folder** is any file or folder on the server, either local or remote.

Suppose you have a project `C:/Projects/My_Project/` with a folder `C:/Projects/My_Project/My_Folder` and a local server with the document root in `C:/xampp/htdocs`. You upload the entire project tree to `C:/xampp/htdocs/My_Project`. In the terms of IntelliJ IDEA, the folder `C:/Projects/My_Project/My_Folder` is referred to as **local** and the folder `C:/xampp/htdocs/My_Project/My_Folder` is referred to as **remote**.

#### ItemDescription

Use this server as default	Click this button to have IntelliJ IDEA apply the settings of the selected configuration by default during automatic upload of changed files. This button is only enabled for the non-default servers; for the server <b>used as default</b> , this button is disabled.
Local Path	In this text box, specify the full path to the desired folder in the project tree. In the simplest case it is the project root. Type the path manually or click the Browse button  and select the desired location in the Choose Local Path dialog box that opens.
Deployment Path	In this text box, specify the folder on the server where IntelliJ IDEA will upload the data from the folder specified in the Local Path text box. Type the path to the folder relative to the <b>server configuration root</b> . If the folder with the specified name does not exist yet, IntelliJ IDEA will create it, provided that you have selected the Create Empty directories checkbox in the <a href="#">Options dialog box</a> . For more details, see <a href="#">Customizing Upload/Download</a> . The text box is not available for server configurations of the type In-place.
Web Path	In this text box, type the path to the folder on the server relative to the <b>server configuration root</b> . Actually, type the relative path you typed in the Deployment Path text box.
Add	Click this button to have a new line added to the list of mappings.
Remove	Click this button to remove the selected mapping from the list.

Use this tab to configure a list of local and remote folders that you do not want to be involved in upload/download.

---

**ItemDescription**

---

**Add local path** Click this button to have an empty line added to the list and specify the location of the folder to be protected against upload/download. Type the path manually or click the Browse button  and choose the required folder in the [dialog that opens](#) .

---

**Add deployment path** Click this button to have an empty line added to the list. Click the Browse button  . The Select remote excluded path dialog box that opens shows the data on the host accessed through the selected server configuration. Select the required folder.

---

**Remove path** Click this button to remove the selected item from the list. The button is only available when a line is selected.

The dialog box opens when you click the Add toolbar button  on the [Deployment](#) page.

Use the dialog box to create **server access configurations** that give you control over interaction between IntelliJ IDEA and servers. Anytime you are going to use a server, you need to define a **server access configurations**, no matter whether your server is on a remote host or on your computer.

#### ItemDescription

---

Name	In this text box, type the name of the new Web server configuration.
Type	<p>From this drop-down list, choose the way to access the server. Use the Up and Down keyboard keys to scroll through the list of server configuration types. The available options are:</p> <ul style="list-style-type: none"><li>– FTP: choose this option to have IntelliJ IDEA access the server via the FTP <a href="#">file transfer protocol</a>.</li><li>– SFTP: choose this option to have IntelliJ IDEA access the server via the <a href="#">SFTP</a> file transfer protocol.</li><li>– FTPS: choose this option to have IntelliJ IDEA access the server via the FTP file transfer protocol over SSL (the <a href="#">FTPS</a> extension).</li><li>– Local or mounted folder: choose this option if the Web server is running in a local or a <a href="#">mounted folder</a> and its <b>document root</b> is <b>NOT</b> the parent of the project root.</li><li>– In-place: choose this option if the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.</li></ul>

---

When editing the server configuration name in the Name text box, use the Up and Down keys on your keyboard to change the preselected server access to type in the Type drop-down list.

Ctrl+Alt+S 

Use this page to specify additional configuration settings for uploading and downloading project files to and from local and remote servers. For more details about various server access configurations, see [Deploying your application](#).

The options specified in this dialog box apply to all defined server configurations regardless of the server type (local, remote) and the data transfer protocol used. Protocol-specific options for server configurations of the type FTP/SFTP/FTPS are defined in the [Advanced Options Dialog](#).

#### ItemDescription

Exclude items by name	In this text box, specify patterns for the names of files and folders that you do not need to be deployed. Use semicolons as delimiters. Wildcards are welcome. The exclusion is applied recursively. This means that if a matching folder has subfolders, the contents of these subfolders are not deployed either.
Operations logging	Use this drop-down list to specify how much detailed logging you need to have. The available options are: <ul style="list-style-type: none"> <li>– Errors only: select this option to have the log show only errors occurred during upload.</li> <li>– Brief: select this option to have all events reflected in the log but without details.</li> <li>– Detailed: select this option to have more details on the upload shown in the log, for example, full file paths.</li> </ul>
Stop operation on the first error	Select this checkbox to have data transfer stopped as soon as an error occurs.
Overwrite up-to-date files	Do one of the following: <ul style="list-style-type: none"> <li>– Select this checkbox to have all the files uploaded no matter whether they have been changed since the previous upload or not.</li> <li>– Clear the checkbox to upload only files that have been changed since the previous upload.</li> </ul>
Preserve files timestamps	Select this checkbox to prevent resetting timestamps of files on upload.
Delete target items when source ones do not exist	If this checkbox is selected, any file in the destination directory will be removed if the file with this name is not involved in the current upload. This option is applicable when synchronization is performed from the <a href="#">Project</a> tool window or from the <a href="#">Remote Host</a> tool window.
Create empty directories	Select this checkbox to have an empty directory on the server created automatically if a new local directory has been created in your project since the last upload in the source folder.
Prompt when overwriting or deleting local items	Select this checkbox to have IntelliJ IDEA ask you for confirmation before overwriting or deleting local items for synchronization during download.
Upload changed files automatically to the default server	From this drop-down list, choose when you want IntelliJ IDEA to automatically upload a file to the default server. The available options are: <ul style="list-style-type: none"> <li>– Always : choose this option to have a file uploaded upon each save, no matter automatic or explicitly invoked.</li> <li>– On explicit save action : choose this option to have a file uploaded after save only if this save was invoked manually by choosing File   Save all or pressing <b>Ctrl+S</b>.</li> <li>– Never : choose this option to suppress automatic upload.</li> </ul> <p>The default server configuration is appointed on the <a href="#">Deployment</a> page by selecting the desired configuration in the list and clicking the Use as Default toolbar button .</p>
Upload external changes	Select this checkbox to have IntelliJ IDEA upload also the local changes that were made using a third-party tool.
Override default permissions on files	Select this checkbox to change the default permissions assigned to uploaded files on remote hosts. Click the Browse button  to open the <a href="#">Files Default Permissions</a> dialog box, where you can manage access to uploaded files on remote hosts by assigning permissions.
Override default permissions on folders	Select this checkbox to change the default permissions assigned to uploaded folders on remote hosts. Click the Browse button  to open the <a href="#">Folders Default Permissions</a> dialog box, where you can manage access to uploaded folders on remote hosts by assigning permissions.
Warn when uploading over newer file	Use this drop-down list to define the version-control policy to apply when uploading files to remote hosts. Depending on this choice, IntelliJ IDEA either checks whether any changes have been made to the corresponding files on the remote host since you downloaded them or just overwrites the remote files. <ul style="list-style-type: none"> <li>– No: choose this option to have the file on the remote host overwritten with its local copy silently. All the changes made to the remote file since your last synchronization will be abandoned.</li> <li>– Compare timestamp and size: if you choose this option, IntelliJ IDEA performs two checks: <ol style="list-style-type: none"> <li>1. Compares the sizes of the local and remote files.</li> <li>2. Compares the remote file timestamp set at the moment of the last synchronization with the current remote file timestamp.</li> </ol> </li> </ul> <p>If the files differ in their size or the remote file timestamps differ, IntelliJ IDEA opens a <a href="#">Difference Viewer for Files</a>, where you can explore and integrate the differences.</p> <p>This type of check depends on the timezone setting. If the timezone setting on your local machine is different from that on the remote host, the check may be successful even though the file versions actually differ.</p>

- Compare content: when this option is chosen, IntelliJ IDEA compares the content of the local and remote files. If any diversions are detected, IntelliJ IDEA opens a [Difference Viewer for Files](#) , where you can explore and integrate the differences.

---

Notify about remote changes      Select this checkbox to receive notifications about changes on the remote host. The checkbox is available only when the Compare timestamp and size: or Compare content: option is selected in the Warn when uploading over newer file drop-down list.

---

SFTP advanced options (IDE level)

---

Add new host key to known\_hosts      Choose whether IntelliJ IDEA should ask about connecting to a host not mentioned in the file `known_hosts` . The following options are available:

- **Always** : always connect and add its record to the file `known_hosts` .
- **Ask** : ask whether IntelliJ IDEA should connect to a host and add its record to the file `known_hosts`
- **Never** : do not connect.

---

Hash hosts in known\_hosts file      If this checkbox is selected, the new host record will be stored in hash format.

The dialog box opens when you click the Advanced Options button in the [Connection](#) tab of the [Deployment](#) page. Use this dialog box to customize upload/download by specifying additional protocol-specific options for server configurations of the type FTP/SFTP/FTPS.

**ItemDescriptionAvailable  
for**

Passive mode	Select this checkbox to set the client on your machine to the <a href="#">passive mode</a> , when it connects to the server to inform about being in the passive mode, receives the port number to listen to, and established data connection through the port with the received number. This mode is helpful when your machine is behind a firewall.	FTP, FTPS
Show and process hidden files	When this checkbox is selected: 1. Hidden files and directories are shown in the <a href="#">Remote Host Tool Window</a> . 2. Hidden files and directories are involved in <a href="#">diff</a> and <a href="#">synchronization</a> operations.  The name of a hidden file or directory starts with a dot ( <code>.</code> ).	FTP, FTPS
Compatibility mode	Select this checkbox to ensure <a href="#">compatibility in child file naming</a> with your FTP server. This option is helpful if the remote FTP server reports the following error:  <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9; margin: 10px 0;">Invalid descendant file name &lt;file name&gt;</div> Selecting this option may slow down synchronization with the server.	FTP
Retrieve accurate files timestamps	Use this drop-down list to specify the <a href="#">MDTM</a> FTP command calling policy to retrieve the last-modified time of a given file on the remote host. The available options are: – Always - select this option to have MDTM called for every file shown in the <a href="#">Remote Host</a> tool window. – On copy - select this option to have MDTM called in the following cases: – To check whether a file is up to date when the Overwrite up-to-date files checkbox in the <a href="#">Options</a> dialog box is cleared. – To preserve the actual time stamp of a file during download. – Never - select this option to suppress calling MDTM.	FTP, FTPS, SFTP
Limit concurrent connections	Select this checkbox to have IntelliJ IDEA restrict the number of connections to be supported simultaneously and specify the maximum number of allowed connections in the text box.	FTP, FTPS, SFTP
Control encoding	In this text box, specify the encoding that matches the encoding used by your server. Accept the default value if you are not sure that it supports UTF-8 encoding.	FTP, FTPS, SFTP
Always use LIST command	Select this checkbox to use the standard <code>LIST</code> command for listing instead of the <code>MLSD</code> command. This lets you avoid problems, for example, failure during upload with the <code>Invalid descendent file name</code> exception if the FTP server supports <code>MLSD</code> and returns <code>cdir</code> .	FTP, FTPS
Send keep alive message each	In this text box, specify how often you want IntelliJ IDEA to send commands to the server to reset the timeout and thus preserve the connection.	FTP, FTPS, SFTP
Use keep alive command	From this drop-down list, choose the commands to be sent to the server to reset the timeout and thus preserve the connection.	FTP, FTPS
Ignore info messages	On some <a href="#">SFTP</a> servers, the <a href="#">SSH banner</a> may be enabled. Every time a connection is established, a pop-up window with an information message may be shown and to continue you would need to click OK. To suppress showing the information pop-up window, select the Ignore info messages checkbox.	SFTP

This dialog opens when you select the **Override default permissions on files** or **Override default permissions on folders** checkbox in the **Options** dialog and click the **Browse** button  next to it.

Use this dialog box to re-assign default server permissions to owners of files or folders, groups of owners, and other users.

The following identifiers are used for permission types:

- R stands for Read .
- W stands for Write .
- X stands for Execute

#### ItemDescription

Owner	In this row, specify what an owner of a file or folder may do by selecting the checkboxes below the corresponding identifiers.
Group	In this row, specify what a group of owners of a file or folder may do by selecting the checkboxes below the corresponding identifiers.
Others	In this row, specify what any one else may do by selecting the checkboxes below the corresponding identifiers.
Octal	In this text box, specify the <a href="#">octal representation</a> of the specified set of permissions. By default, IntelliJ IDEA calculates and re-calculates the value of the field as you select or clear the desired checkboxes. You can also specify the octal value manually.

Specify the containers for running your [Arquillian](#) tests.

## Toolbar

### IconDescription

-  Add a container configuration. Select one of the following:
  - Manual container configuration. Select this option to configure a managed or remote container. You can also use this option to configure an embedded container if the container of interest is not present in the Embedded list. Use ,  and  in the Dependencies section to specify the container implementation.
  - Embedded. Select this option to use an embedded container. Then select the container of interest. Use  in the Dependencies section to fine-tune the container configuration.
-  Remove the selected container configurations.

## Container settings

### ItemDescription

Name	The name of the container configuration.
Arquillian container	For an embedded container: a link to a web page for the corresponding container adapter Maven artifact.
Dependencies	<p>The container adapter implementation represented by a Maven artifact or IntelliJ IDEA library .</p> <ul style="list-style-type: none"><li> Add a Maven artifact or IntelliJ IDEA library.</li><li> Remove the selected items from the list.</li><li> Edit the settings for the selected item. Depending on the container, you can change the adapter version or choose to download the container source code and documentation.</li></ul>
VM options	<p>Options and arguments to be passed to the JVM in which the container runs.</p> <p>When specifying the options, follow these rules:</p> <ul style="list-style-type: none"><li>Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li><li>If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg" or "some arg"</code> .</li><li>If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="\quoted_value\"</code> .</li></ul>
Environment variables	The environment variables to be passed to the corresponding JVM.

From the Run/Debug Configurations dialog: Configure when editing a run/debug configuration for an application server.

Use this page or dialog to manage configurations for the [supported application servers](#) and their settings.

The servers that are already defined in IntelliJ IDEA are shown in the pane under **+** and **-**. When you select a server in this pane, the corresponding configuration settings and associated controls are shown in the area to the right. (If you are editing a run configuration for a particular server (e.g. Tomcat), only the existing configurations for this particular server are shown.)

Use **+** to create server configurations and **-** to remove them.

By the time you start creating a server configuration, the corresponding server must already be installed on your computer. (This isn't necessary for [CloudBees](#).)

Note that the list of servers you can work with depends on which server integration [plugins](#) are currently enabled. See [Enabling application server integration plugins](#).

- [Toolbar](#)
- [Main settings and controls](#)
- [Libraries](#)
- [Additional Libraries for Frameworks](#)
- [Configuration file list \(for Jetty 7 or later versions\)](#)

## Toolbar

### ItemDescription

**+** or  Use this icon or shortcut to create a server configuration (i.e. to define a server in IntelliJ IDEA):

1. If the server list is shown, select the server of interest.
2. In the dialog that opens, specify the server settings and click OK .

For most of the servers, you just need to specify the server installation directory (referred to as the server home). For more information, see [Main settings and controls](#).

**-** or  Use this icon or shortcut to remove the selected application server configuration.

## Main settings and controls

### ItemDescription

Name	The server configuration name.
<Server> Home	The path to the application server installation folder. Click  and select the folder in the <a href="#">dialog that opens</a> .
<Server> Version	The detected application server version (readonly).
<Server> base directory (for Jetty, Tomcat and TomEE)	The path to the server base directory. Click  and select the directory in the <a href="#">dialog that opens</a> .
Register schemas (for JBoss)	To be able to validate JBoss XML configuration files (such as <code>standalone.xml</code> , <code>domain.xml</code> , etc.) when editing them in IntelliJ IDEA, you can register XML schemas (XSDs) available in the JBoss installation: <ol style="list-style-type: none"> <li>1. Click Register schemas .</li> <li>2. To register all the schemas, just click OK in the dialog that opens. If there are schemas that you don't want to register, select those schemas under External Schemas and DTDs , click <b>-</b> and then click OK .</li> </ol> <p>To view or edit the schema list at a later time, use the <a href="#">Schemas and DTDs</a> page in the <a href="#">Settings dialog</a>.</p>
Download client libraries (for CloudBees)	The Tomcat instance embedded in CloudBees is used as a server. This Tomcat instance is included in the CloudBees client libraries which you can download. If the button is inactive, the client libraries (along with the corresponding Tomcat instance) are already available in IntelliJ IDEA.

See also, [Libraries](#), [Additional Libraries for Frameworks](#) and [Configuration file list \(for Jetty 7 or later versions\)](#).

## Libraries

When you create a server configuration, normally, an associated application server [library](#) is created. As a rule, this library includes Servlet, JSP and EJB implementations available in the server distribution.

Use the controls under Libraries to manage the contents of the library.

### ItemDescription

 or  Use this icon or shortcut to add items (classes, sources, documentation, etc.) to the library. In the [dialog that opens](#), select the necessary files and folders. These may be individual `.class` and `.java` files as well as directories and archives (`.jar` and `.zip`) containing such files.

IntelliJ IDEA will analyze the selected files and folders, and automatically assign their contents to the appropriate library categories (Classes, Sources, Documentation, etc.).

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category yourself.

 To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

 Click this icon to make certain library items "excluded" (see [Excluded library items](#)). In the dialog that opens, select the items that you want IntelliJ IDEA to ignore (folders, archives and folders within the archives), and click OK.

 or  When you click this icon or press `Delete` :

- The selected "ordinary" library items are removed from the library.
- The selected excluded items (see [Excluded library items](#)) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

## Additional Libraries for Frameworks

For certain application server configurations (e.g. GlassFish), there is an Additional Libraries for Frameworks list with checkboxes.

Each item in this list, potentially, is a [library](#) that implements the corresponding framework. (Corresponding library files are included in the server distribution.)

When you select a checkbox in the list, the corresponding [application server library](#) is created. The dialog that opens lets you select the [modules](#) in which this library should be used. (As a result, the library is added to [dependencies](#) of the selected modules.)

## Configuration file list (for Jetty 7 or later versions)

For [Jetty 7](#) or later versions, there is a section where the server configuration (`.xml`) or module (`.mod`) files are listed.

This section provides a GUI for editing the file `<jetty_home>\start.ini`. (`start.ini` contains the options for `<jetty_home>\start.jar` which is used to start Jetty.)

Use the checkboxes to make the files active or inactive. Use , , ,  and  to add, remove, replace and reorder the files.

### ItemDescription

**Active** Use the checkboxes to make the files active or inactive. As soon as you deselect a file, the corresponding line in `start.ini` is commented. When you make a file active, the corresponding entry in `start.ini` is uncommented.

**Path** The paths to the corresponding files are shown (readonly). For the files within the Jetty installation directory, the paths are relative to the installation directory. For all the rest of the files, the absolute paths are shown.

 or  Use this icon or shortcut to add a file to the list. In the [dialog that opens](#), select the necessary file and click OK. Adding a file to the list leads to adding a new (commented) entry to `start.ini`.

 or  Use this icon or shortcut to remove the selected file from the list. Note that this operation does not delete the file physically. However, the corresponding entry is removed from `start.ini`.

 or  Use this icon or shortcut to replace the selected file. In the [dialog that opens](#), select the replacement file and click OK.

 or  Use this icon or shortcut to move the selected file one line up in the list.

 or  Use this icon or shortcut to move the selected file one line down in the list.

Use this page to manage your cloud access configurations. Each configuration includes your cloud user account info and related settings.

To create a new configuration, click [+](#) and select the cloud platform of interest. (By the time you start creating a cloud access configuration, you must already have the corresponding cloud user account. See [Working with Cloud Platforms](#) .)

- [- CloudBees](#)
- [- Cloud Foundry](#)
- [- Google App Engine](#)
- [- Heroku](#)
- [- OpenShift](#)
- [- Toolbar](#)

## CloudBees

Specify your [CloudBees](#) user account details and related settings. For additional information, see the [CloudBees documentation](#) .

### ItemDescription

Name	The name of the CloudBees configuration.
Domain	Your CloudBees domain.
Username (email)	The username for your CloudBees account (e.g. your email address).
Password	The password for your CloudBees user account.

## Cloud Foundry

Specify your [Cloud Foundry](#) user account details and related settings. For additional information, see the [Cloud Foundry documentation](#) .

### ItemDescription

Name	The name of the Cloud Foundry configuration.
Version	The Cloud Foundry version that you are using (a.k.a. the Service Broker API version): <ul style="list-style-type: none"> <li>- V1 for version 1.</li> <li>- V2 for version 2.</li> </ul>
Username (email)	Your username for your Cloud Foundry instance (e.g. your email address).
Password	Your password for your Cloud Foundry instance.
Provider (API URL)	The URL of the Cloud Controller in your Cloud Foundry instance (a.k.a. API endpoint or target URL).
Trust self-signed certificates	For version 2 ( V2 ): Select this checkbox for self-signed cloud authentication certificates to be trusted. Otherwise, the self-signed certificates are rejected.
Organization	For version 2 ( V2 ): The target organization (for deploying your applications).
Space	For version 2 ( V2 ): The target space (within the organization).
Cloud instance	For version 1 ( V1 ): One of the following: <ul style="list-style-type: none"> <li>- Global for hosted Cloud Foundry.</li> <li>- Local (vcap.me) for a Cloud Foundry VCAP installation.</li> <li>- Micro - offline for Micro Cloud Foundry used in the offline mode.</li> </ul>
Port	For a Cloud Foundry VCAP instance ( Local (vcap.me) ): The http port ( <code>88</code> by default).
Domain	For a Micro Cloud Foundry instance ( Micro - offline ): The domain name associated with your Micro Cloud Foundry instance.

## Google App Engine

Specify your [Google App Engine Cloud](#) user account details and related settings. For additional information, see the [Google App Engine Cloud documentation](#) .

### ItemDescription

Name	The name of the Google App Engine configuration.
Use passwordless login via OAuth2	Select this option to use the <a href="#">OAuth 2.0</a> authentication.
Login with email and password	Select this option to log in to the cloud using your email and password.
Email	Your Google email address.
Password	Your password.

Remember password  Select this checkbox if you want IntelliJ IDEA to remember your password (e.g. to save it in the password database). See [Passwords](#) .

## Heroku

Specify your [Heroku](#) user account details and related settings. For additional information, see the [Heroku documentation](#) .

### ItemDescription

Name	The name of the Heroku configuration.
Username (email)	The username for your Heroku account (e.g. your email address).
Password	The password for your Heroku user account.
Upload Public SSH Key	To be able to use the cloud, you should upload your public SSH key to it. (This isn't necessary if you did that earlier.) Click the link, click <input type="checkbox"/> in the Upload Public SSH Key dialog, and select your public SSH key file ( <code>.pub</code> ) in the dialog that opens.

## OpenShift

Specify your [OpenShift](#) user account details and related settings. For additional information, see the [OpenShift documentation](#) .

### ItemDescription

Name	The name of the OpenShift configuration.
Server (API URL)	One of the following: <ul style="list-style-type: none"><li>– OpenShift (openshift.redhat.com) for OpenShift Online, the hosted PaaS service in the public cloud.</li><li>– OpenShift Origin (broker.openshift.local) for OpenShift installed on your local computer or on your company network.</li></ul>
Domain	Your OpenShift domain.
Upload Public SSH Key	To be able to use the cloud, you should upload your public SSH key to it. (This isn't necessary if you did that earlier.) Click the link, click <input type="checkbox"/> in the Upload Public SSH Key dialog, and select your public SSH key file ( <code>.pub</code> ) in the dialog that opens.

## Toolbar

Use **+** to create configurations and **-** to delete them.

Ctrl+Alt+S

Use this page to define the way the coverage data will be processed.

### ItemDescription

#### When new coverage is gathered

Show options before applying coverage to the editor	Choose this option to show the Code Coverage dialog every time you launch a new run configuration with code coverage. The coverage options dialog is displayed, when different coverage data have been produced.
Do not apply collected coverage	Choose this option to cancel applying the new code coverage results.
Replace active suites with the new one	Choose this option to have the active suites replaced with the new one every time you launch a new run configuration with code coverage.
Add to active suites	Choose this option to have the new code coverage suite added to the active suites every time you launch a new run configuration with code coverage.
Activate coverage view	Select this checkbox to have the <a href="#">Coverage</a> tool window opened automatically when an application or test is run with coverage.

**Warning!** The following is only valid when Plugin is installed and enabled!

#### Python coverage

Use bundled coverage.py	<p>If this checkbox is selected, IntelliJ IDEA will use the bundled <code>coverage.py</code>.</p> <p>If this checkbox is not selected, IntelliJ IDEA will use the coverage tool included in the selected Python interpreter.</p>
Branch coverage	This checkbox enables branch coverage in <code>coverage.py</code> tool. Thus additional information to the pure line coverage reports is added, marking the coverage of lines with conditional statements as incomplete in case one or more branches haven't been executed:

```

10
11 def demo(b, a, c):
12     d = b ** 2 - 4 * a * c
13     if d >= 0:
14         t(d)
15         disc()
16         print("Line was hit")
17     print("Line 12 didn't jump to line 20")
18     print(root1, root2)
19     return root1, root2
20 else:
21     raise Exception

```

Refer to [this page](#) for details.

Ctrl+Alt+S 

For the Docker page to be available, the Docker integration plugin must be installed.

Specify the settings for accessing the Docker API. If you are going to use [Docker Compose](#), make sure that the Docker Compose executable setting on the [Docker | Tools page](#) is correct.

See also, . [Docker how tos](#) . . .

#### ItemDescription

Name	Description
Connect to Docker daemon with	<p>The name of the configuration.</p> <p>Docker for Mac. For macOS only: If you are using Docker for macOS, this is the recommended connection option. Unix socket. For Linux only: This is the recommended connection option for Linux.</p> <p>Docker Machine. If you are using Docker Toolbox for Windows or macOS, this is the recommended option for connecting to Docker API.</p> <p>The <i>Connection successful</i> message should appear right away. If it doesn't, check your Docker Machine executable setting on the <a href="#">Docker   Tools page</a>.</p> <p>If you have more than one Docker Machine installed and running, use the list to select which of the Machines should be used.</p> <p>TCP socket. If you are using Docker for Windows, this is the usual connection option. This option will also work for Linux, Docker for macOS and Docker Toolbox.</p> <ul style="list-style-type: none"> <li>Engine API URL. Depending on the Docker version and operating system: <ul style="list-style-type: none"> <li>Docker for Windows: <code>tcp://localhost:2375</code> IMPORTANT! In the General section of your Docker settings, turn on the Expose daemon on tcp://localhost:2375 without TLS option.</li> <li>Docker for macOS or Linux: <code>unix:///var/run/docker.sock</code></li> <li>Docker Toolbox for Windows or macOS: <code>https://192.168.99.100:2376</code></li> </ul> </li> <li>Certificates folder The path to the certificates folder. Depending on your Docker version and operating system: <ul style="list-style-type: none"> <li>Docker for Windows, macOS or Linux: This field must be empty.</li> <li>Docker Toolbox for Windows: <code>&lt;your_home_directory&gt;\.docker\machine\machines\default</code></li> <li>Docker Toolbox for macOS: usually, <code>&lt;your_home_directory&gt;/.docker/</code> or its subdirectory.</li> </ul> </li> </ul> <p>Mind the following: since the Certificates folder field specifies any folder with certificates, this field corresponds to the environment variable <code>DOCKER_CERT_PATH</code>. See details at <a href="#">Client modes</a> page of the Docker documentation.</p>
Path mappings	<p>For Windows and macOS: Specify the host - virtual machine path mappings for folders that you are going to map to container <a href="#">volumes</a>.</p> <p>Use  to edit an existing mapping, or  to create a new one. The corresponding directory path in the Docker virtual machine's file system.</li> </ul>

Ctrl+Alt+S 

---

For the Docker | Registry page to be available, the Docker integration plugin must be installed.

---

This page lets you manage your Docker Registry configurations which represent your Docker image repository user accounts.

## Toolbar

### IconDescription

---

	Create a new configuration.
	Delete the selected configurations.

---

## Configuration settings

### ItemDescription

---

Name	The name of the configuration
Address	The image repository service URL, e.g. – registry.hub.docker.com for <a href="#">Docker Hub</a> – quay.io for <a href="#">Quay</a>
Username	The user name for your user account.
Password	Your password.
Email	The email address that you specified when creating your user account.
Server	The associated <a href="#">Docker configuration</a> (used to connect to the service to check that your user account settings are correct).

---

Ctrl+Alt+S 

---

For this page to be available, the Docker integration plugin must be installed and enabled.

---

Specify the settings for working with [Docker Machine \(Docker Toolbox\)](#) and [Docker Compose](#).

#### ItemDescription

---

Docker Machine executable `docker-machine` or an actual path to `docker-machine.exe` (normally located in the Docker Toolbox installation folder).

The default setting `docker-machine` is fine if:

- The actual name of the executable file is `docker-machine`.
- The path to the directory where the file is located is included in the environment variable `Path`.

---

Docker Compose executable `docker-compose` or an actual path to `docker-compose.exe` or `docker-compose.sh` (normally located in the `bin` folder of the Docker installation directory).

The default setting `docker-compose` for Docker Compose executable is fine if:

- The actual name of the executable file is `docker-compose`.
- The path to the directory where the file is located is included in the environment variable `Path`.

IntelliJ IDEA lets you build and run your Android-Gradle applications using [Instant Run](#) feature.

Use this page to specify plugins that are required for your project. In this case IntelliJ IDEA ensures that the plugins that are necessary for your project to work will be available.

#### ItemDescription

---

 or

Click this icon to add a required plugin for your project.

In the dialog that opens, specify the following options:

- Plugin - use this drop-down list to select a plugin that you want to add as required.
- Minimum version - use this field to specify the minimum version of the selected plugin.
- Maximum version - use this field to specify the maximum version of the selected plugin.

---

 or

Click this icon to change the specified plugin or edit its version.

---

 or

Click this icon to remove the specified plugin.

Ctrl+Alt+S 

---

When you select the Languages and Frameworks category in the left-hand pane, its main subcategories are listed in the right-hand part of the dialog.

- JavaScript

- OSGi Framework Instances
- Scala Compile Server
- SQL Dialects
- SQL Resolution Scopes
- Stylesheets
- Play2
- Template Data Languages
- TypeScript
- Web Contexts
- XSLT
- XSLT File Associations
- PHP
- Dart

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript for macOS

Ctrl+Alt+S 

Use the pages in this section to specify the JavaScript language version for your project and configure JavaScript support in it.

In this part:

- [JavaScript Libraries](#)
  - [JavaScript Usage Scope](#)
- [Code Quality Tools](#)
  - [JSLint](#)
  - [JSHint](#)
  - [Closure Linter](#)
  - [JSCS](#)
  - [ESLint](#)
- [Templates](#)
- [Bower](#)
- [Yeoman](#)
- [Meteor](#)
- [PhoneGap/Cordova](#)

#### ItemDescription

**JavaScript Language Version** From this drop-down list, choose the JavaScript language version that represents the set of the language features to use in your project. The available options are:

- [ECMAScript 3](#)
- [ECMAScript 5.1](#)
- [JavaScript 1.8.5](#)
- [ECMAScript 6](#): This version adds support for the features introduced in ECMAScript 2015-2017 as well as some current proposals to the standard.
- [React JSX](#): This version adds support for the JSX syntax on top of ECMAScript 6
- [Flow](#): This version adds support for the Flow syntax.

**Prefer Strict mode** Select this checkbox to have the [strict mode](#) standard applied to JavaScript code. This helps improve your code by enforcing best practices and suppressing insecure ones.

**Only type-based completion**

- When this checkbox is cleared, the completion list contains multiple variants in complicated cases.
- When the checkbox is selected, the completion list strongly depends on the IntelliJ IDEA type inference. This makes completion more precise but in case of poor inference the list may be empty.

By default, the checkbox is cleared.

**Flow package or executable** In this field, specify the path to the `node_modules\flow-bin` package or the Flow binary executable file. To use `node_modules\.bin\flow` make sure the path to Node.js is added to the `PATH` environment variable. The field is available only when Flow is chosen from the JavaScript Language Version drop-down list.

**Use Flow server for:** In this area, specify the basis for coding assistance by selecting or clearing the following checkboxes:

- **Type checking:** When this checkbox is selected, syntax and error highlighting is provided based on the data received from the Flow server. When the checkbox is cleared, only the basic internal IntelliJ IDEA highlighting is available.
- **Navigation, code completion, and type hinting:** When this checkbox is selected, suggestion lists for reference resolution and code completion contain both suggestions retrieved from integration with Flow and suggestions calculated by IntelliJ IDEA. When the checkbox is cleared, references are resolved through IntelliJ IDEA calculation only.

The checkboxes are available only when the path to the [Flow](#) executable file is specified.

**Save all modified files automatically** Keep this checkbox selected to ensure that Flow is applied continuously because Flow checks the current files only after all the other modified files are saved.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Libraries for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Libraries for macOS

Ctrl+Alt+S 

Use this page to set up additional JavaScript libraries to expand the basic assistance provided through the JavaScript [plugin](#). Note that the JavaScript libraries are global.

In this section:

- [Libraries](#)
- [Buttons](#)
- [New Library / Edit Library Dialog Box](#)

## Libraries

### ItemDescription

Enabled	Each checkbox in this column shows whether the corresponding library is available or not: <ul style="list-style-type: none"><li>– A checkbox is selected when the corresponding library is defined and enabled in the current project.</li><li>– A checkbox is marked with a Dash ( - ) if the corresponding library is defined and enabled on a more detailed level, for example, in a directory or in a file.</li><li>– A checkbox is cleared when the corresponding library is disabled.</li></ul>
---------	---

Name	This column shows the names of the directories defined for a project.
------	---

Type	This column shows library types.
------	----------------------------------

## Buttons

### ItemDescription

Add	Click this button to create a new JavaScript library in the <a href="#">New Library</a> dialog box. Refer to the section <a href="#">Configuring JavaScript Libraries</a> .
-----	---

Edit	Click this button to change the name and contents of the selected library in the <a href="#">Edit Library</a> dialog box.
------	---

Remove	Click this button to delete the selected library.
--------	---

Download	Click this button to open the Download Library dialog box, where you can have IntelliJ IDEA download and install one of the popular official JavaScript-related libraries, such as: <ul style="list-style-type: none"><li>– <a href="#">Dojo</a></li><li>– <a href="#">ExtJS</a></li><li>– <a href="#">jQuery</a></li><li>– <a href="#">jQuery UI</a></li><li>– <a href="#">Prototype</a></li><li>– etc.</li></ul>
----------	--

Besides the above listed official libraries, you can download [stubs for TypeScript definition files](#).

Choose the group of libraries in the drop-down list. The available options are Official libraries and TypeScript community stubs. Depending on your choice, IntelliJ IDEA displays a list of available libraries. Select the one to be downloaded and installed, and click Download and Install. You return to the [JavaScript Libraries](#) page where the new library is added to the list. Click OK to save the settings.

Manage scopes	Click this button to configure libraries to be used for specific files and/or directories in the <a href="#">JavaScript. Usage Scope</a> dialog box.
---------------	--

## New Library / Edit Library Dialog Box

### ItemDescription

Name	Specify the library name.
------	---------------------------

Framework type	From this drop-down list, choose the framework to configure as a library.
----------------	---

Version	In this text box, specify the version of the selected framework to use.
---------	---

Visibility	In this area, specify where you want the library to be available for associating with files and folders. The available options are: <ul style="list-style-type: none"><li>– Current project: when this option is chosen, the library can be associated with files and folders within the current project only. If you later try to use the framework with another project, you will have to configure the library anew.</li><li>– Global: choose this option to enable associating the library with any of your IntelliJ IDEA projects.</li></ul>
------------	---

Files	In this section, set up the library contents.
-------	---

 ( Add )	Click this button to attach a JavaScript file or directory from the file system.
---	--

 ( Remove )	Click this button to detach the selected file or directory from a library.
--	--

---

Name	This read-only column shows the name of the selected library file or the names of relevant library files from the selected directory.
------	---

---

Type	Click the column to show the drop-down list of the available versions of library files or directories: debug or release.
------	--

IntelliJ IDEA enables you to create a library containing just one `.js` file, if this file is located on the Internet and can be accessed over HTTP. If you refer to a JavaScript library that is not yet available locally, but is available online, use the [Download library intention action](#) :

The library will be placed to the user home directory, and will appear in the list of configured libraries in the JavaScript - Libraries page of the Settings dialog.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Libraries - Manage Scopes for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Libraries - Manage Scopes for macOS

Ctrl+Alt+S 

The dialog box opens when you click the Manage Scopes button in the [JavaScript Libraries](#) page.

Use this dialog box to define the scopes where the JavaScript libraries should apply for code completion, highlighting and navigation. The scopes may cover the whole project, directories and even individual files. This helps make JavaScript code completion more precise, and avoid too long suggestion lists.

#### ItemDescription

**File/Directory** This column displays the project tree view.

**Library** This column displays libraries for a file or directory, if applicable.

If a library can be specified for a certain node of the project tree view, click the Library column for a selected file or directory, and choose the desired library from the list of available libraries.

If JavaScript libraries are not applicable to a particular node, 'NA' is shown in grey font.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools for macOS

Ctrl+Alt+S 

---

Use the pages under this node to enable the built-in JavaScript code verifiers and configure their behaviour.

In this part:

- [JSLint](#)
- [JSHint](#)
- [Closure Linter](#)
- [JSCS](#)
- [ESLint](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | JSLint for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | JSLint for macOS

Ctrl+Alt+S 

Use this page to enable the built-in JavaScript [JSLint](#) code verifier and configure its behaviour.

#### ItemDescription

Enable	Select this checkbox to have JSLint applied to verify the code in the current project. After that the other controls in the page are enabled.
Tolerate	In this area, specify the discrepancies you want JSLint to consider worth reporting by enabling or disabling <a href="#">JSLint options</a> . By default, discrepancies of all types are considered worth reporting. To have the tool skip discrepancies of a certain type, select the checkbox next to this type.
Assume	In this area, specify for which environments you want global properties predefined.
Stop on first error	Select this checkbox to have the verification process suspend as soon as the first valuable discrepancy is detected.
Safe Subset	Select this checkbox to have <a href="#">ADSafe safe subset rules</a> enforced.
Verify ADsafe	Select this checkbox to have the <a href="#">ADSafe rules</a> enforced.
Indentation	In this text box, type the number of spaces to be used for indentation. This setting corresponds to the <code>indent</code> option.
Maximum line length	In this text box, limit the number of characters acceptable in one line. This setting corresponds to the <code>maxlen</code> option.
Maximum number of errors	In this text box, specify the maximum number of warnings that can be reported. The default setting is 50. This setting corresponds to the <code>maxerr</code> option.
Predefined	In this text box, specify the predefined global variables by names or through object keys. Use commas ( <code>,</code> ) as separators.

**Note** This setting corresponds to the `predef` option.

Validate also	<p>In this area, enable or disable additional verification of HTML, CSS, or JSON context and configure the checking mode, when enabled.</p> <ul style="list-style-type: none"><li>– HTML: select this checkbox to have HTML context verified. Specify how you want HTML event handlers and HTML fragments treated: by default, they are reported as errors. To have the tool skip them, select the Tolerate HTML event handlers and Tolerate HTML fragments checkboxes respectively.</li><li>– CSS: select this checkbox to have CSS context verified. Specify how you want CSS workarounds treated: by default, they are reported as errors. To have the tool skip them, select the Tolerate CSS workarounds checkbox.</li><li>– JSON: select this checkbox to have HTML context verified.</li></ul>
---------------	---

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

[File](#) | [Settings](#) | [Languages and Frameworks](#) | [JavaScript](#) | [Code Quality Tools](#) | [JSHint for Windows and Linux](#)

[IntelliJ IDEA](#) | [Preferences](#) | [Languages and Frameworks](#) | [JavaScript](#) | [Code Quality Tools](#) | [JSHint for macOS](#)

Ctrl+Alt+S 

Use this page to enable the built-in or downloaded JavaScript [JSHint](#) code verifier and configure its behaviour.

#### ItemDescription

**Enable** Select this checkbox to have JSHint applied to verify the code in the current project. After that the other controls in the page are enabled.

**Use config files** Select this checkbox to have the code verified according to the settings from a configuration file. A configuration file is a JSON file with the extension `.jshintrc` that specifies which JSHint options should be enabled or disabled. IntelliJ IDEA will look for a `.jshintrc` file in the working directory. If the search fails, IntelliJ IDEA will search in the parent folder, then again in the parent folder. The process is repeated until IntelliJ IDEA finds a `.jshintrc` or reaches the project root. To have IntelliJ IDEA still run verification when no `.jshintrc` is found in the project, specify the default configuration file to use.  
When this checkbox is selected, the Options area is hidden and the default verification settings are unavailable.

**Version** Use this drop-down list to choose the version of the tool to apply.  
IntelliJ IDEA comes bundled with version 2.9.4, which is used by default. To download another version, choose it from the list.

**Options** In this area, configure JSHint behaviour by enabling or disabling [JSHint options](#). To enable or disable an option, select or clear the corresponding checkbox respectively. The controls in the area fall into two groups:

- Enforcing options: select the checkboxes in this group to enable very strict behaviour of the verification tool and thus allow only safe JavaScript.
- Relaxing options: select/clear the checkboxes in this area to suppress warnings when certain types of discrepancies are detected.
- Environments: select/clear these checkboxes to specify for which environments you want global properties predefined.

The area is available only when the Use config files checkbox is cleared.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | Closure Linter for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | Closure Linter for macOS

Ctrl+Alt+S 

Use this page to enable the JavaScript [Closure Linter](#) code verifier and to configure its behaviour.

#### ItemDescription

Enable	Select this checkbox to have Closure Linter applied to verify the code in the current project. After that the other controls in the page are enabled.
Closure Linter executable file	In this text box specify the path to the Closure Linter executable file: <ul style="list-style-type: none"><li>- <code>&lt;Python_home&gt;\Scripts\jslint.exe</code> for Windows</li><li>- <code>/usr/local/bin/gjslint</code> for Linux and macOS</li></ul>
Configuration file	In this text box, specify the location of the previously created configuration text file to apply.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | JSCS for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | JSCS for macOS

Ctrl+Alt+S 

Use this page to enable the JavaScript [JSCS](#) code verifier and to configure its behaviour.

#### ItemDescription

**Enable** Select this checkbox to have JSCS applied to verify the code in the current project. After that the other controls in the page are enabled.

**Node Interpreter** In this field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click  and configure a new one as described in [Configuring Node.js Interpreters](#).

If you have [appointed one of the installations as default](#), the field displays the path to its executable file.

**JSCS Package** In this field, specify the location of the `jscs` package installed in the current project, see [Installing JSCS](#).

**Configuration File** In this area, appoint the configuration to use.

By default, IntelliJ IDEA first looks for a `jscsConfig` property in the `package.json` file of the current project. If no such property is found, IntelliJ IDEA looks for a `.jscsrc` or a `.jscs.json` configuration file. IntelliJ IDEA starts the search from the folder where the file to be checked is stored, then searches in the parent folder, and so on until reaches the project root. Accordingly, you have to define the configuration to apply either as a `jscsConfig` property in the `package.json` file or in a `.jscsrc` or a `.jscs.json` configuration file, or in a custom JSON configuration file.

You can also apply a predefined set of rules, either independently or in combination with a configuration file. In the latter case, the rules from the configuration file override the predefined rules.

- To have IntelliJ IDEA look for a `jscsConfig` property in the `package.json` file or for a `.jscsrc` or a `.jscs.json` file, choose the Search for config(s) option.
- To use a custom file, choose the Configuration File option and specify the location fo the file in the Path field. Choose the path from the drop-down list, or type it manually, or click the  button and select the relevant file from the dialog box that opens.
- To have a predefined set or rules applied, choose the desired set from the Code Style Preset drop-down list.

**Code Style Preset** From this drop-down list, choose the set of predefined rules associated with the code style you use.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Code Quality Tools | ESLint for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Code Quality Tools | ESLint for macOS

Ctrl+Alt+S 

Use this page to enable the JavaScript [ESLint](#) code verifier and to configure its behaviour. If you are using [JavaScript Standard Style](#) in your application, you can set it as default here.

#### To set the JavaScript Standard Style as default

Open the [Code Style. JavaScript](#) page (in the Settings/Preferences dialog ([Ctrl+Alt+S](#))), choose Editor | Code Style | JavaScript), click Set from, and then choose Predefined Style | JavaScript Standard Style. The style will replace your current scheme.

#### ItemDescription

Enable	Select this checkbox to have ESLint/Standard applied to verify the code in the current project. After that the other controls in the page are enabled.
Node Interpreter	In this field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click  and configure a new one as described in <a href="#">Configuring Node.js Interpreters</a> .  If you have <a href="#">appointed one of the installations as default</a> , the field displays the path to its executable file.
ESLint Package	In this field, specify the location of the <code>eslint</code> or <code>standard</code> package.
Configuration file	In this area, appoint the configuration to use. <ul style="list-style-type: none"><li>– If you choose Automatic search, IntelliJ IDEA looks for a <code>.eslintrc</code> file or tries to detect a configuration defined under <code>eslintConfig</code> in a <code>package.json</code>. IntelliJ IDEA first looks for a <code>.eslintrc</code> or <code>package.json</code> in the folder with the file to be linted, then in its parent folder, and so on up to the project root. If the search fails, ESLint uses its default embedded configuration file.</li><li>– Choose Configuration File to use a custom file and specify the file location in the Path field.</li></ul>
Additional Rules	In this field, specify the location of the files with additional code verification rules. These rules will be applied after the rules from <code>.eslintrc</code> or the above specified custom configuration file and accordingly will override them.
Directory Extra ESLint Options	In this field, specify additional command line options to run ESLint with using spaces as separators. See <a href="#">ESLint Command Line Interface Options</a> for details.

for macOS

Ctrl+Alt+S

On this page, configure processing of **EJS inclusions**, **Handlebars expressions**, and **Mustache templates** in IntelliJ IDEA.

This page only appears in the Settings/Preferences dialog, when the corresponding plugin is downloaded and enabled.

#### ItemDescription

**Handlebars/Mustache** In this area, configure processing of **Handlebars expressions** and **Mustache templates** in IntelliJ IDEA. The settings specified on this page apply to dedicated **Handlebars** and **Mustache** files that have the extension `.hbs` or `.mustache` respectively.

- Automatically insert closing tag:
  - When this checkbox is selected, IntelliJ IDEA automatically inserts the second closing curly brace ( `}` ) of a **Handlebars expression** as soon as you type the first closing one.
 

IntelliJ IDEA also recognizes **triple stashes** ( `{{{` ) that prevent escaping values inside expressions. In this case, IntelliJ IDEA automatically inserts two closing curly braces as soon as you type the first closing one.
  - When this check box is cleared, you have to type the closing curly braces and triple stashes manually.
- Enable formatting:
  - Select this checkbox to have **Handlebars expressions** and **Mustache templates** automatically reformatted during code generation, refactoring, or reformatting ( `Ctrl+Alt+L` ).
  - Clear the checkbox to have the original formatting of **Handlebars expressions** and **Mustache templates** preserved.
- Open HTML files as Handlebars/Mustache:
  - When this checkbox is selected, files with the `.html` extension are treated as **Handlebars/Mustache** files so IntelliJ IDEA recognizes and processes **Handlebars expressions** and **Mustache templates**. The extensions of files remain unchanged but file names are supplied with the  icons.
  - When this checkbox is cleared only files with the `.hbs` extension are treated as **Handlebars/Mustache** files and **Handlebars expressions** and **Mustache templates** within them are recognized and processed.
- Language for comments: From this drop-down list, select the language to inherit the style for comments from. When you enter a line or block comment by pressing `Ctrl+Slash` or `Ctrl+Shift+Slash`, IntelliJ IDEA inserts the comment delimiters that are used in the chosen language, for example, `{{!--}}` for **Handlebars**, `/**/` for JavaScript, `<!-->` for HTML, etc.

For more details about **Handlebars expressions** and **Mustache templates** see <http://handlebarsjs.com/>.

The area is only available when the **Handlebars/Mustache** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

**EJS** In this area, specify delimiters for inclusions of **EJS** in your code. Based on these delimiters, IntelliJ IDEA will recognize and process such inclusions correctly. A pair of delimiters is also referred to as **execute tag**.

- EJS open delimiter: In this text box, type the character string that will indicate the beginning of an EJS inclusion. The default delimiter is `<%`.
- EJS close delimiter: In this text box, type the character string that will indicate the end of an EJS inclusion. The default delimiter is `%>`.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Bower for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Bower for macOS

Ctrl+Alt+S 

On this page, specify the location of the **Bower package manager** executable and configuration files and install, uninstall, or upgrade external tools through it.

#### ItemDescription

Node interpreter	Specify here the location of the Node.js executable. Type the path manually, or choose it from the drop-down list if it was previously used, or click the Browse button  and choose the location in the dialog box that opens. See <a href="#">Node.js</a> for details.
Bower executable	In this field, specify the location of the Bower executable file ( <code>bower.cmd</code> or other depending on the operating system used). Type the path manually, or choose it from the drop-down list if it was previously used, or click the Browse button  and choose the location in the dialog box that opens.
bower.json	In this text box, specify the location of the <code>bower.json</code> file. Type the path manually, or click the Browse button  and choose the location in the dialog box that opens.
Dependencies	<p>The area shows a list of all the -dependent packages that are currently installed on your computer.</p> <ul style="list-style-type: none"><li>- Package: this read-only field shows the name of a package, exactly as it should be referenced if you were installing it in the command line mode.</li><li>- Version: this read-only field shows the version of the package installed on your computer.</li><li>- Latest: this read-only field shows the latest released version of the package. If a package is not up-to-date, it is marked with a blue arrow .</li><li>- Click  to have a new package installed. In the Available Packages dialog box that opens, select the relevant package. Click Install Package when ready.</li><li>- Click  to have the selected package removed.</li><li>- Click  to have the current version of the selected package replaced with the latest released version. The button is enabled only when the selected project is not up-to-date.</li></ul>

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Yeoman and Node.js plugins are installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Yeoman for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Yeoman for macOS

Ctrl+Alt+S

The page is available only when the **Yeoman** and the **NodeJS** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

On this page, specify the location of the **Node.js** executable file and the [Yeoman project generator](#) package installed through **Node Package Manager** .

#### ItemDescription

**Node interpreter** Specify here the location of the Node.js executable. Type the path manually, or choose it from the drop-down list if it was previously used, or click the Browse button  and choose the location in the dialog box that opens. See [Node.js](#) for details.

**Yeoman yo package** In this field, specify the location of the global `yo` package, see [NPM](#) , section Installing an External Tool Globally .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support and Meteor plugins are installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | Meteor for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Meteor for macOS

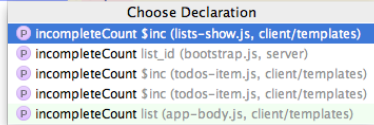

The page is available when the **Meteor** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

**Tip** Changes to the server-side code are uploaded through the IntelliJ IDEA [Live Edit](#) functionality, see [Previewing the changes to the server-side code](#).

#### ItemDescription

Meteor executable	In this field, specify the location of the <b>Meteor</b> executable file (see <a href="#">installing Meteor</a> ).
Automatically exclude ".meteor/local" directory on open project	<ul style="list-style-type: none"><li>When the checkbox is selected, the <code>.meteor/local</code> folder, which is intended for storing the built application, is automatically marked as excluded and is not involved in indexing.</li><li>Clear the checkbox to show the <code>.meteor/local</code> folder and its contents in the Project tool window.</li></ul> <p>By default, <b>excluded</b> files are shown in the project tree. To hide the <code>.meteor/local</code> folder, click the  button on the toolbar of the Project tool window and remove a tick next to the Show Excluded Files option.</p>
Enable Meteor 'Hot code push'	<ul style="list-style-type: none"><li>When the checkbox is selected, IntelliJ IDEA uses the native <a href="#">Meteor hot code pushes functionality</a> to apply the changes you make to the client-side code during a debugging session.</li><li>When the checkbox is cleared, apply the changes to the client-side code by clicking  on the toolbar of the &lt;Configuration name&gt; JavaScript  tab. See <a href="#">Preview the changes to the client-side code</a> for details.</li></ul>
Automatically import Meteor packages as external library	<ul style="list-style-type: none"><li>When the checkbox is selected, IntelliJ IDEA automatically imports the external packages from the <code>meteor/packages</code> file. As a result, IntelliJ IDEA provides full range coding assistance: resolves references to <b>Meteor</b> built-in functions, for example, <code>check(true)</code>, and to functions from third-party packages, provides proper syntax and error highlighting, supports debugging with source maps, etc.</li><li>When this checkbox is cleared, IntelliJ IDEA does not automatically import the external packages from the <code>meteor/packages</code> file. As a result no coding assistance is provided. To improve the situation, open the <code>meteor/packages</code> file in the editor and click the Import packages as library link or run the <code>meteor --update</code> command.</li></ul>
Weak search for Spacebars templates	<ul style="list-style-type: none"><li>Select this checkbox to enable IntelliJ IDEA to search inside Spacebars templates. When this checkbox is selected and you invoke the Go to Declaration action on a helper, IntelliJ IDEA displays a list of all occurrences of this helper in templates. Choose the relevant one from the list.</li></ul>

```
    {{#each lists}}
    <a href="{{pathFor 'listsShow'}}" class="list-todo {{activeListClass}}" title="{{name}}">
      {{#if userId}}
      <span class="icon-lock"></span>
      {{/if}}
      {{#if incompleteCount}}
      <span class="count-list">{{incompleteCount}}</span>
      {{/if}}
      {{name}}
    </a>
    {{/each}}
</div>
</section>
```

- When you invoke Got to Declaration with this checkbox cleared, IntelliJ IDEA does not perform any search and displays a tooltip with the following message: Cannot find declaration to go to.

```
    {{#each lists}}
    <a href="{{pathFor 'listsShow'}}" class="list-todo {{activeListClass}}" title="{{name}}">
      {{#if userId}}
      <span class="icon-lock"></span>
      {{/if}}
      {{#if incompleteCount}}
      <span class="count-list">{{incompleteCount}}</span>
      {{/if}}
      {{name}}
    </a>
    {{/each}}
```

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when JavaScript Support and PhoneGap/Cordova plugins are installed and enabled!

File | Settings | Languages and Frameworks | JavaScript | PhoneGap/Cordova for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | PhoneGap/Cordova for macOS

Ctrl+Alt+S 

The page is available when the **PhoneGap/Cordova** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

#### ItemDescription

PhoneGap/Cordova Executable Path	In this field, specify the location of the executable file <code>phonegap.cmd</code> , <code>cordova.cmd</code> , or <code>ionic.cmd</code> (see <a href="#">Installing PhoneGap/Cordova/Ionic</a> ).
----------------------------------	---

PhoneGap/Cordova Version	This read-only field shows the installed <b>PhoneGap/Cordova/Ionic</b> version that IntelliJ IDEA detects automatically.
--------------------------	--

PhoneGap/Cordova Working Directory	In this field, specify the folder under which the <b>PhoneGap/Cordova/Ionic</b> application files to run are stored.
------------------------------------	--

Automatically exclude 'platforms' directory on open project	Select this checkbox to have the platforms directory marked as excluded automatically when you open the project. As a result, IntelliJ IDEA ignores it during indexing, parsing, and code completion.
---	---

Plugins	<p>In this area, configure a list of plugins to use in your development by installing required packages. The list shows all the <b>PhoneGap/Cordova/Ionic</b> plugins that are currently installed on your computer, both at the <b>global</b> and at the <b>project</b> level.</p> <ul style="list-style-type: none"><li>- To install a plugin, click the Install button <b>+</b> . In the Available Packages dialog box that opens, select the required package.</li><li>To have the plugin installed <b>globally</b> so it is accessible from all your IntelliJ IDEA projects, select the Options checkbox and type <code>--global</code> in the text box. Click Install Package .</li><li>- To remove a plugin, select it in the list and click the Uninstall button <b>-</b> .</li><li>- To upgrade a plugin to the latest available version, select the plugin in the list and click the Upgrade button <b>↑</b> .</li></ul>
---------	--

See [Apache Cordova Plugins](#) and [PhoneGap Plugins](#) for information about plugins and their use.

**Note** For this page to be available, the Playframework Support plugin must be enabled. See [Enabling and Disabling Plugins](#) .

Use this page for specifying the [Play framework](#) settings such as the Play framework installation directory and the working directory for the `play` command-line utility (the Play console).

**ItemDescription**

Download	Click this link to open the <a href="#">Play framework downloads page</a> which lets you select and download the necessary version of the Play framework. (See <a href="#">which versions are supported</a> by IntelliJ IDEA.)
Home	Specify the Play framework installation directory. Type the path in the field, or click <input type="text" value="..."/> ( <input type="text" value="Shift+Enter"/> ) and select the directory in the <a href="#">dialog that opens</a> .
Working directory	Specify the directory from which commands of the <code>play</code> command-line utility are to be run. Usually, this is a root directory of your Play application. Type the path in the field, or click <input type="text" value="..."/> ( <input type="text" value="Shift+Enter"/> ) and select the directory in the <a href="#">dialog that opens</a> .
Show on console run	Select this checkbox to be able to see and modify the Play framework settings discussed above each time you access the <code>play</code> command-line utility in IntelliJ IDEA.

Ctrl+Alt+S

**Note** This page is only available when Python plugin is installed and enabled!

## Template languages pane

### ItemDescription

**Template language** Select the desired template language for your project from the drop-down list. For example, you can mark your project as using Django templates even if it is not a Django project.

The available template languages are:

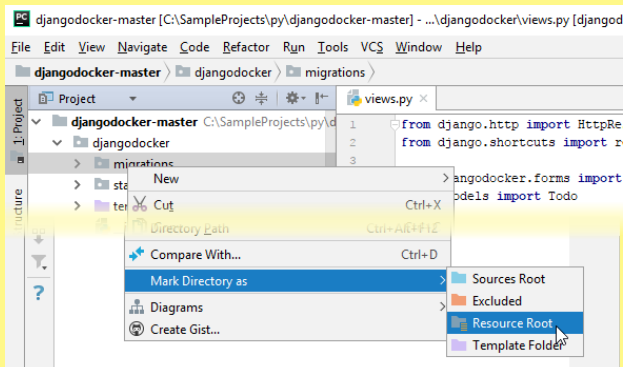

- None : is this option is selected, the project doesn't use any template language.
- [Django](#)
- [Mako](#)
- [Jinja2](#)
- [Chameleon](#)
- [Web2Py](#)

**Template file types** In this section, specify the types of files, where templates will be recognized.

Press **+** to show the list of available file types, and choose the desired one.

Press **-** to delete the selected file type. Note that the default file types (HTML, XHTML, and XML) may not be deleted.

**Tip** Django support skips directories not marked as Django templates, if they are **marked** as Resources:

Ctrl+Alt+S 

The settings on this page define how your XML, HTML and XHTML files are validated.

– [External Schemas and DTDs](#)

– [Ignored Schemas and DTDs](#)

## External Schemas and DTDs

Local XML schema (XSD) and DTD files that are used to validate your XML files are listed in this section.

Each entry is a mapping of a URI that may be referenced in your XML file onto an appropriate local schema or DTD file. Use

,  and  to create, remove and edit the mappings. See also, [Referencing XML Schemas and DTDs](#) .

### ItemKeyboardDescription

#### Shortcut

URI	A URL of an XML schema (XSD) or DTD file (e.g. <code>http://www.example.org/xsds/example.xsd</code> ) or a namespace URI (e.g. <code>http://www.example.org</code> , <code>urn:jboss:domain:1.0</code> ). Readonly. If an XML file references the specified URI, it's validated according to a local file whose path is shown in the Location columns.
Location	Path to corresponding local XSD or DTD file (readonly).
Project	If a checkbox is not selected, a mapping is available in all of your projects. Select the mappings that you want to be available only in the current project.  The selected mappings are stored in <code>.idea/misc.xml</code> or the project <code>.ipr</code> file. These files are normally shared between development team members through version control.

  Use this icon or shortcut to open the [Map External Resource Dialog](#) to define a new mapping between a URI and a local file.

  Use this icon or shortcut to remove the selected mappings from the list.

  Use this icon or shortcut to edit the selected mapping in the [Map External Resource Dialog](#) .

## Ignored Schemas and DTDs

URIs for ignored schemas and DTDs are listed in this section. (If an XML file references a URI listed in this section, IntelliJ IDEA ignores that URI and doesn't mark it as an error in the editor.) Use ,  and  to add, remove and edit the URIs. See also, [Referencing XML Schemas and DTDs](#) .

ItemKeyboard Shortcut	Description
 	Use this icon or shortcut to add a new URI to the list.
 	Use this icon or shortcut to edit the selected URI.
 	Use this icon or shortcut to remove the selected URIs from the list. The corresponding URIs become available for mapping to local XSD or DTD files.

Ctrl+Alt+S 

On this page:

- [Default HTML Language Level](#)
- [Default XML Schema Version](#)

## Default HTML Language Level

Normally, an HTML or an XHTML file has the `<!DOCTYPE>` declaration which states the **language level** of the used in the source code from the file. This language level is used as a standard against which the contents of the file are validated. If an HTML or an XHTML file does not have a `<!DOCTYPE>` declaration, the contents of the file will be validated against the default standard (schema). In the Default HTML Language Level area, choose the default schema to validate HTML and XHTML files without a `<!DOCTYPE>` declaration. The available options are:

- HTML 4 or HTML 5 : Choose one of these options to have files treated as HTML 4 or HTML 5 and validated against one of these standards.
- Other doctype : Choose this option to have HTML files by default validated against a custom DTD or schema and specify the URL of the DTD or schema to be used.

Note that code completion is available in this field: press `Ctrl+Space` to see the list of suggested URLs.

## Default XML Schema Version

In this area, choose the [XSD \(XML Schema Definition\) Schema](#) to validate XML files. The available options are:

- XML Schema 1.1 See [W3C XML Schema Definition Language \(XSD\) 1.1 Part 1: Structures](#) and [W3C XML Schema Definition Language \(XSD\) 1.1 Part 2: Datatypes](#) for details.
- XML Schema 1.0 See [XML Schema Part 1: Structures Second Edition](#) and [XML Schema Part 2: Datatypes Second Edition](#) for details.

Ctrl+Alt+S 

---

Use this dialog to configure your .properties file. This file contains lists of catalog.xml files. The catalog.xml files contain the information on how to resolve various PUBLIC and SYSTEM identifiers during XML processing.

#### ItemDescription

---

Catalog property file

Use this field to specify the location of the .propeties file.

Type the path in the field, or click  and select the required file in the [dialog that opens](#) .

For more detailed description of the properties in the catalog property file, see the example of [Annotated CatalogManager properties file](#) .

Ctrl+Alt+S 

On this page, create a list of your custom [JSON schemas](#) in addition to the system schemas provided by IntelliJ IDEA and configure the scope for each schema, that is, specify the `.json` files to be validated against it. The page consists of two panes: the List of Schemas pane and the Schema Details pane.

On this page:

- [List of Schemas Pane](#)
- [Schema Details Pane](#)
- [Handling Conflicts Among Scopes of Schemas](#)

## List of Schemas Pane

The central pane of the page shows a list of custom JSON schemas against which `.json` files in the current project will be validated. Based on a schema, IntelliJ IDEA checks the structure of `.json` configuration files, reports errors (for example, informs you about missing mandatory properties), provides code completion and documentation look-up.

The pane shows only **custom** schemas that you have previously downloaded or created yourself, in either case, a custom schema must meet the [JSON schema standards](#) and must be located under the project root.

**System** schemas that IntelliJ IDEA provides for all supported frameworks and technologies are not shown in the list.

- To add a schema to the list, click  on the toolbar of the pane and select the relevant schema file under the project root in the dialog box that opens.
- To remove a schema from the list, select it and click  on the toolbar of the pane.
- To configure the scope of a schema, select the schema and specify the files to be validated against it in the right-hand pane of the page.

## Schema Details Pane

The pane shows the details of the schema selected in the List of Schemas pane: the name of the selected schema, the `.json` file that implements it, and a list of files and folders that are validated against the schema.

The list contains the names of specific files, the names of entire directories, and filename patterns. You do not need to specify full paths to files and folders, IntelliJ IDEA searches for files and folders with the specified names and the search is restricted to the the current project.

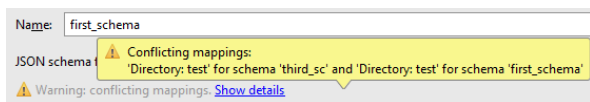

Based on the list, IntelliJ IDEA internally creates a list of files to be validated. Each file is included in the list only once: if a file with the specified name is stored in a directory from the list or its name matches a pattern, the file is still validated only once.

- To add new files or folders to the list, click  on the toolbar of the pane and specify the file, folder, or a file pattern in the [Add JSON Schema Mapping Dialog](#) that opens.
- To remove an item from the list, select it and click  on the toolbar of the pane.

## Handling Conflicts Among Scopes of Schemas

A conflict arises when a file, or a folder, or a pattern belongs to the scopes of two or more schemas. IntelliJ IDEA analyzes scopes in two modes:

- **Static Analysis** detects conflicts in scopes of custom schemas. If a conflict is detected, IntelliJ IDEA displays a warning in the Schema Details pane. To view the overlapping scopes, click the Show details link. IntelliJ IDEA shows a pop-up message where the conflicting scopes and schemas are listed:

- **Dynamic Analysis** detects conflicts in scopes of both system and custom schemas. This type of analysis is started when you open a file that belongs to a certain scope. If a conflict is detected, IntelliJ IDEA displays a warning at the top of the editor tab:

There are several JSON Schemas mapped to this file: first\_schema; third\_sc [Edit JSON Schema Mappings](#)

Click the link to open the [JSON Schema](#) page and edit the scope of the conflicting **custom** schema. Note that you cannot edit the scope of **system** schemas.

---

The dialog box opens when you select a `.json` schema in the list on the [JSON Schema](#) page and click **+** in the right-hand pane. In this dialog, specify the `.json` files to be validated against the selected schema.

---

**ItemDescription**

Files Under	Choose this option to add files stored in a specific folder name to validation. Type the name of the folder manually or click <b>...</b> and choose the folder in the dialog box that opens.
Filename pattern	Choose this option to have all files with the names that match a pattern validated.
File	Choose this option to add files with a specific name to validation. Type the filename manually or click <b>...</b> and choose the file in the dialog box that opens.

Ctrl+Alt+S

Use this page to select the ColdFusion language version and to specify mappings for deploying your application to the [ColdFusion](#) server.

#### ItemDescription

Language Version	Select the ColdFusion language version.
Info	<p>Use this area to specify a ColdFusion debugger server information.</p> <p>Before you specify ColdFusion debugger server port in IntelliJ IDEA, you need to manually set a debugger server port and manually start a debugger server in <a href="#">ColdFusion Administrator</a> .</p> <ul style="list-style-type: none"><li>- User Name - specify a user name that you use to access <a href="#">ColdFusion Administrator</a> .</li><li>- Debugger Server Port - specify a debugger server port that you have set with JVM argument <code>DDEBUGGER_SERVER_PORT=port</code> on the Java and JVM page of the <a href="#">ColdFusion Administrator</a> .</li></ul>
Server Mappings	<p>In this area, set the correspondence between local folders and logical paths on the server.</p> <ul style="list-style-type: none"><li>- Directory Path - specify the folder on your local computer, where the source code and resources to be deployed are stored. Type the path manually or click  and choose the folder in the dialog box, that opens.</li><li>- Logical Path - specify the target folder to deploy the application to. The path should be specified relative to the server root URL defined in the corresponding <a href="#">run configuration</a> .</li><li>-  (  ) - use this icon or shortcut to create a new mapping.</li><li>-  (  ) - use this icon or shortcut to remove the selected item from the list.</li></ul>

Specify where the [JavaFX Scene Builder](#) executable file is located. If you do so, you'll be able to open your FXML files in the Scene Builder right from within IntelliJ IDEA.

---

**ItemDescription**

Path to	Specify the path to the JavaFX Scene Builder executable file.
SceneBuilder	Type the path in the field, or click  ( <b>Shift+Enter</b> ) and select the Scene Builder executable file in the <a href="#">dialog that opens</a> .

**Warning!** The following is only valid when Markdown Support Plugin is installed and enabled!

File | Settings | Languages and Frameworks | Markdown for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | Markdown for macOS

Ctrl+Alt+S

#### ItemDescription

Default layout	From the drop-down list, select how the editor will be shown by default: both editor and preview panes, editor only, or preview only pane.
Auto-scroll preview	Select this checkbox to automatically scroll from the cursor position in the source code to the respective position in the preview.  If this checkbox is selected, the  button becomes pressed in the toolbar.
Render with JavaFX WebView	Select this checkbox to use JavaFX for preview.
Grayscale	Select this checkbox to use grayscale for rendering. This checkbox is only available when Render with JavaFX WebView checkbox is selected.
Custom CSS	
Load from URI	Specify here the path to the desired <code>css</code> file. Click  to find the file in question in the file system.
Add CSS rules	Type a particular CSS to be used for rendering the preview. For example, you can specify here the background color and font weight.

Ctrl+Alt+S 

This page appears in the Settings dialog box, when the **Node.js** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

Node interpreter	<p>In this field, choose the interpreter from the drop-down list or from the dialog that opens when you click .</p> <p>The term <b>local Node.js interpreter</b> denotes a Node.js installation on your computer. The term <b>remote Node.js interpreter</b> denotes a Node.js installation on a remote host or in a virtual environment set up in a Vagrant instance. Here you can choose or configure only a local interpreter. Remote interpreters are configured in the <a href="#">Configure Node.js Remote Interpreter Dialog</a> dialog which can be accessed only from the <a href="#">Run/Debug Configuration: Node.js</a> dialog. See <a href="#">Configuring remote Node.js interpreters</a> for details.</p>
Version	<p>This read-only field shows the current version of the runtime environment.</p>
Coding Assistance	<p>In this area, click Enable to configure the <b>Node.js Core</b> module sources as a <a href="#">JavaScript library</a> and associate it with your project. As a result, IntelliJ IDEA provides code completion, reference resolution, validation, and debugging capabilities for <code>fs</code>, <code>path</code>, <code>http</code>, and other core modules that are compiled into the Node.js binary. When the configuration is completed, IntelliJ IDEA displays information about the currently configured version, the notification Node.js Core Library is enabled, and adds the Disable and the Usage scope buttons.</p> <p>Optionally</p> <p>Configure the scope in which the Node.js Core sources are treated as libraries:</p> <ol style="list-style-type: none"> <li>1. Click Usage scope. The <a href="#">Usage Scope</a> dialog opens.</li> <li>2. Click the relevant directories, and for each of them select the newly configured Node.js Core library from the list.</li> </ol>
Packages	<p>A number of tools are started through <b>Node.js</b>, for example, the <a href="#">CoffeeScript</a>, <a href="#">TypeScript</a>, and <a href="#">Less</a> compilers, <a href="#">YUI</a>, <a href="#">UglifyJS</a>, and <a href="#">Closure</a> compressors, <a href="#">Karma</a> test runner, <a href="#">Grunt</a> task runner, etc. The <b>Node Package Manager (npm)</b> is the easiest way to install these tools, the more so that you have to install <b>Node.js</b> anyway. The <b>Packages</b> area shows a list of all the <b>NPM</b>-dependent packages that are currently installed on your computer.</p> <ul style="list-style-type: none"> <li>– <b>Package</b>: this read-only field shows the name of a package, exactly as it should be referenced if you were installing it in the command line mode.</li> <li>– <b>Version</b>: this read-only field shows the version of the package installed on your computer.</li> <li>– <b>Latest</b>: this read-only field shows the latest released version of the package. If a package is not up-to-date, it is marked with a blue arrow .</li> <li>– Click  to have a new package installed. In the Available Packages dialog box that opens, select the relevant package. To have the package installed globally, select the Options checkbox and type <code>-g</code> in the Options text box. <b>Global</b> installation makes the package available at the IntelliJ IDEA level so it can be used in any IntelliJ IDEA project. Click <b>Install Package</b> when ready.</li> <li>– Click  to have the selected package removed.</li> <li>– Click  to have the current version of the selected package replaced with the latest released version. The button is enabled only when the selected project is not up-to-date.</li> </ul>

---

Use this page to manage project specific and application wide settings of OSGi-based applications.

## Prerequisites

This page appears in the Settings/Preferences dialog, when the Osmorc plugin is enabled.

The plugin is bundled with IntelliJ IDEA and is activated by default. If it is disabled, you can manually [enable the plugin](#).

---

### ItemDescription

OSGi framework	From this drop-down list, select the desired framework. The list contains all the framework instances defined for the currently running IntelliJ IDEA at the IDE level. If the framework instance you need is missing, switch to the <a href="#">Framework Instances</a> page of the IDE-level OSGi settings, and define the required instance there.
Default manifest	Select the path to the default <code>MANIFEST.MF</code> file. This option makes sense for the OSGi facets, where the bundle creation is performed using the existing manifest and facet configuration (the option Use existing manifest and bundle using facet configuration is turned on). If any other type of creating bundles is selected, this field is ignored.
Output path	Type here the path to the directory, where all compiled bundles will be stored, or click the browse button and locate the desired directory in the file system. This path is only used, if Jar output path of the <a href="#">OSGi facet</a> is set to Place in project-wide OSGi output path . Otherwise, this option is ignored, and the bundles are generated to the module output, or facet-specific path.
Apply to all facets	Click this button to apply the specified output path to all OSGi facets in the current project. This button changes Jar output path for all facets; even though the option Place in module's output path has been selected in a facet, it will be changed to Place in project-wide OSGi output path .
Import Bnd/Bndtools projects automatically	Select this checkbox to import Bnd/Bndtools projects automatically if IntelliJ IDEA detects any changes in <code>bnd</code> files. Note that you can manually reimport Bnd/Bndtools project or module by selecting Reimport Projects or Reimport Workspace from the context menu in the Project tool window.

## Prerequisites

This page appears in the Settings/Preferences dialog, when the Osmorc plugin is enabled.

The plugin is bundled with IntelliJ IDEA and is activated by default. If it is disabled, you can manually [enable the plugin](#).

Use this page to add and remove IDE-level framework instance definitions for the currently running IntelliJ IDEA. The set of available framework definitions determine the contents of the OSGi framework drop-down list in the [Project Settings](#) tab.

### ItemDescription

Framework Instances	The field shows a list of all the framework instances that are defined for the currently running IntelliJ IDEA.
Type	This read-only field shows the type of the currently selected definition.
Home directory	This read-only field shows the location of the currently selected framework instance.
Name	This read-only field shows the name of the currently selected definition.
Version	This read-only field shows the version of framework the selected definition is based on.
 or 	Click this button to open the Add OSGi Framework drop-down list and select the type of a new framework instance that you want to configure.  The specified <a href="#">OSGi Framework Instance</a> dialog opens.
 or 	Click this button to open the FrameWork Instance dialog box and edit the definition of the selected framework there. The icon is active if there is at least one framework defined in the Framework Instances field.
 or 	Click this button to remove the selected definition from the list.
	Click these buttons to move up or to move down the selected framework instance.

IntelliJ IDEA lets you use this dialog to configure OSGi framework instance. The OSGi Framework Instance dialog appears when you try to add a new OSGi framework instance from the Add OSGi Framework drop-down list, on the [OSGi Framework Instances](#) page.

#### ItemDescription

---

Home Directory	Use this field to specify the location of your new OSGi framework.
Name	Use this field to specify the name of the framework. By default, this field contains a type of your OSGi framework that you are trying to add.
Version	Use this field to specify the version of the framework. As long as the home directory is specified this field is filled in automatically.

Use this page to define rules that determine the libraries to be included in bundles and have manifest file entries generated based on these rules.

### ItemDescription

**Rules** In this area, configure a list of regular expressions that define the libraries to be included in a bundle.

**Tip** The rules are processed from top to bottom. If a library matches several regular expressions, the one that comes last is applied. Therefore it is recommended that you have the list sorted as follows: the more strict a rule the closer it is to the bottom. For example, it is recommended to put the pattern `*.*` at the top of the list and an exact match in the bottom.

#### ItemCommandDescription

	Add	Click this button to have a new entry added to the list.
	Remove	Click this button to remove the selected entry from the list.
	Copy	Click this button to create a copy of the selected rule.
	Move Up and Move Down	Use these buttons to change the order of rules in the list.

**Library name pattern** In this text box, specify the regular expression that constitutes the entry selected in the Rules list box.

**Note** When a new rule is added to the list, the text box by default shows `*.*`.

**Manifest entries** This read-only field displays the manifest file entries generated on the basis of specified rules. The entries are sorted in accordance with the order of rules in the Rules list box.

**Tip** The Add New line quick fix is available.

**Never bundle** If this checkbox is selected, the libraries that match the currently selected rule are never bundled.

**Process no further rules** Select this checkbox to suppress processing rules that come in the Rules list box after the selected rule.

Use this page to configure an external compile server for your Scala project.

**ItemDescription**

---

**Use external compile server for Scala**      Select this checkbox to activate options for Scala compile server.

---

**JVM SDK**      Use this drop-down list to select an SDK for the Scala compile server.

---

**JVM maximum heap size, MB**      Use this field to specify the maximum heap size available to the process that launches the compiler. The default 1024 Mb is suitable for most of the purposes.

---

**JVM parameters**      Use this field to type the string to be passed to the VM when IntelliJ IDEA launches the compiler. If you need more room to type, click  to open the Java VM command line parameters dialog where the text entry area is larger.

This page lets you specify the SQL dialects (DBMS-specific versions of SQL) used in various scopes.

**Note** For this page to be available, the Database Tools and SQL plugin must be enabled. See [Enabling and Disabling Plugins](#) .

- [Dialect settings](#)
- [Dialect options](#)
- [Example](#)

## Dialect settings

### ItemDescription

Global SQL Dialect	The SQL dialect for all the <code>.sql</code> and <code>.ddl</code> files on your computer; may be redefined in narrower scopes - at the project level, and/or for individual files and directories.
Project SQL Dialect	The SQL dialect for all the <code>.sql</code> and <code>.ddl</code> files in your current project. If <None> is specified, the global SQL dialect is inherited.
Path / SQL Dialect	The SQL dialects for individual files and directories - if different from the global or project dialect. If nothing is specified in this section, all the <code>.sql</code> and <code>.ddl</code> in your project inherit the project dialect, and all the files that are outside the project - the global dialect.

To specify a dialect for a file or directory, click  and select the file or directory in the dialog that opens. Then click  or the SQL Dialect cell, and select the dialect.

The dialects specified explicitly are shown in black. The inherited dialects (unless you close the dialog) are shown in gray italic.

## Dialect options

When specifying a dialect, in addition to particular dialects, you can select:

- <None> or <Clear> . As a result, a dialect from a higher level is inherited.
- <Generic SQL>. This means that no particular dialect is specified. As a result, basic SQL92-based coding assistance is provided including completion and highlighting for SQL keywords, and table and column names. Syntax error highlighting is not available. So the file contents are always shown as syntactically correct. Also, automatic code reformatting isn't possible.

## Example

Say, most of the SQL script files on your computer are for PostgreSQL. In the current project, you are developing the scripts for Oracle but in one of the directories in your project there are the scripts for MySQL. In such a situation, you'd specify:

- Global SQL dialect: PostgreSQL
- Project SQL dialect: Oracle
- `<PathToMySQLScriptsFolder>` : MySQL

This page lets you specify the data sources, databases and schemas that should be used to resolve unqualified ("short") names of database object in your SQL files.

**Note** For this page to be available, the Database Tools and SQL plugin must be enabled. See [Enabling and Disabling Plugins](#) .

– [Settings](#)

– [Example](#)

## Settings

### ItemDescription

Project mapping	The set of data sources, databases and schemas used by default by all the SQL files in your project to resolve unqualified names of database objects.
Path / Resolution Scope	<p>Mappings for individual files and directories. If nothing is specified in this section, all the SQL files in your project use the project mapping.</p> <p>To specify a different mapping for a file or directory, click <b>+</b> and select the file or directory in the dialog that opens. Then click <b>OK</b> or the Resolution Scope cell, and select the necessary data sources, databases and schemas.</p> <p>The mappings specified explicitly are shown in black. The mappings inherited from a higher level (unless you close the dialog) are shown in gray italic.</p>

## Example

You have two data sources, one for your production database and the other one - for your test database. The tables in both databases have the same names but slightly different structures. And you keep the SQL scripts for your production and test databases separately, in two different folders.

In such a situation, you'd map the folder with the production scripts onto the production data source, and the folder with the test scripts onto the test data source.

The other possibility would be to use the project mapping for your production data source and specify the mapping for the test scripts folder separately, or vice versa.

Ctrl+Alt+S 

---

The page shows a list of links to the pages where you can activate and configure various tools related to working with CSS, Sass, and SCSS code.

- [Dialects](#)
- [Compass](#)
- [Stylelint](#)

This page lets you specify which dialects are used in your project.

A dialect may be set at the project level, and also at the level of a directory or a file.

If a dialect is not specified explicitly, it is inherited from a higher hierarchical level.

The dialects specified explicitly are shown in black. The inherited values are shown in gray italic.

<b>Item</b>	<b>Description</b>
File/Directory	This column shows the hierarchy of files and folders in the project. Each row corresponds to a directory or a file.
CSS Dialect	Specify the dialect to be used. Click the cell of interest and select the necessary option from the list.  In addition to particular dialects, you can select: – Clear. This will clear the corresponding cell. As a result, an option from a higher hierarchical level will be inherited.

Ctrl+Alt+S 

Use this page to integrate the [Compass framework](#) with IntelliJ IDEA and thus enable compilation of Sass and SCSS files from Compass-specific projects into CSS. For details, see [Using File Watchers](#) .

**Tip** IntelliJ IDEA implements the Compass functionality with a bundled plugin, which can be completely disabled by clearing the Sass support checkbox on the the Plugins page of IntelliJ IDEA settings ( [Ctrl+Alt+S](#) ).

Make sure that [Ruby](#) is installed on your computer.

For more details, see [Sass and SCSS in Compass Projects](#) .

#### ItemDescription

Enable Compass support	Select this checkbox to activate Compass support including the possibility to compile Sass and SCSS files from your Compass project into CSS.
Compass executable file	In this field, specify the location of the <code>compass</code> executable file under the Ruby installation. Type the path manually, for example, <code>C:\Ruby200-x64\bin\compass</code> , or choose it from the drop-down list, or click the Browse button  and choose the location of the <code>compass</code> file in the dialog box that opens.
Config path	In this field, specify the location of the project Compass configuration file <code>config.rb</code> . Type the path manually, for example, <code>C:\my_projects\compass_project\config.rb</code> , or choose it from the drop-down list, or click the Browse button  and choose the location of the <code>compass</code> file in the dialog box that opens. The Compass configuration file <code>config.rb</code> is generated during project set-up through <code>compass create</code> or <code>compass init</code> commands.

Ctrl+Alt+S 

---

Use this page to enable the CSS [Stylelint](#) code verifier in your project and to configure its behaviour.

#### ItemDescription

---

Enable	Select this checkbox to activate the Stylelint support.
Node Interpreter	<p>In this field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click  and configure a new one as described in <a href="#">Configuring Node.js Interpreters</a> .</p> <p>If you have <a href="#">appointed one of the installations as default</a> , the field displays the path to its executable file.</p>
Stylelint package	In this field, specify the location of the <code>stylelint</code> package installed globally or in the current project, see <a href="#">Stylelint</a> .

- [Compiler](#)
- [Routes](#)
- [Other](#)

**Note** This page is available when the Scala plugin is enabled. For more information, see [Enabling and Disabling Plugins](#) .

## Compiler

Use this tab to manually specify settings for the Play2 compiler if they were not generated automatically during the project import or if the project was created with an external tool such as [gen-idea](#) .

### ItemDescription

Use SBT Watcher	Select this checkbox to separately execute an SBT process with <code>~compile:test</code> command. In this case IntelliJ IDEA monitors project sources and recompiles the project when changes are detected.
Use Play 2 compiler for this project	Select this checkbox to use the Play 2 compiler version to enable the Play 2 compiler for this project explicitly .
Don't compile the project within IDEA before run	Select this checkbox if you do not want to compile the project before run. SBT will additionally compile the necessary source files.
Play2 module	Use this field to specify the Play 2 module for this project.
Project uri	Use this field to specify the SBT project's root address. For the imported projects, the SBT project's root matches the content root of the IntelliJ IDEA project.
Additional SBT options	Use this field to specify additional options that you can pass directly to SBT. For example, <code>-Xmx2048M</code> .

## Routes

Use this tab to configure settings for the routes file in your project.

### ItemDescription

Minimum space for routes formatting	Use this field to set a minimum space for routes formatting.
Ignore URL depth in route files	Select this checkbox to ignore the URL depth in the routes files.
Re-format routes file on Enter	Select this checkbox to reformat new entry in your routes file when you press Enter .

## Other

Use this tab to configure additional settings for your Pla2 project.

### ItemDescription

Exclude 'target' dir on refresh	By default, when you refresh a project the 'target' directory is excluded. Clear this checkbox if you want to include the 'target' directory when you refresh your project.
Set template imports manually	Select this checkbox to add the Play2 framework's imports manually to your project.

---

To get coding assistance for [template data languages](#), specify where in your project those languages are used.

You can set a default template data language for a project and optionally assign custom template languages for files and directories.

**Item****Description**

---

Project Language	From this list, choose the default template data language for the entire project.
Path	The field shows a list of files and folders where you want to apply a custom template data language instead of the default one set for the entire project. To add an item to the list, click  and choose the required file or folder in the dialog box that opens.
Language	To set a custom template data language for a file or directory, click the Language cell to the right of it and choose the language from the list.

Ctrl+Alt+S 

In this dialog:

- Specify the Node.js interpreter and the `typescript` package to use in your project.
- Choose whether you want to use the [TypeScript Language Service](#) or to get coding assistance from IntelliJ IDEA only.
- Configure the behaviour of the built-in compiler.

**Tip** By default, the TypeScript Language Service checkbox is selected.

## Node interpreter

In this field, specify the location of the **Node.js** interpreter to use. In most cases, IntelliJ IDEA detects it and fills in the field automatically.

## TypeScript

From this drop-down list, choose the version of the TypeScript to use (IntelliJ IDEA displays the currently chosen version):

- Bundled: choose this option to use the `typescript` package that comes bundled with IntelliJ IDEA without attempting to find another `typescript` package.
- Select: choose this option to use a custom `typescript` package instead of the one bundled with IntelliJ IDEA. Choose the path to the relevant package in the dialog that opens.

## TypeScript Language Service

Select this checkbox to get native support from the [TypeScript Language Service](#) according to the up-to-date specifications.

As a result:

- Syntax and error highlighting is based on the annotations from the **TypeScript Language Service**.
- Completion lists contain both suggestions from the **TypeScript Language Service** and suggestions calculated by IntelliJ IDEA.
- TypeScript code is compiled into JavaScript.

Use the controls below to configure integration with the **Angular Language Service** and compilation into JavaScript.

### ItemDescription

Also for projects without <code>config.json</code>	When this checkbox is selected, the TypeScript Language Service also processes projects that do not contain a <code>tsconfig.json</code> configuration files. In this case, the default scope is the entire project.
Angular Language Service	IntelliJ IDEA supports integration with the <a href="#">Angular language service</a> developed by the Angular team to improve code analysis and completion for Angular-TypeScript projects. Note that the Angular language service works only with the projects that use Angular 2.3.1 or higher and TypeScript version compatible with it. The Angular language service is activated by default so IntelliJ IDEA starts it automatically together with the TypeScript service and shows all the errors and warnings in your TypeScript and HTML files both in the editor and in the <a href="#">TypeScript Tool Window</a> . By default the checkbox is selected.
Recompile on changes	<ul style="list-style-type: none"> <li>– When this checkbox is selected, the compiler "wakes up" upon any change to a TypeScript file.</li> <li>– When this checkbox is cleared, the compiler ignores changes to TypeScript files. To re-activate the compiler, open the <a href="#">TypeScript Tool Window</a> ( View   Tool Windows   TypeScript ), click  on the toolbar, and choose the currently opened file or Compile all from the list.</li> </ul> <p>If you have not opened the TypeScript tool window yet and it is not available from the View menu, choose Help   Find Action , then find and launch the TypeScript Compile All action from the list.</p>
Compile scope	<p>From this drop-down list, choose the scope in which compiler will work when you click Compile and choose Compile All in the <a href="#">TypeScript Tool Window</a>. The available options are:</p> <ul style="list-style-type: none"> <li>– Project Files: all the files within the project content roots (see <a href="#">Configuring projects</a>).</li> <li>– Project Production Files: all the files within the project content roots excluding test sources.</li> <li>– Project Test Files: all the files within the project test source roots.</li> <li>– Open Files: all the files that are currently opened in the editor.</li> </ul> <p>VCS Scopes: these scopes are only available if your <a href="#">project is under version control</a>.</p> <ul style="list-style-type: none"> <li>– Changed Files: all changed files, that is, all files associated with all existing <a href="#">changelists</a>.</li> <li>– Default: all the files associated with the <a href="#">changelist</a> <code>Default</code>.</li> </ul> <p>Alternatively, click the Browse button and configure a custom scope in the Scopes dialog box that opens. For more details on scopes, see the pages <a href="#">Scopes</a> and <a href="#">Scopes dialog</a>.</p>
Options	In this field, specify the command line options to be passed to the TypeScript Language Service when the <code>tsconfig.json</code> file is not found. See the list of acceptable options at <a href="#">TSC arguments</a> . Note that the <code>-w</code> or <code>--watch</code> ( Watch input files ) option is irrelevant.

Ctrl+Alt+S

Use this page to activate integration with the [TSLint](#) code verifier and configure its behaviour.

#### ItemDescription

Enable	Select this checkbox to have TSLint applied to verify the code in the current project. After that the other controls in the page are enabled.
Node Interpreter	<p>In this field, specify the Node.js interpreter to use. Choose one of the configured interpreters or click <input type="button" value="..."/> and configure a new one as described in <a href="#">Configuring Node.js Interpreters</a> .</p> <p>If you have <a href="#">appointed one of the installations as default</a> , the field displays the path to its executable file.</p>
TSLint Package	In this field, specify the location of the <code>tslint</code> package installed globally or in the current project, see <a href="#">TSLint</a> .
Configuration File	<p>In this area, appoint the configuration to use. By default, IntelliJ IDEA first looks for a <code>tslint.json</code> configuration file. IntelliJ IDEA starts the search from the folder where the file to be checked is stored, then searches in the parent folder, and so on until reaches the project root. If no <code>tslint.json</code> file is found, TSLint uses its default embedded configuration file. Accordingly, you have to define the configuration to apply either in a <code>tslint.json</code> configuration file, or in a custom JSON configuration file, or rely on the default embedded configuration.</p> <ul style="list-style-type: none"><li>- To have IntelliJ IDEA look for a <code>tslint.json</code> file, choose the Search for tslint.json option. If no <code>tslint.json</code> file is found, the default embedded configuration file will be used.</li><li>- To use a custom file, choose the Configuration File option and specify the location fo the file in the Path field. Choose the path from the drop-down list, or type it manually, or click the <input type="button" value="..."/> button and select the relevant file from the dialog box that opens.</li></ul>
Additional Rules Directory	In this field, specify the location of the files with additional code verification rules. These rules will be applied after the rules from <code>tslint.json</code> or the above specified custom configuration file and accordingly will override them.

Ctrl+Alt+S

The dialog box opens when you select the Use TypeScript Service checkbox and click Configure next to it on the [TypeScript](#) page. Use the dialog box to configure TypeScript code completion and activate or disable integration with the [Angular language service](#) in [TypeScript-Angular](#) projects.

#### ItemDescription

- |                 |   |
|-----------------|---|
| Code completion | <ul style="list-style-type: none"><li>- Select this checkbox to get native support from the <a href="#">TypeScript Language Service</a> according to the up-to-date specifications. As a result:<ul style="list-style-type: none"><li>- Syntax and error highlighting is based on the annotations from the <a href="#">TypeScript Language Service</a> .</li><li>- Completion lists contain both suggestions from the <a href="#">TypeScript Language Service</a> and suggestions calculated by IntelliJ IDEA.</li><li>- TypeScript code is compiled into JavaScript.</li></ul></li><li>- Clear the checkbox to have only suggestions from IntelliJ IDEA.</li></ul> |
|-----------------|---|

By default, the checkbox is selected.

- |                     |  |
|---------------------|--|
| Use Angular service | <p>The checkbox is only available in <a href="#">TypeScript-Angular</a> projects when you are using <a href="#">Angular 2.3.1</a> or higher with a compatible version of <a href="#">TypeScript</a> and the <code>@angular/language-service</code> package is installed in the project root. Select the checkbox to activate the <a href="#">Angular language service</a> in your project. The <a href="#">Angular language service</a> is activated by default so IntelliJ IDEA starts it automatically together with the <a href="#">TypeScript service</a> and shows all the errors and warnings in your TypeScript and HTML files both in the editor and in the <a href="#">TypeScript Tool Window</a> .</p> |
|---------------------|--|

Use this dialog box to specify the Web context settings that IntelliJ IDEA uses to resolve Web paths in HTML and JSP for a file, directory, or the entire project.

The dialog box is available only when the **Java Server Pages Integration** plugin is installed and enabled. The plugin is bundled with IntelliJ IDEA and activated by default. If it is not, enable it as described in [Enabling and Disabling Plugins](#) .

---

**ItemDescription**

---

File/Directory

Select the file, or directory, or project to specify a Web context for.

 Expand the nodes in the tree until you access the required item.

---

Web Context

In this drop-down list, select the relevant Web context.

If you select the Clear option, Web paths in the corresponding file or directory are resolved using the Web context setting inherited from the parent.

Ctrl+Alt+S

---

This page appears if [XPath View+XSLT Support](#) plugin is enabled. Use this page to configure [XSLT support](#) at the IntelliJ IDEA level.

#### ItemDescription

---

Show Associated Files in Project View	Select this checkbox to have <a href="#">XML files associated with XSLT</a> stylesheets displayed in the <a href="#">project view</a> . Associated XML files are displayed below the corresponding stylesheets.
---------------------------------------	--

Ctrl+Alt+S

Use this page to associate an XSLT stylesheet file with XML files. This is necessary to enable error highlighting and enhanced completion for element and attribute names in XSLT node-selections.

#### ItemDescription

Project XSLT Files	The pane shows all the XSLT files in a project tree view, grouped by modules and their content roots.
Associated Files	The pane shows all the XML file associated with the selected XSLT file.
	Click this button to select the XML file that should be associated with the selected XSLT file. See the description of the <a href="#">dialog that opens</a> . The button is available only when an XSLT file is selected in the Project XSLT Files pane.
	Click this button to cancel the association between the XML file selected in the Associated Files pane and the XSLT file selected in the Project XSLT Files pane.

for macOS

Ctrl+Alt+S

The page and all the pages under this node are available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

Use this page to configure PHP development and unit testing support in the project by choosing one of the available PHP interpreters, see [Configuring Local PHP Interpreters](#) .

**ItemTooltip** **Description**  
and

**Shortcut**

PHP language level	<p>In this drop-down list, specify the <b>PHP</b> functionality scope to get coding assistance for. Each functionality scope is associated with the PHP version that supports this functionality. Currently <b>PHP 5.3</b> , <b>PHP 5.4</b> , <b>PHP 5.5</b> , <b>PHP 5.6</b> , <b>PHP 7</b> , <b>PHP 7.1</b> , and <b>PHP 7.2</b> levels are supported.</p> <p>No correlation between the PHP version used in the project and the language level is enforced. Although the language version of each interpreter is detected automatically, you can still tell IntelliJ IDEA to provide you with coding assistance that corresponds to another language level. However, if you attempt to use a code construct that is not supported by the specified language level, IntelliJ IDEA suggests a <a href="#">Switch to PHP &lt;version&gt; quick-fix</a> .</p>
CLI Interpreter	<p>From this drop-down list, choose the PHP interpreter to use in the current project by default. The list contains all the currently configured local and remote PHP interpreters. See <a href="#">Configuring Local PHP Interpreters</a> and <a href="#">Configuring Remote PHP Interpreters</a> for details.</p>
	<p><b>Reload</b></p> <p>Click this button to make sure that the configuration you have chosen points at the relevant installation. If no PHP executable is detected at the specified directory, IntelliJ IDEA displays the corresponding error message.</p>
	<p><b>Show phpinfo</b></p> <p>Click this button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the <a href="#">CLI Interpreters</a> dialog box are not listed.</p>
	<p><b>Shift+Enter</b></p> <p>Click this button next to the CLI Interpreter drop-down list to create a new IntelliJ IDEA-wide PHP installation configuration in the <a href="#">CLI Interpreters</a> dialog box, that opens, see <a href="#">Configuring Local PHP Interpreters</a> and <a href="#">Configuring Remote PHP Interpreters</a> .</p>
Include path	<p>The area shows a list of configured <b>include paths</b> . Include paths are used for code completion and reference resolution in some functions/methods that use file paths as arguments, for example, <code>require()</code> or <code>include()</code> .</p> <ul style="list-style-type: none"> <li>- Use the <b>+</b> and <b>-</b> buttons to add and remove paths.</li> <li>- Use the <b>↑</b> and <b>↓</b> buttons to change the order of items in the list.</li> <li>- Press the <b>↕</b> toggle button to have the paths sorted alphabetically in the ascending order.</li> </ul>

Ctrl+Alt+S

The dialog box opens when you click the Browse button  next to the CLI Interpreter drop-down list in the Development environment section of the [PHP](#) page.

Use this dialog box to configure PHP engines as interpreters, see [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#). In this dialog box, you can add new interpreters and edit or remove the existing ones.

The dialog box consists of two panes. The left-hand pane lists all the configured PHP interpreters, both local and remote ones, and contains a toolbar for adding, removing, and copying PHP interpreter configurations. The contents of the right-hand pane depend on the type of the interpreter currently selected in the left-hand pane. Use the controls in this pane to edit the settings of the selected interpreter and even choose its type, if necessary.

- [Left-hand pane](#)
- [Right-hand pane](#)
- [Configuration options dialog](#)

## Left-hand pane

The left-hand pane lists all the configured PHP interpreters, both local and remote ones, and contains a toolbar for adding, removing, and copying PHP interpreter configurations.

### Item Tooltip Description

	<b>Add</b>	Click this button to add a new PHP interpreter to the list. From the drop-down list, choose the type of the interpreter ( <i>Local</i> or <i>Remote</i> ), and configure a local interpreter in the right-hand pane or a remote interpreter in the <a href="#">Configure PHP Remote Interpreter Dialog</a> dialog that opens.
	<b>Delete</b>	Click this button to remove the selected interpreter from the list.
	<b>Copy</b>	Click this button to create a new interpreter with the settings copied from the selected one.

## Right-hand pane

The contents of the right-hand pane depend on the type of the interpreter currently selected in the left-hand pane. Use the controls in this pane to edit the settings of the selected interpreter and even choose its type, if necessary.

### Type of the selected interpreter

Local	<ul style="list-style-type: none"> <li>– <b>Name</b> : In this text box, type the identifier to distinguish the interpreter from others, for example, <code>php_installation_&lt;version&gt;</code>.</li> <li>– <b>PHP executable</b> : In this text box, specify the path to the PHP engine. Type the path manually or click the Browse button  and choose the executable file in the dialog box that opens. IntelliJ IDEA detects the version of PHP and displays it in the PHP version read-only field. IntelliJ IDEA also detects the debugging engine and the <code>php.ini</code> configuration file. The type of the debugging engine associated with the PHP interpreter and its version are displayed in the Debugger read-only field. If no debugger is detected or you have disabled it in <code>php.ini</code> file (see <a href="#">Configuring Xdebug for Using in the On-Demand Mode</a>), the field shows <b>Debugger: Not installed</b>.</li> <li>– The location of <code>php.ini</code> is displayed in the Configuration file read-only field. To edit the <code>php.ini</code> in IntelliJ IDEA, click <b>Open in Editor</b>.</li> <li>–  ( <b>Reload</b> ) : Click this button to check that the specified PHP home directory actually contains a PHP executable file. If no PHP executable is detected at the specified location, IntelliJ IDEA displays the corresponding error message.</li> <li>–  ( <b>Show phpinfo</b> ) : Click this button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the <a href="#">CLI Interpreters</a> dialog box are not listed.</li> <li>– <b>Debugger extension</b>: in this text box, specify the location of the Xdebug extension to enable IntelliJ IDEA to activate it when necessary. Starting with version 2016.2, IntelliJ IDEA supports the <b>On-Demand</b> mode where you can disable debugger for your global PHP installation, and have it enabled automatically on demand only when you are debugging your command-line scripts or when you need code coverage reports. This lets your command line scripts (including Composer and unit tests) run much faster.</li> <li>– <b>Configuration Options</b> : Use this text box to customize the configuration settings of the installation by composing a string of configuration directives to be passed through the <a href="#">-d command line option</a> and thus add new entries to the <code>php.ini</code> file. Click the Browse button  to open the Configuration Options dialog box and create a list of new <code>php.ini</code> entries there.</li> </ul>
-------	--

Remote interpreter accessible through SSH	<ul style="list-style-type: none"> <li>– <b>Host</b>: in this field, type the name of the host on which the interpreter is installed.</li> <li>– <b>Port</b>: in this field, type the port which the SSH server on the remote host listens to. The</li> </ul>
---	---

default port number is 22.

- User name: in the field, type the user name under which you are registered on the SSH server.
- Auth type: from this drop-down list, choose the authentication method.
  - To access the host through a password, choose Password from the Auth type drop-down list, specify the password, and select the Save password checkbox to have IntelliJ IDEA remember it.
  - To use [SSH authentication](#) via a key pair, choose Key pair (OpenSSH or PuTTY) . To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the [OpenSSH](#) utility.  
Specify the path to the file where your private key is stored and type the passphrase (if any) in the corresponding text boxes. To have IntelliJ IDEA remember the passphrase, select the Save passphrase checkbox.
  - If your SSH keys are managed by a credentials helper application (for example, [Pageant](#) on Windows or [ssh-agent](#) on Mac and Linux), choose Authentication agent (ssh-agent or Pageant) .
- Name : In this text box, type the identifier to distinguish the interpreter from others, for example, `php_installation_<version>` .
- PHP executable : In this text box, specify the path to the PHP engine. Type the path manually or click the Browse button  and choose the executable file in the dialog box that opens. IntelliJ IDEA detects the version of PHP and displays it in the PHP version read-only field.  
IntelliJ IDEA also detects the debugging engine and the `php.ini` configuration file. The type of the debugging engine associated with the PHP interpreter and its version are displayed in the Debugger read-only field. If no debugger is detected or you have disabled it in `php.ini` file (see [Configuring Xdebug for Using in the On-Demand Mode](#) ), the field shows Debugger: Not installed .  
  
The location of `php.ini` is displayed in the Configuration file read-only field. To edit the `php.ini` in IntelliJ IDEA, click Open in Editor .
-  (Reload) : Click this button to check that the specified PHP home directory actually contains a PHP executable file. If no PHP executable is detected at the specified location, IntelliJ IDEA displays the corresponding error message.
-  ( Show phpinfo ) : Click this button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the [CLI Interpreters](#) dialog box are not listed.
- Debugger extension: in this text box, specify the location of the Xdebug extension to enable IntelliJ IDEA to activate it when necessary.  
Starting with version 2016.2, IntelliJ IDEA supports the On-Demand mode where you can disable debugger for your global PHP installation, and have it enabled automatically on demand only when you are debugging your command-line scripts or when you need code coverage reports. This lets your command line scripts (including Composer and unit tests) run much faster.
- Configuration Options : Use this text box to customize the configuration settings of the installation by composing a string of configuration directives to be passed through the [-d command line option](#) and thus add new entries to the `php.ini` file. Click the Browse button  to open the Configuration Options dialog box and create a list of new `php.ini` entries there.

---

Remote interpreter on a Vagrant instance

- Name : In this text box, type the identifier to distinguish the interpreter from others, for example, `php_installation_<version>` .
- PHP executable : In this text box, specify the path to the PHP engine. Type the path manually or click the Browse button  and choose the executable file in the dialog box that opens. IntelliJ IDEA detects the version of PHP and displays it in the PHP version read-only field.  
IntelliJ IDEA also detects the debugging engine and the `php.ini` configuration file. The type of the debugging engine associated with the PHP interpreter and its version are displayed in the Debugger read-only field. If no debugger is detected or you have disabled it in `php.ini` file (see [Configuring Xdebug for Using in the On-Demand Mode](#) ), the field shows Debugger: Not installed .  
  
The location of `php.ini` is displayed in the Configuration file read-only field. To edit the `php.ini` in IntelliJ IDEA, click Open in Editor .
-  (Reload) : Click this button to check that the specified PHP home directory actually contains a PHP executable file. If no PHP executable is detected at the specified location, IntelliJ IDEA displays the corresponding error message.
-  ( Show phpinfo ) : Click this button to have IntelliJ IDEA display a separate information window where you can examine the installation details and view the list of loaded extensions and configured options. Please note that the options specified in the Configuration Options field of the [CLI Interpreters](#) dialog box are not listed.
- Debugger extension: in this text box, specify the location of the Xdebug extension to enable IntelliJ IDEA to activate it when necessary.  
Starting with version 2016.2, IntelliJ IDEA supports the On-Demand mode where you can disable debugger for your global PHP installation, and have it enabled automatically on demand only when you are debugging your command-line scripts or when you need code coverage reports. This lets your command line scripts (including Composer and unit tests) run much faster.
- Configuration Options : Use this text box to customize the configuration settings of the installation by composing a string of configuration directives to be passed through the [-d command line option](#) and thus add new entries to the `php.ini` file. Click the Browse button  to open the Configuration Options dialog box and create a list of new `php.ini` entries there.

	Remove Click this button to remove the selected entry from the list. 
	Up / Down Use these buttons to move the selected entry up or down in the list. The order of entries in the list determine the order in which they are passed through the <a href="#">-d command line option</a> .  / 

Ctrl+Alt+S

The dialog box is available only when the **PHP Remote Interpreter** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

The dialog box opens when you click the Add toolbar button  in the left-hand pane of the **CLI Interpreters** dialog box and choose Remote... from the drop-down menu.

Use this dialog box to configure access to PHP engines installed on remote hosts or in development environments set up in **Vagrant** or **Docker** instances.

#### ItemDescription

Vagrant	<p>This option is available only when the <b>Vagrant</b> repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the <b>JetBrains plugin repository</b> as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a>.</p> <p>Choose this option to configure access to a PHP interpreter installed in a <b>Vagrant instance</b> using your <b>Vagrant</b> credentials. Technically, it is the folder where the <b>VagrantFile</b> configuration file for the desired environment is located. Based on this setting, IntelliJ IDEA detects the <b>Vagrant host</b> and shows it as a link in the <b>Vagrant Host URL</b> read-only field.</p> <p>To use an interpreter configuration, you need <b>path mappings</b> that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. IntelliJ IDEA evaluates path mappings from the <code>VagrantFile</code> configuration file.</p>
Deployment Configuration	<p>This option is available only when the <b>Remote Hosts Access</b> plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the <a href="#">Plugins settings</a> page as described in <a href="#">Enabling and Disabling Plugins</a>.</p> <p>Choose this option to configure access to a PHP interpreter on a remote host using a <b>server access configuration</b>. This option is available only if you have at least one <b>server access configuration</b> of the type SFTP, see <a href="#">Creating a Remote Server Configuration</a>.</p> <p>From the <b>Deployment Configuration</b> drop-down list, choose the <b>server access configuration</b> of the SFTP type according to which you want IntelliJ IDEA to connect to the target host. If the settings specified in the chosen configuration ensure successful connection, IntelliJ IDEA displays the URL address of the target host as a link in the <b>Deployment Host URL</b> field.</p> <p>To use an interpreter configuration, you need <b>path mappings</b> that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. By default, IntelliJ IDEA retrieves path mappings from the chosen server access (deployment) configuration. If the configuration does not contain path mappings, IntelliJ IDEA displays the corresponding error message.</p> <p>To fix the problem, open the <a href="#">Deployment</a> page under the <b>Build, Execution, Deployment</b> node, select the relevant server access configuration, switch to the <b>Mappings</b> tab, and map the local folders to the folders on the server as described in <a href="#">Creating a Remote Server Configuration</a>, section <b>Mapping Local Folders to Folders on the Server</b> and the <b>URL Addresses to Access Them</b>.</p>
SSH Credentials	<p>Choose this option to configure access to a PHP interpreter on a remote host through SSH credentials. In the fields of the dialog box, specify the following:</p> <ul style="list-style-type: none"> <li>– <b>Host:</b> in this field, type the name of the host on which the interpreter is installed.</li> <li>– <b>Port:</b> in this field, type the port which the SSH server on the remote host listens to. The default port number is 22.</li> <li>– <b>User name:</b> in the field, type the user name under which you are registered on the SSH server.</li> <li>– <b>Auth type:</b> from this drop-down list, choose the authentication method. <ul style="list-style-type: none"> <li>– To access the host through a password, choose <b>Password</b> from the <b>Auth type</b> drop-down list, specify the password, and select the <b>Save password</b> checkbox to have IntelliJ IDEA remember it.</li> <li>– To use <a href="#">SSH authentication</a> via a key pair, choose <b>Key pair (OpenSSH or PuTTY)</b>. To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the <a href="#">OpenSSH</a> utility. Specify the path to the file where your <b>private key</b> is stored and type the passphrase (if any) in the corresponding text boxes. To have IntelliJ IDEA remember the passphrase, select the <b>Save passphrase</b> checkbox.</li> </ul> </li> <li>– If your SSH keys are managed by a credentials helper application (for example, <a href="#">Pageant</a> on Windows or <a href="#">ssh-agent</a> on Mac and Linux), choose <b>Authentication agent (ssh-agent or Pageant)</b>.</li> </ul> <p>To use an interpreter configuration, you need <b>path mappings</b> that set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. IntelliJ IDEA first attempts to retrieve path mappings itself by processing all the available application-level configurations. If IntelliJ IDEA finds the configurations with the same host as the one specified above, in the <b>Host</b> field, the mappings from these configurations are merged automatically. If no configurations with this host are found, IntelliJ IDEA displays an error message informing you that path mappings are not configured.</p> <p>To fix the problem, open the <a href="#">Deployment</a> page under the <b>Build, Execution, Deployment</b> node, select the server access configuration in question, switch to the <b>Mappings</b> tab, and map local folders to folders on the server as described in <a href="#">Creating a Remote Server Configuration</a>, section <b>Mapping Local Folders to Folders on the Server</b> and the <b>URL Addresses to Access Them</b>.</p>
Docker	<p>This option is available only when the <b>PHP Docker</b> and <b>Docker Integration</b> plugins are enabled. The plugins are activated by default. If the plugins are disabled, enable them on the <a href="#">Plugins settings</a> page as described in <a href="#">Enabling and Disabling Plugins</a>.</p> <p>Choose this option to configure access to a PHP interpreter running in a Docker container. In the fields of the dialog</p>

box, specify the following:

- In the **Server** field, specify the **Docker configuration** to use, see [Docker](#) . Choose a configuration from the drop-down list or click  next to it and create a new configuration in the **Docker** dialog box that opens.
- In the **Image name** field, specify the base Docker image to use. Choose one of the previously downloaded or your custom images from the drop-down list or type the image name manually, for example, `php:latest` or `php:7.0-cli` . When you later launch the run configuration, Docker will search for the specified image on your machine. If the search fails, the image will be downloaded from the image repository specified on the [Registry](#) page.

---

**PHP Interpreter Path**

In this field, specify the location of the **PHP** executable file in accordance with the configuration of the selected remote development environment. By default IntelliJ IDEA suggests the `/usr/bin/php` folder for remote hosts and Vagrant instances and `php` for Docker containers. To specify a different folder, click the **Browse** button  and choose the relevant folder in the dialog box that opens. Note that the **PHP** home directory must be open for edit. When you click **OK** , IntelliJ IDEA checks whether the **PHP** executable is actually stored in the specified folder.

- If no **PHP** executable is found, IntelliJ IDEA displays an error message asking you whether to continue searching or save the interpreter configuration anyway.
- If the **PHP** executable is found, you return to the **Interpreters** where the installation folder and the detected version of the **PHP** interpreter are displayed.

Ctrl+Alt+S

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Use this page to configure the behaviour of the Xdebug and Zend Debugger.

#### ItemDescription

**Pre-configuration** This area shows brief guidelines for installing a debugger, generating bookmarklets through which you will [start/stop a debugging session by controlling the debugger cookie](#), and starting [Zero-Configuration Debugging](#).

**External Connections** In this area, specify how you want IntelliJ IDEA to treat connections received from hosts and through ports that are not registered as [deployment server configurations](#).

- Ignore external connections through unregistered server configurations: Select this checkbox to have IntelliJ IDEA ignore connections received from hosts and through ports that are not registered as deployment server configurations. When this checkbox is selected, IntelliJ IDEA does not attempt to create a deployment server configuration automatically.
- Break at first line in PHP scripts: Select this checkbox to have the debugger stop as soon as connection between it and IntelliJ IDEA is established (instead of running automatically until the first breakpoint is reached). Alternatively turn on the *Run | Break at first line in PHP scripts* option on the main menu.
- Max. simultaneous connections: Use this spin box to limit the number of external connections that can be processed simultaneously.

**Xdebug** Use the controls in this area to configure debugging using the Xdebug tool.

- Debug port: in this text box, specify the port for IntelliJ IDEA and the Xdebug engine to communicate through. This must be exactly the same port number as specified in the `php.ini` file:

```
xdebug.remote_port = <port_number>
```

By default, Xdebug listens on port 9000.

- Can accept external connections: select this checkbox to enable IntelliJ IDEA to accept any incoming connections from Xdebug engines through the port specified in the Debug port text box.
- Force break at the first line when no path mapping is specified: Select this checkbox to have the debugger stop as soon as it reaches and opens a file that is not mapped to any file in the project on the [Servers](#) page. The debugger stops at the first line of this file and [Debug Tool Window. Variables](#) shows the following error message: `Cannot find a local copy of the file on server <path to the file on the server>` and a link [Click to set up mappings](#). Click the link to open the [Resolve Path Mappings Problem](#) dialog box and map the problem file to its local copy. When this checkbox cleared, the debugger does not stop upon reaching and opening an unmapped file, the file is just processed, and no error messages are displayed.
- Force break at the first line when the script is outside the project: Select this checkbox to have the debugger stop at the first line as soon as it reaches and opens a file outside the current project. With this checkbox cleared, the debugger continues upon opening a file outside the current project.

**Zend Debugger** Use the controls in this area to configure debugging using the Zend Debugger tool.

- Debug port: In this text box, specify the port for IntelliJ IDEA and the Zend Debugger engine to communicate through. Type the port number within the `tunnel` specified in the `php.ini` file through `zend_debugger.tunnel_min_port` and `zend_debugger.tunnel_max_port`. For details, see <http://files.zend.com/help/previous-version/Zend-Server-4-Community-Edition/zenddebugger.html>
  - Can accept external connections: Select this checkbox to enable IntelliJ IDEA to accept any incoming connections from Zend Debugger engines through the port specified in the Debug port text box.
  - Settings broadcasting port: In this text box, specify the port through which the debugger settings are passed to the debugging toolbar in the browser.
  - Automatically detect IDE IP: when this checkbox is selected, IntelliJ IDEA detects all the host IP addresses to be sent to Zend Debugger through the `debug_host` parameter. All the detected IP addresses are listed in the text box to the right. Autodetection of IP address is helpful when you use [Vagrant](#), or [VirtualBox](#), or other virtualization tool.
- Clear the checkbox to block autodetection of host IP addresses and specify the required ones explicitly in the text box.
- Ignore Z-Ray system requests: Select this checkbox to block requests from the [Z-Ray system](#) if they annoy you by invoking the IntelliJ IDEA debugger too often.

**Tip** If starting the Zend Debugger tool fails with the message "Port is busy", specify a port number of your choice higher than 10000.

**Evaluation** – Show array and object children in Debug Console: Select this checkbox to show the output for arrays and objects in the [Console](#) pane, see [Debug Tool Window. Console](#). When the checkbox is cleared, the output is not displayed.

- Safe evaluation mode in value hints and Watches Frame:
  - When this checkbox is selected, IntelliJ IDEA checks that the expression or code fragment to be evaluated does not contain any undefined elements and informs you about any discrepancies detected.
  - If the checkbox is cleared, an exception appears if IntelliJ IDEA encounters any undefined elements during evaluation.

See [Evaluating Expressions](#) for details.

- Import namespace and use statements from evaluation context: When this checkbox is selected, during a debugging session IntelliJ IDEA is aware of the current namespace and of all the imported namespaces at the execution point. This information is used for calculating and showing [Watches](#) and [Evaluating Expressions](#) to ensure that IntelliJ IDEA debug evaluations are identical with the actual result of the PHP code execution.

By default, the checkbox is selected.

The result of executing the following code is `true` (or showing 1 in the browser):

```
<?php
namespace Too\Car;
class Car{};
$my_car = new Car();
echo $my_car instanceof Car;
```

If the Import namespace and use statements... checkbox is selected, evaluating the `$my_car instanceof Car` expression and the `$my_car instanceof Car` watch will also show this result:

However if you clear the checkbox, `Watches` and `Evaluate Expression` will be executed in the global context. This means that instead of `$my_car instanceof Car` you will need to use the fully qualified class name `$my_car instanceof \Too\Car\Car`.

#### Advanced Settings

- Detect path mappings from deployment configurations:
  - When this checkbox is selected, IntelliJ IDEA attempts to retrieve path mappings for debugging in a remote environment from the [server access configuration](#) ( [deployment configuration](#) ).
  - When the checkbox is cleared, you have to specify the path mappings manually.

See [Validating the Configuration of a Debugging Engine](#) , [Web Server Debug Validation Dialog](#) , and [Configuring Remote PHP Interpreters](#) for details.

- Notify if debug session was finished without being stopped: Select this checkbox to have IntelliJ IDEA display a notification when no breakpoints are hit during [Zero-Configuration](#) debugging. This may happen if the path mappings are not configured or configured erroneously, or if you have not set any breakpoints. In the latter case, enabling selecting the [Break at First Line in PHP Scripts](#) checkbox in the [External Connections](#) area or turning the [Run | Break at First Line in PHP Scripts](#) option on the main menu may also help. If the checkbox is cleared, no debugging sessions is established and the PHP script is just executed without being suspended.
- Pass required configuration options through command line (still need to enable debug extension manually): select this checkbox to have debugger configuration options passed through a command line.

for macOS

Ctrl+Alt+S

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, specify the scripts requests to which you want IntelliJ IDEA to ignore during debugging. This approach can be useful, when your application contains scripts that use AJAX. Suppose you have a `menu-ajax-script.php` that "reloads" a part of your web page. This script works properly so you do not need to debug it. However, this script is still requested during the debugging session. To have incoming connections to this script ignored, add the `menu-ajax-script.php` script to the **skipped paths** list. You can also group such scripts into folders and add these folders to the "ignore list".

#### ItemDescription

**Notify about skipped paths** Select this checkbox to have IntelliJ IDEA inform you every time it receives a request to a script to be skipped.

**Skipped paths** This list box shows the scripts and folders to ignore requests to.

**+** Click this button to have a new line added to the list. Then click the Browse button  and in the dialog box that opens choose the file or folder to skip connections to.

**Add (**  
**Alt+Insert )**

**-** Click this button to have the selected item removed from the list.

**Remove (**  
**Alt+Delete )**

Ctrl+Alt+S

---

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, enable, disable, and re-configure your access to debugging PHP applications in the multiuser mode via an [Xdebug proxy server](#).

#### ItemDescription

---

IDE key	In this text box, specify the name for the Proxy server to identify connections from your IDE. This should be the value of the <code>xdebug.idekey</code> setting in your currently active <code>php.ini</code> configuration file.
Host	In this text box, specify the host on which the Xdebug proxy server resides.
Port	In this text box, specify the port which IntelliJ IDEA will listen to during a proxy debugging session.

Ctrl+Alt+S

The page and all the pages under this node are available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

On this page, specify the PHP methods and functions which you want the debugger to skip in addition to the common list of items to be skipped which is defined on the [Stepping](#) page.

#### ItemDescription

**Skip magic methods** Select this checkbox to suppress stepping into [PHP magic methods](#) and any other methods or functions with names starting with a double underscore `__` .

**Skip constructors** Select this checkbox to suppress stepping into [constructors](#) .

**Skipped Methods** In this area, create a list of specific methods that you do not want IntelliJ IDEA to step into.  
To add a method to the list

Click and in the Add Method dialog box that opens type the name of the required function or the fully qualified name of the required method in the format:

- `\Namespace\Class->Method` for non-static methods.
- `\Namespace\Class::staticMethod` for static methods.

To remove a method from the list

Select the method to allow stepping into and click .

**Skipped Files** In this area, create a list of specific files that you do not want IntelliJ IDEA to step into. This is helpful when you are using a framework with numerous core files stepping into which is not necessary and only wastes your time.  
To add a file to the list

Click , then click in the newly added line, and then select the file to skip in the dialog box that opens.

To remove a file from the list

Select the file to allow stepping into and click .

Ctrl+Alt+S 

The page is available only when the **PHP** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, configure HTTP access for debugging engines to interact with local and remote Web servers and set correspondence between files on the server and their local copies in the IntelliJ IDEA project. The settings from debug server configurations are used when debugging with run/debug configurations of the type **PHP Web Application** or **PHP Remote Debug** and during **Zero-Configuration Debugging** sessions.

## Toolbar and common options

Use the toolbar buttons to manage the list of configurations.

### ItemTooltip Description and shortcut

+	Add	Click this button to define a new configuration. 
-	Delete	Click this button to remove the selected configuration from the list. 
	Import	Click this button to open the <a href="#">Import from Deployment Configuration Dialog</a> dialog box. In this dialog box, choose a configuration to access the application on the server and use the host and port settings from it. The dialog box also shows the path mappings retrieved from the deployment configuration. You need to transform relative paths on the server into absolute paths: <ul style="list-style-type: none"> <li>- For an <b>FTP</b>, <b>SFTP</b>, or <b>FTPS</b> server access configuration, specify the absolute path to the server deployment root. This path will be added as a prefix to the path from the Root Path text box on the <a href="#">Deployment: Connection Tab</a>.</li> <li>If you are not sure about this absolute path, you can open the Remote Host tool window, choose the required deployment configuration, position the cursor at the root folder, and choose Copy Path on the context menu, see <a href="#">Accessing Files on Web Servers</a> for details. Alternatively, contact your hosting provider.</li> <li>- For a server access configuration of the type <b>Local</b> or <b>Mounted Folder</b>, specify the absolute path to the document root of the server or to the mounted folder. This path should be the one specified in the Folder field on the <a href="#">Deployment: Connection Tab</a>.</li> <li>- For <b>Inplace Server</b> configurations no mappings are required because the local and remote paths are the same in this case.</li> </ul> <p>See <a href="#">Configuring Synchronization with a Web Server</a> for details.</p>

## Configuration Details

In this area, specify the connection parameters and mappings to be used during debugging sessions. Note that the Validate Remote Environment button has been removed from this page, this functionality is now available through Run | Web Server Debug Validation on the main menu.

### ItemDescription

Name	In this text box, type the name of the server debug configuration.
Host	In this text box, type the name of the host where the target application is deployed.
Port	In this text box, type the port to connect to the specified host through. If you are using localhost on your machine, this setting should correspond with the port specified in the configuration file of the local Web server where the application will be executed or debugged.
Debugger	From this drop-down list, select the debug engine to use. The available options are: <ul style="list-style-type: none"> <li>- Xdebug</li> <li>- Zend Debugger</li> </ul>
Use path mappings	<ul style="list-style-type: none"> <li>- Select this checkbox, if you are working on a remote Web server, that is, when the Web server is on a physically remote host, or the Web server is installed on your machine but your project is outside the Web server document root. Also select the checkbox if you are using symlinks.</li> </ul> <p>Map the absolute paths to the files and folders on the server with absolute paths to your project files in the local file system using the Path on server and File/Directory fields respectively.</p> <ul style="list-style-type: none"> <li>- File / Directory: This read-only field displays the files and folders of the current project. Select a file or a folder to</li> </ul>

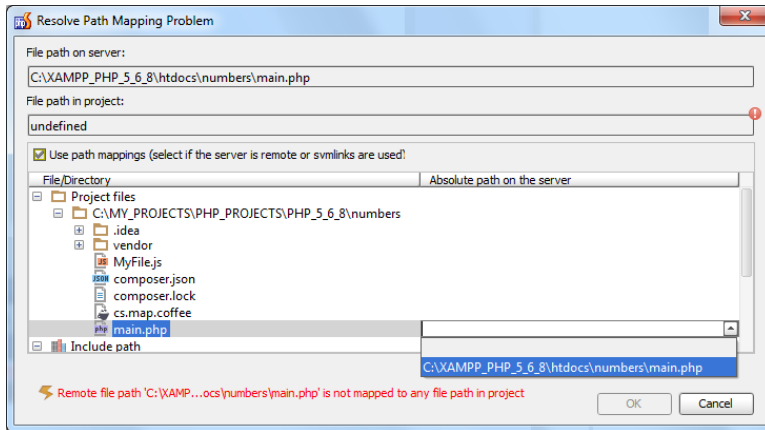

be used as the local copy.

- Path on server: In this field, specify the absolute path to the file or folder on the target server to which the selected local file or folder corresponds. Type the path manually or select it from the drop-down list.
- Clear this checkbox if you are working right on your Web server so your project root is under the server document root. In this case the absolute paths to the files on the Web server and the absolute paths to the corresponding files in your project are the same.

If you do not specify any path mappings and start debugging an application that is not under the server document root, IntelliJ IDEA displays an error message:

The Click to set up path mappings link brings up the Resolve Path Mappings Problem dialog box, where you can define the path mappings:

When you click OK and leave the dialog box, IntelliJ IDEA selects the Use path mappings checkbox on the Servers page automatically.

Shared

Select this checkbox to share the debug server configuration across a team. The host/port settings and the path mappings are stored in the `.idea/php.xml` file is available to all team members through a version control system. Note that mappings are shared only for directories inside the project.

Ctrl+Alt+S

The dialog box is available only when the **PHP** and **Remote Hosts Access** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

The dialog box opens when you click the Import button  on the toolbar of the [Servers](#) page.

In this dialog box, choose a configuration to access the application on the server and use the host and port settings from it.

#### ItemDescription

**Deployment** From this drop-down list, choose the server access configuration (deployment configuration) to copy the server access settings from. The list contains all the available deployment configurations. To create a new configuration, click  and specify new settings in the [Deployment: Connection Tab](#) dialog box that opens. In the text box below, specify the absolute path to the server deployment root folder, the name of the text box depends on the type of the selected server access configuration: Absolute path to the deployment root for **FTP / SFTP / FTPS** or Remote path to the mounted folder for **Local or mounted folder**.

This path will be added as a prefix to the path from the Root Path text box on the [Deployment: Connection Tab](#).

If you are not sure about this absolute path, you can open the Remote Host tool window, choose the required deployment configuration, position the cursor at the root folder, and choose Copy Path on the context menu, see [Accessing Files on Web Servers](#) for details. Alternatively, contact your hosting provider.

**Absolute path to the deployment root/** Depending on the type of the server access configuration chosen from the Deployment drop-down list, specify one of the following:

- For an **FTP**, **SFTP**, or **FTPS** server access configuration, specify the absolute path to the server deployment root. This path will be added as a prefix to the path from the Root Path text box on the [Deployment: Connection Tab](#). If you are not sure about this absolute path, you can open the Remote Host tool window, choose the required deployment configuration, position the cursor at the root folder, and choose Copy Path on the context menu, see [Accessing Files on Web Servers](#) for details. Alternatively, contact your hosting provider.
- For **Local or mounted folder**, type the absolute path to the **server root** as specified in the Folder field of the [Import from Deployment Configuration Dialog](#) dialog box.
- For **Inplace Server** configurations no mappings are required because the local and remote paths are the same in this case.

**Preview** The area shows the host/port and the path mappings retrieved from the chosen server access configuration (deployment configuration). When you choose the deployment configuration to use, the Absolute path on the server field shows relative paths mapped to the project files and folders in the chosen configuration, that is, paths to files and folders relative to the deployment root. As you specify the absolute path to the deployment root (the server root for FTP/SFTP/FTPS or the mounted folder), the contents of the field are updated automatically and finally the field shows absolute paths on the server.

Specify how IntelliJ IDEA will set up correspondence between files on the server and their local copies. Based on these mappings, IntelliJ IDEA will open local copies of currently processed files.

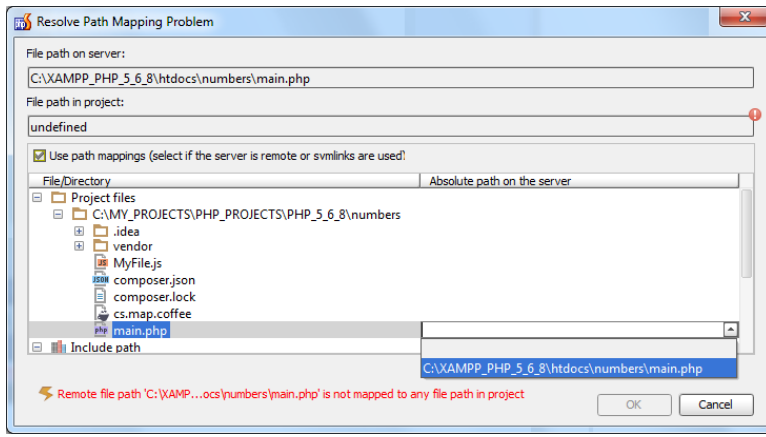

Path mappings in **PHP Debug Server** configurations look very similar to the path mappings in server access (deployment) configurations. Unfortunately, they cannot be reused, as deployment configurations uses relative paths while **PHP Debug Servers** configurations rely on absolute paths.

- Select the Use path mappings checkbox if you are working on a remote Web server, that is, when the Web server is on a physically remote host, or the Web server is installed on your machine but your project is outside the Web server document root. Also select the checkbox if you are using symlinks. Map the absolute paths to the files and folders on the server with absolute paths to your project files in the local file system using the Path on server and File/Directory fields respectively.
  - File / Directory:** This read-only field displays the files and folders of the current project. Select a file or a folder to be used as the local copy.
  - Path on server:** In this field, specify the absolute path to the file or folder on the target server to which the selected local file or folder corresponds. Type the path manually or select it from the drop-down list.
- Clear the Use path mappings checkbox if you are working right on your Web server so your project root is under the server document root. In this case the absolute paths to the files on the Web server and the absolute paths to the corresponding files in your project are the same.

If you do not specify any path mappings and start debugging an application that is not under the server document root, IntelliJ IDEA displays an error message:

The Click to set up path mappings link brings up the Resolve Path Mappings Problem dialog box, where you can define the path mappings:

When you click OK and leave the dialog box, IntelliJ IDEA selects the Use path mappings checkbox on the [Servers](#) page automatically.

On this page:

- [Code Sniffer Page](#)
- [Code Sniffer Dialog](#)

## Code Sniffer Page

File | Settings | Languages and Frameworks | PHP | Code Sniffer for Windows and Linux

IntelliJ IDEA | Preferences | Languages and Frameworks | PHP | Code Sniffer for macOS

Ctrl+Alt+S

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, choose the Code Sniffer script to use.

### ItemDescription

**Configuration** From this drop-down list, choose the script to use:

- To use the script associated with a specific remote PHP interpreter, choose the name of this interpreter.
- To use the script associated with the default project interpreter, that is, the one chosen on the PHP page of the Settings dialog box, choose By default project interpreter.
- To use a local script, choose Local. In this case the local Code Sniffer will be executed no matter which PHP interpreter - local or remote - is used in the project. Note that there can be only one Local configuration for Code Sniffer because IntelliJ IDEA runs a script ( `phpcs.bat` for Windows or `phpcs` for Linux) which contains a path to a PHP engine.

**Ignored files** This area displays a list of files that Code Sniffer skips. IntelliJ IDEA suggests adding a new file to the list during inspection when waiting for response from the Code Sniffer exceeds the limit specified in the Tool process timeout field. This is done to prevent slowing down processing. For each file, IntelliJ IDEA displays its name and location.

- To delete a file from the list and have Code Sniffer process it again, select the file and click the Remove file button .
- To remove all the files from the list, click the Clean the list button .

## Code Sniffer Dialog

The dialog box opens when you click  next to the Configuration drop-down list on the Code Sniffer page.

Use this dialog box to configure local Code Sniffer scripts, scripts associated with remote PHP interpreters, see [PHP Code Sniffer](#), and configure Code Sniffer's behaviour.

The left-hand pane of the dialog box shows all the configured Code Sniffer scripts, one of them is of the type **Local**, and others are named after the remote PHP interpreters with which the scripts are associated. When you select a configuration, the right-hand pane shows its details.

- To configure or edit the **Local** script, select Local and specify the location of `phpcs.bat` or `phpcs` in the PHP Code Sniffer path field.
- To configure a new script associated with a remote PHP interpreter:
  1. Click  on the toolbar.
  2. In the Code Sniffer by Remote Interpreter dialog box that opens, choose the remote PHP interpreter to use the associated script from. If the list does not contain a relevant interpreter, click  and configure a remote interpreter in the CLI Interpreters dialog box as described in [Configuring Remote PHP Interpreters](#).  
When you click OK, IntelliJ IDEA brings you back to the Code Sniffer dialog box where the new **Code Sniffer** configuration is added to the list and the right-hand pane shows the chosen remote PHP interpreter, the path to the Code Sniffer associated with it, and the advanced PHP Code Sniffer options.

### ItemDescription

**PHP Code Sniffer (phpcs) Path** In this text box, specify the location of the Code Sniffer utility `phpcs` or `phpcs.bat`. If the script is associated with a PHP interpreter, IntelliJ IDEA detects the path to it and fills in the field automatically but you can edit it if necessary. In either case, type the path manually or click the Browse button  and select the path in the dialog box, that opens.

To check that the specified path to `phpcs.bat` or `phpcs` ensures interaction between IntelliJ IDEA and Code Sniffer, that is, the tool can be launched from IntelliJ IDEA and IntelliJ IDEA will receive problem reports from it, click the Validate button. This validation is equal to running the `phpcs --version` command. If validation passes successfully, IntelliJ IDEA displays the information on the detected Code Sniffer version.

**Interpreter** The field shows the chosen PHP interpreter to use the Code Sniffer from.

**Maximum number of messages per file** In this text box, set the upper limit for the total number of messages to be reported for a file. All the messages above this limit will be rejected. IntelliJ IDEA will display the following warning right in the code: `Too many PHP Code Sniffer messages` and suggest adding the file to the Ignored files list.

**Tool process timeout** In this text box, specify how long you want IntelliJ IDEA to wait for a result from PHP Code Sniffer, whereupon the process is killed to prevent excessive CPU and memory usage. This gives you the capability to fine tune the PHP

Code Sniffer process behavior depending on the configuration of your computer and the rule sets used.

Ctrl+Alt+S

The page is available only when the **PHP** and the **Command Line Tool Support** plugins are enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

On this page, enable execution of [Composer Dependency Manager](#) commands through the dedicated user interface and appoint the default `composer.json` for the IntelliJ IDEA project.

#### ItemDescription

Path to composer.json	<p>In this text box, specify the location of the <code>composer.json</code> that you want to use as <b>default</b> . All the Composer commands invoked from <i>Tools   Composer</i> on the main menu will be executed in accordance with the settings from this configuration file.</p> <p>You can have several <code>composer.json</code> files in one IntelliJ IDEA project. For each <code>composer.json</code> , actions are invoked from its context menu in the editor or in the Project view.</p>
Add packages as libraries	<p>Use this checkbox to configure the open-for-edit status of Composer packages. To protect packages under <code>vendor/**</code> against editing, leave the checkbox selected (this is the default setting).</p> <p>If you want to edit Composer packages under <code>vendor/**</code> , clear the checkbox.</p>
Synchronize IDE settings with composer.json	<p>Select this checkbox to automatically detect the PHP language level and configure project Source and Test roots based on the configuration from <code>composer.json</code> .</p> <p>IntelliJ IDEA is aware of PSR-0/PSR-4 source roots and of their namespace prefixes declared in the <code>autoload</code> and <code>autoload-dev</code> sections in <code>composer.json</code> . IntelliJ IDEA also detects the PHP language level based on the <code>php</code> setting in the <code>require</code> section.</p> <p>Because <code>composer.json</code> contains the most up-to-date information about the project configuration, this automatic synchronization ensures that the Source and Test folder exactly match the project structure and the correct PHP language level is set automatically. Learn more about PSR and autoload from the <a href="#">Composer official website</a> . For examples and details in synchronizing settings, see <a href="#">PhpStorm blog</a> .</p>
PHP interpreter	<p>Choose one of the configured PHP interpreters from the list. See <a href="#">Configuring Remote PHP Interpreters</a> for details.</p>
Path to composer.phar	<p>In this text box, specify the location of the <code>composer.phar</code> archive.</p>
Click here to download from getcomposer.org	<p>Click this link to download <code>composer.phar</code> from the official storage and specify the folder to store the archive in. This instance of Composer will be available in the current project only. To use it in the command line mode, <a href="#">configure it as a command line tool</a> .</p>

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Use this page to integrate PHP-specific testing frameworks with IntelliJ IDEA in the current project. With IntelliJ IDEA, you can run a debug [PHPUnit](#), [Behat](#), [Codeception](#), and [PHPSpec](#) tests.

## What does the Test Frameworks page show?

The page consists of two panes:

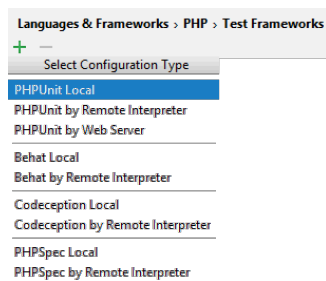

- The central pane shows existing configurations of test frameworks for different interpreters.
- The contents of the right-hand pane depend on the test framework and the type of the selected interpreter.

## How do I configure a test framework in a project?

**Tip** In local configurations the default project PHP interpreter is used, see [Default project CLI interpreters](#).

### 1. Step 1: Choose how you will use the framework

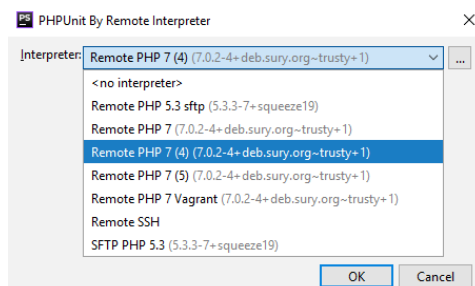

Click **+** and choose the relevant configuration type from the list:

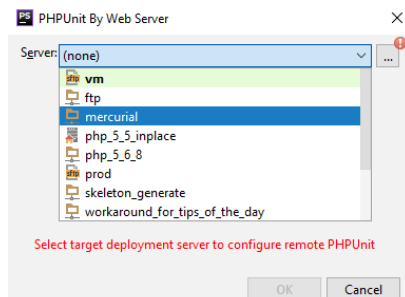

You can configure any test framework to use with a local or remote PHP interpreter. PHPUnit can also be configured to run by a Web Server via HTTP.

### 2. Step 2: For a remote configuration, choose the PHP interpreter

In the dialog box that opens, choose one of the configured PHP interpreters:

To use PHPUnit with a web server, choose the target deployment configuration:

### 3. Step 3: In the right-hand pane, choose where to take the test framework from

For Behat, PHPSpec, and Codeception, type the path to the framework executable.

For PHPUnit, specify the type of framework installation you are using, the available options are *composer autoloader* (`autoload.php`), or `phpunit.phar` archive, or `PEAR`.

### 4. Step 4: Check the chosen remote PHP interpreter, path mappings, or target deployment server

For remote configurations, the pane also shows the chosen PHP interpreter and the path mappings or the target

deployment server.

## 5. Step 5: Optionally

Specify the configuration file. For PHPUnit, you can also specify a bootstrap file to use.

## PHPUnit

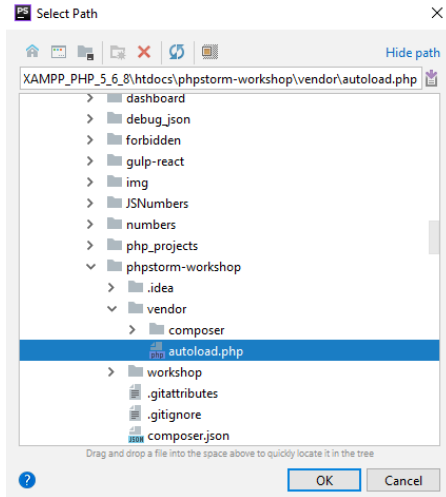

In this pane, configure installations of PHPUnit to be used with PHP interpreters.

### PHPUnit Library

In this area, specify the type of PHPUnit installation. The available options are:

Use Composer autoloader

Choose this option to run PHPUnit installed by the [Composer Dependency Manager](#). The package is retrieved and loaded by the `autoload.php` file from the `vendor` folder.

Specify the location of `autoload.php` in the *Path to script* text box.

Path to phunit.phar

Choose this option to run PHPUnit from the `.phar` archive.

- If you already have a `phunit.phar` archive in your project, specify its location in the *Path to phunit.phar* text box. Type the path manually or click  and select the file in the dialog box that opens.
  - If you have no `.phar` archive on your computer yet, click the [Download phunit.phar ...](#) link to have IntelliJ IDEA download it automatically.
- In either case, IntelliJ IDEA will load the archive before test execution.

Load from include path

Choose this option to have IntelliJ IDEA run the PHPUnit from PEAR configured as an [include path](#) on the [PHP](#) page of the [Settings / Preferences Dialog](#).

### CLI Interpreter

This area shows:

- The remote *PHP CLI Interpreter* to use PHPUnit with.
- The *Path Mappings* between your local sources and the sources inside the Vagrant instance, or the Docker container, or on the remote host.
- The *Docker container settings* that will be used to start the container from an image. These settings may include the volume configuration, the exposed port, the network, etc.

In most cases, IntelliJ IDEA detects the path mappings and the container settings and fills in all the fields automatically. Alternatively, click  next to the field in question and specify the settings manually. See [Configuring Remote PHP Interpreters](#) for details.

### Web Server

The read-only field shows the deployment configuration to use PHPUnit with, see [Deploying your application](#) for details.

**Tip** The *CLI Interpreter* field is read-only. Click  to update the chosen interpreter in the [Interpreters dialog box](#).

**Tip** The area is shown only for *PHPUnit by Remote Interpreter* configurations.

**Tip** The field is available only for *PHPUnit by Web Server* configurations.

### Test Runner

In this area, appoint the configuration `XML` file to use for launching and executing scenarios.

By default, PHPUnit looks for a `phpunit.xml` configuration file in the project root folder or in the `config` folder. You can

appoint a custom configuration file.

You can also type the path to a bootstrap file to have PHP script always executed before launching tests. In the text box, specify the location of the script. Type the path manually or click  and select the desired folder in the [dialog that opens](#).

---

**Default configuration file** Select this checkbox to specify your own `xml` configuration file. This file will be later used as default in all PHPUnit run/debug configurations.  
In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.

Clear the checkbox to have PHPUnit use the `phpunit.xml` configuration file from the project root folder or from the `config` folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.

---

**Default bootstrap file** Select this checkbox to have PHP script always executed before launching tests. In the text box, specify the location of the script. Type the path manually or click  and select the desired folder in the [dialog that opens](#).

## Behat

**Tip** This pane is available only when the Behat Support plugin is installed and enabled on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins and Enabling and Disabling Plugins](#).

**Tip** The *CLI Interpreter* field is read-only. Click  to update the chosen interpreter in the [Interpreters dialog box](#).

**Tip** The area is shown only for *Behat by Remote Interpreter* configurations.

In this pane, configure installations of the [Behat](#) framework available through configured local and remote PHP interpreters.

### CLI Interpreter

This area shows:

- The remote *PHP CLI Interpreter* to use Behat with.
- The *Path Mappings* between your local sources and the sources inside the Vagrant instance, or the Docker container, or on the remote host.
- The *Docker container settings* that will be used to start the container from an image. These settings may include the volume configuration, the exposed port, the network, etc.

In most cases, IntelliJ IDEA detects the path mappings and the container settings and fills in all the fields automatically. Alternatively, click  next to the field in question and specify the settings manually. See [Configuring Remote PHP Interpreters](#) for details.

### Behat Library

In this area, specify the Behat installation to use.

---

**Path to Behat executable** In this text box, specify the location of the `behat.phar` archive or the folder with the Behat executable file. Behat does not necessarily have to be installed under the current project root. You can type the path manually or click  and choose the relevant location in the dialog box that opens.

---

**Behat releases** Click this link to navigate to the Behat repository on github where you can choose the relevant version of `behat.phar` archive.

---

**Behat version** This read-only field shows the version of the specified Behat installation. IntelliJ IDEA detects the version when you click the *Refresh* icon . The default value is *Not installed*.

### Test Runner

In this area, appoint the configuration `.ym1` file to use for launching and executing scenarios.

By default, Behat looks for a `behat.ym1` configuration file in the project root folder or in the `config` folder. You can appoint a custom configuration file.

---

**Default configuration file** Select this checkbox to specify your own `.ym1` configuration file. This file will be later used as default in all Behat run/debug configurations.  
In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.

Clear the checkbox to have Behat use the `behat.ym1` configuration file from the project root folder or from the `config` folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.

## Codeception

**Tip** This pane is available only when the Codeception Framework plugin is installed and enabled on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins and Enabling and Disabling Plugins](#).

**Tip** The *CLI Interpreter* field is read-only. Click  to update the chosen interpreter in the [Interpreters dialog box](#).

**Tip** The area is shown only for *Codeception by Remote Interpreter* configurations.

In this pane, configure installations of the [Codeception](#) framework available through configured local and remote PHP interpreters.

### CLI Interpreter

This area shows:

- The remote *PHP CLI Interpreter* to use Codeception with.
- The *Path Mappings* between your local sources and the sources inside the Vagrant instance, or the Docker container, or on the remote host.
- The *Docker container settings* that will be used to start the container from an image. These settings may include the volume configuration, the exposed port, the network, etc.

In most cases, IntelliJ IDEA detects the path mappings and the container settings and fills in all the fields automatically. Alternatively, click  next to the field in question and specify the settings manually. See [Configuring Remote PHP Interpreters](#) for details.

### Codeception Library

In this area, specify the Codeception installation to use.

Path to Codeception executable	In this text box, specify the location of the <code>codeception.phar</code> archive or the folder with the Codeception executable file.
Codeception releases	Click this link to navigate to the Codeception repository on github where you can choose the relevant version of <code>codeception.phar</code> archive.
Codeception version	This read-only field shows the version of the specified Codeception installation. IntelliJ IDEA detects the version when you click the <i>Refresh</i> icon  . The default value is <i>Not installed</i> .

### Test Runner

In this area, appoint the configuration `.yaml` file to use for launching and executing scenarios.

By default, Codeception looks for a `codeception.yaml` configuration file in the project root folder. You can appoint a custom configuration file.

Default configuration file	Select this checkbox to specify your own <code>.yaml</code> configuration file. This file will be later used as default in all Codeception run/debug configurations. In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.  Clear the checkbox to have Codeception use the <code>codeception.yaml</code> configuration file from the project root folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.
----------------------------	--

## PHPSpec

**Tip** This pane is available only when the PHPSpec BDD Framework plugin is installed and enabled on the [Plugins page](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

**Tip** The *CLI Interpreter* field is read-only. Click  to update the chosen interpreter in the [Interpreters dialog box](#).

**Tip** The area is shown only for *PHPSpec by Remote Interpreter* configurations.

In this pane, configure installations of the [PHPSpec](#) toolset available through configured local and remote PHP interpreters.

### CLI Interpreter

This area shows:

- The remote *PHP CLI Interpreter* to use PHPSpec with.
- The *Path Mappings* between your local sources and the sources inside the Vagrant instance, or the Docker container, or on the remote host.
- The *Docker container settings* that will be used to start the container from an image. These settings may include the volume configuration, the exposed port, the network, etc.

In most cases, IntelliJ IDEA detects the path mappings and the container settings and fills in all the fields automatically. Alternatively, click  next to the field in question and specify the settings manually. See [Configuring Remote PHP Interpreters](#) for details.

## PHPSpec Library

In this area, specify the PHPSpec installation to use.

**Tip** The field is shown for *Local* configurations only.

---

**Path to PHPSpec executable** In this text box, specify the location of `phpspec`. PHPSpec does not necessarily have to be installed under the current project root.  
If no path to PHPSpec is specified for a *Local* interpreter, IntelliJ IDEA does not provide full support of PHPSpec, for example, it does not show suggestion for code completion and does not resolve references.

---

**Prefix ('spec\_prefix')** This read-only field shows the namespace prefix for specifications. IntelliJ IDEA detects `spec_prefix` from the configuration file specified in the *Default Configuration File* field. The default value is `spec`. See [PHPSpec Configuration: PSR-4](#) and [PHPSpec Configuration: Spec and Source Location](#) for details.

## Test Runner

In this area, appoint the configuration `.yaml` file to use for launching and executing specifications.

By default, PHPSpec looks for a `phpspec.yaml` or a `phpspec.yaml.dist` configuration file in the project root folder. You can appoint a custom configuration file.

---

**Default configuration file** Select this checkbox to specify your own `.yaml` configuration file. This file will be later used as default in all PHPSpec run/debug configurations.  
In the text box, specify the location of the configuration file to use. Type the path manually or click  and choose the file in the dialog box that opens.

Clear the checkbox to have PHPSpec use the `phpspec.yaml` or `phpspec.yaml.dist` configuration file from the project root folder. If no such file is found, test execution fails, therefore it may be more reliable to specify the configuration file explicitly.

On this page:

- [Mess Detector Page](#)
- [Mess Detector Dialog](#)

## Mess Detector Page

[File](#) | [Settings](#) | [Languages and Frameworks](#) | [PHP](#) | [Mess Detector for Windows and Linux](#)

[IntelliJ IDEA](#) | [Preferences](#) | [Languages and Frameworks](#) | [Mess Detector for macOS](#)

The page is available only when the **PHP** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, choose the Mess Detector script to use.

### ItemDescription

**Configuration** From this drop-down list, choose the script to use:

- To use the script associated with a specific remote PHP interpreter, choose the name of this interpreter.
- To use the script associated with the default project interpreter, that is, the one chosen on the PHP page of the Settings dialog box, choose *By default project interpreter*.
- To use a local script, choose *Local*. In this case the local Mess Detector will be executed no matter which PHP interpreter - local or remote - is used in the project. Note that there can be only one *Local* configuration for Mess Detector because IntelliJ IDEA runs a script (`phpmd.bat` for Windows or `phpmd` for Linux) which contains a path to a PHP engine.

**Ignored files** This area displays a list of files that Mess Detector skips. IntelliJ IDEA suggests adding a new file to the list during inspection when waiting for response from the Mess Detector exceeds the limit specified in the Tool process timeout field. This is done to prevent slowing down processing. For each file, IntelliJ IDEA displays its name and location.

- To delete a file from the list and have Mess Detector process it again, select the file and click the Remove file button .
- To remove all the files from the list, click the Clean the list button .

## Mess Detector Dialog

The dialog box opens when you click  next to the Configuration drop-down list on the Mess Detector page.

Use this dialog box to configure local Mess Detector scripts, scripts associated with remote PHP interpreters, see [PHP Mess Detector](#), and configure Mess Detector's behaviour.

The left-hand pane of the dialog box shows all the configured Mess Detector scripts, one of them is of the type *Local*, and others are named after the remote PHP interpreters with which the scripts are associated. When you select a configuration, the right-hand pane shows its details.

- To configure or edit the *Local* script, select *Local* and specify the location of `phpmd.bat` or `phpmd` in the PHP Mess Detector path field.
- To configure a new script associated with a remote PHP interpreter:
  1. Click  on the toolbar.
  2. In the Mess Detector by Remote Interpreter dialog box that opens, choose the remote PHP interpreter to use the associated script from. If the list does not contain a relevant interpreter, click  and configure a remote interpreter in the CLI Interpreters dialog box as described in [Configuring Remote PHP Interpreters](#).  
When you click OK, IntelliJ IDEA brings you back to the Mess Detector dialog box where the new **Mess Detector** configuration is added to the list and the right-hand pane shows the chosen remote PHP interpreter, the path to the Mess Detector associated with it, and the advanced PHP Mess Detector options.

### ItemDescription

**PHP Mess Detector (phpmd) Path** In this text box, specify the location of the Mess Detector utility `phpmd` or `phpmd.bat`. If the script is associated with a PHP interpreter, IntelliJ IDEA detects the path to it and fills in the field automatically but you can edit it if necessary.

In either case, type the path manually or click the Browse button  and select the path in the dialog box, that opens.

To check that the specified path to `phpmd.bat` or `phpmd` ensures interaction between IntelliJ IDEA and Mess Detector, that is, the tool can be launched from IntelliJ IDEA and IntelliJ IDEA will receive problem reports from it, click the Validate button. This validation is equal to running the `phpmd --version` command. If validation passes successfully, IntelliJ IDEA displays the information on the detected Mess Detector version.

**Interpreter** The field shows the chosen PHP interpreter to use the Mess Detector from.

**Maximum number of messages per file** In this text box, set the upper limit for the total number of messages to be reported for a file. All the messages above this limit will be rejected. IntelliJ IDEA will display the following warning right in the code: `Too many PHP Mess Detector messages` and suggest adding the file to the Ignored files list.

**Tool process timeout** In this text box, specify how long you want IntelliJ IDEA to wait for a result from PHP Mess Detector, whereupon the process is killed to prevent excessive CPU and memory usage. This gives you the capability to fine tune the PHP Mess Detector process behavior depending on the configuration of your computer and the rule sets used.

Ctrl+Alt+S

On this page, integrate PHP frameworks with IntelliJ IDEA in the current project. The settings for each framework are shown in a separate area. A framework-specific area is shown only when the corresponding plugin (Drupal Support, Joomla! Support, or WordPress Support) is installed and enabled on the [Plugins settings](#) page as described in [Installing, Updating and Uninstalling Repository Plugins](#)

## Drupal

In this section, configure integration with [Drupal](#) in a project.

Enable Drupal integration	When the checkbox is selected you can use the specified below Drupal installation via the IntelliJ IDEA interface.
Drupal installation path	In this text box, specify the root folder of the <i>Drupal</i> installation.
Set up PHP   Include paths	<ul style="list-style-type: none"><li>– Select this checkbox to have <i>Drupal</i> include paths automatically configured for the project. After you leave the dialog box, the following paths will be added to the <i>Include Paths</i> list on the <a href="#">PHP</a> page: <code>&lt;drupal installation root&gt;/includes</code> , <code>&lt;drupal installation root&gt;/modules</code> , and <code>&lt;drupal installation root&gt;/sites/all/modules</code></li><li>– Clear the checkbox to configure the include paths manually.</li></ul>
Version	From this drop-down list, choose the version of Drupal to use, the supported versions are 6, 7, and 8.

## Joomla!

In this section, configure integration with [Joomla!](#) in a project.

Enable Joomla! integration	When the checkbox is selected you can use the specified below Joomla! installation via the IntelliJ IDEA interface.
Joomla! installation path	In this text box, specify the root folder of the <i>Joomla!</i> installation.

## WordPress

**Tip** To use WordPress in the command line mode, configure it as a command line tool in [Command Line Tool Support: WP-CLI](#).

In this area, configure integration with the [WordPress Content Management System](#) in the current project to work with the system through the IntelliJ IDEA user interface.

Enable WordPress Integration	When the checkbox is selected you can use the specified below WordPress installation via the IntelliJ IDEA interface.
WordPress Installation Path	In this text box, specify the folder where WordPress is installed. This folder should contain the <code>wp-admin</code> and <code>wp-includes</code> subdirectories.

The page is available only when the Phing Support plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

On this page, enable Phing integration in the current project.

---

**ItemDescription**

---

Path to Phing executable	In this text box, specify the location of the <code>phing.bat</code> file. Type the path manually or click the Browse button  and choose the file location in the dialog box that opens.
--------------------------	---

Ctrl+Alt+S

This page is available only when the **PHP** and **Blade** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

The page consists of the following tabs:

- [Text Tags](#)
- [Directives](#)

## Text Tags

In this tab, specify the delimiters to use in **Blade** templates. According to these settings, IntelliJ IDEA recognizes templates and provides error highlighting and code completion for them.

The fields in the tab show the opening and closing characters for [raw tags](#) , [content tags](#) , and [escaped tags](#) .

The fields are filled in with the default values in compliance with [Blade Templates 5.1](#) . If you are using an earlier version, you can specify the relevant custom delimiters and IntelliJ IDEA will provide coding assistance according to the new rules.

## Directives

In this tab, manage [Blade directives](#) for use in IntelliJ IDEA. The tab lists all the currently available **Blade** directives, for those that have parameters, the prefixes and suffixes are also shown. When you start, the list contains only **predefined** directives.

You can edit these directives as well as create custom ones.

### ItemDescription

- |            |   |
|------------|---|
| Directives | <p>The tab lists all the currently available <b>Blade</b> directives, for those that have parameters, the prefixes and suffixes are also shown. When you start, the list contains only <b>predefined</b> directives. You can edit these directives as well as create custom ones.</p> <ul style="list-style-type: none"> <li>- Add directive (+) click this button to define a new directive. Specify the directive's name in the Name text box. If the new directives requires a prefix and a suffix, select the Has parameter checkbox and type the prefix and suffix to use in the Prefix and Suffix text boxes respectively. IntelliJ IDEA will automatically enclose the prefix and suffix in opening and closing brackets and quotes and add a colon separator : so the parameters will look as follows: (" &lt;prefix&gt;:&lt;suffix&gt;" ) .</li> <li>To edit an existing directive, select it in the list and change the values in the text boxes below. To restore the original definition, click the Reset to defaults button  .</li> <li>- Remove directive(s) (-) click this button to remove the selected directive from the list.</li> <li>- Reset to defaults (🔄) click this button to restore the original definition of the selected directive.</li> </ul> |
|------------|---|

Name	In this text box, specify the name of a new directive or edit the name of the selected one.
------	---

Has parameter	<p>Select this check bo to specify a prefix and a suffix for a new directive or for the one selected in the list. When the checkbox is selected, the Prefix and Suffix text boxes are available for editing. Specify the required directive parameters. If the new directives requires a prefix and a suffix, select the Has parameter checkbox and type the prefix and suffix to use in the Prefix and Suffix text boxes respectively. IntelliJ IDEA will automatically enclose the prefix and suffix in opening and closing brackets and quotes and add a colon separator : so the parameters will look as follows: (" &lt;prefix&gt;:&lt;suffix&gt;" ) .</p>
---------------	---

Ctrl+Alt+S

In this dialog box, activate and configure the support of the **Google App Engine for PHP** in an existing IntelliJ IDEA project. For more details, see [Preparing to Develop a Google App for PHP Application](#).

---

#### ItemDescription

- 
- |  |   |
|--|---|
| Enable Google App Engine for PHP support | <ul style="list-style-type: none"><li>– When this checkbox is selected, IntelliJ IDEA provides assistance in developing PHP applications intended for running in the <a href="#">Google PHP Runtime Environment</a>. This support includes coding assistance and the possibility to run and debug such PHP applications on the local Google development server.</li><li>– When the checkbox is cleared, no assistance in developing PHP applications for running in the Google runtime environment is provided and all the controls on the page are disabled.</li></ul> |
| SDK directory                            | In this field, specify the folder where the <b>Google App Engine for PHP</b> SDK is stored.   |
| Python executable                        | In this field, specify the path to the <b>Python</b> executable file, version 2.7 is required.  |
| App Engine Account Settings              | In this area, choose the way to authenticate to the development server, the available options are: <ul style="list-style-type: none"><li>– Use passwordless login via OAuth2: choose this option to use the <a href="#">OAuth 2.0 protocol</a>. To save the <b>token</b> achieved through the <a href="#">Google Developers Console</a>, clear the Do not save token checkbox.</li><li>– Log in with email and password: choose this option to use your <b>Gmail</b> address and password.</li></ul>  |

Ctrl+Alt+S

The page is available only when the PHP plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Use this dialog box to specify the delimiters to enclose [Smarty](#) tags in.

#### ItemDescription

Smarty left delimiter	In this text box, specify the desired opening delimiter. By default, the field shows the opening curly brace <code>{</code> .
Smarty right delimiter	In this text box, specify the desired closing delimiter. By default, the field shows the closing curly brace <code>}</code> .
Use Smarty 3 whitespace policy	When this checkbox is selected, delimiters followed by whitespace will not be parsed as template tags. The checkbox is available when <a href="#">Smarty 3.0</a> or higher is used.

Ctrl+Alt+S

#### ItemDescription

Enable Dart support in project <project name>	<ul style="list-style-type: none"><li>– When this checkbox is selected, IntelliJ IDEA provides assistance in coding, testing, running, and debugging Dart applications and enables you to configure the Dart SDK and the Dartium browser.</li><li>– When the checkbox is cleared, no assistance in developing Dart applications is provided and all the controls on the page are disabled.</li></ul>
Dart SDK Path	In this text box, specify the location of the downloaded Dart SDK . Type the path manually or click  and choose the path in the dialog box that opens. If IntelliJ IDEA recognizes the Dart SDK correctly, its revision number is displayed in the Version read-only field.
Version	In this read-only field, IntelliJ IDEA shows the revision number of the detected Dart SDK , provided that the SDK is recognized correctly.
Check SDK update	<p>When this checkbox is selected, IntelliJ IDEA checks whether the specified above version of SDK is the latest one. If a newer version of SDK is available, IntelliJ IDEA displays a pane at the top of the active editor informing you that a newer SDK version has been released. Do one of the following:</p> <ul style="list-style-type: none"><li>– Click the Download SDK link and download it from the site.</li><li>– If you have already downloaded the latest SDK version, click the Dart Settings link to switch to the Dart page of the Settings dialog box and specify the new SDK location.</li></ul> <p>From the drop-down list, choose the release types of SDK to look in, the available options are:</p> <ul style="list-style-type: none"><li>– Stable channel</li><li>– Stable and Dev channels</li></ul>
Dartium Path	In this text box, specify the location of the Dartium executable (Windows and Linux)/Dartium application (macOS). Type the path manually or click  and choose the path in the dialog box that opens. Learn more about Dart web tools from the the <a href="#">Dart Official website</a> ,

Ctrl+Alt+S

### On this page

- Integrate installations of Web browsers with IntelliJ IDEA, activate or deactivate launching Web browsers from IntelliJ IDEA .
- Specify whether a browser will be launched by running its executable file or through the default system command .
- Appoint the **default IntelliJ IDEA browser** in which IntelliJ IDEA will **open HTML and JSP files** upon request by default, that is, when no browser is specified explicitly .

## Browsers

In this section, specify which browsers will be available for previewing HTML or JSP output. The section shows a **predefined list of browsers** , possibly extended with previously configured **custom browser installations** . Each browser is presented as a separate table row.

IntelliJ IDEA is shipped with a predefined list of most popular browsers which you may like to install and use. The items are added to the list in advanced and are not based on the information on actually installed browsers. IntelliJ IDEA presumes that you install browsers according to a standard procedure. Based on this assumption, each browser in this predefined list is assigned an **alias** which stands for the path to its executable file, as IntelliJ IDEA supposes it to be. If in your actual browser installation the path to the executable file is different, you need to specify it explicitly in the Path field.

In addition to the predefined browsers, you can configure as many custom browser installations as you need using the controls on the toolbar.

### ColumnDescription

Active	Select this checkbox to enable the use the respective browser from IntelliJ IDEA. The browser will be added to the context menu of the Open in Browse menu item and its icon will be displayed in the Browsers pop-up toolbar. If this checkbox is cleared, the corresponding browser icon will not appear in the icons toolbar or pop-up menu.
Name	In this column, specify the browser name.
Family	In this column, specify the family to which the browser belongs.
Path	In this column, specify the path to the executable. If the browser was installed according to a standard installation procedure, most likely the <b>alias</b> shown in the Path field points at the right location of the executable file. To specify the path explicitly, click  in the Path field and choose the actual location of the executable file in the dialog box that opens. In the <a href="#">dialog that opens</a> , choose the path to the executable file of the corresponding browser.

## Toolbar

### ItemDescription

	Click this button to add a custom browser to the list.
	Click this button to delete the selected customer browser from the list. Note that you cannot delete the browsers from the predefined list.
	Click this button to specify a custom profile for <b>Firefox</b> or a browser of the <b>Chrome</b> family. The button is available only when Firefox and Chrome are selected. In the Firefox Settings dialog box, specify the <a href="#">Firefox browser profile</a> to use for previewing output: <ul style="list-style-type: none"> <li>– Path to "profiles.ini" : in this text box, specify the location of the <code>profiles.ini</code> file, which determines the Firefox profile to be used.</li> <li>– Profile : from this drop-down list, select the desired predefined profile to use. Learn more at <a href="#">Firefox browser profile</a> .</li> </ul> In the Chrome Settings dialog box: <ul style="list-style-type: none"> <li>– Command line options : In this text box, enter the command line options to launch an instance of Chrome. If you need more space, click  , or press <code>Shift+Enter</code> to open the editor box. Learn more about Chrome command line options by opening <code>chrome://flags</code> in <b>Chrome</b> .</li> <li>– Use custom profile directory : Select this checkbox to define a user-specific Chrome profile to use and specify the location of the <code>chrome-user-data</code> directory, which determines the Chrome profile to be used. Learn more about Chrome profiles at <a href="#">Multi-profiles</a> .</li> </ul>
	Use these buttons to move the selected browser up or down in the list. The order of browsers is important for rendering external resources and previewing files with Web contents.
	Click this button to create a copy of the selected browser.

## Default Browser

In this section, specify the **default IntelliJ IDEA browser** that will be used by default for rendering external resources and previewing files with Web contents. This browser will be referred to as Default in the context menu when you choose View | Open in Browser on the main menu or Open in Browser on the context menu of a file.

### ItemDescription

Default browser	Select the default browser from the drop-down list. The possible options are: <ul style="list-style-type: none"> <li>– System default : Select this option to accept your operating system default Web browser as default for IntelliJ</li> </ul>
-----------------	---

#### IDEA

- First listed : Select this option to have IntelliJ IDEA launch the first browser in the list. Change the order of browsers using the  and  icons on the toolbar.
- Custom path : Select this option to specify another Web browser as default for IntelliJ IDEA. Type the path to the executable file of the browser or click  and select the path in the dialog box that opens.

---

Show browser  
popup in the  
editor

- If this checkbox is selected, the popup window with the enabled browsers appears in the HTML or JSP files.
- If this checkbox is not selected, this popup window does not show up, thus helping you read or edit code.

Ctrl+Alt+S 

The page is available when the **File Watchers** plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

IntelliJ IDEA integrates with various third-party [compilers](#) that run in the background and translate Less, Sass, SCSS, and Stylus into CSS, or CoffeeScript into JavaScript, as well as compress JavaScript and CSS.

To use a compiler in IntelliJ IDEA, you need to configure it as a **File Watcher**. For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template.

The output of a File Watcher is stored in a separate file. Each predefined template suggests the type of the output file depending on the compiler type. By default the output file is created in the same folder as the input file when the File Watcher is invoked for the first time, after that this file is only updated. However, in the Project tree view, the output file is shown under the original file which is shown as a node. This is done to improve visibility so you can easier locate necessary files.

File watchers have two dedicated **code inspections**:

- The **File watcher available** inspection is runs in every file where a predefined File Watcher is applicable. If the project has no relevant File Watcher configured, IntelliJ IDEA suggests to add one.
- The **File watcher problems** inspection is invoked by a running File Watcher and highlights errors specific for it.

Use this page to create project File Watchers based on predefined IntelliJ IDEA File Watcher templates. The page consists of two parts:

- A list of **File Watchers** available in the current project. To activate a **File Watcher**, select the check box next to it. If an error occurs while a **File Watcher** is running, the **File Watcher** is automatically disabled.
- A toolbar to manage this list.

#### ItemTooltip/ Description

	and shortcut	
	Add 	Click this button to open the Choose template pop-up list and choose the relevant type of <b>File Watcher</b> . After that IntelliJ IDEA opens the <a href="#">New Watcher</a> dialog box for customizing the predefined <b>File Watcher</b> according to the settings of the current project.
	Edit 	Click this button to update the settings of the selected <b>File Watcher</b> in the <a href="#">Edit Watcher</a> dialog box. The update is applied to the current project <b>File Watcher</b> only, it does not affect the predefined IntelliJ IDEA-level template.
	Remove 	Click this button to remove the selected <b>File Watcher</b> . The <b>File Watcher</b> is no longer applied to the files in the current project. Note that this action does not affect the corresponding predefined template which is still available at the IntelliJ IDEA level.
	Up(  )  Down (  )	Use these buttons to change the order of <b>File Watcher</b> in the list. This determines the order of launching <b>File Watchers</b> , if more than one are enabled.
	Copy	Use this button to create a copy of the selected file watcher.
	Import	Click this button to import an existing file watcher and add it to the list of available file watchers.
	Export	Click this button to export the selected watchers to <code>watchers.xml</code> file, located under the user's home.

Ctrl+Alt+S 

The dialog opens when you click the Add  or Edit  button on the [File Watchers page](#). Use the dialog box to create a project File Watcher based on a predefined IntelliJ IDEA File Watcher template or to edit an existing project File Watcher.

Each template contains the settings that are optimal for the selected compiler. So in most cases, all you need is specify the path to the compiler executable.

## Name

**Name** In this text box, type the name of the File Watcher. By default, IntelliJ IDEA suggests the name of the selected predefined template.

## Files to watch

**Tip** By default, the field shows the file type in accordance with the chosen predefined template.

**Tip** See [Scope](#) for details.

**Tip** This option is available only for Babel, Closure Compiler, Compass, Jade, Less, Sass / SCSS, Stylus, UglifyJS, and YUI Compressor JS.

**File type** Use this drop-down list to specify the expected type of input files. The File Watcher will consider only files of this type as subject for analyzing and processing. File types are recognised based on [associations between file types and file extensions](#).

**Scope** Use this drop-down list to define the range of files the File Watcher can be applied to. Changes in these files will invoke the File Watcher either immediately or upon save or frame deactivation, depending on the status of the Auto-save edited files to trigger the watcher checkbox. Choose one of the predefined scopes from the drop-down list or click  and configure a custom scope in the Scopes dialog that opens.

**Track only root files** When the File Watcher is invoked in a file, IntelliJ IDEA detects all the files where it is included. For each of the detected files, in its turn, IntelliJ IDEA again detects the containing files. This operation is repeated recursively until IntelliJ IDEA reaches the files that are not included anywhere [within the specified scope](#). These files are referred to as root files (do not confuse with content roots).

- When this checkbox is selected, the File Watcher runs only against the root files.
- When the checkbox is cleared, the File Watcher runs against the file from which it is invoked and against all the files in which this file is included recursively within the specified scope.

Note that the Scope setting overrides the Track only root files checkbox setting: if a dependency is outside the specified scope, the File Watcher is not applied to it.

## Tool to run on changes

**Tip** `.jar` archives are also acceptable but defining `PATH` variables for them is not supported.

**Tip** When specifying the arguments, follow these rules:

- Use spaces as separators.
- If an argument contains spaces, enclose them or the entire argument in double quotes: `some "arg"` Or `"some arg"`.
- If an argument contains double quotes, use backslashes to escape them: `-Dmy.prop="quoted_value"`.

In this area, configure interaction with the compiler: specify the executable file to use, the arguments to pass to it, and customize the default template settings for input and output.

**Program** In this text box, specify the path to the executable file of the compiler (`.exe`, `.cmd`, `.bat`, or other depending on the specific tool.) Type the path in the text box, or click  and choose the path in the dialog that opens, click Insert Macro button and select the relevant macro from the list in the [Macros](#) dialog.

**Arguments** In this text box, define the arguments to pass to the compiler and thus influence its behaviour. Among other cases, use this text box to change the default output location, that is, specify a custom location where you want the compiler to store the files generated during compilation. Note that if you re-define the default output location here you need to clear the Create output file from stdout checkbox in the Advanced Options area because otherwise the content of your generated file will be overwritten by the compiler's output stream.

**Output paths to refresh** In this text box, specify the files where the compiler stores its output: the resulting source code, source maps, and dependencies. In other words, tell IntelliJ IDEA where it should search for the files generated through compilation.

Please note, that changing the value in this text box does not make the compiler store its output in another location. To do that, specify the desired output location in the Arguments text box: type the output paths using colons as separators or click the Insert Macro button to open the [Macros](#) dialog box and select the desired pattern from the list.

## Working Directory and Environment Variables

**Tip** If you leave the field empty, IntelliJ IDEA uses the directory of the file where the File Watcher is invoked.

**Working directory** In this text box, specify the directory to which the compiler will be applied. Because the tool is always invoked in the context of a file, the default working directory is the directory of the current file. The default working directory is specified in all predefined templates through a `$FileDir$` macros. To specify a custom working directory, type the path to it in the text box, or click  and choose the directory in the Select Path dialog box, or click Insert Macro and select the desired macro from the list in the [Macros](#) dialog box.

**Environment variables** Use this text box to specify a the `PATH` variable for a tool that is required for starting the compiler but is not referenced in the path to it.

## Advanced Options

**Tip** Some compilers generate a `standard output stream (stdout)` file, others do not, which may lead to errors. Therefore it is strongly recommended that you preserve the default setting.

**Auto-save edited files to trigger the watcher**

- When this checkbox is selected, IntelliJ IDEA immediately saves a file as soon as you edit it so the File Watcher wakes up immediately.
- When the checkbox is cleared, the File Watcher starts upon save ( `File | Save All` ) or when you move the focus from IntelliJ IDEA (upon frame deactivation).

**Trigger watcher regardless of syntax errors**

- When the checkbox is selected, the File Watcher start regardless of the syntactical correctness of a file. The File Watcher will start upon update, save, or frame deactivation, depending on the status of the Auto-save edited files to trigger the watcher checkbox.
- When this checkbox is cleared, the File Watcher ignores all triggers in files that are syntactically invalid and starts only in error-free files.

**Create output file from stdout**

- When this checkbox is selected, IntelliJ IDEA reads the native compiler output ( `standard output stream (stdout)` ) and generates the resulting files from it.
- When the checkbox is cleared, the compiler writes its output directly to the files specified in the Output paths to refresh field.

**Show console**

From this drop-down list, choose when you want the File Watcher to open the console.

- Always: with this option, the console opens when the File Watcher starts.
- Error: with this option, the File Watcher opens the console only if any errors occur during compilation.
- Never: choose this option to suppress opening the console at all.

**Output Filters**

Click this button to open the [Output Filters dialog](#) where you can manage the list of filters to distinguish the output of the File Watcher from other output. These filters make the basis for:

1. Displaying paths to the File Watcher output files as links in error and other messages and logs. When you click such link, the corresponding file is opened in the editor. For example, to get useful error messages displayed, specify the following expression in the Regular expression to match output field of the [Add/Edit Filter Dialog](#) :

```
$FILE_PATH$: $LINE$ $MESSAGE$
```

2. Error highlighting in the output files.

## Examples of customizing the behaviour of a compiler

Any compiler is an external, third-party tool. Therefore the only way to influence a compiler is pass arguments to it just as if you were working in the command line mode. These arguments are specific for each tool. Below are two examples of customizing the default output location for the [CoffeeScript compiler](#) .

Suppose, you have a project with the following folder structure:

By default, the generated files will be stored in the folder where the original file is. You can change this default location and have the generated files stored in the `js` folder. Moreover, you can have them stored in a flat list or arranged in the folder structure that repeats the original structure under the `app` node.

– To have all the generated files stored in the output `js` folder without retaining the original folder structure under the `app` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir$\js\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir$\js\${FileNameWithoutExtension}.js:$ProjectFileDir$\js\${FileNameWithoutExtension}.map
```

As a result, the project tree looks as follows:

- To have the original folder structure under the `app` node retained in the output `js` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir$\js\${FileDirRelativeToProjectRoot}\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir$\js\${FileDirRelativeToProjectRoot}\${FileNameWithoutExtension}.js:$ProjectFileDir$\js
```

As a result, the project tree looks as follows:

Ctrl+Alt+S 

Define third-party standalone applications (code generators and analyzers, pre- and post-processors, database utilities, etc.) as external tools to be able to run them from IntelliJ IDEA.

You can pass contextual information (like the currently selected file, or your project source path) to the external tools, view the tool output, and more.

The tools defined on this page appear as commands in the Tools menu and in various context menus. They can also be assigned keyboard shortcuts (see the [Configuring Keyboards and Mouse Shortcuts](#) section).

## Toolbar icons

### IconDescription

	Add a definition of an external tool. (The <a href="#">Create Tool dialog</a> will open.)
	If an individual tool is selected: delete the tool definition. If a tool group is selected: delete the definitions of all the tools within the selected group.
	Edit the definition of the selected tool. (The <a href="#">Edit Tool dialog</a> will open.)
	Move the selected tool one line up or down within the group. (The order of tools defines the order of items in corresponding menus.)
	Create a copy of the selected definition and then edit that copy. (The <a href="#">Copy Tool dialog</a> will open.)

## Checkboxes

Use the checkboxes to enable or disable the tools and the tool groups. The items that are not currently selected are not available in the Tools and context menus.

Edit the settings for your external tool.

#### ItemDescription

Name	The name of the tool that appears as a command name in the Tools menu and the context menus. See also, <a href="#">Show in</a> .
Group	The group the tool belongs to. The tool groups correspond to submenus in the Tools menu and the context menus. Select an existing group from the list or type the name for a new group.
Description	The tool description (optional).
Options	
Synchronize files after execution	Make IntelliJ IDEA aware of changes in the file system when the tool completes its execution.
Open console	Open the console for viewing the tool output such error messages, etc.
Output Filters	Open the <a href="#">Output Filters dialog</a> to manage the output filters associated with the tool. (The output filters are used to turn absolute file paths and line numbers in the tool output into hyperlinks. You'll be able to use those links to open the corresponding files in the editor.)
Show console when a message is printed to standard output stream	Make the output console active and bring it forward when the corresponding event occurs.
Show console when a message is printed to standard error stream	The same as the previous option but for stderr.
Show in	Specify in which menus the command for running the tool should be included. Main menu means the Tools menu. The rest of the options correspond to context menus in various places.
Tool settings	
Program	The path to the executable file to be run. Use  to select the file, Insert macro to open the <a href="#">Macros dialog</a> to select a macro. (Macros are resolved at runtime and let you specify context information such as currently selected file, your project source paths, etc.)
Parameters	The parameters to be passed to the program the way you'd specify them on the command line. Use Insert macro to open the <a href="#">Macros dialog</a> to select a macro. When specifying the parameters, follow these rules: <ul style="list-style-type: none"><li>– Use spaces to separate individual parameters.</li><li>– If a parameter includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg"</code> or <code>"some arg"</code> .</li><li>– If a parameter includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li></ul>
Working directory	The path to the current working directory for the program. Use  to select the directory, Insert macro to open the <a href="#">Macros dialog</a> to select a macro.

---

Specify the filter for transferring absolute file paths and line numbers in the tool output into hyperlinks.

#### ItemDescription

Name	The name of the filter.
Description	The filter description (optional).
Regular expression to match output	<p>The text pattern to be matched against the tool output to identify linkable references. The pattern can include text and the following placeholder variables:</p> <ul style="list-style-type: none"><li>- <code>\$FILE_PATH\$</code> - the portion of the output that corresponds to an absolute path to a source file. Required.</li><li>- <code>\$LINE\$</code> - a line number reference.</li><li>- <code>\$COLUMN\$</code> - a column reference.</li></ul>

The variables are inserted by right-clicking the field and then selecting the necessary item from the list that is shown.

#### Example

If your tool outputs the lines similar to

```
Error parsing C:\Demos\src\converter\MetersToInches.xml:103 Missing Closing Tag
```

the pattern `$FILE_PATH$:LINE$` will turn `C:\Demos\src\converter\MetersToInches.xml:103` into a hyperlink to the line number `103` in the file `MetersToInches.xml` .

From the [Create/Edit/Copy Tool dialog](#) : Output Filters

---

This dialog lets you manage the output filters associated with an external tool. (The output filters are used to turn absolute file paths and line numbers in the tool output into hyperlinks.)

---

**ItemDescription**

---

-  Create a new filter. (The [Add Filter dialog](#) will open.)

---

-  Delete the selected filter.

---

-  Edit the selected filter. (The [Edit Filter dialog](#) will open.)

---

-  Move the selected filter one line up or down in the list. (For each line in the output, the first matching filter is used.)

From the [Create/Edit/Copy Tool dialog](#) : Insert macro

---

Select the macro to be inserted.

**ItemDescription**

---

Macros	The list of available macros with their descriptions.
Macro preview	The value of the selected macro in the current context.

Ctrl+Alt+S 

While the default shell in IntelliJ IDEA's terminal (`Alt+F12`) works fine, many developers prefer to use their favorite shell. For example, Windows users may want to use **PowerShell** or **Cmder**, Linux and macOS users may want to use **zsh** instead of the default terminal shell. On this settings page, you can customize which shell will be used in the terminal.

**Tip** IntelliJ IDEA implements the terminal functionality with a bundled plugin, which can be completely disabled by clearing the Terminal check box on the the Plugins page of IntelliJ IDEA settings (`Ctrl+Alt+S`).

#### ItemDescription

Start directory	Specify the working directory where the terminal will be launched.
Shell path	Specify the shell that will run by default. Here are some values for different shells: <ul style="list-style-type: none"> <li>- PowerShell: <code>powershell</code></li> <li>- Cmder: <code>"cmd" /k ""\vendor\init.bat"</code> (note the <code>CMDER_ROOT</code> environment variable has to be set)</li> <li>- Cygwin: <code>"C:\cygwin\bin\bash.exe" --login -i</code></li> <li>- Zsh: <code>/bin/zsh</code></li> <li>- Bash: <code>/bin/bash</code> (or bash for Windows: <code>bash.exe</code>)</li> </ul>
Tab name	Specify the default name of a new session tab. Note that a session tab can be renamed.
Audible bell	If this option is selected, the console plays the bell sound on incoming escape sequence.
Close session when it ends	If this option is selected, the current session ends automatically when the corresponding process ends (for example, by kill).
Mouse reporting	If this option is selected, the embedded local terminal supports the mouse pointer.
Copy to clipboard on selection	If this option is selected, the text selected in the Terminal is automatically copied to clipboard.
Paste on middle mouse button click	If this option is selected, you can paste clipboard contents by clicking the middle mouse button.
Override IDE shortcuts	If this option is selected, the Terminal tool window handles keyboard shortcuts differently from IntelliJ IDEA. If this checkbox is cleared, the IntelliJ IDEA key bindings are used.
Shell integration	If this option is selected, the terminal first loads a custom <code>.rc</code> config file (located in the <code>terminal</code> folder under <code>plugins</code> of IntelliJ IDEA distribution) which provides an additional set-up, and then the user's <code>.rc</code> file. <p><b>Note</b> Note that presently shell integration works for Bash/sh (<code>bashrc</code>), zsh (<code>zshrc</code>) and fish shell (<code>config.fish</code>).</p>

Ctrl+Alt+S

This page is available only when the **Command Line Tool Support** plugin is installed and enabled as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

IntelliJ IDEA supports running commands of popular third-party or user-defined PHP tools: [Symfony 1.1+](#), [Symfony2](#), [Zend Framework 1](#), [Zend Framework 2 \(ZFTool\)](#), [Yii](#), [Composer](#), [Drush 5.8+](#), [Laravel](#) and [Doctrine](#) (Symfony console-based), [WordPress Command Line Interface](#).

The page shows a list of all PHP-specific and custom command line tools integrated with IntelliJ IDEA. Tools with inconsistencies in the `.xml` descriptor are marked with

**Tip** PHP-specific command line tools work only with [local PHP interpreters](#).

#### ItemTooltip Description and shortcut

Enabled		When the checkbox in this column is selected, the commands defined within the corresponding command line tool can be executed from IntelliJ IDEA.
Alias		In this text box, specify the character string to use in command calls instead of the full path to the tool. For example, by default, IntelliJ IDEA assigns the following aliases: <code>s</code> for Symfony, <code>zf</code> for Zend Framework, and <code>c</code> for Composer.
Tool Path		In this text box, specify the location of the tool's executable file.
Type		This read-only field shows the official name of the third party command line tool. The column is available only if the Show tool type checkbox is selected. For custom command line tools, the fields in this column are empty.
Show tool type		If this checkbox is selected, the Type column is added to the table of available tools.
Show console in		In this area, specify where you want to enter commands. The available options are: <ul style="list-style-type: none"> <li>– Pop-up - choose this option to have the Command Line Tools Input pane opened in a separate pop-up window and type commands there.</li> <li>– Tool window - choose this option to enter commands in the Input field in the bottom of the dedicated <a href="#">Command Line Tools Console</a> tool window.</li> </ul>
Console encoding		From this drop-down list, choose the character set to show the tool's output in the <a href="#">Command Line Tools Console Tool Window</a> .
	Add	Click this button to open the Command Line Tools dialog box and select the tool to integrate with IntelliJ IDEA. Depending on your choice, IntelliJ IDEA opens one of the following dialog boxes for specifying the location of the selected tool: <ul style="list-style-type: none"> <li>– <a href="#">Command Line Tool Support: Symfony</a></li> <li>– <a href="#">Command Line Tool Support: Zend Framework 1</a></li> <li>– <a href="#">Command Line Tool Support: Composer</a></li> <li>– <a href="#">Command Line Tool Support: Tool Settings</a></li> <li>– <a href="#">Command Line Tool Support: Drush</a></li> <li>– <a href="#">Command Line Tool Support: Zend Framework 2</a></li> <li>– <a href="#">Command Line Tool Support: WP-CLI</a></li> </ul>
	Remove	Click this button remove the selected tool from the list.
	Edit	Click this button to change the definition file of the selected tool.
	Reload command list from executable	Click this button to refresh the list of commands of the selected tool.
	Open definition in editor	Click this button to open the <code>.xml</code> file with commands of the selected tool in the editor.

---

The dialog box opens when you click the Add button and choose Symfony in the Choose Tool to Add dialog box.

Use the dialog box to configure [Symfony](#) support in IntelliJ IDEA.

#### ItemDescription

---

Path to Symfony	<p>In this text box, specify the location of the Symfony executable file:</p> <ul style="list-style-type: none"><li>- <code>&lt;symfony_home&gt;/data/bin/symfony</code> for Symfony 1.2.</li><li>- <code>&lt;symfony_home&gt;/data/bin/symfony.bar</code> for Symfony 1.4.</li><li>- <code>&lt;symfony_home&gt;/app/console</code> for Symfony 2.</li></ul> <p>IntelliJ IDEA parses the contents of the specified file for Symfony commands.</p>
Path to PHP executable	Specify the location of the PHP interpreter to use.
Symfony component version	From this list, choose the version to use.

**Tip** The tool works only with [local PHP interpreters](#) .

The dialog box opens when you click the Add button and choose Zend Framework 1 Tool in the Choose Tool to Add dialog box.

Use the dialog box to configure [Zend Framework](#) support in IntelliJ IDEA.

#### ItemDescription

---

Path to zf tool	In this text box, specify the location of the <code>&lt;Zend-Framework-home&gt;/zf.bat</code> file. IntelliJ IDEA parses the contents of the specified file for Zend Framework commands.
-----------------	--

Ctrl+Alt+S

The dialog box opens when you click the Add button and choose Composer in the Choose Tool to Add dialog box.

In this dialog box, enable the use of [Composer Dependency Manager](#) in the command line mode by specifying the way to launch Composer and appointing the file to look for Composer commands in.

**Note** For this functionality to be available, you need to install the [Command Line Tool Support](#) plugin from the [Plugins Repository](#).

IntelliJ IDEA parses the contents of the specified `.phar` archive or executable file for Composer commands. When the file analyses is completed, IntelliJ IDEA returns to the *Command Line Tools Support* page where the specified file is added to the list of command line tools available in IntelliJ IDEA.

Integration with Composer is provided at the IntelliJ IDEA level, so once configured, the tool can be used in all your IntelliJ IDEA projects. Just activate or de-activate it when necessary depending on you needs.

#### ItemDescription

**Composer.phar or PHP script** Choose this option to launch **Composer** through a PHP script or have IntelliJ IDEA detect and start the launcher in the `composer.phar` archive. In this mode, IntelliJ IDEA provides coding assistance and allows you to execute scripts.

- Path to PHP executable: In this field, specify the location of the PHP engine installation folder.
- Path to composer.phar or composer: In this text box, specify the location of the `composer.phar` archive.

**Composer executable** Choose this option to launch Composer through the `composer` executable file. In this mode, you do not get coding assistance and cannot execute scripts because no PHP engine is appointed for it.

In the Path to executable field, specify the location of the `composer` executable file.

**Tip** The tool works only with [local PHP interpreters](#).

The dialog is available only when the **Command Line Tool Support** plugin is installed and enabled as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

---

The dialog box opens when you click **+** on the **Command Line Tool Support** and choose Custom Tool in the Choose Tool to Add dialog box.

---

**ItemDescription**

Tool Name	Specify the name of your custom tool.
Tool path	Specify the location of the tool definition <code>.xml</code> file. See <a href="#">How do I define my own command line tool?</a> .
Alias	Type the character string to use in command calls instead of the full path to the tool.
Description	Provide a brief explanation of the tool functionality.

Ctrl+Alt+S

The dialog box opens when you click the Add button and choose Drush in the Choose Tool to Add dialog box. Use the dialog box to configure **Drush** support in IntelliJ IDEA.

**Drush** is a command line shell and scripting interface for [Drupal](#). With IntelliJ IDEA, you can use **Drush 5.8** and higher. For more details, see [Drupal](#).

#### ItemDescription

**Path to Drush** In this text box, specify the path to the **Drush** executable file. IntelliJ IDEA automatically fills in the default location, which is usually `C:/ProgramData/Drush/drush.bat` on Windows and `/usr/bin/drush` on Mac OS or Linux. If you followed the standard installation procedure, the predefined path will be correct, just click OK, whereupon IntelliJ IDEA loads command definitions automatically and returns to the Command Line Tool Support page.

---

The dialog box opens when you click the Add button and choose Zend Framework 2 Tool in the Choose Tool to Add dialog box.

Use the dialog box to configure [Zend Framework](#) support in IntelliJ IDEA.

#### ItemDescription

---

Path to zf.php or zftool.phar	In this text box, specify the location of the <code>&lt;Zend-Framework-home&gt;/zf.php</code> or <code>&lt;Zend-Framework-home&gt;/zf.php</code> file or the path to the <code>zftool.phar</code> archive. IntelliJ IDEA parses the contents of the specified file for Zend Framework commands.
-------------------------------	---

---

PHP Interpreter	Choose one of the configured PHP interpreters from the list in the Execution area. See <a href="#">Configuring Remote PHP Interpreters</a> for details.
-----------------	---

**Tip** The tool works only with [local PHP interpreters](#).

---

The dialog box opens when you click the Add button and choose Composer in the Choose Tool to Add dialog box.

In this dialog box, enable the use of [WordPress Content Management System](#) in the command line mode by specifying the way to launch WordPress .

#### ItemDescription

---

Installed via PHAR	Choose this option to launch WordPress through a PHP script or have IntelliJ IDEA detect and start the launcher in the <code>wp-cli.phar</code> archive. <ul style="list-style-type: none"><li>– PHP Interpreter: choose one of the configured PHP interpreters from the list in the Execution area. .</li><li>– Path to phar: In this text box, specify the location of the <code>wp-cli.phar</code> archive.</li></ul>
--------------------	--

---

Executable available (installed via Composer, etc.)	Choose this option to launch WordPress through an executable file which is available when you install WordPress using a package management tool, for example, Composer.
---	---

---

Path to wp.bat	In this field, specify the location of the <code>wp.bat</code> or <code>wp</code> executable file. If you used Composer, the default location is <code>\vendor\wp\cli\bin\wp</code> or <code>\vendor\wp\cli\bin\wp.bat</code> . Type the path manually or click the Browse button  and choose the desired location in the dialog box that opens.
----------------	---

**Tip** The tool works only with [local PHP interpreters](#) .

From the [database](#) , [Hibernate](#) and [JPA](#) consoles: 

From the [data editor](#) :  | Settings

The Database and subordinate pages contain the settings related to working with databases and SQL.

There are the following groups of settings on the Database page:

- [Console](#)
- [Execute in Console](#)
- [Quick Documentation](#)
- [DDL editor](#)

Other pages in the Database section:

- [Data Views](#)
- [User Parameters](#)
- [CSV Formats](#)

See also:

- [SQL Dialects](#)
- [SQL Resolution Scopes](#)

## Console

The settings in this section relate to showing various information in [database consoles](#) .

### ItemDescription

**Show query results in new tab** You can select to view query results on individual tabs, or on one and the same tab. If the checkbox is selected, a new tab with the query result will open each time you run a query ( `SELECT` ). In this way, you can keep the results of all the queries that you have run.

If this checkbox is not selected, the same tab is used to show your query results. When you run a query, the information on the tab is updated to show the result, and a new tab doesn't open.

In this case, when you get the result that you want to keep, you can pin the tab to the tool window ( on the toolbar or Pin Tab in the context menu for the tab).

**Show error notifications in editor** If this checkbox is not selected, the information about the errors is shown only in the output pane. If, in addition, you want the error notification bar to appear in the input pane, select the checkbox. The error notification bar may be particularly useful when running sequences of SQL statements. If an error occurs in such cases, the error notification bar lets you select how to react.

For more information, see [Using the error notification bar](#) .

**Always review parameters before execution** When you run a statement with parameters, IntelliJ IDEA memorizes the parameter values. Each next time you execute the statement:

- If this option is on, IntelliJ IDEA shows you the last used parameter values so that you can change them before

actually running the statement.

- If this option is off, IntelliJ IDEA executes the statement right away without showing you the parameter values.

**Track creation and deletion of databases/schemas** When you create a new schema or database, or delete a schema or database (see e.g. [Creating a database or schema](#)):

- If this option is on, the new schema or database is shown in the Database tool window right away. Deleted schemas and databases are immediately removed from the Schemas popup in the Database tool window and from the list on the Schemas tab in the Data Sources and Drivers dialog.
- If this option is off, the new schema or database isn't shown unless you visualize it manually, see [Showing and hiding schemas](#). Deleted schemas and databases that were selected for viewing will stay in the corresponding lists unless deselected.

## Execute in Console

This section contains the options for the Execute command. You can assign up to three different execute configurations, each with its own behavior and shortcut.

### ItemDescription

**When inside a statement execute** If the cursor is inside a statement, the following options are available:

- Ask what to execute. A list of statements that can be run is shown and you can select the statement or statements.

- Smallest statement. The smallest of the possible statements is executed. For example, when the cursor is inside a subquery, the subquery is executed.
- Largest statement. The largest possible statement is executed. For example, when the cursor is inside a subquery, an outer statement is executed.
- Largest statement or batch. For Transact-SQL (SQL Server and Sybase), the current batch of statements is executed. For all other dialects - the same as the previous option.
- Whole script. All the statements are executed.

**otherwise execute** If the cursor is outside of a statement, e.g. on a blank line or within a comment, the following options are available:

- Nothing. None of the statements is executed.
- Whole script. All the statements are executed.
- Everything below caret. All the statements after the cursor position are executed.

**for selection execute** If something is currently selected, the following options are available:

- Exactly as one statement. Exactly what is selected is executed as a single statement.
- Exactly as statements. Exactly what is selected is executed. If the selection contains more than one statement, the statements are executed as separate statements.
- Smart expand to script. If there is at least one statement border within the selection, the selection is expanded to form a sequence of valid statements. This sequence is then executed. Otherwise, precisely what is selected is executed.

## Quick Documentation

This section contains the settings for the quick documentation view, see [Viewing basic info about an item](#).

### ItemDescription

**Show first rows** When showing quick documentation for a table, include data for a number of first rows.

**Number of preview rows** The number of rows to be shown for a table in the quick documentation view.

## DDL editor

### ItemDescription

**Show confirmation on close** When trying to close the Add Database, the Add Schema or the [Create / Modify Table dialog](#) by clicking Cancel or pressing `Escape`:

- If this option is on, you are asked for a confirmation.
- Otherwise, the dialog closes right away.

The settings on this page define how table data are shown and modified in your [database](#) , [Hibernate](#) and [JPA](#) consoles, and [data editors](#) .

### ItemDescription

**Result set page size** The number of table rows to be shown at a time, on one "page". Here is an example when this number is set to 2:

	id	name	symbol	notes
1	1	Hydrogen	H	Lightest element on the periodic table&Most abundant...
2	2	Helium	He	Second most abundant element in the observable univer...

If you don't want to limit the number of rows displayed simultaneously, specify zero (0).

**Result set prefetch size** Data from databases are retrieved in chunks. The number in this field defines the number of rows in such chunks. A bigger number means fewer IDE - DB round trips but more memory for storing a chunk.

**Filter history size** The number of most recently used filtering conditions to memorize for a table in a data editor. Here is an example when this number is set to 2. (The filter history box contains two most recently used conditions.)

	id	name	symbol	notes
2	2	Helium	He	Second most abundant element in th...
3	3	Lithium	Li	Soft, silver-white metal&Never occ...
3	3	Lithium	Li	Soft, silver-white metal&Never occ...

**Max LOB length (bytes)** The maximum size of a binary large object to be loaded in bytes.

**Data Modification / Submit changes immediately** When this option is off, the changes you make to data in a table are accumulated in IntelliJ IDEA unless you carry out the Submit command (  on the toolbar, Submit in the context menu or `Ctrl+Enter` ). Before you submit the changes, you can revert them ( Revert in the context menu or `Ctrl+Z` ). When this option is on, the changes are submitted right away.

See [Submitting and reverting changes](#) .

Generally, only the question mark ( ? ) is treated as a parameter in SQL statements. On this page, you can specify which other characters and their sequences should be treated as parameters, and in which places.

The patterns for SQL parameters are specified by means of regular expressions.

#### ItemDescription

**Enable in console and SQL files** If the checkbox is selected, the parameter patterns are applied to SQL (in SQL files and database consoles). The usage scope, if necessary, may be limited at the level of [individual patterns](#).  
If this checkbox is not selected, the patterns are not used in SQL files and consoles irrespective of which usage scope is specified for individual patterns.

**Enable in string literals with SQL injection** If the checkbox is selected, the parameter patterns are applied to string literals [injected](#) with SQL. The usage scope, if necessary, may be limited at the level of [individual patterns](#).  
If this checkbox is not selected, the patterns are not used in string literals irrespective of which usage scope is specified for individual patterns.

**Parameter patterns** The table shows the parameter patterns and their usage scopes. The patterns are specified using regular expressions. Values in parentheses are treated as parameter names. The patterns available initially have the following meanings:

- `\d+` - a question mark followed by one or more digits, e.g. `?69` in which case `69` would be the parameter name.
- `:(\w+)` - a colon followed by one or more word characters, e.g. `:x`, `:value`, `:parameter_1`.
- `%w+` - `%` followed by one or more word characters, e.g. `%xyz`.
- `\${[^\$\\]*}` - `$`, then `{`, then any character except `$`, `{` or `}` zero or more times, then `}`, e.g. `$( )`, `$(value)`.
- `\${([^\^]+)}` - `$`, then `(`, then any character except `)` one or more times, then `)`, e.g. `$(x)`.
- `\$(\w+)\$` - `$`, then one or more word characters, then `$` again, e.g. `$x1$`.
- `\#(\w+)\#` - `#`, then one or more word characters, then `#` again, e.g. `#field_3#`.

Use **+** ( `Alt+Insert` ), **-** ( `Alt+Delete` ), **↑** ( `Alt+Up` ) and **↓** ( `Alt+Down` ) to add, delete and reorder the patterns.

To edit a pattern or its usage scope, click the pattern and use the following controls:

- In scripts. Clear this checkbox if the pattern shouldn't be used in SQL files and database consoles.
- In literals. Clear this checkbox if the pattern shouldn't be used in string literals injected with SQL.
- All (the link text may be different). Click the link and deselect the languages in which the pattern shouldn't be used.

This page contains the settings for converting table data into delimiter-separated values formats (e.g. CSV, TSV) and vice versa.

When working on the conversion settings, use the preview in the right-hand part of the page.

#### ItemDescription

Formats	<p>The list of the available delimiter-separated values formats is shown. Each format is a named set of corresponding conversion settings. Select the format whose settings you want to view or edit.</p> <p>Use , ,  and  to create, delete and reorder the formats;  to create a copy of the selected format.</p>
Value separator	Select or type the character for separating individual values.
Row separator	Select or type the character for separating rows.
Null value text	The text to be used as a value if a cell contains <code>null</code> (an unknown value).
Add row prefix/suffix	<p>Row prefix and suffix are character sequences which in addition to the row separator indicate the beginning and end of a row.</p> <p>If necessary, click the link and specify the row prefix and suffix in the fields that appear.</p>
Quotation	<p>Each line in the area under Quotation is a quotation pattern (see <a href="#">Quote values</a>). A quotation pattern includes:</p> <ul style="list-style-type: none"> <li>– The left quotation character, the one inserted before a value.</li> <li>– The right quotation character, the one inserted after a value; usually, the same as the left quotation character.</li> <li>– An escape method or character for the cases when the quotation character is part of a value. E.g. Escape: duplicate means that if a quotation character occurs within a value, it is doubled. (You can specify your own escape character instead.)</li> </ul> <p>If there is more than one pattern, the first of the patterns is used.</p> <p>Use , ,  and  to create, delete and reorder the patterns.</p> <p>To start editing an existing pattern, just click the pattern of interest.</p>
Quote values	<p>Specify in which cases the values should be quoted (i.e. enclosed within quotation characters).</p> <ul style="list-style-type: none"> <li>– When needed. A value is quoted only if it contains the value and/or the row separator.</li> <li>– Always. Any value is quoted in its text representation.</li> </ul>
Trim whitespaces	If this checkbox is not selected, the Unicode whitespace characters that precede and follow the value separators are treated as parts of the corresponding values. If this checkbox is selected, the corresponding whitespace characters are ignored or removed.
First row is header	If this checkbox is selected, the first row is treated as containing column names. The settings that appear under Header Format have the same meanings as the ones above but are applied to the first row.
First column is header	If this checkbox is selected, the first column is treated as containing row names.

Use this dialog box to appoint the a remote Web server or a Vagrant instance (virtual machine) to access through the SSH terminal, configure connection with the destination environment, and choose the encoding to use in the SSH terminal.

Make sure the **SSH Remote Run** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

---

#### ItemDescription

Connection settings	<p>In this section, appoint the a remote Web server or a Vagrant instance (virtual machine) to access through the SSH terminal and specify where the connection settings should be taken from:</p> <ol style="list-style-type: none"><li>1. Current Vagrant: select this option to have the commands in the SSH Terminal executed on the currently running Vagrant virtual machine. For details, see <a href="#">Vagrant</a> .</li><li>2. Deployment server: select this option to have the commands in the SSH Terminal executed on the local or remote Web server accessible through one of the <a href="#">server access configurations</a> . From the drop-down list, choose the server access configuration that specifies the destination environment and the settings to establish connection to it.<ul style="list-style-type: none"><li>– Select server on every run: if this option is selected, you will have to choose the desired server access configuration from the pop-up window, every time you choose Tools   Start SSH Session on the main menu.</li><li>– If the desired server access configuration does not appear in the drop-down list, click the link <a href="#">Configure Servers</a> , and define one in the <a href="#">Deployment</a> page. For details, see the <a href="#">Configuring Synchronization with a Remote Host</a> section.</li></ul></li></ol>
Default encoding	<p>From this drop-down list, select the desired encoding to be used in the SSH terminal.</p>

Ctrl+Alt+S

Use this page to configure the default visibility settings and layout for diagrams.

On this page:

– [Content pane](#)

– [Controls](#)

## Content pane

Select the checkboxes next to the elements to be shown on diagrams.

### ItemDescription

#### Show Difference

**Details** If this checkbox is selected, all the specified details of the elements will be shown in the UML class diagram for a revision. If this checkbox is not selected, only node elements will be included in diagram.

#### Java Class Diagrams

**Class Elements** Select the checkboxes to show members (fields, constructors, methods, properties and inner classes) within the node elements:

In diagram, use toolbar buttons , , , , and .

**Dependencies** Select the checkboxes below to show dependency links in diagram.

#### DB Diagrams

**Key columns** For the primary key columns to be shown when a diagram opens, select this checkbox. When viewing a diagram in the editor, use  on the toolbar to show or hide the corresponding columns.

**Columns** For the columns other than the primary key columns to be shown when a diagram opens, select this checkbox. When viewing a diagram in the editor, use  on the toolbar to show or hide the corresponding columns.

#### Project Modules

**Libraries** If this checkbox is selected, libraries will be shown in UML diagrams for modules.

#### ActionScript/Flex

**Class Elements** Select the checkboxes below to show members (fields, constructors, methods, and properties) within the node elements. In diagram, use toolbar buttons , , , and .

#### JPA ER Diagram

**Properties** If this checkbox is selected, properties of entity classes are shown when a JPA ER diagram opens. When viewing a diagram in the editor, you can show or hide these properties by using  on the toolbar.

**Embeddables** If this checkbox is selected, embeddable objects are shown when a JPA ER diagram opens. When viewing a diagram in the editor, you can show or hide the embeddables by using  on the toolbar.

**Superclasses** If this checkbox is selected, superclasses of entity classes are shown when a JPA ER diagram opens. When viewing a diagram in the editor, you can show or hide the superclasses by using  on the toolbar.

#### EJB ER Diagram

**Properties** If this checkbox is selected, properties of entity beans are shown when an EJB ER diagram opens. When viewing a diagram in the editor, you can show or hide these properties by using  on the toolbar.

**Embeddables** If this checkbox is selected, embeddable objects are shown when an EJB ER diagram opens. When viewing a diagram in the editor, you can show or hide the embeddables by using  on the toolbar.

**Superclasses** If this checkbox is selected, superclasses of entity beans are shown when an EJB ER diagram opens. When viewing a diagram in the editor, you can show or hide the superclasses by using  on the toolbar.

#### BPMN 2.0 Diagram

**Details** For element details to be shown when a BPMN diagram opens, select this checkbox.

#### CDI Dependencies Diagram

**@Inject** If this checkbox is selected, injection points are shown when a CDI dependency diagram opens. When viewing a diagram in the editor, you can show or hide the injection points by using  on the toolbar.

**@Produces** If this checkbox is selected, producer methods and fields are shown when a CDI dependency diagram opens. When viewing a diagram in the editor, you can show or hide the producer methods and fields by using  on the toolbar.

**@Decorator** If this checkbox is selected, decorator bean classes are shown when a CDI dependency diagram opens. When viewing a diagram in the editor, you can show or hide the decorators by using  on the toolbar.

---

### Spring

**Local context** If this checkbox is selected, local context will be shown in diagrams. To enable showing local context in the Diagram tab in the editor, click  .

**Properties** If this checkbox is selected, property files will be shown in diagrams. To enable showing property files in the Diagram tab in the editor, click  .

---

### Spring Integration

**Show Labels** If this checkbox is selected, labels will be shown in diagrams. To enable showing labels in the Diagram tab in the editor, click  .

---

### Spring Web Flow

**Details** If this checkbox is selected, details will be shown in diagrams.

**Events** If this checkbox is selected, events will be shown in diagrams.

**Sub Flows** If this checkbox is selected, Sub Flows will be shown in diagrams.

**Note** More nodes appear in this pane depending on the installed and enabled plugins.

## Controls

### ItemDescription

**Default layout** Select the desired layout from the drop-down list. Node elements in newly created diagrams will be arranged according to the selected layout.

**Default scope** Select scope from the drop-down list. Specifying a scope helps you avoid showing in diagram the unnecessary hierarchies. You can define scopes for your project in the [Scopes page](#) of the Settings dialog.

**Fit content after layout** If this checkbox is selected, then after applying a layout selected on the diagram context menu, all diagram elements will be resized to fit into the current diagram area. In diagram, use the  toolbar button.

**Do relayout when new elements were added** If this checkbox is selected, diagram layout will be performed automatically after adding new elements.

**Enable colors** If this checkbox is selected, relationship links will be shown colored.

Ctrl+Alt+S 

On this page, specify the default behavior of the [Differences viewer](#) .

#### ItemDescription

---

Diff	
Context lines	Use the slider to specify the amount of context lines that will not collapse, when in a Differences viewer you click the button  to <a href="#">collapse the unchanged fragments</a> .
Go to the next file after reaching last change	If this checkbox is selected, IntelliJ IDEA will suggest to click  /  once more and compare other files
Merge	
Automatically apply non-conflicting changes	If this checkbox is selected, the interactive merge tool automatically merges all non-conflicting changes. This is an equivalent to clicking  in the <a href="#">Merge</a> dialog.
Highlight modified lines in gutter	Select this checkbox if you want added/modified lines (relative to the base revision) to be highlighted in the gutter of the Merge dialog.

Ctrl+Alt+S 

If necessary, specify external tools for comparing files and folders, and associated settings.

#### ItemDescription

Use external diff tool	Select this checkbox to have IntelliJ IDEA use an external tool for comparing files or folders.
Path to executable	<p>In this text box, specify the path to the executable file of the desired external diff tool. Use the Browse button , if necessary.</p> <p>This field is only available, when Use external diff tool checkbox is selected.</p>
Use by default	<p>Select this checkbox to have IntelliJ IDEA use the specified external tool for comparing files or folders by default.</p> <p>If this checkbox is not selected, IntelliJ IDEA will use the built-in diff tool. To invoke an external tool, click the button  on the toolbar of the <a href="#">Differences viewer</a> .</p> <p>This field is only available, when Use external diff tool checkbox is selected.</p>
Parameters	<p>Use this field to set the diff tool parameters.</p> <div style="background-color: #ffff00; padding: 5px;"><p><b>Note</b> Note that different diff tools have different parameters. You need to specify all the necessary parameters in proper order.</p></div> <p>This field is only available, when Use external diff tool checkbox is selected.</p>
Use external merge tool	Select this checkbox to have IntelliJ IDEA use an external merge tool. In the text box below, specify the path to the executable file of the desired external tool. Use the Browse button  , if necessary.
Path to executable	<p>In this text box, specify the path to the executable file of the desired external merge tool.</p> <p>Use the Browse button , if necessary.</p> <p>This field is only available, when Use external merge tool checkbox is selected.</p>
Parameters	<p>Use this field to set the merge tool parameters.</p> <div style="background-color: #ffff00; padding: 5px;"><p><b>Note</b> Note that different merge tools have different parameters. You need to specify all the necessary parameters in proper order.</p></div> <p>This field is only available, when Use external merge tool checkbox is selected.</p>

Ctrl+Alt+S

## Python External Documentation

### ItemDescription

**Module Names** This column shows the names of the modules, whose documentation you want to have visible in browser on invoking View | External Documentation , or pressing **Shift+F1** .

**URL Pattern** This column shows existing patterns of the URLs to the external documentation, or its local address. If external documentation resides locally, specify the local path to it .

Click this button to add to the list a new module and its URL pattern or local address.

Click this button to change the name and/or URL pattern of the selected module.

Double-clicking an entry in the table produces same result.

Delete the selected module from the list.

## Add/Edit Documentation URL

### ItemDescription

**Module name** Type module name in the text field.

**URL pattern** In this text field, create the desired pattern, using plain text and macros from the Available Macros field. Note that documentation can also reside locally.

**Insert** Click this button to add the selected macro to the pattern.

**Warning!** This page only appears when Python Plugin is installed and enabled!

File | Settings | Tools | Python Integrated Tools for Windows and Linux

IntelliJ IDEA | Preferences | Tools | Python Integrated Tools for macOS

Ctrl+Alt+S

Use this page to configure requirements management file, default test runner, and documentation strings treatment.

#### ItemDescription

**Package requirements file** Type the name of the [requirements file](#) , or click the browse button, and select the desired requirements file from file system using the [Select Path](#) dialog.

**Default test runner** Select the test run/debug configuration that IntelliJ IDEA will suggest every time you choose Run on the context menu of a test case.  
The possible options are:

- Unittests
- py.test
- Nostests
- Twisted Trial

**Docstring format** Select the format of the documentation strings to be recognized by IntelliJ IDEA. Depending on the selected docstring format, IntelliJ IDEA will generate the stub documentation comments and render text in the [Quick Documentation](#) lookup:

- **Plain** : on pressing [Enter](#) or Space after opening quotes, an empty stub is generated; quick documentation shows as plain text.
- **reStructuredText** : on pressing [Enter](#) or Space after opening quotes, stub doc comment is generated according to [reStructuredText](#) format; the quick documentation is rendered by Docutils.
- **Epytext** : on pressing [Enter](#) or Space after opening quotes, stub doc comment is generated according to the [epytex](#) format; quick documentation is rendered by [epydoc](#) .
- **NumPy** : on pressing [Enter](#) or Space after opening quotes, stub doc comment is generated according to the [NumPy](#) format; the quick documentation is rendered by [Napoleon](#) and Docutils.
- **Google** : on pressing [Enter](#) or Space after opening quotes, stub doc comment is generated according to [Google](#) format; the quick documentation is rendered by [Napoleon](#) and Docutils.

All types of docstrings feature:

- Proper generation of docstrings
- Updates after applying intention actions and quick-fixes
- Coding assistance
- Autocompletion for section headers

Note that the information provided in the docstrings, is used for code insight.

**Analyze Python code in docstrings** If this checkbox is selected, IntelliJ IDEA highlights the code examples and performs syntax checks and code inspections.

If this checkbox is not selected, the code fragments inside docstrings are not analyzed.

**Sphinx working directory** Specify here the path to the directory that contains `*.rst` files.

**Note** For recognizing custom roles, point to the directory with `conf.py` .

**Treat \*.txt files as reStructuredText** If this checkbox is selected, the files with `*.txt` extension will be highlighted same way, as the files with `*.rst` extension.

Ctrl+Alt+S 

Define remote applications that require SSH access as external tools to be able to run them from IntelliJ IDEA.

You can pass contextual information (like the currently selected file, or your project source path) to the external tools, view the tool output, and more.

The tools defined on this page appear as commands in the Tools menu and in various context menus. They can also be assigned keyboard shortcuts (see the [Configuring Keyboards and Mouse Shortcuts](#) section).

## Toolbar icons

### IconDescription

	Add a definition of an external tool. (The <a href="#">Create Tool dialog</a> will open.)
	If an individual tool is selected: delete the tool definition. If a tool group is selected: delete the definitions of all the tools within the selected group.
	Edit the definition of the selected tool. (The <a href="#">Edit Tool dialog</a> will open.)
	Move the selected tool one line up or down within the group. (The order of tools defines the order of items in corresponding menus.)
	Create a copy of the selected definition and then edit that copy. (The <a href="#">Copy Tool dialog</a> will open.)

## Checkboxes

Use the checkboxes to enable or disable the tools and the tool groups. The items that are not currently selected are not available in the Tools and context menus.

Edit the settings for your external tool.

#### ItemDescription

Name	The name of the tool that appears as a command name in the Tools menu and the context menus. See also, <a href="#">Show in</a> .
Group	The group the tool belongs to. The tool groups correspond to submenus in the Tools menu and the context menus. Select an existing group from the list or type the name for a new group.
Description	The tool description (optional).
Options	
Synchronize files after execution	Make IntelliJ IDEA aware of changes in the file system when the tool completes its execution.
Open console	Open the console for viewing the tool output such error messages, etc.
Output Filters	Open the <a href="#">Output Filters dialog</a> to manage the output filters associated with the tool. (The output filters are used to turn absolute file paths and line numbers in the tool output into hyperlinks. You'll be able to use those links to open the corresponding files in the editor.)
Show console when a message is printed to standard output stream	Make the output console active and bring it forward when the corresponding event occurs.
Show console when a message is printed to standard error stream	The same as the previous option but for stderr.
Show in	Specify in which menus the command for running the tool should be included. Main menu means the Tools menu. The rest of the options correspond to context menus in various places.
Connection settings	In this section, appoint the to access through the SSH terminal and specify where the connection settings should be taken from: <ol style="list-style-type: none"> <li>1. Current Vagrant: select this option to have the commands in the SSH Terminal executed on the currently running Vagrant virtual machine. For details, see <a href="#">Vagrant</a> .</li> <li>2. Deployment server: select this option to have the commands in the SSH Terminal executed on the local or remote Web server accessible through one of the <a href="#">server access configurations</a> . From the drop-down list, choose the server access configuration that specifies the destination environment and the settings to establish connection to it. <ul style="list-style-type: none"> <li>– Select server on every run: if this option is selected, you will have to choose the desired server access configuration from the pop-up window, every time you choose Tools   Start SSH Session on the main menu.</li> <li>– If the desired server access configuration does not appear in the drop-down list, click the link <a href="#">Configure Servers</a> , and define one in the <a href="#">Deployment</a> page. For details, see the <a href="#">Configuring Synchronization with a Remote Host</a> section.</li> </ul> </li> </ol>
Tool settings	
Program	The path to the executable file to be run. Use  to select the file, Insert macro to open the <a href="#">Macros dialog</a> to select a macro. (Macros are resolved at runtime and let you specify context information such as currently selected file, your project source paths, etc.)
Parameters	The parameters to be passed to the program the way you'd specify them on the command line. Use Insert macro to open the <a href="#">Macros dialog</a> to select a macro. When specifying the parameters, follow these rules: <ul style="list-style-type: none"> <li>– Use spaces to separate individual parameters.</li> <li>– If a parameter includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg" Or "some arg"</code> .</li> <li>– If a parameter includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li> </ul>
Working directory	The path to the current working directory for the program. Use  to select the directory, Insert macro to open the <a href="#">Macros dialog</a> to select a macro.

Ctrl+Alt+S 

IntelliJ IDEA provides its own storage for trusted certificates. Use this page to manage this storage.

#### ItemShortcutDescription

Accept non-trusted certificates automatically	Select this option if you want non-trusted certificates (i.e. the certificates that are not added to the list) to be accepted automatically, without sending a request to the server.
	<p> Add a trusted server certificate to the list. Select the certificate file in the <a href="#">dialog that opens</a>.</p> <p>The certificate file should have an extension <code>.crt</code>, <code>.cer</code> or <code>.pem</code>.</p> <p>For a trusted certificate, the certificate information is shown in the lower part of the page.</p>
	<p> Remove the selected trusted certificate from the list.</p>

Ctrl+Alt+S 

This page appears in the Settings/Preferences dialog, when the Settings Repository plugin is enabled.

The plugin is bundled with IntelliJ IDEA and is activated by default. If it is disabled, you can manually [enable the plugin](#).

Use this page to configure the **Settings Repository** feature that allows you to share your IDE settings between different instances of IntelliJ IDEA (or other IntelliJ platform-based) products installed on different computers.

**Tip** The settings you are going to share must be stored in a Git repository.

#### ItemDescription

**Auto Sync** Select this checkbox, if you want your local settings to be automatically synchronized with the settings stored in the repository every time you perform an Update Project or a Push operation, or when you close your project or exit IntelliJ IDEA.  
If this option is disabled, you can manually update your settings by choosing VCS | Sync Settings from the main menu.

**Read-only sources** Use this section to configure additional repositories containing any types of settings you want to share, including live templates, file templates, schemes, deployment options, etc.  
These repositories cannot be overwritten or merged, just used as a source of settings as is.

Use the following controls to manage the read-only repositories:

 Click this button to add the URL of the GitHub repository that contains the settings you want to share.

 Click this button to remove the selected repository from the list.

 Click this button to edit the URL of the selected source.

 Use these buttons to move up/down in the list.

 Click this button to clone the selected URL.

Ctrl+Alt+S 

On this page, create a list of run/debug configurations to be launched automatically on the project start. This may be helpful if you run some **Grunt** or **Gulp.js** tasks or **npm scripts** on a regular basis. All you need is just add the run/debug configurations that launch such tasks or scripts to the list of **startup tasks**.

**ItemTooltipDescription**

Run Configuration	This read-only field shows the names of the run configurations to be launched on the project start.
Shared	<p>When this checkbox is selected, the corresponding task is available for other team members. Note that you can share only those run configurations that are already marked as shared in their definitions.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p>
+	<p><b>Add</b> Click this button to add one of the run/debug configurations that are currently defined in the project to the list of tasks to be executed on the project start. Choose the relevant configurations from the list or choose Edit Configurations to open the <a href="#">Run/Debug Configurations Dialog</a> dialog and define a required configuration in it.</p>
-	<p><b>Remove</b> Click this button to delete the selected task from the list.</p>
	<p><b>Edit</b> Click this button to open the <a href="#">Run/Debug Configurations Dialog</a> dialog with the settings from the selected configuration and update them as required.</p>

This feature is only supported in the Ultimate edition.

File | Settings | Vagrant for Windows and Linux

IntelliJ IDEA | Preferences | Vagrant for macOS

Ctrl+Alt+S

On this page, enable [Vagrant](#) support in IntelliJ IDEA, specify the location of the `VagrantFile`, and handle the list of `Vagrant` base boxes to use in creation of virtual boxes (instances).

Before you start working with `Vagrant`, make sure that:

1. [Vagrant](#) is downloaded and installed.
2. Install and enable the Vagrant plugin as described in the sections [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

**Vagrant executable** Specify the fully qualified address of the executable file: `vagrant.bat` for Windows, `vagrant` for Unix and macOS. Type the path manually, or click the browse button and locate the desired file in the [Select vagrant executable](#) dialog box.

**Instance folder** Specify here the fully qualified path to the directory, where the task `vagrant init` has been executed, and the `VagrantFile` is initialized and stored.  
A `VagrantFile` is a configuration file that defines the instance (virtual machine) you need. The file contains the virtual IP address, port mappings, and the memory size to assign. The file can specify which folders are shared and which third-party software should be installed. According to the `VagrantFile` your instance (virtual machine) is configured, provisioned against the relevant `Vagrant` base box, and deployed on your computer. A `VagrantFile` is created through the `vagrant init` command.

When creation of an instance (virtual machine) is invoked either through the `vagrant up` command or through the Tools | Vagrant | Up menu option, IntelliJ IDEA looks for the `VagrantFile` in the directory specified in the Instance folder field. For more information, see <http://docs.vagrantup.com/v2/vagrantfile/>.

You can create a `VagrantFile` in any directory and appoint it as instance folder. If the field is empty, IntelliJ IDEA will treat the project root as the instance folder and look for a `VagrantFile` in it.

**Provider** Use this field to specify the [provider](#) to be used by `vagrant up` command. If this field is left blank, the default provider is used.

**Environment variable** Click the ellipsis button or press `Shift+Enter` to specify the shell variables to be used to configure the providers' behavior.

#### Boxes and Plugins tabs

**Boxes** This list shows the predefined [Vagrant base boxes](#) available in IntelliJ IDEA. Each item presents a `Vagrant` base box on which Vagrant configures and launches its instances (virtual machines). The entries of this list correspond to the output of the command `vagrant box list`.

 `Alt+Insert` Click this button to download a new base box. This command corresponds to `vagrant box add <name> <URL>`. By default, IntelliJ IDEA suggests the URL to the `lucid32` box

 `Alt+Delete` Click this button to remove the selected `Vagrant` base box. So doing, the box and the nested files are physically deleted from the disk. This command corresponds to `vagrant box remove <name>`

**Plugins** Use this table to view and change the list of available plugins.

 `Alt+Insert` Click this button to install a new Vagrant plugin.

 `Alt+Delete` Click this button to remove the selected plugin.

 Click this button to update the selected plugin.

 Use this button to attach a license to the selected plugin.

This feature is only supported in the Ultimate edition.

File | Settings | Tools | XPath Viewer for Windows and Linux

IntelliJ IDEA | Preferences | Tools | XPath Viewer for macOS

Ctrl+Alt+S

IntelliJ IDEA | Preferences | Tools | XPath Viewer

Ctrl+Alt+S

This page appears if [XPath View+XSLT Support](#) plugin is enabled. In this page, configure the IntelliJ IDEA behaviour during interactive execution of XPath expressions.

#### ItemDescription

Scroll first hit into visible area	Select this checkbox to have the editor automatically scroll to the first XPath match.
Use node at cursor as context node	Select this checkbox to have the entered XPath expression use the currently selected node (tag/attribute/pi, etc.) as its context node and evaluate the expression relatively to this node.
Highlight only start tag instead of whole tag content	Do one of the following: <ul style="list-style-type: none"><li>– Select this checkbox to have only the name of a matching tag highlighted.</li><li>– Clear this checkbox to have the entire content of a matching tag highlighted.</li></ul>
Add error stripe markers for each result	Select this checkbox to have each match supplied with an error stripe marker which can be quickly navigated to. The tooltip of each marker shows the matched content.
Show actions in Toolbar	Select this checkbox to have buttons that invoke XPath -related actions displayed on the <a href="#">Main Toolbar</a> .
Show actions in Main Menu	When this checkbox is selected, XPath -related actions are available from the main menu.
Colors	In this area, configure color indication during execution of XPath expressions. Clicking on the color box will open the <a href="#">Select Color</a> dialog in which you can modify the current color indication. <ul style="list-style-type: none"><li>– Highlight Color - in this area, select the color to indicate XPath matches in the editor.</li><li>– Context Node Color - in this area, select the color to indicate the current context node.</li></ul>

Ctrl+Alt+S

Use this dialog box to specify the default server name and port for generating URL addresses of Web services, as well as the paths to installation directories of Web service engines that cannot be enabled directly via dedicated [facets](#) .

**ItemDescription**

External engines	<p>In this section, specify the paths to the installation directories of external Web service engines. Enter the path manually, or click the Browse button  and select the path in the dialog that opens. The following external engines are supported:</p> <ul style="list-style-type: none"><li>- <a href="#">Glassfish / JAX-WS 2.2 RI / Metro 1.X / JWSRP 2.2</a></li><li>- <a href="#">Apache Axis 2</a></li><li>- <a href="#">CXF</a></li><li>- <a href="#">JBoss</a></li><li>- <a href="#">Xml Beans</a></li><li>- <a href="#">WebSphere 6.x</a></li></ul>
Server name	<p>In this text box, specify the default name of the server to be used in URL addresses. IntelliJ IDEA suggests <code>localhost</code> .</p>
Server port	<p>In this text box, specify the default port number to be used in URL addresses. IntelliJ IDEA suggests <code>8080</code> .</p>
Prefix path for web services URL	<p>In this text box, specify the default prefix to be used in URL addresses of Web services. IntelliJ IDEA suggests <code>/services</code> .</p>
Maximum VM heap size when launching tools (Mb)	<p>In this text box, specify the default maximum heap size in Mbs that will be used when a Web service is launched.</p>

Ctrl+Shift+Alt+S

The Project Structure dialog lets you manage your [project](#) and IDE-level elements such as [modules](#) , [facets](#) , [libraries](#) , [artifacts](#) and [SDKs](#) .

In most of the cases, there are two panes in the left-hand part that implement a two-level selector. The only exception is when you select `Project` . There is only one selector pane in this case.

## Load Paths

Use this tab to specify the path where `require` and `load` statements will look for files. The specified paths will be used in [code completion](#) for `require` and `load` . If the load path is not defined, code completion will suggest only the paths relative to the project root.

Item	Tooltip	Description and shortcut
	Add	Click this button to add a new root to the load path using the <a href="#">Select Path dialog</a> . 
	Remove	Click this button to delete the currently selected root from the load path. 

## i18n Folders

Use this tab to specify the path where IntelliJ IDEA will search for the directories with locales.

If the load path is not defined, code completion will suggest only the paths relative to the project root.

Item	Tooltip	Description and shortcut
Folders with locales		This area displays the directories where locales files reside.
	Add	Click this button to add a new folder with locales. Find the desired folder in the <a href="#">Select Path dialog</a> . 
	Remove	Click this button to delete the selected directories from the list. 

## Category selector

The leftmost pane is for selecting a category. There are two groups of categories in this pane.

The first group ( `Project Settings` ) provides access to the elements of your current project. In the second group ( `Platform Settings` ) are the IDE-level entities that are available in all of your projects.

When you select a category in the leftmost pane, the pane to the right shows a list (or, if appropriate, a tree) of elements belonging to this category.

The toolbar icons `Back` and `Forward` are for moving back and forward in the history of selected categories.

## Element selector

The element selector pane lets you manage the elements in the corresponding category.

When you select an element, its settings are shown on a page to the right.

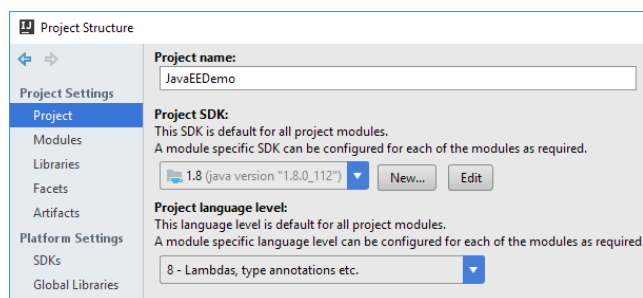

To perform various operations with the elements, use the toolbar icons, context menu commands (accessed by right-clicking an element), or keyboard shortcuts.

The following functions are available for all element types. Complete lists of commands for different element categories (modules, libraries, etc.) are provided in the corresponding sections.

**IconCommandShortcutDescription**

---

	New		Use this icon, command or shortcut to create a new element (module, library, etc.).
	Delete		Use this icon, command or shortcut to delete the selected elements.

Specify the project name, [SDK](#) , language level, and the compiler output path.

#### ItemDescription

**Project name** Use this field to edit the project name.

**Project SDK** Select the [project SDK](#) .  
If the desired SDK is not present in the list, click New and select the necessary [SDK type](#) . Then, in the [dialog that opens](#) , select the SDK home directory and click OK .

To view or edit the name and [contents](#) of the selected SDK, click Edit . (The [SDK page](#) will open.)

**Project language level** Select the Java language level to be supported. The selected level will be used as the project default.

The available options correspond to JDK versions:

- 1.3 - Plain old Java
- 1.4 - 'assert' keyword
- 5.0 - 'enum' keyword, autoboxing, etc.
- 6.0 - @Override in interfaces
- 7.0 - Diamonds, ARM, multi-catch, etc.
- 8.0 - Lambda support, type annotations, etc.

An individual language level may be set for [any of your modules](#) .

Note that if the target level is not explicitly defined (the compiler option `-target` ), it is considered equal to the source language level.

Thus, if `-target` is not explicitly defined, it will be synchronized with the language level.

**Project compiler output** Specify the path to the directory in which IntelliJ IDEA will store the compilation results. Click  to select the directory in the [Select Path dialog](#) .

Two subdirectories in the specified directory will be created:

- `production` for production code.
- `test` for test sources.

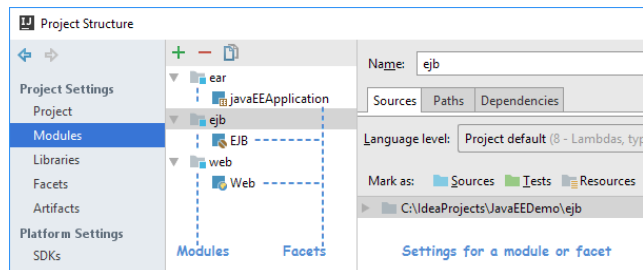

In these subdirectories, individual output directories will be created for each of your modules.

The output paths may be [redefined at the module level](#) .

Ctrl+Shift+Alt+S | Modules

Modules

When you select the Modules category in the Project Structure dialog, a hierarchical view of existing module groups, modules, facets and, for Flash modules, build configurations is shown in the element selector pane. (Facets and build configurations are shown as module elements.)

Use the toolbar icons, context menu commands or keyboard shortcuts to manage the sets of elements shown (see below).

To view or edit the settings for an element (module, facet or build configuration), select the element of interest, and use the page to the right of the selector pane.

In this section:

- [Module Page](#)
- [Facet Page](#)
- [Module Page for a Flash Module](#)
- [Build Configuration Page for a Flash Module](#)

## Toolbar icons, context menu commands and shortcuts

### IconCommandShortcutDescription

	New		Create a new module, facet, or, for a Flash module, a new build configuration.
	Delete		Delete the selected element (module, facet, etc.).
	Copy		Create a copy of the selected module, or, for a Flash module, a copy of a build configuration.
	Find Usages		Find usages of the selected module, facet or build configuration in the project.
	Hide Module Groups		If there are module groups: hide or show the module groups. See <a href="#">Configuring projects</a> .
	Expand All		Expand all the tree nodes to see their contents.
	Collapse All		Collapse all the tree nodes and show only the top-level nodes.
	Move Module to Group		This is an "entry point command" for grouping your modules and working with module groups.

The Module page opens in the right-hand part of the [Project Structure dialog](#) when you select a module in the [element selector pane](#) .

Use the Name field to edit the module name. Other settings are available on the following tabs:

- [Sources Tab](#)
- [Paths Tab](#)
- [Dependencies Tab](#)
- [Plugin Deployment Tab](#)
- [Mobile Module Settings Tab](#)
- [Mobile Build Settings Tab](#)

Use the Sources tab of the [Module page](#) to select the supported language level for Java and to configure the module contents.

The module contents are configured by adding and removing the module [content roots](#) as well as by assigning individual folders (within the content roots) to categories such as sources and test sources, and also by excluding the folders.

- [Language level list](#)
- [The left-hand pane](#)
- [The right-hand pane](#)

## Language level list

### ItemDescription

Language level	Use this list to select the Java language level for the module. The available options correspond to JDK versions. You can select the <a href="#">level set for the project</a> (the option <Use project language level> ) or set an individual level for the module.
----------------	---

## The left-hand pane

The left-hand pane shows a tree of folders for a module [content root](#) . If the module has more than one content root, the structure shown corresponds to the content root selected in the right-hand pane.

The folders belonging to different categories have different icons.

The following table lists the available toolbar buttons (the **Icon** column) and explains their functions (the **Description** column). Note that the corresponding functions can also be accessed as the context menu commands. These are listed in the **Command** column.

Most of the icons/commands work as toggles, and can be used to cancel the corresponding assignment (to make a folder "an ordinary folder").

### IconCommandDescription

	Sources	Use this icon or command to assign the selected folder or folders to the source folder category.
	Tests	Use this icon or command to assign the selected folder or folders to test sources.
	Resources	For Java modules: use this icon or command to assign the selected folder or folders to resources.
	Test Resources	For Java modules: use this icon or command to assign the selected folder or folders to test resources.
	Excluded	Use this icon or command to make the selected folder <a href="#">excluded</a> .
	New Folder	Use this command to create a folder in the selected folder. Specify the name for the new folder in the New Folder dialog that opens.

Exclude files. The files and folders whose names match at least one of the specified patterns are made [excluded](#) .

## The right-hand pane

The right-hand pane shows the module [content roots](#) .

For each content root, a categorized view of the module folders is provided. The categories are the source folders, test source folders, etc.

The "ordinary" folders are not shown in this view.

The individual folders within the categories are identified by their paths. The folder paths are all relative to the module root folder (content root).

The folder paths, functionally, are hyperlinks that let you jump to the corresponding folders in the tree shown in the left-hand pane.

If a module has more than one content root, selecting a content root in the right-hand pane also switches the tree view in the left-hand pane. That is, when you click somewhere within the content root area, the folder structure of this particular content root is shown in the left-hand pane.

The following table lists the controls available in the right-hand pane (icons) and describes their functions.

### IconTooltipDescription

	Add Content Root	Use this icon to add a content root. Select the folder to be added as a content root in the <a href="#">dialog that opens</a> .
	Remove Content	Use this icon to remove the corresponding content root from the list of the content roots.

## Entry

---

-  **Edit** Available in Java modules for folders marked as containing sources or resources.
- properties** Use this icon to open the Edit Root Properties dialog in which you can specify:
- A package prefix for the selected source folder.  
Specifying the package prefix (e.g. `com.mycompany.myapp`) eliminates the necessity to create the corresponding folder structure (e.g. `com/mycompany/myapp`). For more information, see [Configuring projects](#).
  - An output path for the selected resource folder. See [Configuring projects](#).
  - Whether the folder contains generated sources or resources (the For generated sources or For generated resources checkbox).
- 
-  **Unmark** Use this icon to remove the folder from the corresponding category. As a result, the folder becomes "an ordinary folder", that is, not belonging to any specific category.

Use the Paths tab of the [Module page](#) to configure the compiler output paths for the module, and also to specify the locations of external JavaDocs and external annotations associated with the module.

- [Compiler output](#)
- [JavaDoc](#)
- [External Annotations](#)

## Compiler output

### ItemDescription

---

Inherit project compile output path    Select this option to use the [paths specified for the project](#) .

---

Use module compile output path    Select this option if you want to set the compiler output paths for this module individually. Specify the associated settings:

- Output path. Specify the directory for the production classes. Use  (  ) to select the directory in the [Select Output Path dialog](#) .
- Test output path. Specify the directory for the test classes. Use  (  ) to select the directory in the [Select Test Output Path dialog](#) .
- Exclude output paths. Select this checkbox to make the output directories [Configuring projects](#) .

## JavaDoc

Use the available controls to compose the list of locations where external JavaDocs associated with the module are stored.

### IconShortcutDescription

---

     Use this icon or shortcut to add a JavaDoc file to the list.

---

     Use this icon or shortcut to remove the selected item from the list.

---

    Use this icon to add a URL of online JavaDoc.

## External Annotations

Use  and  to manage the list of locations (directories) for [external annotations](#) associated with the module.

### IconShortcutDescription

---

     Use this icon or shortcut to add a directory to the list.

---

     Use this icon or shortcut to remove the selected item from the list.

On this tab, you can define the module SDK and form the list of [module dependencies](#) .

- [Main settings and controls](#)
- [Context menu commands for dependency items](#)
- [Sorting the list of dependencies](#)

## Main settings and controls

### ItemDescription

**Module SDK** Select the module [SDK](#) . (To associate the project SDK with the module, select Project SDK . Note that if you change the project SDK later, the module SDK will change accordingly.)  
If the desired SDK is not present in the list, click New and select the necessary [SDK type](#) . Then, in the [dialog that opens](#) , select the SDK home directory and click OK .  
  
To view or edit the name and [contents](#) of the selected SDK, click Edit . (The [SDK page](#) will open.)

**List of dependencies** Shown below the module SDK is the list of [module dependencies](#) . Use [+](#), [-](#), [↑](#) and [↓](#) to add, remove and reorder the items ([libraries](#) and modules). Use the cells in the header row to sort the list, see [Sorting the list of dependencies](#) .  
When you compile or run your code, the list of dependencies is used to form the [classpath](#) for the compiler or JVM. (Native Library Locations, if any, are added to `java.library.path` rather than the classpath.)

Scope. This setting lets you control the classpath separately for your [Configuring projects](#) and [test sources](#) , and for the build and the run phases. (The classpath may be different when 1) your sources are compiled 2) your test sources are compiled 3) your compiled sources are run 4) your tests are run. The Scope option defines the classpaths in which the dependency is to be included.)

Select the necessary option from the list:

- **Compile.** The dependency is included in the classpath for your sources and test sources at the compilation and run phases.
- **Test.** The dependency is included in the classpath only for your test sources at the compilation and run phases.
- **Runtime.** The dependency is included in the classpath for your sources and test sources but only at the run phase.
- **Provided.** For your sources, the dependency is included in the classpath only at the compilation phase. This is useful when there is a container (e.g. a [web container](#) of an application server) that provides the corresponding dependency at runtime.  
For your test sources, the dependency is included in the classpath both at the build and run phases.

[Application server libraries](#) , normally, are included in dependency lists with the scope Provided.

The following table summarizes the classpath information for the possible dependency scopes.

Scope	Sources, when compiled	Sources, when run	Tests, when compiled	Tests, when run
Compile	+	+	+	+
Test	-	-	+	+
Runtime	-	+	-	+
Provided	+	-	+	+

Note that IntelliJ IDEA is different from some other build tools (e.g. Gradle and Maven) in the way it processes dependencies for test sources. If your module (module A) depends on another module (module B), IntelliJ IDEA assumes that the test sources in the module A depend not only on the sources in the module B but also on its test sources. Consequently, the test sources of B are also included in the corresponding classpaths.

**Export.** This option lets you control the compilation classpath for the modules that depend on this one.

Select the checkbox if you want the item to be exported as a dependency along with the module. That is, if there is a module that depends on this one, the items with the Export option on will be included in the compilation classpath of the dependent module.

Note that this setting doesn't affect the runtime classpath. At runtime, all the dependencies of the current module are included in the classpath for the modules that depend on this module.

Also note that the dependency scopes may change when exported. For example:

- A module A depends on a module B, and the scope of this dependency is Compile.
- B depends on a library L, and the scope of this dependency is Test.

If L has the Export option on, then the scope of the dependency of A on L will effectively be Test.

This and also some other interesting practical cases are listed in the following table.

A on B dependency, specified scope	B on L dependency, specified scope	A on L dependency, resulting scope
Compile	Compile	Compile
Compile	Test	Test
Test	Compile	Test
Test	Test	Test

Controls for working with the dependencies

- + ( **Alt+Insert** ). Use this icon or shortcut to add a [library](#) or a module to the list of the module dependencies. Select one of the following options:
  - Jars or directories. Select this option to create a new module library and add it to the list of dependencies. In the [dialog that opens](#) , select the files and folders to be included in the library. These may be individual `.class` and `.java` files, directories and archives ( `.jar` and `.zip` ) containing such files as well as directories with Java native libraries ( `.dll` , `.so` or `.jnlib` ).
  - Library. Select this option to add one or more of the existing project, global or application server libraries to the list of dependencies. In the dialog that opens, select the library or libraries and click **Add Selected** .
  - Module Dependency. Select this option to specify the modules that the current module should depend on.
- ( **Alt+Delete** ). Use this icon or shortcut to remove the selected item or items from the list of dependencies.
- ↑ ( **Alt+Up** ) and ↓ ( **Alt+Down** ). Use these icons and shortcuts to move the selected item up or down in the list. See [Configuring projects](#) .
- 🔍 ( **F4** ). Use this icon or shortcut to open the [Configure Library dialog](#) to edit the library.

**Dependency storage format** Select the format for storing the dependencies (as an IntelliJ IDEA module, or as Eclipse project). This option is helpful for the teams that use different development tools.

## Context menu commands for dependency items

Item	Description
Edit	For a library: use this command to edit the selected library. (The <a href="#">Configure Library dialog</a> will open.)
Remove	Use this command to remove the selected item or items from the list of dependencies.
Navigate ( <b>F4</b> )	Use this command or shortcut to see details for the selected item. An appropriate page of the Project Structure dialog will open, if any.
Find Usages	Use this command to see the list of modules where the selected dependency is used. Clicking a module in that list, opens the <a href="#">Module Page</a> for the corresponding module.
Analyze This Dependency	Use this command to perform a dependency analysis for the selected item and display the results in the <a href="#">Dependency Viewer</a> .
Move to Project Libraries or Move to Global Libraries	For a module library: Use this command to move the selected library to a higher <a href="#">level</a> (project or global).
Copy to Module Libraries	For a global or project library: Use this command to create a copy of the selected library at the module <a href="#">level</a> .

## Sorting the list of dependencies

You can sort the dependencies by their names and scopes by clicking the cells in the header row.

If you click a cell once, the list is sorted by the corresponding column in the ascending order. The sorting marker appears in the cell: ▲ . When you click the cell for the second time, the information is sorted in the descending order. To show this, the sorting marker changes its appearance: ▼ . Finally, when you click the cell for the third time, the initial unsorted state is resorted.

Note that the sorting operations don't change the actual order of dependencies.

When the list is sorted, the icons for changing the order of dependencies are inactive.

Use the Plugin Deployment tab of the [Module page](#) to specify the settings related to deploying your plugin.

Note that this tab is available for Plugin modules only, see [Plugin Development Guidelines](#) .

#### ItemDescription

---

Path to META-INF\plugin.xml Specify the path to the directory in which the directory `META-INF` with the file `plugin.xml` inside should be located. Use  ( `Shift+Enter` ) to select the directory in the [Select META-INF Directory Location dialog](#) . `plugin.xml` is a plugin descriptor that contains general information about the plugin. This information includes the plugin name, description and version, the lowest IntelliJ IDEA build number with which it works as well as descriptions of the component and actions.

IntelliJ IDEA needs this file to be able to load the plugin.

`plugin.xml` should be located in the directory with the name `META-INF` .

---

Use user manifest Select this checkbox if you want a custom manifest file to be included in the plugin distribution. Specify the path to the file. Use  ( `Shift+Enter` ) to select the file in the [Select manifest.mf dialog](#) .

Note that this tab is available for J2ME modules only. The settings depend on the Java Mobile toolkit (SDK) being used, see [J2ME](#) .

– [Settings for Java Wireless Toolkit \(WTK\)](#)

– [Settings for DoJa](#)

## Settings for Java Wireless Toolkit (WTK)

### ItemDescription

MIDlet-Name	In this text box, specify the MIDlet suite name (corresponds to the JAD MIDlet-Name property). This option is necessary to identify MIDlet suite on a device.
MIDlet-JAR-URL	In this text box, specify the MIDlet JAR location. This option is also necessary to identify MIDlet suite on a device. The JAR file will be installed from the location MIDlet-JAR-URL afterward. You can specify the location manually, or click the ellipsis button and select the necessary location in the <a href="#">dialog that opens</a> .
MIDlet-Vendor	In this text box, specify the MIDlet vendor name, that is, the MIDlet suite provider.
MIDlet-Version	In this text box, specify your MIDlet version number.
Optional Settings	Click this button to open the <a href="#">Optional MIDP Settings</a> dialog box where you can set additional options that are not generally required.
Defined MIDlets	<p>In this area, define the MIDlets to form your MIDlet suite. A defined MIDlet contains the following information:</p> <ul style="list-style-type: none"><li>– The MIDlet name under which the MIDlet will be presented to the user.</li><li>– The icon to indicate the MIDlet (optional).</li><li>– The name of the class that implements the MIDlet and that will be called by the application manager to load the MIDlet.</li></ul> <p>Use the buttons Add , Edit and Remove to create, update, and delete MIDlet definitions.</p> <p>Use the buttons Move Up and Move Down to change the order of MIDlets. This order determines the order in which the MIDlets are invoked.</p>
Keep user defined JAD file	Select this checkbox to create the JAD file with the settings specified above.

## Settings for DoJa

### ItemDescription

AppName	In this text box, type the application name (50 bytes maximum).
PackageUrl	In this text box, specify the URL address to access the application. Make sure the URL is an ASCII-format string. Also, an IP address cannot be specified directly.
AppClass	In this text box, specify the application main class name (255 bytes maximum). This should be a subclass name of <code>com.nttdocomo.ui.IApplication</code> .
Optional Settings	Click this button to open the <a href="#">Optional MIDP Settings</a> dialog box where you can set additional options that are not generally required.
Keep user defined JAM file	Select this checkbox to create the <code>JAM</code> file with settings specified above.

The dialog box opens when you click the Optional Settings button on [Mobile SDK Specific Options](#) page of the [New Project From Scratch](#) Wizard.

Use this dialog box to specify additional options that are not generally required. The contents of the dialog box depend on the mobile development tool used:

- [Java Wireless Toolkit \(WTK\)](#) .
- [DoJa](#) .

## WTK

### ItemDescription

MIDlet-Description	In this text box, provide a description of your MIDlet suite.
MIDlet-Icon	In this text box, specify the location of the MIDlet suite presentation <code>.png</code> file within the <code>.jar</code> .
MIDlet-Data-Size	In this text box, type the minimum number of bytes of persistent data required by the MIDlet.
MIDlet-Info-URL	In this text box, specify the URL to access more information about the MIDlet suite and/or the vendor.
MIDlet-Delete-Confirm	In this text box, type the message to be shown when the user is prompted to confirm deletion of the MIDlet suite.
MIDlet-Install-Notify	In this text box, specify the URL to send <code>POST</code> request to confirm successful installation of this MIDlet suite.
User Defined Settings	In this area, compose a list of user-defined attributes related to specific MIDlets. For each attribute, specify a key and a value . Use the Add and Remove buttons to manage the contents of the list. Use the Move Up and Move Up buttons to define the order of settings. This order determines the priority in which the settings are applied.

## DoJa

### ItemDescription

AppVersion	In this text box, specify the application version (10 bytes maximum).
ConfigurationVer	In this text box, specify the J2ME configuration version, for example, <code>CLDC-1.0</code> .
ProfileVer	In this text box, specify the version of the i-mode Java Application runtime environment profile, for example, <code>DoJa-1.5oe</code> .
SPsize	In this text box, specify the size of the ScratchPad in bytes.
AppParam	In this text box, specify the parameters of the main class (255 bytes maximum).
UseNetwork	In this text box, specify <code>http</code> for applications that use network functionality.
TargetDevice	Specify here a model name if the application is targeted to a particular model(128 bytes maximum). Do not set this option for applications targeted to all models.
LaunchAt	To have your application launched automatically at the specific time, specify the required time in this text box.
AppTrace	Choose the On value to have some information output using <code>System.out.println()</code> or <code>System.err.println()</code> after the i-Appli is terminated.
DrawArea	In this text box, specify the size of the application drawing area, for example, <code>120x130</code> .
GetUtn	When this option is selected, the application refers to the handset identification code and IC chip information on its SIM or UIM card.

Note that this tab is available for J2ME modules only.

#### ItemDescription

JAR File	In this text box, specify the location of the <code>JAR</code> file that will contain all the MIDlet classes in the suite, the Java classes shared between MIDlets, and the resource files.
JAD/JAM File	In this text box, specify the location of the <code>JAD</code> or <code>JAM</code> file (depending on the SDK used). This file contains a predefined set of attributes (such as <code>MIDlet-Name</code> , <code>MIDlet-JAR-URL</code> , etc.) according to which the device application management software identifies, retrieves, and installs your application.
Use user manifest	Select this checkbox to have the <code>JAR</code> file supplied with a custom manifest file. If this case, the <code>MIDlet-Name</code> , <code>MIDlet-Version</code> , and <code>MIDlet-Vendor</code> should have the same values in both the <code>JAD</code> and the manifest files, otherwise the application manager will fail to load the <code>JAR</code> file.
Setup mobile exploded directory	Select this checkbox, to have a copy of the mobile module package as a separate folder and specify the location of this folder in the text box below. <div style="background-color: #ffff00; padding: 5px;"><b>Tip</b> For WTK, you can set the exploded directory as the directory where the emulator takes applications. This means that it should correspond to the <code>WTK_Installation_Dir/apps/Project_Name/bin/</code> directory.</div>
Exclude from module content	Select this option to have IntelliJ IDEA exclude the replicated package from the module contents.
Create Mobile Resources Directory	Select this checkbox to have resources stored in a separate folder and specify the location of this folder in the text box below.

When you select a framework (a [facet](#)) in the [element selector pane](#), the settings for the framework are shown in the right-hand part of the dialog.

The settings vary depending on the framework (the facet type):

- [Android Facet Page](#)
- [AspectJ Facet Page](#)
- [Android-Gradle Facet Page](#)
- [EJB facet page](#)
- [Google App Engine Facet Page](#)
- [GWT Facet Page](#)
- [Hibernate and JPA Facet Pages](#)
- [Java EE Application facet page](#)
- [JSF Facet Page](#)
- [OSGi Facet Page](#)
- [Seam Facet Page](#)
- [Struts Facet Page](#)
- [Struts 2 Facet Page](#)
- [Tapestry Facet Page](#)
- [Web facet page](#)
- [Web Services Facet Page](#)
- [Web Services Client Facet Page](#)

Use this page to configure the settings of an Android [facet](#) attached to a specific module.

In this section:

- [Common Android facet options](#)
- [Structure tab](#)
- [Generated Sources tab](#)
- [Packaging tab](#)
- [ProGuard tab](#)
- [Multi-dex tab](#)

## Common Android facet options

In this area, configure the facet general settings.

### ItemDescription

Library module	Select this checkbox to turn this module into a library module, so that other Android application projects can reference its source code and resources.
Update "project.properties" file automatically	Select this option if you want the <code>project.properties</code> file to be updated automatically when one of the following options is enabled or disabled: <ul style="list-style-type: none"> <li>– Library module</li> <li>– Enable manifest merging</li> </ul>
Reset paths to defaults	Click this button to return to the default Android facet settings.

## Structure tab

In this tab, specify the location of the key application components in the module tree structure. Based on these settings, IntelliJ IDEA supports code completion, resolves references, and provides other types of coding assistance.

### ItemDescription

Manifest file	In this text box, specify the path to the <a href="#">AndroidManifest.xml</a> file. This file contains the information that is required to run the application. It must be located in the module root directory.
Resources directory	In this text box, specify the path to the folder where the <a href="#">application resources</a> are stored. Resources located in this directory are assigned IDs and can be referenced through the <code>R.java</code> file or from XML resource definition files. The default location is <code>&lt;module root&gt;/res</code> .
Assets directory	In this text box, specify the path to the folder where the <a href="#">application assets</a> are stored. Files located in this directory are not assigned IDs and cannot be referenced through the <code>R.java</code> file or from XML resource definition files. You can access this directory like a normal file system and read data from these files using the <a href="#">AssetManager</a> . The default location is <code>&lt;module root&gt;/assets</code> .
Native libs directory	In this text box, specify the path to the folder where the <a href="#">Android native libraries</a> are stored. The default location is <code>&lt;module root&gt;/libs</code> .

## Generated Sources tab

In this tab, specify the location of the application source files.

### ItemDescription

Generate sources automatically	Select this option if you want the <code>R.java</code> , <code>AndroidManifest.java</code> and <code>.aidl</code> files to be generated automatically based on the definitions of resources and the <code>AndroidManifest.xml</code> file.
R.java and Manifest.java files	In this area, specify the target folder for the <code>R.java</code> file that contains IDs of all resources defined in your project, and the <code>AndroidManifest.java</code> file that contains permissions. To change the default location, type the path manually or click the Browse button  and select the target folder in the dialog that opens.
AIDL files	In this area, specify the target folder for the <code>.aidl</code> files generated by the AIDL Compiler. To change the default location, type the path manually or click the Browse button  and select the target folder in the dialog that opens.

## Packaging tab

In this tab, configure the behavior of the [Android Asset Packaging Tool \(aapt\)](#) that is responsible for creating an `.apk` file.

### ItemDescription

Use resource directory specified at "Structure" section	Select this option if you want the compiler to use the resources from the location specified in the Resources directory field in the Structure tab.
---	---

Use custom resource directory	Select this option if you want the package to contain resources from a location different from the one specified in the Resources directory field in the Structure tab. Type the path manually or click the Browse button  and select the target folder in the dialog that opens.
Include assets from dependencies into APK	Select this option if you want to include <a href="#">assets</a> from dependencies into the application package.
Rename manifest package	Select this option if you want the application ID to be changed on build time, and specify the new name (for more information, see <a href="#">Renaming an Application Package</a> ). This option is only available for Application modules.
Enable manifest merging	Select this option if you want to automatically merge manifest files of library modules with the manifest file of the application that contains this library module (for more information, see <a href="#">Sharing Android Source Code and Resources Using Library Projects</a> ). This option is only available for Application modules.
Additional command line parameters	In this text box, type the additional parameters to be passed to the <a href="#">Android Asset Packaging Tool(aapt)</a> . If the set of additional parameters does not fit into the text box, click  and specify the parameters in the dialog that opens. For example, if you want to include resources of a certain type in an uncompressed format, type <code>-o &lt;file extension for this type of resources&gt; .</code>
APK path	Specify the target directory for the <code>.apk</code> file that will be generated as a result of Android module compilation. Select a folder from the drop-down list, or click the Browse button  and specify the path in the dialog that opens.
Custom debug keystore	In this text box, specify the location of the keystore where the debug key you want to use is located. Type the path manually or click the Browse button  and select a folder in the dialog that opens.
Include test code and resources into APK	Select this option to include sources and resources located under the test roots into the debug APK created on build time. Test data is never included in the release APK that is generated via the <a href="#">Generate Signed APK wizard</a> .
Pre-dex external jars and Android library dependencies	<p>During the application packaging, the <code>.class</code> files of a library module are converted into <code>.dex</code> files. This operation is referred to as <a href="#">dexing</a> . Finally, the <code>.dex</code> files output from the library module is included in the final application <code>.apk</code> (learn more about the building procedure from <a href="#">Building and Running</a> ).</p> <p>As a rule, the contents of a library module remain unchanged. In this case you can have them <code>dexed</code> only once, whereupon the output <code>.dex</code> files are included in the <code>.apk</code> . This approach is referred to as <a href="#">pre-dexing</a> .</p> <p>By default, IntelliJ IDEA pre-dexes library mode dependencies as well as external <code>jars</code> that have not been updated since the previous build. You can change these settings so that all <code>.class</code> files are always dexed.</p> <p>When this option is selected, <code>.dex</code> files output from <code>.class</code> files of library modules or external <code>.jars</code> are pre-dexed. That means they are not dexed anew if the corresponding <code>.class</code> files have not been updated since the previous build. If this checkbox is cleared, all <code>.class</code> files are dexed on each build.</p> <p>This option is unavailable for Library modules.</p>

## ProGuard tab

In this tab, enable the [ProGuard](#) tool used to obfuscate the application during packaging.

### ItemDescription

Proguard logs directory	This text box shows the default location of the ProGuard logs. To modify the location, click the Browse button  and select a folder in the dialog that opens.
Run ProGuard when building debug APK	Select this option if you want IntelliJ IDEA to <a href="#">obfuscate the debug APK</a> through integration with the built-in <a href="#">ProGuard</a> tool. Note that for release application packages, there is a dedicated checkbox in the <a href="#">Generate Signed APK wizard</a> and in <a href="#">Project Structure   Artifacts   Android tab</a> .
Config file paths	This text box shows the default location of the <code>proguard-project.txt</code> configuration file that is created automatically together with an Android module. To modify the location, click the Browse button  and select a folder in the dialog that opens.

## Multi-dex tab

In this tab you can configure the [multi-dex support](#) .

### ItemDescription

Enable multi-dex support	Select this checkbox to enable Android multi-dex feature.
Main dex list	Specify the main dex list.
Minimal main dex	Select this checkbox for minimal main dex. This option lets you put only classes that are selected by main dex list into the main dex.

---

The page is available only if the AspectJ support [plugins](#) are enabled. See [Enabling AspectJ Support Plugins](#) .

On this page, you can:

- Specify that the AspectJ compiler [ajc](#) should be used only for post-compile weaving.
- Specify the `ajc` command-line option `aspectpath` for the module.

#### ItemDescription

---

**Post-compile weave mode** If you select this checkbox, `javac` is used to compile the source code. Then, `ajc` is used to weave the compiled class files. As a result, the overall process takes less time.  
**IMPORTANT:** Don't select this checkbox if there are `.aj` aspects in the module. That is, you should select this checkbox only if all the aspects are defined as `@Aspect` -annotated Java classes (in `.java` files).

---

**Aspect path** Use the available controls to form the `aspectpath` for the module.

-  ( `Alt+Insert` ). Use this icon or shortcut to add libraries and other modules. Select the necessary libraries and modules in the dialog that opens. (To choose from, dependencies of the module are suggested.)
-  ( `Alt+Delete` ). Use this icon or shortcut to remove the selected items from the list.
-  ( `Alt+Up` ). Use this icon or shortcut to move the selected item one line up in the list.
-  ( `Alt+Down` ). Use this icon or shortcut to move the selected item one line down in the list.

Use this page to configure the settings of an Android-Gradle [facet](#) attached to a specific module.

In this section:

- [Properties tab](#)
- [Signing tab](#)
- [Flavors tab](#)
- [Build Types tab](#)
- [Dependencies tab](#)

## Properties tab

This tab lets you specify properties for your `build.gradle` file.

### ItemDescription

Compile SDK Version	Use this drop-down list to select the compilation target.
Build Tool Version	Use this drop-down list to select a version of the build tool.
Library Repository	Specify the library repository. By default, <code>jcenter</code> repository is used for the Android-Gradle application. For more information, see <a href="#">jcenter repository</a> .
Ignore Assets Pattern	Use this field to specify asset patterns that you want to ignore.
Incremental Dex	Use this drop-down list to set an incremental dexing. You can choose <code>true</code> or <code>false</code> option, or leave it blank.
Source Compatibility	Use this drop-down list to select the Java version compatibility for the Java source compilation.
Target Compatibility	Use this drop-down list to select the Java version to generate Java classes.

## Signing tab

This tab lets you specify settings for signing configurations. The fields become editable when you add the `config` class in the left-hand area of the tab. You can also delete `config` classes that you don't need.

### ItemDescription

Name	This field displays a name of the <code>config</code> class that you have selected. You can modify the name, however, it should be a recognizable Java identifier.
Key Alias	Use this field to enter the name of your private key store file.
Key Password	Use this field to enter the password for the private key.
Store File	Use this field to enter a location of your private key store file. Alternatively, click Browse button  and select the target folder in the dialog that opens.
Store Password	Use this field to enter the password of your store file.

## Flavors tab

This tab lets you specify settings for flavors' configuration. The fields become editable when you add the `flavor` in the left-hand area of the tab. You can also delete the flavor entry that you don't need.

### ItemDescription

Name	This field displays a name of the <a href="#">build flavor</a> that you have selected. You can modify the name.
Min Sdk Version	Use this field to add the minimum SDK version for the flavor.
Application Id	Use this field to add an application ID.
Proguard File	Use this field to enter the location of the <a href="#">Proguard file</a> . Alternatively, click Browse button  and select the target folder in the dialog that opens.
Signing Config	Use this drop-down list to select a name of the <code>config</code> class that you have selected in the Signing tab.
Target Sdk Version	Use this drop-down list to select the target SDK version for your build flavor.
Test Instrumentation Runner	Use this field to enter the name of a class for running test cases. By default, the test class name is <code>android.test.InstrumentationTestRunner</code> .
Test Application Id	Use this field to enter an application id for your testing.
Version Code	Use this field to enter an integer value that represents the version of the application code, relative to other versions.
Version Name	Use this field to enter a string value that represents the release version of the application code, as it should be shown to users.

## Build Types tab

This tab lets you specify the settings for [Android build types](#) . By default, debug and release versions are created and displayed in the left-hand area of the tab. You can add a new entry or delete an existing one.

### ItemDescription

Name	This field displays a name of the <a href="#">build type</a> that you have added. You can modify the name.
Debuggable	Use this property to set it to either <code>true</code> or <code>false</code> depending on the build type.
Jni Debug Build	Use this property to set it to either <code>true</code> or <code>false</code> depending on the build type.
Signing Config	Use this drop-down list to select a name of the <code>config</code> class that you have selected in the Signing tab.
Renderscript Debug Build	Use this property to set <a href="#">Renderscript</a> debug build to either <code>true</code> or <code>false</code> depending on the build type.
Renderscript Optim Level	Use this property to set the optimization level for the renderscript compiler. The default value is 3.
Minify Enabled	Use this property to set the minification of your code to either <code>true</code> or <code>false</code> depending on the build type.
Pseudo Locales Enabled	Use this property to set the <a href="#">pseudo locales</a> to either <code>true</code> or <code>false</code> depending on the build type.
Proguard File	Use this field to enter the location of the <a href="#">Proguard file</a> . Alternatively, click Browse button  and select the target folder in the dialog that opens.
Application Id Suffix	Use this field to enter the suffix of your application id.
Version Name Suffix	Use this field to enter the version name suffix.
Zip Align	Use this drop-down list to set <a href="#">zipalign</a> for the file. You can use either <code>true</code> or <code>false</code> depending on the build file.

## Dependencies tab

Use this tab to specify [dependencies](#) for your application.

### ItemDescription

Scope	<p>Use this setting to control the classpath separately for your <a href="#">sources</a> and <a href="#">sources</a> , and for the build and the run phases. (The classpath may be different when 1) your sources are compiled 2) your test sources are compiled 3) your compiled sources are run 4) your tests are run. The Scope option defines classpaths in which you include the dependency.)</p> <p>You can select from the following options:</p> <ul style="list-style-type: none"><li>– Compile - use this option to include the dependency in the classpath for your sources at the compilation and run phases.</li><li>– Provided - use this option include a dependency that is provided by the runtime environment.</li><li>– APK - use this option to include the dependency in .apk file that will be generated as a result of Android module compilation.</li><li>– Test compile - use this option to include the dependency in the classpath for your test sources at the test compilation phase.</li><li>– Debug compile - use this option to include the dependency in the classpath for the debug build type at the compilation phase.</li><li>– Release compile - use this option to include the dependency in the classpath for the release build type at the compilation phase.</li></ul>
-------	--

 or 	<p>Use this icon or shortcut to add a <a href="#">library</a> or a module to the list of the module dependencies. Select one of the following options:&gt;</p> <ul style="list-style-type: none"><li>– Jars or directories. Select this option to create a new module library and add it to the list of dependencies. In the <a href="#">dialog that opens</a> , select the files and folders to be included in the library. These may be individual <code>.class</code> and <code>.java</code> files, directories and archives ( <code>.jar</code> and <code>.zip</code> ) containing such files as well as directories with Java native libraries ( <code>.dll</code> , <code>.so</code> or <code>.jnilib</code> ).</li><li>– Library. Select this option to add one or more of the existing project, global or application server libraries to the list of dependencies. In the dialog that opens, select the library or libraries and click Add Selected .</li><li>– Module Dependency. Select this option to specify the modules that the current module should depend on.</li></ul>
---	---

 or 	<p>Use this icon or shortcut to remove the selected item or items from the list of dependencies.</p>
---	--

 or  and  or 	<p>Use these icons and shortcuts to move the selected item up or down in the list. See <a href="#">Configuring projects</a> .</p>
---	---

Use this page to edit the settings for your EJB [facet](#) .

#### ItemDescription

Name	The name of the facet.
Deployment Descriptors	<p>Form the list of deployment descriptors for your application.</p> <p> (  ). Create <code>ejb-jar.xml</code> and add it to the list. The function is not active if the corresponding descriptor is already present in the list.</p> <p> (  ). Remove the selected descriptor from the list.</p> <p> (  ). Replace the selected descriptor with another one of the same type.</p> <p>Add Application Server specific descriptor. Create an application server-specific deployment descriptor (e.g. <code>glassfish-ebj-jar.xml</code> , <code>jboss.xml</code> ) and add it to the list.</p>
Source roots for EJB classes	<p>Select the <a href="#">source roots</a> to be included in an <a href="#">artifact</a> . Note:</p> <ul style="list-style-type: none"><li>- If the '&lt;ModuleName&gt;' compile output element is present in an artifact configuration, the classes for all the source roots are included in the corresponding artifact irrespective of which source roots are selected here.</li><li>- To include only the classes from the source roots selected on this page, use the following when configuring the artifact:    JavaEE Facet Classes   EJB (in &lt;ModuleName&gt; ) . As a result, the corresponding element in the artifact configuration will be shown as '&lt;ModuleName&gt;' module: 'EJB' facet classes .</li></ul>

Use this page to view and change Google App Engine [facet](#) settings.

Note that the Google App Engine facet is not tied to the Web facet. Both facets are independent.

#### ItemDescription

---

Path to Google App Engine SDK installation directory	Specify the path to the directory where <a href="#">Google App Engine SDK for Java</a> is installed.
App Engine account	In this section, specify your Google account credentials.
Run Enhancer for the following classes and packages on make	<p>If this checkbox is selected, the <code>dataanucleusenhance</code> step will be executed after each make . Use Add and Remove buttons to specify the classes and packages to be processed by the enhancer.</p> <p>By default, the state of this checkbox corresponds to the facet settings made on <a href="#">creating the Google App Engine project</a> .</p>
Persistence	This field shows persistence type defined on <a href="#">creating the Google App Engine project</a> . You can select a different one from the drop-down list. Selected persistence type defines which particular enhancer will be used on compilation.

Use this page to configure the individual settings of a GWT [facet](#) attached to a particular module.

### ItemDescription

**Path to GWT installation** In this drop-down list, select the location of the GWT SDK. If necessary, click  and select the necessary location in the [dialog that opens](#) .

directory

**Target Web Facet** In this drop-down list, select where GWT components should be ascribed. The available options are:

- None: the generated files will not be ascribed to any web facet.
- Web: the generated files will be ascribed to a `war` /`exploded` directory. This option is available only if the GWT application is placed in a Web module with a [Web facet](#) .

**JavaScript output style** In this drop-down list, select the optimization style that the compiler will apply to the generated JavaScript code. The following options are available:

- Obfuscated. Choose this option to get the output smaller and thus faster to load. The function names in the output JavaScript code are unpredictable.
- Pretty. Choose this option to get the output readable to a human.
- Detailed. Choose this option to get the output with even more detail, for example, verbose variable names.

**Compiler maximum heap size** In this text box, specify maximum heap size in Mb that will be used by the GWT compiler. In order to have GWT Compiler launched, you need to add GWT Compiler Output element to the artifact. (Project Structure | Artifacts | Output Layout)

Thus GWT Compiler is launched on artifact build, and the generated files are stored in the artifact's output directory.

**Additional compiler VM options** In this text box, specify additional VM options, for example, the ones for compiling and running large GWT projects. When specifying the options, follow these rules:

- Use spaces to separate individual options, for example, `-client -ea -Xmx1024m` .
- If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, `some "arg` or `"some arg"` .
- If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, `-Dmy.prop=\"quoted_value\"` .

**Compiler parameters** In this text box, specify the [options to be passed to the GWT compiler process](#) in the format of a command line. Use the same rules as for specifying the [VM options](#) .

**GWT Module** This read-only list shows all the GWT modules in your project. To have a GWT module involved in the [make process](#) , select the checkbox next to the name of the module in the list. The [make process](#) is automatic re-compilation of all the module or project sources that have been changed since the last compilation.

**Output Relative Path** In this text box, specify the output path relative to the GWT modules compile output root.

**Download GWT** Click this button to download the GWT SDK.

**Create Artifact** To launch GWT compiler, you need to have an artifact configured with GWT Compiler output element added in the Output Layout tab. Click this button to automatically create an artifact with configured output layout.

---

Use this page to manage configuration and object/relational mapping files, and to download missing libraries.

#### ItemDescription

---

Descriptors	<p>Use the controls in this section to manage configuration and O/R mapping files such as <code>hibernate.cfg.xml</code> for Hibernate, and <code>persistence.xml</code> and <code>orm.xml</code> for JPA.</p> <p> ( <code>Alt+Insert</code> ). Add an existing file or create a new one. In the dialog that opens, specify the file location and name.</p> <p> ( <code>Enter</code> ). Replace the selected file with another (existing) file. In the dialog that opens, specify the file that you want to use as a replacement.</p> <p> ( <code>Alt+Delete</code> ). Remove the selected file from the list. In the dialog that opens, specify whether you want to physically delete the file. (Otherwise, only the file association with the facet will be removed.)</p>
Default JPA Provider	<p>For JPA: When <code>persistence.xml</code> is created, this setting affects the <code>&lt;provider&gt;</code> element in that file. For example, <code>&lt;provider&gt;org.eclipse.persistence.jpa.PersistenceProvider&lt;/provider&gt;</code> will be generated for EclipseLink. There will be no <code>&lt;provider&gt;</code> element if <code>&lt;no provider&gt;</code> is selected.</p>
Fix	<p>If there are missing libraries, click this button to fix the problem. (The <a href="#">Setup Library dialog</a> will open.)</p>

---

Use this page to edit the settings for your Java EE Application [facet](#).

#### ItemDescription

---

**Name**      The name of the facet.

---

**Deployment**      Form the list of [deployment descriptors](#) for your application.

**Descriptors**      + ( [Alt+Insert](#) ) . Create `application.xml` and add it to the list. The function is not active if the corresponding descriptor is already present in the list.

— ( [Alt+Delete](#) ) . Remove the selected descriptor from the list.

↵ ( [Enter](#) ) . Replace the selected descriptor with another one of the same type.

Add Application Server specific descriptor. Create an application server-specific deployment descriptor (e.g. `glassfish-application.xml` , `jboss-app.xml` ) and add it to the list.

Ctrl+Shift+Alt+S

Use this page to configure the JSF [facet](#) settings.

Note that you can download the JSF component libraries such as ICEfaces, OpenFaces, PrimeFaces and RichFaces by "adding" the corresponding facets to a JSF facet.

#### ItemDescription

---

Facelets support	<p>Select the required <a href="#">Facelets</a> support option.</p> <p>This is the project-level setting. The selected option is set for all modules in the current project.</p> <ul style="list-style-type: none"><li>- Auto. Automatic Facelets detection. The XHTML files are treated as Facelets or ordinary XHTML files depending on whether the module has a JSF facet or not. In the modules that have a JSF facet, all XHTML files are considered Facelets. If a module does not have a JSF facet, all XHTML files in it are treated as ordinary XHTML files.</li><li>- Enabled. All XHTML files in the project are treated as Facelets.</li><li>- Disabled. All XHTML files in the project are considered not to be Facelets and are treated as ordinary XHTML files.</li></ul>
------------------	--

Use this page to configure support of [OSGi](#) bundles generation.

**Note** Prerequisite: Osmorc plugin should be enabled.

The available tabs are:

- [General](#)
- [Bundle JAR](#)
- [Manifest Generation](#)

## General Tab

### ItemDescription

Bundle Creation	<p>In this area, specify the bundling method and appoint the OSGi Bundle manifest file to use (or specify the way to create a new one). The available options are:</p> <ul style="list-style-type: none"> <li>- Create manifest using facet settings and bundle using facet configuration - select this option to have bundles assembled according to the configuration settings specified in the <a href="#">Bundle JAR</a> tab and the manifest file generated according to the settings of the <a href="#">Manifest Generation</a> tab.</li> <li>- Use existing manifest and bundle using facet configuration - select this option to have bundles assembled according to the configuration settings specified in the <a href="#">Bundle JAR</a> tab and use an existing manifest file of your choice.</li> </ul> <p>In the Manifest file location area, appoint the manifest file to apply.</p> <ul style="list-style-type: none"> <li>- Select the Use project default option to use the manifest file that is appointed default for the current project in the <a href="#">OSGi: Project Settings</a> dialog box.</li> <li>- Alternatively, select Custom option to use a custom manifest file. In the text box, type the path to the desired file relative to the project root or click the Browse button  and choose the desired location in the <a href="#">dialog that opens</a>.</li> </ul> <p>- Create using bnd and ignore facet configuration - select this option to have bundles assembled using the bnd .</p> <p>In the Bnd file location text box, specify the path to the <code>.bnd</code> file to use. Type the path manually or click the Browse button  and choose the desired location in the <a href="#">dialog that opens</a>.</p> <ul style="list-style-type: none"> <li>- Create using Bundlor and ignore facet configuration - select this option to have bundles assembled using Bundlor . Bundlor helps you simplify the creation and maintenance of the OSGi metadata of each bundle.</li> </ul> <p>In the Bundlor file location text box, specify the path to the file to use. Type the path manually or click the Browse button  and choose the desired location in the <a href="#">dialog that opens</a>.</p>
-----------------	---

Maven Synchronization	<p>In this area you can select the following option:</p> <p>Do not synchronize facet settings with Maven - if you select this checkbox, OGGi facet settings will not be synchronized with Maven. It might be helpful if you want to save facet settings that are different from the settings in pom.xml file when you reimport from the Maven project.</p>
-----------------------	--

## Bundle JAR Tab

**Warning!** The controls in this tab are not available if you have selected the Create using bnd and ignore facet configuration option in the [General](#) tab.

### ItemDescription

JAR filename	Use this field to specify the name of your bundle JAR file.
JAR output path	<p>Use this area to specify the location of the bundle JAR file. You can select from the following options:</p> <ul style="list-style-type: none"> <li>- Place in module's output path - select this option to place the OSGi bundle JAR in module's output path.</li> <li>- Place in project-wide OSGi bundle output path - select this option to place the bundle JAR in project's output path that you specified in the <a href="#">OSGi: Project Settings</a> dialog box.</li> <li>- Place in this path - select this option to place the OSGi bundle JAR manually. You can either type the location in text field or click the Browse button  and choose the desired location in the <a href="#">dialog that opens</a>.</li> </ul>
Always Rebuild Bundle JAR	Select this checkbox to have the OSGi bundle JAR file rebuilt upon every module make.
Additional JAR Contents	<p>In this area, specify extra sources to be packaged into the JAR and the target location where to store the packaging results.</p> <ul style="list-style-type: none"> <li>- Source File/Folder - this read-only field shows the full path to the sources to package.</li> <li>- Destination File/Folder (Relative to JAR Root - this read-only field shows where to place the packaging results.</li> <li>-  (  ) - use this icon or shortcut to open the Choose Source File or Folder dialog box, where you can specify the desired extra sources to be included in the JAR file.</li> <li>-  (  ) - use this icon or shortcut to open the Choose Source File or Folder dialog box, where you can choose a different extra source file or folder.</li> <li>-  (  ) - use this icon or shortcut to remove the selected source - destination mapping from the list.</li> </ul>
File Ignore Pattern (regex)	Use this field to exclude items you do not need from the JAR file after the compilation. Bundles are assembled using bnd tool. This parameter acts as bnd directive <code>-donotcopy</code> .

For example, you usually do not copy CVS and .svn directories. So, the default, in this case, is `(CVS|.svn)`. The syntax for the parameter is as follows:

```
-donotcopy= (CVS|.svn|.+.bak|~.+)
```

## Manifest Generation Tab

**Warning!** The controls in this tab are only available when the Create manifest using facet settings and bundle using facet configuration option is selected in the [General](#) tab.

### ItemDescription

Symbolic Name	In this text box, specify an alias to refer to the bundle.
Bundle Activator	In this text box, specify the class that implements the OSGi activator. Type the class name or click the Browse button  and choose it in the Select Bundle Activator Class dialog box, that opens.
Bundle Version	In this text box, specify the version of the framework integrator used.
Additional Properties	In this text box, type additional properties to be included in the <code>manifest.mf</code> manifest file. Syntax highlighting, auto-completion, and intention actions are available.

File | Project Structure | Modules | <module> | Seam

File | Project Structure | Facets | Seam (<module>)

---

Use this page to select the [Seam](#) version, and download missing libraries.

---

Here you can edit settings for the selected [Struts facet](#) . The following tabs are available:

– [Struts Features tab](#)

– [Validation tab](#)

## Features tab

### ItemDescription

---

**Select Struts version** The drop-down list is disabled and shows the Struts version specified during the creation of the dedicated facet.

**[Struts taglib](#)** The component provides a set of JSP custom tag libraries that help developers create interactive form-based applications. [Struts tags](#) help with everything from displaying error messages to dealing with nested ActionForm beans.

**[Struts El-taglib](#)** The [Struts El](#) component expands the Struts taglib component with JSTL (the JavaServer Pages Standard Tag Library) as a foundation technology. This option is available only after you have enabled the Struts taglib component.

**[Tiles](#)** The component is a templating system that can be used to create a common look and feel for a Web application. Tiles can also be used to create reusable view components.

**[Validator](#)** The component provides the functionality to validate the form data both on the server side and the client side. The Validator Framework uses two XML configuration files:

- `validator-rules.xml` defines the standard reusable validation routines, that are used in `validation.xml` to define the form specific validations.
- `validation.xml` defines the validations applied to a form bean.

**[Struts-Faces](#)** The component supports the use of [JavaServer Faces \(JSF\)](#) user interface technology in a Struts-based Web application.

**[Scripting](#)** The Struts Scripting component allows Struts Actions to be written in the scripting language of your choice.

**[Extras](#)** The Struts Extras component provides several popular but non-essential classes.

## Validation tab

### ItemDescription

---

**Disable property keys validation** Excludes [Struts property keys](#) from validation.

The page is available only for modules with enabled Struts 2 support.

Use this page to configure the settings for an individual Struts 2 [facet](#) attached to a particular module.

The following tabs are available:

- [File Sets tab](#)
- [Features tab](#)

## File Sets tab

### ItemDescription

---

 or  Use this icon or shortcut to create a new file set or add a file to the selected file set. (The [Edit File Set dialog](#) will open.)

---

 or  Use this icon or shortcut to edit the selected file set. (The [Edit File Set dialog](#) will open.)

---

 or  Use this icon or shortcut to remove the selected file or file set.

## Features tab

### ItemDescription

---

Disable .properties-based I18N support      Disable internalization support for message resource keys, e.g. for `<message key="...">` in `validation.xml`, the `key` attribute in Struts UI taglib, etc.

---

For this page to be available, the Tapestry Support [plugin](#) must be enabled.

Use this page to specify the [configuration settings](#) for your [Tapestry](#) application.

**ItemDescription**

---

Filter Name	Specify the filter name for your application. By convention, the filter name is almost always <code>_app</code> , but you can use any name you want.
-------------	---

---

Application Package	Specify the root package for your application.
---------------------	--

Use this page to edit the settings for your Web facet .

### ItemDescription

**Name** The name of the facet.

**Deployment Descriptors** Form the list of [deployment descriptors](#) for your application.

+ ( **Alt+Insert** ). Create `web.xml` and add it to the list. The function is not active if the corresponding descriptor is already present in the list.

- ( **Alt+Delete** ). Remove the selected descriptor from the list.

↵ ( **Enter** ). Replace the selected descriptor with another one of the same type.

Add Application Server specific descriptor. Create an application server-specific deployment descriptor (e.g. `glassfish-web.xml` , `jboss-web.xml` ) and add it to the list.

**Web Resource Directories** Specify the directories that contain your web app resources such as web pages, images, etc. (the Web Resource Directory column) and their locations in the corresponding [artifact](#) (the Path Relative to Deployment Root column).

For the resource directories to be included in an artifact, you should make sure that the artifact configuration contains a Web facet resources element. (All the resource directories are included in an artifact as a whole.) In that case, / in the Path Relative to Deployment Root column corresponds to the root of that element in the artifact configuration.

**Source Roots** Select the [source roots](#) to be included in an [artifact](#) . Note:

- If the '<ModuleName>' compile output element is present in an artifact configuration, the classes for all the source roots are included in the corresponding artifact irrespective of which source roots are selected here.

- To include only the classes from the source roots selected on this page, use the following when configuring the artifact: + | JavaEE Facet Classes | Web (in <ModuleName>). As a result, the corresponding element in the artifact configuration will be shown as '<ModuleName>' module: 'Web' facet classes .

From the [Web facet page](#) :  or  in the [Web Resource Directories](#) section .

#### ItemDescription

---

Web resource directory path	The path to a directory that contains your web app resources such as web pages, images, etc.
Relative path in deployment directory	The location of the web resource directory in the corresponding <a href="#">artifact</a> . / in this field corresponds to the root of the Web facet resources element in an artifact configuration.

The page is available only for modules with enabled Web Services support.

Use this page to configure the settings of a Web Services [facet](#).

---

**ItemDescription**

Select WS Engine      Select the archive with the libraries that support the development of a particular Web services type.

The page is available only for modules with enabled Web Services client support.

Use this page to configure the settings of a Web Services Client [facet](#).

---

**ItemDescription**

Select WS Engine	Select the archive with the libraries that support the development of the client side for Web services of a specific type.
------------------	--

This page opens in the right-hand part of the [Project Structure dialog](#) when you select a Flash module in the [element selector pane](#) .

Use this page to edit the module name and configure the module contents.

The module contents are configured by adding and removing the module content roots as well as by assigning individual folders (within the content roots) to source folders, test source folders and also by excluding the folders.

- [Name field](#)
- [The left-hand pane](#)
- [The right-hand pane](#)

## Name field

### ItemDescription

Name	Description
Name	Use this field to edit the module name.

## The left-hand pane

The left-hand pane shows a tree of folders for a module [content root](#) . If the module has more than one content root, the structure shown corresponds to the content root selected in the right-hand pane.

The folders belonging to different categories have different icons.

The following table lists the available toolbar buttons (the **Icon** column) and explains their functions (the **Description** column). Note that the corresponding functions can also be accessed as the context menu commands. These are listed in the **Command** column.

Most of the icons/commands work as toggles, and can be used to cancel the corresponding assignment (to make a folder "an ordinary folder").

### IconCommandDescription

Icon	Command	Description
	Sources	Use this icon or command to assign the selected folder or folders to the source folder category.
	Tests	Use this icon or command to assign the selected folder or folders to test sources.
	Excluded	Use this icon or command to make the selected folder <a href="#">excluded</a> .
	New Folder	Use this command to create a folder in the selected folder. Specify the name for the new folder in the New Folder dialog that opens.

Exclude files. The files and folders whose names match at least one of the specified patterns are made [excluded](#) .

## The right-hand pane

The right-hand pane shows the module [content roots](#) .

For each content root, a categorized view of the module folders is provided. The categories are the source folders, test source folders, etc.

The "ordinary" folders are not shown in this view.

The individual folders within the categories are identified by their paths. The folder paths are all relative to the module root folder (content root).

The folder paths, functionally, are hyperlinks that let you jump to the corresponding folders in the tree shown in the left-hand pane.

If a module has more than one content root, selecting a content root in the right-hand pane also switches the tree view in the left-hand pane. That is, when you click somewhere within the content root area, the folder structure of this particular content root is shown in the left-hand pane.

The following table lists the controls available in the right-hand pane (icons) and describes their functions.

### IconTooltipDescription

Icon	Tooltip	Description
	Add Content Root	Use this icon to add a content root. Select the folder to be added as a content root in the <a href="#">dialog that opens</a> .
	Remove Content Entry	Use this icon to remove the corresponding content root from the list of the content roots.
	Unmark	Use this icon to remove the folder from the corresponding category. As a result, the folder becomes "an ordinary folder", that is, not belonging to any specific category.

The Build Configuration page opens in the right-hand part of the [Project Structure dialog](#) when you select a build configuration of a Flash module in the [element selector pane](#) .

Use this page to edit the settings for the selected build configuration.

- [General tab](#)
- [Dependencies tab](#)
- [Compiler Options tab](#)
- [AIR Package tab](#)
- [Android tab](#)
- [iOS tab](#)

Use this tab to edit such build configuration settings as its name, [type](#), output file name and folder, etc.

#### ItemDescription

Name	Use this field to edit the name of the build configuration.
Type	<p>A brief description of the build configuration <a href="#">type</a>, for example, <a href="#">ActionScript application for web (Flash Player)</a> which means:</p> <ul style="list-style-type: none"><li>- The target platform is Web.</li><li>- The output type is Application (SWF).</li><li>- The application is pure ActionScript (i.e. it doesn't use the Flex framework).</li></ul> <p>To change the build configuration type, click Change and specify the build configuration properties in the dialog that opens.</p>
Main class	<p>For the Application and the Runtime-loaded module output types: the <a href="#">main class of the SWF file</a>.</p> <p>Edit the name of the class right in the field or click <input type="button" value="..."/> (<a href="#">Shift+Enter</a>) and select the necessary class in the Choose Main Class dialog.</p>
Output file name	Use this field to edit the name and extension of the output file.
Output folder	<p>The folder in which the output file is generated.</p> <p>Edit the path to this folder right in the field or click <input type="button" value="..."/> (<a href="#">Shift+Enter</a>) and select the necessary folder in the <a href="#">dialog that opens</a>.</p>
Use HTML wrapper	<p>For Web Applications: select this option if you want an <a href="#">HTML wrapper</a> to be included in the output.</p> <ul style="list-style-type: none"><li>- Folder with template. Specify the path to the folder where the files that constitute an HTML wrapper template are located.<ul style="list-style-type: none"><li>- To select an existing folder with the wrapper template files, click <input type="button" value="..."/> (<a href="#">Shift+Enter</a>) and select the folder in the <a href="#">dialog that opens</a>.</li><li>Note that the corresponding folder must contain the file <code>index.template.html</code> and this file must contain the token <code>\${swf}</code>.</li><li>- To create a new folder with the wrapper template files, click Create and specify the folder location and the wrapper options in the <a href="#">Create HTML Wrapper Template dialog</a>.</li></ul></li></ul> <p>During the compilation, the tokens contained in the template (<code>index.template.html</code>) are replaced with the appropriate values. For example, <code>\${swf}</code> is replaced with the <code>.swf</code> file name. The resulting <code>.html</code> wrapper file will have the same name as the <code>.swf</code> file.</p> <p>See also, <a href="#">Using the SWF metadata tag to control HTML wrapper properties</a>.</p>
Runtime-loaded modules	<p>For Web and Desktop Applications: if your application has modular structure (see <a href="#">Modular applications overview</a> in Flex documentation), you can use this field to specify dependencies on the corresponding runtime-loaded modules (RLMs).</p> <p>Click <input type="button" value="+"/> (<a href="#">Shift+Enter</a>). In the <a href="#">Runtime-Loaded Modules dialog</a> that opens:</p> <ul style="list-style-type: none"><li>- To add a dependency, click <input type="button" value="+"/> (<a href="#">Alt+Insert</a>) and select the main class of the corresponding RLM in the Choose Main Class of Runtime-Loaded Module dialog that opens.</li><li>- To optimize the module SWF file size, select the Optimize checkbox.</li><li>- To replace a class with a different one, click the corresponding Main Class table cell, click <input type="button" value="..."/> (<a href="#">Shift+Enter</a>), and select the necessary class in the dialog that opens.</li><li>- To remove dependencies from the list, select the dependencies (RLMs) to be removed and click <input type="button" value="-"/> (<a href="#">Alt+Delete</a>).</li></ul> <p>Note that there is also an alternative way of specifying dependencies on RLMs: you can add dependencies on RLM build configurations on the <a href="#">Dependencies tab</a>.</p> <p>See also, <a href="#">Configuring dependencies for modular applications</a>.</p>
Runtime style sheets	<p>For Web and Desktop Applications: if necessary, specify the <code>.css</code> files that should be compiled into <a href="#">runtime style sheets</a>.</p> <p>Click <input type="button" value="+"/> (<a href="#">Shift+Enter</a>). In the CSS Files To Compile dialog that opens:</p> <ul style="list-style-type: none"><li>- To add a <code>.css</code> file to the list, click <input type="button" value="+"/> (<a href="#">Alt+Insert</a>) and select the necessary file in the <a href="#">dialog that opens</a>.</li><li>- To replace a file which is already in the list with a different one, click the corresponding entry, click <input type="button" value="..."/> (<a href="#">Shift+Enter</a>), and select the file in the <a href="#">dialog that opens</a>.</li><li>- To remove items from the list, select the items to be removed and click <input type="button" value="-"/> (<a href="#">Alt+Delete</a>).</li></ul>
Skip compilation	Select this option if you do not intend to compile your module using this build configuration. If you do so, the build configuration will only affect your code validation and (error) highlighting.

Use this tab to configure the build configuration build path (the [build configuration dependencies](#) ).

#### ItemDescription

---

**Flex/AIR SDK** The Flex or AIR [SDK](#) associated with the build configuration.  
Select the SDK from the list or click New and select the folder containing the necessary SDK in the [dialog that opens](#) .

To edit the current SDK, click Edit . (The [SDK page](#) of the Project Structure dialog will open.)

Note that the necessary SWCs from the specified SDK are selected automatically depending on the build configuration type.

---

**Target player** For the Web target platform only: the version of Flash player the build configuration output is intended for.  
If the SDK includes more than one player version, you can choose which of the corresponding SWCs should be used.

---

**Component set** For Flex framework-based build configurations (the Web and Desktop output types only): select the Flex 4 component set or sets:

- Spark + MX. Select this option to be able to use the Spark and MX components (SWCs) available in the SDK.
- Spark only. The names of this and the following option are self-explanatory.
- MX only.

Note how the list of dependencies changes depending on your selection.

---

**Framework linkage** For Flex framework-based build configurations: select the [linkage type](#) for the Flex framework components included in the build configuration dependencies. (The set of available options depends on the [build configuration type](#) .)

---

 or  Use this icon or shortcut to add another dependency. Select:

- Build Configuration to add a dependency on a build configuration that generates a library or a runtime-loaded module (RLM).  
Note that for Web and desktop applications, the dependencies on RLMs can alternatively be specified on the [General tab](#) in the [Runtime-loaded modules field](#) . See also, [Configuring dependencies for modular applications](#) .
- New Library to add a dependency on third-party libraries. Select the libraries of interest in the [dialog that opens](#) .
- Project or Global Library to add a dependency on a global or project library. Select the libraries of interest in the Choose Libraries dialog.

---

 or  Use this icon or shortcut to remove the selected dependency.

---

 Click this icon to edit the selected third-party library in the Configure Library dialog.

Use this tab to manage the [compiler options](#) for the build configuration as well as the associated project and module defaults.

See the descriptions of the compiler options in Flex documentation:

- [For applications](#)
- [For libraries](#)

#### ItemDescription

**Option** The option name or the name of a group of options. The groups of options are shown as nodes which you can expand or collapse.  
Note that each option has an associated Restore Default Value context menu command. Use this command to restore the module default for an option.

Also note that you can quickly find an option of interest among the options that are currently shown. Click somewhere within the area where the compiler options and their values are shown and start typing the text which, as you expect, is present within the option name. The Search for box appears which contains the text that you are typing. As soon as it's possible to identify an option basing on the text that you have typed, this option is highlighted in the table.

**Value** The option value. In most of the cases, to start editing a value, you should click the corresponding table cell. Generally, the way to edit a value depends on which value the corresponding option may have:

- The options that you can turn on or off are controlled by checkboxes. The actual option values in such cases are `true` or `false`.
- If an option value is a string, the value is edited right in the field.
- If a value represents a path to a certain location (for example, a path to a file), you can edit such a value right in the field. Alternatively, you can use  ( `Shift+Enter` ) to select the necessary location in the [corresponding dialog](#).
- If an option value represents a list, such a value cannot be edited directly. To edit the value, use  ( `Shift+Enter` ). This will open a dedicated dialog for managing the list items.

**Legend** The options whose values are inherited from the default sets of different levels (the IDE, project, or module) and the ones having specific values (that is, whose values are redefined at the level of the build configuration) are shown differently.  
The legend shows how to distinguish between these four categories of options.

**Copy resource files to output folder** For Applications: select this checkbox if you want resource files to be copied to the output folder. Specify which files within the module source roots should be treated as the resource files:

- All except \*.as and \*.mxm1. All the files with the extensions other than `.as` and `.mxm1` are considered to be the resource files.
- According to resource patterns. The files that match the resource patterns are treated as the resource files. Click the resource patterns link to view or edit the resource patterns. (The settings in the dialog that opens correspond to those on the [Compiler page](#) in the Settings dialog.)

Files and folders excluded from compilation won't be copied to the output folder. See [Excludes](#).

**Files to include in output \*.swc** For Libraries: if necessary, specify additional files and folders that should be included in the resulting `.swc` file. Click  ( `Shift+Enter` ). In the Files And Folders To Include In \*.swc dialog that opens:

- To add a file or folder to the list, click  ( `Alt+Insert` ) and select the necessary file or folder in the [dialog that opens](#).
- To replace a file or folder which is already in the list with a different file or folder, click the corresponding entry, click  ( `Shift+Enter` ), and select the file or folder in the [dialog that opens](#).
- To remove items from the list, select the items to be removed and click  ( `Alt+Delete` ).

Please note the following:

- For the source files ( `.as` , `.mxm1` and `.fxg` ) to be included, all such files should be selected individually, as separate files. That is, if you select a folder, none of the `.as` , `.mxm1` and `.fxg` files contained therein will be included in the `.swc` file.
- Files and folders excluded from compilation won't be included in the `.swc` file. See [Excludes](#).

**Additional compiler configuration file** You have an option of specifying a compiler configuration file, an XML file that contains the compiler settings that are used in addition to those specified in the table.  
The additional compiler configuration file, usually, is a file that you compose yourself. Alternatively, this may be a file generated by means of the Maven plugin, or the like.

You can find examples of the configuration files in the directory `<Flex_SDK_directory>\frameworks`.

Note that in the case of contradictions, the settings in the configuration file take precedence over the ones specified in the table.

To specify the configuration file, click  ( `Shift+Enter` ) and select the necessary file in the [dialog that opens](#).

**Inherited options** In this field, the compiler options inherited from upper levels (module and project) are shown (readonly).

**Additional compiler configuration file** If necessary, specify the compiler options to be used in addition to those in the table and in the additional compiler configuration file.  
When specifying the options, you can use [path variables](#). These include the predefined variables `${MODULE_DIR}`, `${PROJECT_DIR}` and `${USER_HOME}`, and also the ones set on the [Path Variables page](#) of the [Settings dialog](#). The format to be used is:

```
-some-option=${PATH_VARIABLE_NAME}/relative/path
```

For example:

```
-dump-config=${MY_PATH_VARIABLE}/config_dump.xml
```

To separate individual options, use spaces.

If you need more room to type, click  ( Shift+Enter ) to open the Additional Compiler Options dialog where the text entry area is larger.

---

Project Defaults Click this button to edit the project defaults in the Default Compiler Options For Project dialog.

---

Module Defaults Click this button to edit the module defaults in the Default Compiler Options For Module dialog.

Use this tab to manage the settings related to packaging your Desktop (AIR) application.

Note that this tab is available only if the target platform of the build configuration is Desktop (AIR) and the output type is Application.

#### ItemDescription

Application descriptor	<p>Specify the <a href="#">application descriptor</a> to be used:</p> <ul style="list-style-type: none"><li>– Generated. An auto-generated descriptor will be used.</li><li>– Custom template. The descriptor generated according to the specified template will be used.</li></ul> <p>To use an existing template, click  ( <a href="#">Shift+Enter</a> ) and select the template file in the <a href="#">dialog that opens</a> .</p> <p>To create and use a new file, click Create . In the <a href="#">Create AIR Descriptor Template dialog</a> that opens, specify the descriptor file properties and click Create .</p> <p>When the template is used for generating the application descriptor (e.g. during the compilation or packaging), the text in the <code>&lt;content&gt;</code> element is replaced with the name and extension ( <code>.swf</code> ) of the application file.</p>
Package file name	<p>Specify the name of the resulting package file.</p>
Files and folders to package	<p>In addition to the <a href="#">application SWF file</a> , you may also want other application assets to be packaged. If so, specify the locations of these additional assets.</p> <ul style="list-style-type: none"><li>– Path to file or folder. Edit the absolute path to the file or folder where the desired asset resides. Use  ( <a href="#">Shift+Enter</a> ) to select the file or folder in the <a href="#">corresponding dialog</a> .</li><li>– Its relative path in package. Specify the relative asset location in the package.</li><li>–  ( <a href="#">Alt+Insert</a> ). Use this icon or shortcut to add another asset to the list. Select the asset location in the <a href="#">dialog that opens</a> .</li></ul> <p>Note that for assets within the module source roots, their relative locations in the package, by default, will be set the same as in the source folder. That is, for a file <code>&lt;src&gt;\images\my_icon.png</code> , its relative location in the package, by default, will be <code>images\my_icon.png</code> .</p> <ul style="list-style-type: none"><li>–  ( <a href="#">Alt+Delete</a> ). Use this icon or shortcut to remove the selected item or items from the list.</li></ul>
Use temporary self-signed certificate	<p>Select this option to sign the package with a pre-installed self-signed certificate. Otherwise, specify the settings related to signing the package (see below).</p>
Keystore file	<p>Specify the path to the keystore file. (This is where a private key and corresponding certificate are stored.)</p> <p>Type the path in the field or click  ( <a href="#">Shift+Enter</a> ) and select the keystore file in the <a href="#">dialog that opens</a> .</p> <p>(If your <a href="#">keystore type</a> is <code>PKCS12</code> , your keystore file, most probably, has the <code>.p12</code> extension.)</p>
Keystore type	<p>Specify your keystore type. The default value <code>PKCS12</code> corresponds to a keystore file with the <code>.p12</code> extension.</p>
More options or Less options	<p>Click the link to show or hide the options described below.</p>
Key alias	<p>Specify the key alias.</p> <p>Note that the alias is not necessary if the keystore contains only one key.</p>
Provider class	<p>Specify the <a href="#">Java Cryptography Architecture (JCA)</a> provider for the specified keystore type.</p>
TSA (time-stamping authority)	<p>Specify the URL of an <a href="#">RFC3161</a> -compliant time-stamp server to time-stamp the digital signature.</p>

Use this tab to manage the settings related to packaging your application for Android.

Note that this tab is available only if the target platform of the build configuration is Mobile (AIR Mobile) and the output type is Application.

#### ItemDescription

Enabled	Turn this option on if you are going to use the build configuration for creating an application descriptor and packaging your application for Android.
Application descriptor	<p>Specify the <a href="#">application descriptor</a> to be used:</p> <ul style="list-style-type: none"><li>– Generated. An auto-generated descriptor will be used.</li><li>– Custom template. The descriptor generated according to the specified template will be used.</li></ul> <p>To use an existing template, click  ( <a href="#">Shift+Enter</a> ) and select the template file in the <a href="#">dialog that opens</a> .</p> <p>To create and use a new file, click Create . In the <a href="#">Create AIR Descriptor Template dialog</a> that opens, specify the descriptor file properties and click Create .</p> <p>When the template is used for generating the application descriptor (e.g. during the compilation or packaging), the text in the <code>&lt;content&gt;</code> element is replaced with the name and extension ( <code>.swf</code> ) of the application file.</p>
Package file name	Specify the name of the resulting package file.
Files and folders to package	<p>In addition to the <a href="#">application SWF file</a> , you may also want other application assets to be packaged. If so, specify the locations of these additional assets.</p> <ul style="list-style-type: none"><li>– Path to file or folder. Edit the absolute path to the file or folder where the desired asset resides. Use  ( <a href="#">Shift+Enter</a> ) to select the file or folder in the <a href="#">corresponding dialog</a> .</li><li>– Its relative path in package. Specify the relative asset location in the package.</li><li>–  ( <a href="#">Alt+Insert</a> ). Use this icon or shortcut to add another asset to the list. Select the asset location in the <a href="#">dialog that opens</a> .</li></ul> <p>Note that for assets within the module source roots, their relative locations in the package, by default, will be set the same as in the source folder. That is, for a file <code>&lt;src&gt;\images\my_icon.png</code> , its relative location in the package, by default, will be <code>images\my_icon.png</code> .</p> <ul style="list-style-type: none"><li>–  ( <a href="#">Alt+Delete</a> ). Use this icon or shortcut to remove the selected item or items from the list.</li></ul>
Use temporary self-signed certificate	Select this option to sign the package with a pre-installed self-signed certificate. Otherwise, specify the settings related to signing the package (see below).
Keystore file	<p>Specify the path to the keystore file. (This is where a private key and corresponding certificate are stored.)</p> <p>Type the path in the field or click  ( <a href="#">Shift+Enter</a> ) and select the keystore file in the <a href="#">dialog that opens</a> .</p> <p>(If your <a href="#">keystore type</a> is <code>PKCS12</code> , your keystore file, most probably, has the <code>.p12</code> extension.)</p>
Keystore type	Specify your keystore type. The default value <code>PKCS12</code> corresponds to a keystore file with the <code>.p12</code> extension.
More options or Less options	Click the link to show or hide the options described below.
Key alias	<p>Specify the key alias.</p> <p>Note that the alias is not necessary if the keystore contains only one key.</p>
Provider class	Specify the <a href="#">Java Cryptography Architecture (JCA)</a> provider for the specified keystore type.

Use this tab to manage the settings related to packaging your application for iOS.

Note that this tab is available only if the target platform of the build configuration is Mobile (AIR Mobile) and the output type is Application.

#### ItemDescription

Enabled	Turn this option on if you are going to use the build configuration for creating an application descriptor and packaging your application for iOS.
Application descriptor	<p>Specify the <a href="#">application descriptor</a> to be used:</p> <ul style="list-style-type: none"><li>– Generated. An auto-generated descriptor will be used.</li><li>– Custom template. The descriptor generated according to the specified template will be used.</li></ul> <p>To use an existing template, click  ( <a href="#">Shift+Enter</a> ) and select the template file in the <a href="#">dialog that opens</a> .</p> <p>To create and use a new file, click Create . In the <a href="#">Create AIR Descriptor Template dialog</a> that opens, specify the descriptor file properties and click Create .</p> <p>When the template is used for generating the application descriptor (e.g. during the compilation or packaging), the text in the <code>&lt;content&gt;</code> element is replaced with the name and extension ( <code>.swf</code> ) of the application file.</p>
Package file name	Specify the name of the resulting package file.
Files and folders to package	<p>In addition to the <a href="#">application SWF file</a> , you may also want other application assets to be packaged. If so, specify the locations of these additional assets.</p> <ul style="list-style-type: none"><li>– Path to file or folder. Edit the absolute path to the file or folder where the desired asset resides. Use  ( <a href="#">Shift+Enter</a> ) to select the file or folder in the <a href="#">corresponding dialog</a> .</li><li>– Its relative path in package. Specify the relative asset location in the package.</li><li>–  ( <a href="#">Alt+Insert</a> ). Use this icon or shortcut to add another asset to the list. Select the asset location in the <a href="#">dialog that opens</a> .</li></ul> <p>Note that for assets within the module source roots, their relative locations in the package, by default, will be set the same as in the source folder. That is, for a file <code>&lt;src&gt;\images\my_icon.png</code> , its relative location in the package, by default, will be <code>images\my_icon.png</code> .</p> <ul style="list-style-type: none"><li>–  ( <a href="#">Alt+Delete</a> ). Use this icon or shortcut to remove the selected item or items from the list.</li></ul>
Provisioning profile	<p>Specify the location of your iOS provisioning profile.</p> <p>Type the path in the field or click  ( <a href="#">Shift+Enter</a> ) and select the provisioning profile in the <a href="#">dialog that opens</a> .</p> <p>For information on provisioning profiles, see <a href="#">How to Create a Provisioning Profile for iPhone</a> , <a href="#">Getting Your Provisioning Certificate to be Recognized by Your iPhone</a> or other online resources.</p>
Keystore file	<p>Specify the path to the keystore file. (This is where a private key and corresponding certificate are stored.)</p> <p>Type the path in the field or click  ( <a href="#">Shift+Enter</a> ) and select the keystore file in the <a href="#">dialog that opens</a> .</p> <p>(Your keystore file, most probably, has the <code>.p12</code> extension.)</p>
Apple iOS SDK	<p>If you want to use a particular Apple iOS SDK to package your application, you can specify the path to that SDK this field. For example, if you have built an extension with the latest iOS SDK, you may want to use that SDK when packaging your application.</p> <p>Type the path in the field or click  ( <a href="#">Shift+Enter</a> ) and select the SDK installation folder in the <a href="#">dialog that opens</a> .</p>
Additional ADT options	<p>If necessary, specify additional command-line options to be passed to ADT. (ADT is a tool used for application packaging.) For more information, see <a href="#">ADT package command</a> in Adobe AIR documentation.</p> <p>If you need more room to type, click  ( <a href="#">Shift+Enter</a> ) to open the Additional ADT Options dialog where the text entry area is larger.</p>

**Ctrl+Shift+Alt+S** | Libraries or Global Libraries

Libraries or Global Libraries

When you select the Libraries or the Global Libraries [category](#) in the [Project Structure dialog](#) , a list of existing project or global [libraries](#) is shown in the [element selector pane](#) .

Use the toolbar icons, context menu commands or keyboard shortcuts to manage the libraries ([see below](#) ).

To view or edit the name and contents of a library, select the library of interest, and use the [page to the right](#) of the selector pane.

## Toolbar icons, context menu commands and shortcuts

### IconCommandShortcutDescription

<b>+</b>	New Project Library or New Global Library	<b>Alt+Insert</b>	Create a new project or global library. See <a href="#">Creating a library</a> .
<b>-</b>	Delete	<b>Delete</b>	Delete the selected library.
	Copy		Create a copy of the selected library.
	Move to Global Libraries		For a project library: move the selected project library to the global (IDE) level. See <a href="#">Moving a library onto a higher level</a> .
	Copy to Project Libraries		For a global library: create a copy of the selected global library at the project level. See <a href="#">Creating a copy of a library at a lower level</a> .
	Add to Modules		Add the selected project or global library to <a href="#">dependencies</a> of one or more of your <a href="#">modules</a> . In the dialog that opens, select the corresponding modules.
	Find Usages	<b>Alt+F7</b>	Find usages of the selected library in the project.

The Project Library or the Global Library page opens in the right-hand part of the [Project Structure dialog](#) when you select a project or global [library](#) in the [element selector pane](#) .

Use this page to edit the library name and to manage the library contents.

The set of the available controls depends on whether you are working with a Java or ActionScript/Flex library, or a JavaScript library.

- [Controls for a Java or ActionScript/Flex library](#)
- [Controls for a JavaScript library](#)

## Controls for a Java or ActionScript/Flex library

### ItemDescription

**Change Version** This button may be available for a library that implements a certain framework or technology (e.g. JSF, Spring) in cases when IntelliJ IDEA can make version-specific file replacements in the library. In such cases, when you click this button, the [Downloading Options dialog](#) opens in which you can select the necessary library version, and also the files to be downloaded.

As a result, the files in the library will be replaced with the downloaded files.

 or  Use this icon or shortcut to add items (classes, sources, documentation, etc.) to the library. In the [dialog that opens](#) , select the necessary files and folders. For a Java library, these may be individual `.class` and `.java` files, directories and archives (`.jar` and `.zip` ) containing such files as well as directories with Java native libraries (`.dll` , `.so` or `.jnilib` ). For an ActionScript/Flex library, these may be raw ActionScript 3 libraries, `.swc` , `.jar` and `.zip` files, the directories containing such files, and so on.

IntelliJ IDEA will analyze the selected files and folders, and automatically assign their contents to the appropriate library categories (Classes, Sources, Documentation, Native Library Locations, etc.).

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category yourself.

 To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

 Click this icon to make certain library items "excluded" (see [Excluded library items](#) ). In the dialog that opens, select the items that you want IntelliJ IDEA to ignore (folders, archives and folders within the archives), and click OK .

 or  When you click this icon or press `Delete` :  
 – The selected "ordinary" library items are removed from the library.  
 – The selected excluded items (see [Excluded library items](#) ) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

## Controls for a JavaScript library

### ItemDescription

 or  Use this icon or shortcut to add items to the library. Select one of the following options:  
 – **Attach Files or Directories.** Select this option to add JavaScript files. In the dialog that opens, select the necessary files and folders. These may be individual JavaScript files and the directories containing such files.

IntelliJ IDEA will analyze the selected files and folders, and automatically assign the JavaScript files to the appropriate categories. [Minified files](#) will be assigned to the Release category; ordinary (uncompressed) files will be assigned to the Debug category.

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category (Release or Debug) yourself.

– **Attach Debug Version(s).** Select this option to add a single uncompressed JavaScript file or a directory containing such files.  
 Note that IntelliJ IDEA won't analyze the contents of the selected files. If you select a [minified JavaScript file](#) or a directory containing minified JavaScript files, the corresponding file or files will still be added to the library.

– **Attach Release Version(s).** Select this option to add a single [minified JavaScript file](#) or a directory containing such files.  
 Note that IntelliJ IDEA won't analyze the contents of the selected files. If you select an ordinary (uncompressed) JavaScript file or a directory with such files, the corresponding file or files will still be added to the library.

– **Specify Documentation URL.** Select this option to make external online documentation available in IntelliJ IDEA. Specify the documentation URL in the dialog that opens.

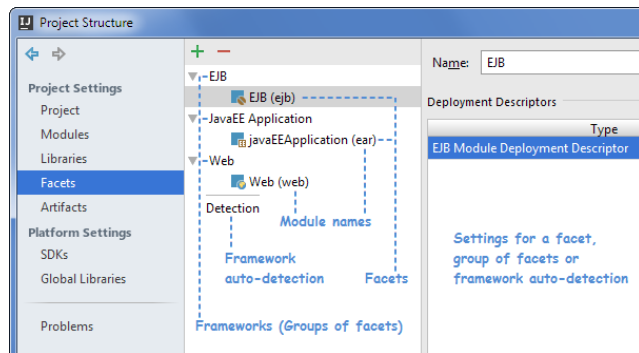

– **Download Documentation.** For jQuery: select this option to download and include jQuery documentation in the library.

 Click this icon to make certain library items "excluded" (see [Excluded library items](#) ). In the dialog that opens, select the folders that you want IntelliJ IDEA to ignore, and click OK .

 or  When you click this icon or press `Delete` :  
 – The selected "ordinary" library items are removed from the library.  
 – The selected excluded items (see [Excluded library items](#) ) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

Ctrl+Shift+Alt+S | Facets

Facets

- [Framework auto-detection](#)

Settings for individual [facets](#) (frameworks):

- [Android Facet Page](#)
- [AspectJ Facet Page](#)
- [Android-Gradle Facet Page](#)
- [EJB facet page](#)
- [Google App Engine Facet Page](#)
- [GWT Facet Page](#)
- [Hibernate and JPA Facet Pages](#)
- [Java EE Application facet page](#)
- [JSF Facet Page](#)
- [OSGi Facet Page](#)
- [Seam Facet Page](#)
- [Struts Facet Page](#)
- [Struts 2 Facet Page](#)
- [Tapestry Facet Page](#)
- [Web facet page](#)
- [Web Services Facet Page](#)
- [Web Services Client Facet Page](#)

## Framework auto-detection

To disable [framework auto-detection](#), clear the Enable framework detection checkbox.

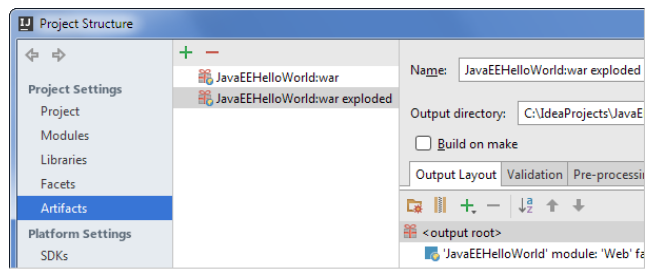

To exclude an individual framework from auto-detection, click [+](#), select the framework, and then select where auto-detection should be disabled:

- In the whole project.
- In directory. Select the directory where auto-detection should be disabled.

Ctrl+Shift+Alt+S | Artifacts

Artifacts

[Artifact configurations](#)

[Artifact configuration settings](#)

- General settings (Name, Type, etc.)
- Output Layout Tab
- Validation Tab
- Pre-Processing Tab
- Post-Processing Tab
- Android Tab
- Java FX tab

**ItemDescription**

---

Name	The name of the artifact configuration and also that of the artifact.
Type	The artifact type. Defines the artifact format and structure, highlighting of problematic parts in the artifact layout as well as the options that IntelliJ IDEA suggests (or assumes acceptable) in relation to the artifact composition.
Output directory	The artifact, when built ( Build   Build Artifacts ), is placed into the directory whose path is specified in this field. If the artifact is not going to be used on its own but only as a part of other artifacts, the field may be left empty. In this case, the artifact will not appear in the suggestion list on choosing Build   Build Artifacts and no target will be generated for it in <code>build.xml</code> on choosing Build   Generate Ant Build .
Build on make	Build the artifact automatically when building the project ( Build   Make Project ).

---

The Output Layout tab lets you specify the artifact structure and contents. The tab includes the following areas:

- The artifact layout pane (the left-hand one) shows the artifact structure and provides the means for changing it. You can create directories (📁) and archives (📦), add copies of compiled module sources, libraries, artifacts, files, etc. (+) as well as sort (📄) and reorder the items (↕). Note that the order of items, sometimes, may be **important**.
- The manifest file properties area (in the lower part of the artifact layout pane; available only for JAR, WAR and EAR files) lets you specify which manifest file is associated with the archive. It also lets you view and edit the values for the "most popular" `MANIFEST.MF` header fields.
- The Available Elements pane shows the elements that can be but are not yet added to the artifact. (The top level in this view just provides grouping for the elements.) For adding the elements to the artifact, this pane provides the options that generally work quicker (you can use double-clicks and drag-and-drop) than those in the artifact layout pane.

## Reordering the items

The order of items is important when there are elements that lead to producing files with the same name in the same directory. In such situations, only the file from the element that comes first will be included in the artifact.

To see the actual order of items, release 📄. Then use ↕ or ↕ to reorder the items.

## Artifact layout pane: context menu commands

Most of the commands have self-explanatory names. Here, we explain only the commands whose purpose may be unclear.

Command	Description
Extract Artifact	Transform the selected items into a new separate artifact. As a result: 1) a new artifact is created, 2) the selected items are moved to that new artifact, and 3) a copy of the new artifact is included in the old artifact in place of the initially selected items.
Inline Artifact	In a sense, this is the reverse to extracting an artifact and is used to make a "container artifact" independent of the artifact whose copy it contains. Let's assume, artifact A contains a copy of artifact B. As a result of inlining the copy of artifact B: 1) The copy of B in A is replaced with the contents of B and, from this moment on, can be edited independent of B. 2) The artifact B itself remains unchanged.
Surround with	In place of the selected items, create a directory or archive, and move the selected items into that directory or archive.

If you are using Oracle WebLogic Server, you can use its deployment descriptor validation extension. Click  and select the server version.

The tab is available only for the artifacts that can be deployed to a server.

If you want IntelliJ IDEA to run an Ant target before building the artifact, select the Run Ant target checkbox and specify the target. (The corresponding build file must already be [added to your project](#).)

To specify the parameters to be passed to the target, use the Properties section.

After the artifact is built, you can process it further by running an Ant target. To do that, select the Run Ant target checkbox and specify the target. (The corresponding build file must already be [added to your project](#).)

To specify the parameters to be passed to the target, use the Properties section.

In this tab, configure the Android Application Package to be generated.

#### ItemDescription

Type	<p>Select one of the following options from the drop-down list:</p> <ul style="list-style-type: none"><li>– Debug signed with default certificate : select this option to sign the extracted application packaged in the <b>debug mode</b> using the debug keystore or a key that is generated by the Android SDK tools. The following predefined values are used:<ul style="list-style-type: none"><li>– Keystore name : <code>debug.keystore</code></li><li>– Keystore password : <code>android</code></li><li>– Key alias : <code>androiddebugkey</code></li><li>– CN (common name): <code>CN=Android Debug,O=Android,C=US</code></li></ul></li><li>– Debug signed with custom certificate : Select this option to sign the extracted application packaged in the <b>debug mode</b> using a debug keystore or a key that you specify yourself. You can generate a new certificate, or reuse an existing one. Reusing a certificate may be useful, for example, if you have several applications and you want them all signed with the same certificate to be able to store them in the same folder on an Android device. When this option is selected, the Key store , Key store password , Key alias , and Key password fields become available.</li><li>– Release unsigned : select this option if you want to run a package on an emulator for test purposes, and want to have it extracted without a release signature.</li><li>– Release signed : select this option to extract and sign your application so that it can be published an run on physical devices. When this option is selected, the Key store , Key store password , Key alias , and Key password fields become available.</li></ul>
------	--

**Note** Note that the **debug mode** signature is only sufficient for testing and debugging Android applications, and does not allow publishing them.

Key store path	In this text box, specify the location of the file where the key will be stored. Type the path manually or click the Choose existing button to choose the relevant file in the <a href="#">dialog that opens</a> .
----------------	--

Create new	Click this button to open the <a href="#">New Key Store Dialog</a> and configure a new key store and/or a release key to be generated.
------------	--

Choose existing	Click this button to have your package signed with a key from an existing key store file. Choose the relevant key store file in the <a href="#">dialog that opens</a> .
-----------------	---

**Tip** Later you can choose to use an existing key from this keystore, or to have a new key generated in it.

Key store password	In this text box, type the password for the selected key store.
--------------------	---

Key alias	In this text box, specify the alias to address the key to be used.
-----------	--

Key password	In this text box, specify the password to access the selected key.
--------------	--

Run ProGuard	Select this option if you want IntelliJ IDEA to <a href="#">obfuscate the debug APK</a> through integration with the built-in <a href="#">ProGuard</a> tool.
--------------	--

Config file paths	This text box shows the default location of the <code>proguard-project.txt</code> configuration file that is created automatically together with an Android module.
-------------------	---

Show content of elements	<p>Select this option if you want the contents of certain elements to be displayed in the layout tree. Click the  button to specify the elements whose contents you want to be shown:</p> <ul style="list-style-type: none"><li>– Show Library Files</li><li>– Show Content of Included Artifacts</li><li>– Show Content of JavaEE Facets</li><li>– Show Content of JPA Resources</li></ul>
--------------------------	--

Use this tab to specify the settings for packaging your JavaFX application or application [preloader](#) .

The settings depend on the artifact type (JavaFx Application or JavaFx Preloader).

– [JavaFx Application settings](#)

– [JavaFx Preloader settings](#)

## JavaFx Application settings

### ItemDescription

Application class	The qualified application main class name. Normally, this is the class that extends the <code>javafx.application.Application</code> class and contains the <code>main()</code> method.
Title	The application title. In technical terms, this is the information for the <code>&lt;title&gt;</code> element in the corresponding <a href="#">deployment descriptor JNLP file</a> . If not specified, the title <code>Sample JavaFX Application</code> is used.
Vendor	The name of the application vendor (i.e. the information for the <code>&lt;vendor&gt;</code> element in the JNLP file). If not specified, the text <code>Unknown vendor</code> is used.
Description	A brief description of the application (i.e. the information for the <code>&lt;description&gt;</code> element in the JNLP file). If not specified, the text <code>Sample JavaFX 2.0 application</code> is used.
Width	The width of the application window in pixels. This parameter is used mainly by the applications embedded in a Web page.
Height	The height of the application window in pixels. This parameter is used mainly by the applications embedded in a Web page.
HTML Parameters	You may want to pass dynamic parameters to the application that runs in the Web Start or embedded in browser modes from the <a href="#">corresponding HTML page</a> . In that case, you should create a <code>.properties</code> file and specify the necessary set of named parameters in that file. Then you should specify the path to the <code>.properties</code> file in this field.
Application Parameters	You may want to pass named and unnamed parameters to the application. In that case, you should create a <code>.properties</code> file and specify the necessary parameters in that file. Then you should specify the path to the <code>.properties</code> file in this field. (The specified parameters will be included in the <a href="#">generated deployment descriptor JNLP file</a> .) Example  If the <code>.properties</code> file contains <pre>arg1=value1  arg2</pre> the following elements will be generated within <code>&lt;jfx:javaafx-desc&gt;</code> : <pre>&lt;fx:param name="arg1" value="value1"/&gt;  &lt;fx:argument&gt;arg2&lt;/fx:argument&gt;</pre>
Update in background	Use this checkbox to set the <code>check</code> attribute of the <code>&lt;update&gt;</code> element in the JNLP file. (This element is used to specify how Java Web Start should handle the application updates.) If selected, <code>&lt;update check="background"/&gt;</code> . The JNLP client will check for updates in the background while the application is being launched.  If not selected, <code>&lt;update check="always"/&gt;</code> . The JNLP client will always check for updates before launching the application.
Native bundle	The native bundles to be generated. (A native bundle is an operating system-specific self-contained application package. Such a bundle contains an application itself as well as a JRE, JavaFX runtime and a platform-specific application launcher.) Select: <ul style="list-style-type: none"> <li>– none. No OS-specific bundles are created. The application is packaged into the following files: <ul style="list-style-type: none"> <li>– <code>&lt;artifact_name&gt;.jar</code>. This file contains the compiled class files and images.</li> <li>– <code>&lt;artifact_name&gt;.jnlp</code>. This is a deployment descriptor JNLP file for Web deployment modes (Web Start and embedded in browser).</li> <li>– <code>&lt;artifact_name&gt;.html</code>. This file contains basic code for running the application in the Web Start and embedded in browser modes.</li> </ul> </li> <li>– all. All the bundles listed below are generated.</li> <li>– deb. A Debian software package for Debian GNU/Linux is generated.</li> <li>– dmg. An Apple disk image file for macOS is generated.</li> <li>– exe. An executable file for Windows is generated.</li> <li>– image. A bundle image for the OS that you are using is generated.</li> <li>– msi. A Windows Installer (Microsoft Installer) file is generated.</li> <li>– rpm. A Red Hat Package Manager file for Linux is generated.</li> </ul>
Convert css to bin	Select this checkbox if you want your application CSS file to be converted into binary format. (This may improve the application performance, especially for "large" CSS files.)
Enable signing	Select this checkbox if you want the application package to be digitally signed. IntelliJ IDEA can generate a key and the corresponding self-signed certificate, or an existing key may be used to sign

the package.

To select which way of signing should be used, click Edit Certificates . Then, in the Choose Certificate dialog that opens, select:

- Self signed. The package will be signed with the generated self-signed certificate.
- Signed by key. The package will be signed with your private key. Specify the associated settings:
  - Alias. Specify your private key alias.
  - Keystore. Specify the path to the keystore file. (This is where your private key and corresponding certificate are stored.)
  - Storepass. Specify the password for accessing the keystore.
  - Keypass. Specify the password for accessing the key.

## JavaFx Preloader settings

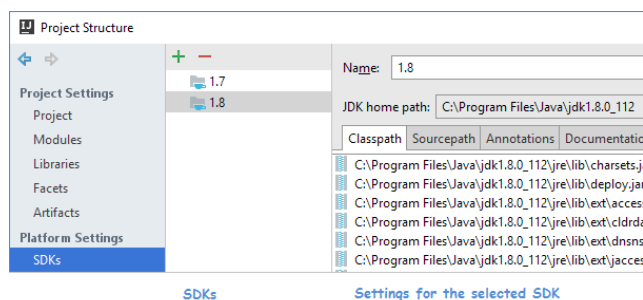

### ItemDescription

---

Preloader class	The qualified application preloader class name.
-----------------	---

Ctrl+Shift+Alt+S | SDKs

SDKs

When you select SDKs in the left-hand pane of the Project Structure dialog, the SDKs defined in IntelliJ IDEA are shown. So you can add and remove SDKs, look for their usages in the project as well as manage their settings.

- [Adding and removing SDKs. Looking for SDK usages](#)
- [Managing SDK settings](#)

## Adding and removing SDKs. Looking for SDK usages

The corresponding functions are accessed by means of the toolbar icons, context menu commands or keyboard shortcuts.

### IconCommandShortcutDescription

Icon	Command	Shortcut	Description
+	Add New SDK	Alt+Insert	Define a new SDK. Select the <a href="#">SDK type</a> and then specify the SDK home directory.
-	Delete	Delete	Remove the selected SDKs from the list.
	Find Usages	Alt+F7	Look for usages of the selected SDK in the project.

## Managing SDK settings

The settings for the selected SDK are shown in the right-hand part of the dialog. These settings depend on the [SDK type](#).

- [SDKs. Flex](#)
- [SDKs. Flexmojos SDK](#)
- [SDKs. Java](#)
- [SDKs. IntelliJ IDEA](#)
- [SDKs. Mobile](#)

Use this page to configure the selected Flex SDK . This includes managing the corresponding [path lists](#) on the Classpath , Sourcepath and Documentation Paths tabs.

#### ItemDescription

**Name** Use this field to edit the name of the SDK.

**Flex SDK home path** Specify the Flex SDK home directory.  
Use  (  ) to select the SDK installation directory in the Select Home Directory for Flex SDK dialog.

 or  Use this icon or shortcut to add one or more files and/or folders to the list.  
In the [dialog that opens](#) , select the necessary files and/or folders and click OK .

 or  Use this icon or shortcut to remove the selected items from the list.

 or  For the tab Documentation Paths : To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

When importing a [Flexmojos](#) project, IntelliJ IDEA automatically creates a Flexmojos SDK that lets you launch the Flex compiler and debugger.

Use the Flexmojos SDK page to view and edit the Flexmojos SDK settings.

---

**ItemDescription**

Name	Use this field to edit the name of the SDK.
Flex Compiler POM	In this field, the path to your compiler <code>pom</code> file is shown (readonly).
Flex Compiler/Debugger Classpath	In this area, the files included in the compiler shell classpath are shown (readonly).
AIR Debug Launcher	Specify the path to the <code>ad1.exe</code> file.
AIR Runtime (directory or zip file)	Specify the path to the AIR runtime directory or archive.

Use this page to configure the selected Java [SDK](#) . This includes specifying the paths to the [class files](#) , [sources](#) , [external annotations](#) and documentation.

#### ItemDescription

---

**Name** Use this field to edit the name of the SDK.

---

**JDK home path** Specify the JDK home directory.  
Use  ( [Shift+Enter](#) ) to select the SDK installation directory in the Select Home Directory for JDK dialog.

---

 or Use this icon or shortcut to add one or more files and/or folders to the list.  
[Alt+Insert](#) In the [dialog that opens](#) , select the necessary files and/or folders and click OK .

---

 or Use this icon or shortcut to remove the selected items from the list.  
[Alt+Delete](#)

---

 or [Alt+S](#) For the tab Documentation Paths : To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

Use this page to specify the settings related to the IntelliJ Platform Plugin SDK . (This is an SDK type for [IntelliJ IDEA plugin development](#) .)

Configure the paths to the [class files, sources](#) , [external annotations](#) and documentation.

The page includes the following tabs with similar controls:

- Classpath
- Sourcepath
- Annotations
- Documentation Paths

#### ItemDescription

Name	Use this field to edit the name of the SDK.
IntelliJ Platform Plugin SDK home path	Specify the IntelliJ Platform Plugin SDK home directory. Actually, this is the IntelliJ IDEA installation directory. Use  ( <a href="#">Shift+Enter</a> ) to select the SDK installation directory in the Select Home Directory for IntelliJ Platform Plugin SDK dialog.
Sandbox Home	Specify the sandbox directory, where IntelliJ IDEA will deploy plugins. Use  ( <a href="#">Shift+Enter</a> ) to select the necessary directory in the Sandbox Home dialog.
Internal Java Platform	Select the internal Java SDK.
 or 	Use this icon or shortcut to add one or more files and/or folders to the list. In the <a href="#">dialog that opens</a> , select the necessary files and/or folders and click OK .
 or 	Use this icon or shortcut to remove the selected items from the list.
 or 	For the tab Documentation Paths : To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

Use this page to configure the selected Java ME [SDK](#) (Mobile SDK). This includes specifying the paths to the [class files](#), [sources](#), [external annotations](#) and documentation.

Note that Java ME support is available in the Community edition of IntelliJ IDEA via a free plugin.

#### ItemDescription

Name	Use this field to edit the name of the SDK.
Mobile SDK home path	Specify the Mobile SDK home directory. Use  ( <a href="#">Shift+Enter</a> ) to select the SDK installation directory in the Select Home Directory for Mobile SDK dialog.
Use default profile and configuration versions	Choose this option to have your application developed in compliance with the default set of <a href="#">Mobile Information Device Profiles (MIDP)</a> and <a href="#">Connected Limited Device Configurations (CLDC)</a> . This ensures that your application will fit maximum number of targeted platforms. The supported MIDP and CLDC are listed in a read-only field.
Use custom profile and configuration versions	Choose this option to have your application developed in compliance with <a href="#">Mobile Information Device Profiles (MIDP)</a> and <a href="#">Connected Limited Device Configurations (CLDC)</a> of your choice. In this case, your application will fit a restricted number of targeted platforms. Specify the required MIDP and CLDC in the text boxes.
Preverify parameters	Specify the parameters to be passed to the <a href="#">preverify utility</a> . This utility checks your compiled code for compliance with the targeted environment.
Choose Java SDK	Select the internal Java SDK, if any is registered with IntelliJ IDEA.
 or <a href="#">Alt+Insert</a>	Use this icon or shortcut to add one or more files and/or folders to the list. In the <a href="#">dialog that opens</a> , select the necessary files and/or folders and click OK.
 or <a href="#">Alt+Delete</a>	Use this icon or shortcut to remove the selected items from the list.
 or <a href="#">Alt+S</a>	For the tab Documentation Paths : To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

Using shortcuts is a major way to maximum efficiency and productivity of IntelliJ IDEA. This part lists keystroke combinations and their functions for the Default keymap defined in [Keymap](#) dialog box.

**Warning!** The key combinations documented in this part may fail to perform the function described, if you are using a [customized keymap](#) .

To get a printable copy of the default keymap, choose Help | Default Keymap Reference on the main menu.

**Tip** Note that in certain operating systems the key and mouse combinations may not work as described here. In this case, it's necessary to tweak the operating system's keymap. For example, if you are using Ubuntu, mind the windows manager, whose [shortcuts conflict](#) with that of IntelliJ IDEA

In this part:

- [Keyboard Shortcuts By Keystroke](#)
- [Keyboard Shortcuts By Category](#)
- [Mouse Reference](#)

In this part you can find reference information on keyboard shortcuts grouped by keystroke:

- [Alt](#)
- [Alt+Shift](#)
- [Ctrl](#)
- [Ctrl+Alt](#)
- [Ctrl+Shift](#)
- [Function Keys](#)
- [Insert, Delete and Navigation Keys](#)
- [Shift](#)
- [Ctrl+Alt+Shift](#)

To view a full list of available shortcuts, navigate to File | Settings and click Keymap under IDE Settings .

This section lists and describes the keyboard shortcuts that include the **Alt** key:

– [Alt+Alphanumeric keys](#)

– [Alt+Navigation keys](#)

– [Alt+Function \(F\) keys](#)

## Alt+Alphanumeric keys

**ShortcutFunctionUse this shortcut to...**

<b>Alt+O</b>	Export to Text File	Export a tool window's content to a text file.
<b>Alt+Q</b>	Context Info	Show the current method or class declaration when it is not visible.
<b>Alt+Number</b>	Open tool window	Open a tool window with the corresponding number.
<b>Alt+Slash</b>	Code completion / Expand word	Expand string at caret to any word in the visible scope that starts with the same characters.
<b>Alt+Back Quote</b>	VCS operations	Show quick list with the most required version control commands.

## Alt+Navigation keys

**ShortcutFunctionUse this shortcut to...**

<b>Alt+Delete</b>	Safe Delete	Delete selected class/method/field checking its usages.
<b>Alt+Enter</b>	Show Intention Action	Display <a href="#">intention actions</a> (if any) for a code where the caret is currently located.
<b>Alt+Home</b>	Activate Navigation Bar	Bring focus to the Navigation bar.
<b>Alt+Insert</b>	Create new entity	Depending on the context: <ul style="list-style-type: none"><li>– In the navigation views: create a new class, file or directory, using the New pop-up menu.</li><li>– In the editor: create constructors, accessor methods, EJB components, Maven dependencies, and test methods, using the Generate pop-up menu. See <a href="#">Generating Code</a> , <a href="#">Creating Maven Dependencies</a> , <a href="#">Creating Test Methods</a> .</li></ul>
<b>Alt+Down</b>	Navigate to Next Method	Navigate to the next method declaration in the active editor tab.
<b>Alt+Left</b>	Select Previous Tab	Depending on the context: <ul style="list-style-type: none"><li>– When several tabs are opened in the editor or a view, open the next tab to the left (or the last tab if the current one is the first).</li><li>– In the <a href="#">Differences Viewer for Files</a> invoked from the <a href="#">Update Project Info</a> tab of the <a href="#">Version Control</a> tool window, compare the local copy of the previous file with its update from the server.</li></ul>
<b>Alt+Right</b>	Select Next Tab	Depending on the context: <ul style="list-style-type: none"><li>– When several tabs are opened in the editor or a view, open the next tab to the right (or the first tab if the current one is the last).</li><li>– In the <a href="#">Differences Viewer for Files</a> invoked from the <a href="#">Update Project Info</a> tab of the <a href="#">Version Control</a> tool window, compare the local copy of the next file with its update from the server.</li></ul>
<b>Alt+Up</b>	Navigate to Previous Method	Navigate to the previous method declaration in the active editor tab.

## Alt+Function (F) keys

**ShortcutFunctionUse this shortcut to...**

<b>Alt+F1</b>	Select Target	Move focus from the current file, class, method or reference to a data source table to a view suggested in the Select Target pop-up menu. See <a href="#">Navigating Between IDE Components</a> .
<b>Alt+F7</b>	Find Usages	Initiate <a href="#">search for usages</a> .
<b>Alt+F8</b>	Evaluate Expression	Debugger: Evaluate an arbitrary expression.
<b>Alt+F9</b>	Run to Cursor	Debugger: Run to the line where the caret is located.

This section lists and describes the keyboard shortcuts that include the `Shift+Alt` keys:

**ShortcutFunctionUse this shortcut to...**

<code>Shift+Alt+F7</code>	Force Step Into	Step into the method called in the current execution point, even if this method is to be skipped.
<code>Shift+Alt+F8</code>	Force Step Over	Run until the next line in this method or file, skipping the methods referenced at the current execution point and ignoring breakpoints.
<code>Shift+Alt+F9</code>	Debug	Quickly select run/debug configuration and debug/edit it.
<code>Shift+Alt+F10</code>	Run	Quickly select run/debug configuration and run/edit it.

This section lists and describes the keyboard shortcuts that include the `Ctrl` key:

- [Ctrl+Alphanumeric keys](#)
- [Ctrl+Navigation keys](#)
- [Ctrl+Symbol keys](#)
- [Ctrl+Numpad keys](#)
- [Ctrl+Function \(F\) keys](#)

## Ctrl+Alphanumeric keys

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+A</code>	Select All	Select the entire text in the active editor.
<code>Ctrl+B</code>	Navigate to Declaration	Navigate directly to an element's declaration from any usage.
<code>Ctrl+C</code>	Copy	Copy selected text to the Clipboard.
<code>Ctrl+D</code>	Duplicate Line or Block	Duplicate selected block or line at caret.
<code>Ctrl+E</code>	Recent Files Recent find usages	Show the list of <a href="#">recently opened files</a> . When the Find tool window has the focus, use this shortcut to show the list of <a href="#">recent find usages results</a> .
<code>Ctrl+F</code>	Find	Initiate <a href="#">text search</a> in the editor.
<code>Ctrl+G</code>	Navigate to Line	Navigate the to a line with the specified number in the current file.
<code>Ctrl+H</code>	Type Hierarchy	Browse hierarchy for the selected class.
<code>Ctrl+I</code>	Implement Methods	<a href="#">Implement</a> methods of the base interface/class in the current class.
<code>Ctrl+J</code>	Insert Live Template	Show a pop-up list of Live Templates starting with a specified prefix.
<code>Ctrl+M</code>	Scroll to Center	Scroll a line at caret to the center of the screen.
<code>Ctrl+N</code>	Navigate to Class	Jump to a class in the project with the specified name.
<code>Ctrl+O</code>	Override Methods	Override base class methods in the current class.
<code>Ctrl+P</code>	Parameter Info	Show parameters of the method call at the caret.
<code>Ctrl+Q</code>	Quick documentation	Show a pop-up window with documentation for the symbol at caret. In the <a href="#">Database tool window</a> : show a pop-up window that displays the <code>create table</code> query for the database table at the caret and the first 10 rows of the table.
<code>Alt+Mouse Button2</code>		
<code>Ctrl+R</code>	Replace	Call the Replace Text dialog box.
<code>Ctrl+S</code>	Save All	Save all files and settings.
<code>Ctrl+U</code>	Navigate to Super Method	Navigate to a super method declaration of a method at caret
<code>Ctrl+V</code>	Paste	Paste from the Clipboard.
<code>Ctrl+W</code>	Select Word at Caret	Successively select expanding blocks of text, starting from the word at caret. (Use this shortcut repeatedly to select expressions.)
<code>Ctrl+X</code>	Cut	Cut to the Clipboard.
<code>Ctrl+Y</code>	Delete Line at Caret	Delete a word starting from the current caret location up to the end of word.
<code>Ctrl+Z</code>	Undo	Undo last operation.
<code>Ctrl+Shift+Z</code>	Redo	Redo last undone operation.
<code>Ctrl+Number</code>	Navigate to bookmark	Navigate to a numbered bookmark with corresponding number.

## Ctrl+Navigation keys

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+Tab</code>	Switcher	Navigate between the files opened in the editor, and tool windows.
<code>Ctrl+Backspace</code>	Delete to Word Start	Delete a word starting from the current caret location up to the word start.

Ctrl+Delete	Delete to Word End	Delete a word starting from the current caret location up to the word end.
Ctrl+End	Move to Text End	Move the caret to the end of text.
Ctrl+Enter	Split Line or Open Item	Depending on the context: <ul style="list-style-type: none"> <li>- In the editor: Intelligently split the current line into 2 lines, shifting quotes, etc. as necessary.</li> <li>- In the Tool Windows: Open an Editor tab or tabs for the selected item or items, respectively.</li> <li>- On the context menus of the modules in the <a href="#">Project Tool Window</a> , <a href="#">Dependency Viewer</a> , and <a href="#">Module Dependencies tool window</a> : open the <a href="#">Modules structure</a> .</li> </ul>
Ctrl+Home	Move to Text Start	Jump to the beginning of the text.
Ctrl+C	Copy	Copy a current line or a selected code block to the Clipboard.
Ctrl+Space	Basic Code Completion	Complete code for any class, method or variable.
Ctrl+Page Down	Navigate to Page Bottom	Move the caret down to the page bottom.
Ctrl+Page Up	Navigate to Page Top	Move the caret up to the page top.
Ctrl+Down	Scroll Down	Move line at caret one down, preserving syntactical correctness.
Ctrl+Left	Move to Previous Word	Move the caret to the previous word.
Ctrl+Right	Move to Next Word	Move the caret to the next word.
Ctrl+Up	Scroll Up	Move line at caret one up, preserving syntactical correctness.
Ctrl+Shift+Up		
Ctrl + End	Ctrl + Home /	Select text from the caret position to the beginning/end of the current line.

## Ctrl+Symbol keys

**ShortcutFunctionUse this shortcut to...**

Ctrl+Open Bracket	Move to Code Block Start	Move the caret to the beginning of the current code block, highlighting its limits.
Ctrl+Close Bracket	Move to Code Block End	Move the caret to the end of the current code block, highlighting its limits.
Ctrl+Slash	Comment with Line Comment	Comment/uncomment current line or selected block with line comments.
Ctrl+Numpad/		
Ctrl+=	Expand All	Expand all folding blocks.
Ctrl+NumPad Plus		
Ctrl+NumPad -	Collapse All	Collapse all folding blocks.

## Ctrl+Numpad keys

**ShortcutFunctionUse this shortcut to...**

Ctrl+Numpad/	Comment with Line Comment	Comment/uncomment current line or selected block with line comments.
Ctrl+Slash		
Ctrl+NumPad Plus	Expand All	Expand all folding blocks.
Ctrl+=		
Ctrl+NumPad -	Collapse All	Collapse all folding blocks.

## Ctrl+Function (F) keys

**ShortcutFunctionUse this shortcut to...**

Ctrl+F1	Error Description	Show an error or warning description at the caret.
Ctrl+F3	Find Word at Caret	Search in the editor for the word where the caret is currently located.
Ctrl+F6	Change Method Signature	Refactor a selected method signature and update all references.
	Find Usages in File	Initiate <a href="#">search for usages</a> .

Ctrl+F7		
Ctrl+F8	Toggle Breakpoint	Toggle breakpoint at caret.
Ctrl+F9	Make Project	Compile all modified and dependent files in a project.
Ctrl+F11	Toggle Bookmark with mnemonic.	Turn bookmark with mnemonic on or off.
Ctrl+F12	File Structure Pop-up	Show the current file structure in the File Structure pop-up window for quick navigation.

This section lists and describes the keyboard shortcuts that include the `Ctrl+Alt` keys:

- [Ctrl+Alt+Alphanumeric keys](#)
- [Ctrl+Alt+Navigation keys](#)
- [Ctrl+Alt+Function \(F\) keys](#)

## Ctrl+Alt+Alphanumeric keys

ShortcutFunctionUse this shortcut to...

<code>Ctrl+Alt+B</code>	Navigate to Implementation	<a href="#">Navigate to implementation</a> of an item at the caret.
<code>Ctrl+Alt+C</code>	Extract Constant	<a href="#">Replace selected expression with a constant</a> (static final field) (Refactoring).
<code>Ctrl+Alt+F</code>	Extract Field	<a href="#">Put the selected expression result into a field</a> (Refactoring).
<code>Ctrl+Alt+G</code>	Run Grails target	Execute Grails target with the specified target name.
<code>Ctrl+Alt+H</code>	Call Hierarchy	Browse call hierarchy for the selected method. See page <a href="#">Viewing Structure and Hierarchy of the Source Code</a>
<code>Ctrl+Alt+I</code>	Auto-indent Lines	Indent current line or selected block according to the <a href="#">Code Style settings</a> .
<code>Ctrl+Alt+J</code>	Surround with Live Template	<a href="#">Surround the selection with one of the Live Templates</a> .
<code>Ctrl+Alt+M</code>	Extract Method	<a href="#">Create a method</a> from the selected code (Refactoring).
<code>Ctrl+Alt+N</code>	Inline	<a href="#">Inline the selected method/variable</a> (Refactoring).
<code>Ctrl+Alt+P</code>	Extract Parameter	Turn the selected expression into a <a href="#">method parameter</a> (Refactoring).
<code>Ctrl+Alt+T</code>	Surround with	<a href="#">Surround selected code</a> fragment with <code>if</code> , <code>while</code> , <code>try/catch</code> , or another construct.
<code>Ctrl+Alt+V</code>	Extract Variable	Put selected expression result into a variable (Refactoring). See page <a href="#">Extract Variable</a> .
<code>Ctrl+Alt+Y</code>	Synchronize	Detect all externally changed files and reload them from disk.

## Ctrl+Alt+Navigation keys

ShortcutFunctionUse this shortcut to...

<code>Ctrl+Alt+Enter</code>	Start new line before current one	Start a new line before the current one.
<code>Ctrl+Alt+Down</code>	Navigate to Next/Previous Occurrence	Navigate to the next/previous found item.
<code>Ctrl+Alt+Up</code>	Back	Undo last navigation operation. See page <a href="#">Navigating to Navigated Items</a>
		<b>Note</b> On a macOS computer, you can also use the three-finger right-to-left swipe gesture.
<code>Ctrl+Alt+Right</code>	Forward	Redo last undone navigation operation. See page <a href="#">Navigating to Navigated Items</a>
		<b>Note</b> On a macOS computer, you can also use the three-finger left-to-right swipe gesture.
<code>Ctrl+Alt+Home</code>	Navigate to Related Symbol	Navigates between files with the various relationships. See <a href="#">Navigation In Source Code</a> .

## Ctrl+Alt+Function (F) keys

ShortcutFunctionUse this shortcut to...

<code>Ctrl+Alt+F6</code>	Switch to another coverage suite.	Open the Coverage Suites popu-up window and select the desired suite to run.
<code>Ctrl+Alt+F7</code>	Show usages	Show usages of a symbol at the caret. See page <a href="#">Viewing Usages of a Symbol</a>
<code>Ctrl+Alt+F8</code>	Quick Evaluate Expression	<a href="#">Evaluate an arbitrary expression</a> without calling Evaluate Expression dialog box.
<code>Ctrl+Alt+F9</code>	Force Run To Cursor	Run to the line where the caret is located, ignoring breakpoints. See page <a href="#">Stepping Through the Program</a> .

This section lists and describes the keyboard shortcuts that include the `Ctrl+Shift` keys:

- [Ctrl+Shift+Alphanumeric keys](#)
- [Ctrl+Shift+Navigation keys](#)
- [Ctrl+Shift+Symbol keys](#)
- [Ctrl+Shift+Numpad keys](#)
- [Ctrl+Shift+Function \(F\) keys](#)

## Ctrl+Shift+Alphanumeric keys

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+Shift+A</code>	Find Action	Find an action, bypassing menus. See <a href="#">Finding Actions</a> .
<code>Ctrl+Shift+B</code>	Navigate to Type Declaration	<a href="#">Navigate to type declaration</a> of a variable or a method call at caret.
<code>Ctrl+Shift+E</code>	Navigate to Recently Changed File	Show the list of <a href="#">recently updated files</a> .
<code>Ctrl+Shift+F</code>	Find in Path	Initiate <a href="#">text search in the specified path</a> .
<code>Ctrl+Shift+H</code>	Method Hierarchy	Browse hierarchy for the selected class.
<code>Ctrl+Shift+J</code>	Join Lines	<a href="#">Concatenate</a> selected lines into one or concatenate a line where the caret is currently located with the next line.
<code>Ctrl+Shift+N</code>	Navigate to File	Jump to the specified <a href="#">file</a> in project.
<code>Ctrl+Shift+R</code>	Replace in Path	Initiate <a href="#">text replacement in the specified path</a> .
<code>Ctrl+Shift+U</code>	Toggle Case	<a href="#">Toggle case</a> of the selected text fragment.
<code>Ctrl+Shift+V</code>	Paste from History	Paste from recent Clipboards. See page <a href="#">Cutting, Copying and Pasting</a>
<code>Ctrl+Shift+W</code>	Deselect Word at Caret	Remove sequential selection made by the <a href="#">Select Word at Caret action</a> .
<code>Ctrl+Shift+Z</code>	Redo	<a href="#">Redo the last Undo operation</a> .
<code>Ctrl+Shift+Semicolon</code>	Show recent tests	<a href="#">View the list of recently performed tests.</a>

## Ctrl+Shift+Navigation keys

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+Shift+End</code>	Move to Text End with Selection	Select text from the current caret position to the end of text, and move caret to the end of text. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+Home</code>	Move to Text Start with Selection	Select text from the current caret position to the start of text, and move caret to the start of text. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+Right</code>	Move to Word End with Selection	Select text from the current caret position to the end of word, and move caret to the end of word. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+Left</code>	Move to Word Start with Selection	Select text from the current caret position to the beginning of the current word, and move caret to the beginning of this word. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+V</code>	Paste from History	Paste from recent Clipboards. See page <a href="#">Cutting, Copying and Pasting</a>
<code>Ctrl+Shift+Space</code>	<a href="#">SmartType Code Completion</a>	Complete code, filtering the lookup list based on an expected type.
<code>Ctrl+Shift+Page Down</code>	Navigate to Page Bottom with Selection	Move the caret down to the page bottom selecting the text. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+Page Up</code>	Navigate to Page Top with Selection	Move the caret up to the page bottom selecting the text. See page <a href="#">Selecting Text in the Editor</a> .
<code>Ctrl+Shift+Down</code>	Move Line Down	Move line at caret one down, preserving syntactical correctness. See page <a href="#">Adding, Deleting and Moving Code Elements</a> .
<code>Ctrl+Shift+Up</code>	Move Line Up	Move line at caret up, preserving syntactical correctness. See page <a href="#">Adding, Deleting and Moving Code Elements</a> .
<code>Ctrl+Shift+Backspace</code>	Last Edit Location	Jump to the place of the last editing.

## Ctrl+Shift+Symbol keys

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+Shift+Open Bracket</code>	Move to Code	Move the caret to the beginning of the current code block, selecting the code
--------------------------------------	--------------	---

	Block Start with Selection	from the initial caret location. See page <a href="#">Selecting Text in the Editor</a> .
<a href="#">Ctrl+Shift+Close Bracket</a>	Move to Code Block End with Selection	Move the caret to the end of the current code block, selecting the code from the initial caret location. See page <a href="#">Selecting Text in the Editor</a> .
<a href="#">Ctrl+Shift+Slash</a>	Comment with Block Comment	Comment/uncomment code with block comments. See page <a href="#">Commenting and Uncommenting Blocks of Code</a> .
<a href="#">Ctrl+NumPad Plus</a>	Expand All	Expand all folding blocks. See page <a href="#">Folding Code Elements</a> .
<a href="#">Ctrl+Shift+NumPad -</a>	Collapse All	Collapse all folding blocks. See page <a href="#">Folding Code Elements</a> .

## Ctrl+Shift+Numpad keys

**ShortcutFunctionUse this shortcut to...**

<a href="#">Ctrl+Shift+Numpad/</a>	Comment with Block Comment	Comment/uncomment code with block comments. See page <a href="#">Commenting and Uncommenting Blocks of Code</a> .
<a href="#">Ctrl+Shift+Numpad+</a>	Expand All	Expand all folding blocks. See page <a href="#">Folding Code Elements</a> .
<a href="#">Ctrl+NumPad Plus</a>		
<a href="#">Ctrl+Shift+Numpad-</a>	Collapse All	Collapse all folding blocks. See page <a href="#">Folding Code Elements</a> .

## Ctrl+Shift+Function (F) keys

**ShortcutFunctionUse this shortcut to...**

<a href="#">Ctrl+Shift+F4</a>	Close Active Tab	Close an active tab in a tool window. See page <a href="#">Editor</a> .
<a href="#">Ctrl+Shift+F7</a>	Highlight Usages in File / Highlight Method Exit Points	<a href="#">Highlight usages</a> of a symbol where the caret is currently located. If the caret is placed on one of the method's exit points, like <code>return</code> , all method exit points are highlighted.
<a href="#">Ctrl+Shift+F8</a>	<a href="#">View breakpoints</a>	View/manage all breakpoints/watchpoints
<a href="#">Ctrl+Shift+F9</a>	Compile	<a href="#">Compile</a> the selected file or package.

This section describes default mappings for the function (F) keys.

**ShortcutFunctionUse this shortcut to...**

F1	Help	Invoke reference page.
F2	Activate in-place editing	In a GUI Designer form, enable in-place editing of the name of a selected UI component.
F3	Search for next/previous occurrence	Navigate to the next/previous occurrence of a selected word in the editor.
Shift+F3		
F4	Edit Source	Depending on the context: <ul style="list-style-type: none"><li>– In Tool Windows: Open an Editor tab or tabs for the selected item or items (including GUI forms), and give focus to the last opened file.</li><li>– On the context menus of the modules in the <a href="#">Project Tool Window</a> , <a href="#">Dependency Viewer</a> , and <a href="#">Module Dependencies tool window</a> : open the <a href="#">Modules structure</a> .</li></ul>
F5	Copy	Create a copy of a selected class/file/directory in the same or a different package.
F6	Move	Move a selected class/package/static member to another package/class and correct all references.
F7	Step Into	Step to the next executed line (during debugging).
F8	Step Over	Step to the next line in the current file (during debugging).
F9	Resume Program	Resume program execution (during debugging).
F11	Toggle Bookmark	Turn anonymous bookmark on or off.
F12	Jump to Last Window	Activate a last focused tool window.

This section describes default mappings for the `Insert`, `Delete` and the navigation keys.

**ShortcutFunctionUse this shortcut to...**

<code>Delete</code>	Delete	Depending on the context: <ul style="list-style-type: none"><li>- In the editor: delete selected symbol/block.</li><li>- In the <a href="#">Find tool window</a>: exclude items from the search results.</li><li>- In the <a href="#">Version Control tool window</a>: delete an item from a changelist.</li><li>- In other views: remove the selected item or items.</li></ul>
<code>Down</code>	Move down	Move the caret one line down.
<code>End</code>	Move to Line End	Move the caret to the end of line.
<code>Home</code>	Move to Line Start	Move the caret to the beginning of line.
<code>Insert</code>	Toggle Insert/Overwrite	Toggle Insert/Overwrite modes in the editor. The shape of the cursor changes according to the current mode.
<code>Left</code>	Move left	Move the caret one character to the left.
<code>Page Down</code>	Page down	Move the caret one page up.
<code>Page Up</code>	Page up	Move the caret one page up.
<code>Right</code>	Move right	Move the caret one character to the right.
<code>Tab</code>		In the editor: <ul style="list-style-type: none"><li>- With any selection: indent selected line(s).</li><li>- Without any selection: insert a tab symbol (or corresponding number of space.characters).</li></ul> In a lookup list: <ul style="list-style-type: none"><li>- No code after the caret in the editor: select an item (like <code>Enter</code>)</li><li>- Some code after the caret in the editor: select an item and replace the code after the caret with it.</li></ul>
<code>Up</code>	Move up	Move the caret one line up.

This section lists and describes the keyboard shortcuts that include the **Shift** key:

- [Shift+Navigation keys](#)
- [Shift+Function \(F\) keys](#)

## Shift+Navigation keys

**ShortcutFunctionUse this shortcut to...**

<b>Shift+Down</b>	Down with Selection	Move the caret one line down selecting the text.
<b>Shift+End</b>	Move to Line End with Selection	Move the caret to the end of line, selecting text.
<b>Shift+Enter</b>	Start New Line	Start a new line after the current one, positioning the caret in accordance with the current indentation level (equal to sequential pressing End, Enter).
<b>Shift+Escape</b>	Hide Active Window	Hide the currently active tool window.
<b>Shift+Home</b>	Move to Line Start with Selection	Move the caret to the beginning of line, selecting the text.
<b>Shift+Left</b>	Left with Selection	Move the caret one character to the left selecting the text.
<b>Shift+Page Down</b>	Page Down with Selection	Move the caret one page down selecting the text.
<b>Shift+Page Up</b>	Page Up with Selection	Move the caret one page up selecting the text.
<b>Shift+Right</b>	Right with Selection	Move the caret one character to the right selecting the text.
<b>Shift+Tab</b>	Unindent Selection	Move selected block to the previous indent level.
<b>Shift+Up</b>	Up with Selection	Move the caret one line up selecting the text.

## Shift+Function (F) keys

**ShortcutFunctionUse this shortcut to...**

<b>Shift+F1</b>	External Documentation	Open browser with the documentation for the selected item. Refer to <a href="#">Viewing Inline Documentation</a> for details.
<b>Shift+F2</b>	One of the following: <ul style="list-style-type: none"><li>- Navigate to Previous Highlighted Error.</li><li>- Stop Program.</li></ul>	Depending on whether you are editing or debugging: <ul style="list-style-type: none"><li>- When editing: Navigate to the previous found error/warning.</li><li>- When debugging: Terminate the debugging session.</li></ul>
<b>F3</b> / <b>Shift+F3</b>	Search for next/previous occurrence	Jump to the next/previous occurrence of the selected word in the editor.
<b>Shift+F6</b>	Rename	<a href="#">Rename</a> a statement and correct all references. (Refactoring).
<b>Shift+F7</b>	Move to Previous Difference/Smart Step Into	Move to a previous difference in a view./ Select the method to step in, if the current line contains multiple method call expressions. (Debugger).
<b>Shift+F8</b>	Step Out	Step to the first executed line after returning from a current method.
<b>Shift+F9</b>	Debug	<a href="#">Debug</a> application.
<b>Shift+F10</b>	Run	<a href="#">Run</a> application.
<b>Shift+F11</b>	Show Bookmarks	Open <a href="#">Bookmarks</a> dialog to manage existing bookmarks and navigate between them.
<b>Shift+F12</b>	Restore Default layout	Restore the default IntelliJ IDEA layout (tool windows positions, buttons location and order). To restore the default layout, check the option Store Current Layout as Default in the Window menu.

This section lists and describes the keyboard shortcuts that include the `Ctrl+Shift+Alt` keys.

**ShortcutFunctionUse this shortcut to...**

<code>Ctrl+Shift+Alt+C</code>	Copy Relative Path	Copy a reference (a relative path) of a symbol to the Clipboard.
<code>Ctrl+Shift+Alt+N</code>	Go to Symbol	<a href="#">Navigate to a symbol</a> with the specified name.
<code>Ctrl+Shift+Alt+H</code>	Pop up Hector	Open the <a href="#">Highlighting level</a> pop-up window.
<code>Ctrl+Shift+Alt+S</code>	Project Structure	Open <a href="#">Project Structure</a> dialog box.
<code>Ctrl+Shift+Alt+U</code>	Show Uml Diagram	<a href="#">Open UML Class diagram</a> for a class or package.
<code>Ctrl+Shift+Alt+V</code>	Paste Simple	Paste the last entry from the Clipboard as plain text.
<code>Ctrl+Shift+Alt+L</code>	Show Reformat File Dialog	Show <a href="#">reformatting dialog</a> .
<code>Ctrl+Shift+Alt+I</code>	Run Inspection by Name	Execute an inspection <a href="#">by its name</a> .
<code>Ctrl+Shift+Alt+Insert</code>	New Scratch File	Create a <a href="#">new scratch file</a> with the selected language.

In this part you can find reference information about the keyboard shortcuts grouped by functional categories:

**FunctionShortcutUse this  
shortcut to...**

Comment with Line Comment	Ctrl+Slash	Comment/uncomment current line or selected block with line comments.
Comment with Block Comment	Ctrl+Shift+Slash	Comment/uncomment code with block comments.
Quick Documentation	Ctrl+Q / Alt+Button2 Click	Show a pop-up window with the documentation for the symbol at the caret.
Show Table Data	Ctrl+Q	Show a pop-up window that displays the <code>create table</code> query for the database table at the caret and the first 10 rows of the table.
Pop-up Hecor	Ctrl+Shift+Alt+H	Show the Highlighting level pop-up window to configure highlighting in the current file.
Parameter Info	Ctrl+P	Show parameters of the method call at the caret.
Context Info	Alt+Q	Show the current method or class declaration when it is not visible.
Error Description	Ctrl+F1	Show an error or warning description at the caret.
External Documentation	Shift+F1	Open browser with the documentation for the selected item.
Override Methods...	Ctrl+O	Override base class methods in the current class.
Implement Methods...	Ctrl+I	Override base interface/class methods in the current class.
Surround with...	Ctrl+Alt+T	Surround selected code fragment with <code>if</code> , <code>do</code> , tags or other constructs. In the GUI Designer, use this shortcut to <a href="#">wrap</a> selected components into a container.
Generate	Alt+Insert	Generate constructors, accessor methods, EJB components, Maven dependencies in the <code>pom.xml</code> files, using the Generate pop-up menu.
Basic Code Completion	Ctrl+Space Alt+Slash	Code completion for any class, method or variable.
SmartType Code Completion	Ctrl+Shift+Space	Code Completion filtering the lookup list basing on expected type.
Expand Word	Alt+Slash	Goes through the names of classes, methods, keywords and variables in the current visibility scope.
Insert Live Template...	Ctrl+J	Show a pop-up list of starting with a specified prefix.
Surround with Live Template...	Ctrl+Alt+J	Surround the selection with one of the templates.
Next Template Variable	Tab	In templates: move the caret to the next template variable.
Previous Template Variable	Shift+Tab	In templates: move the caret to the previous template variable.

**FunctionShortcutUse this shortcut to...**

Enter		Depending on the context: <ul style="list-style-type: none"> <li>- In a lookup list: select an item.</li> <li>- In the editor: enter a new line and set the caret at its beginning.</li> </ul>
Tab		In the editor: <ul style="list-style-type: none"> <li>- With selection: indent selected lines.</li> <li>- Without selection: insert a tab symbol (or corresponding number of space characters).</li> </ul> In a lookup list: <ul style="list-style-type: none"> <li>- No code after the caret: select an item.</li> <li>- Some code after the caret: select an item and substitute the code after the caret with it.</li> </ul>
Delete		Depending on the context: <ul style="list-style-type: none"> <li>- In the editor: delete selected symbol/block.</li> <li>- In a usage view: exclude a selected item.</li> <li>- In other views: remove selected items.</li> </ul>
Backspace		Delete a character to the left of the caret.
Undo		Undo last operation.
Redo		Redo last undone operation.
Cut		Cut a current line or a selected code block to the Clipboard.
Copy		Copy a current line or a selected code block to the Clipboard.
Paste		Paste from the Clipboard to the caret location.
Paste from History		Paste selected entry from the Clipboard to the caret location.
Up		Move the caret one line up.
Up with Selection		Move the caret one line up selecting the text.
Down		Move the caret one line down.
Down with Selection		Move the caret one line down selecting the text.
Left		Move the caret one character to the left.
Left with Selection		Move the caret one character to the left selecting the text.
Right		Move the caret one character to the right.
Right with Selection		Move the caret one character to the right selecting the text.
Go to Page Bottom		Move the caret down to the page bottom.
Go to Page Bottom with Selection		Move the caret down to the page bottom, selecting the text.
Go to Page Top		Move the caret up to the page top.
Go to Page Top with Selection		Move the caret up to the page bottom, selecting the text.
Page Down		Move the caret one page down.
Page Down with Selection		Move the caret one page down, selecting the text.
Page Up		Move the caret one page up.
Page Up with Selection		Move the caret one page up, selecting the text.
Scroll Down		Scroll the text one line down.
Scroll to Center		Scroll a line at caret to the center of the screen.
Scroll Up		Scroll the text one line up.
Move to Line End		Move the caret to the end of line.
Move to Line End with Selection		Move the caret to the end of line, selecting the text.
Move to Line Start		Move the caret to the beginning of line.
Move to Line Start with Selection		Move the caret to the beginning of line, selecting the text.
Move to Next Word		Move the caret to the next word.
Move to Next Word with Selection		Move the caret to the next word, selecting it.
Move to Previous Word		Move the caret to the previous word.
Move to Previous Word with Selection		Move the caret to the previous word, selecting it.

Move to Text End	Ctrl+End	Move the caret to the end of text.
Move to Text End with Selection	Ctrl+Shift+End	Move the caret to the end of text, selecting it.
Move to Text Start	Ctrl+Home	Move the caret to the beginning of text.
Move to Text Start with Selection.	Ctrl+Shift+Home	Move the caret to the beginning of text, selecting it.
Select All	Ctrl+A	Select the entire text opened in the editor.
Delete Line at Caret	Ctrl+Y	Delete the line where the caret is currently located.
Delete to Word End	Ctrl+Delete	Delete the word starting from the current caret location up to the word end.
Delete to Word Start	Ctrl+Backspace	Delete the word starting from the current caret location up to the word start.
Toggle Insert/Overwrite	Insert	Toggle insert/overwrite modes.
Duplicate Line or Block	Ctrl+D	Duplicate selected block or the line at the caret.
Toggle Case	Ctrl+Shift+U	Toggle case of the selected text block.
Move to Code Block End	Ctrl+Close Bracket	Move the caret to the current code block end, highlighting the block limits.
Move to Code Block End with Selection	Ctrl+Shift+Close Bracket	Move the caret to the current code block end, selecting the code beginning from the initial caret location.
Move to Code Block Start	Ctrl+Open Bracket	Move the caret to the current code block start, highlighting the block limits.
Move to Code Block Start with Selection	Ctrl+Shift+Open Bracket	Move the caret to the current code block start, selecting the code beginning from the initial caret location.
Start New Line	Shift+Enter	Start a new line after the current one positioning the caret in accordance with the current indentation level.
Start New Line Before Current One	Ctrl+Alt+Enter	Start a new line before the current one.
Join Lines	Ctrl+Shift+J	Concatenate the selected lines into one or concatenate the line where the caret is currently located with the next line.
Split Line	Ctrl+Enter	Split the selected line at the point where the caret is located, leaving the caret at the end of the first line.
Select Word at Caret	Ctrl+W	Select successively increasing code blocks starting from the current caret location.
Unselect Word at Caret	Ctrl+Shift+W	Remove sequentially the selection made by the action.
Indent Selection	Tab	Move the selected block to the next indentation level.
Unindent Selection	Shift+Tab	Move the selected block to the previous indentation level.
Auto-Indent Lines	Ctrl+Alt+I	Indent the current line or selected block according to the <a href="#">Code Style</a> settings.

**CommandShortcutDescription**

Expand	Ctrl+NumPad Plus	Expand the current collapsed fragment
Collapse	Ctrl+NumPad -	Collapse the current folding region
Expand Recursively	Ctrl+Alt+NumPad Plus	Expand the current folded fragment and all the subordinate collapsed folding regions within that fragment
Collapse Recursively	Ctrl+Alt+NumPad -	Collapse the current folding region and all the subordinate folding regions within it
Expand All	Ctrl+Shift+NumPad Plus	Expand all collapsed fragments within the selection, or, if nothing is selected, expand all the collapsed fragments in the current file
Collapse All	Ctrl+Shift+NumPad -	Collapse all folding regions within the selection, or, if nothing is selected, collapse all the folding regions in the current file
Expand to level   1, 2, 3, 4 or 5	Ctrl+NumPad *, 1	Expand the current fragment and all the nested fragments up to the specified level
	Ctrl+NumPad *, 2	
	Ctrl+NumPad *, 3	
	Ctrl+NumPad *, 4	
	Ctrl+NumPad *, 5	
Expand all to level   1, 2, 3, 4 or 5	Ctrl+Shift+NumPad *, 1	Expand all the collapsed fragments in the file up to the specified nesting level
	Ctrl+Shift+NumPad *, 2	
	Ctrl+Shift+NumPad *, 3	
	Ctrl+Shift+NumPad *, 4	
	Ctrl+Shift+NumPad *, 5	
Fold Selection / Remove region	Ctrl+Period	Collapse the selected fragment and create a custom folding region for it to make it "foldable" / Expand the current fragment and remove the corresponding custom folding region to make the fragment "unfoldable"
Fold Code Block	Ctrl+Shift+Period	Collapse the code fragment between the matched pair of curly braces {} and create a custom folding region for that fragment to make it "foldable"

**FunctionShortcutUse this  
shortcut to...**

Make Project	Ctrl+F9	Compile all modified and dependent files in a project.
Compile	Ctrl+Shift+F9	Compile selected file/package.
Run	Shift+F10	Run a program.
Choose configuration and run	Shift+Alt+F10	Quickly select run/debug configuration and run or edit it.
Rerun	Ctrl+F5	Repeat execution with the same settings, with the same tab of the Run tool window having the focus.
Rerun without losing the focus in the editor	Shift+F10	Repeat execution with the same settings, with the same tab of the editor having the focus.
Debug	Shift+F9	Debug a program.
Choose configuration and debug	Shift+Alt+F9	Quickly select run/debug configuration and debug or edit it.
Step Over	F8	Step to the next line in the current file. See <a href="#">Stepping Through the Program</a> .
Step Into	F7	Step to the next executed line. See <a href="#">Stepping Through the Program</a> .
Smart Step Into	Shift+F7	Select the method to step in, if the current line contains multiple method call expressions. See <a href="#">Choosing a Method to Step Into</a> .
Step Out	Shift+F8	Step to a first executed line after returning from the current method. See <a href="#">Stepping Through the Program</a> .
Force Step Over	Shift+Alt+F8	Run until the next line in this method or file, skipping the methods referenced at the current execution point and ignoring breakpoints. See <a href="#">Stepping Through the Program</a> .
Force Step Into	Shift+Alt+F7	Steps into the method called in the current execution point even if this method is to be skipped. See <a href="#">Stepping Through the Program</a> .
Run to Cursor	Alt+F9	Run to the line where the caret is located. See <a href="#">Stepping Through the Program</a> .
Force Run To Cursor	Ctrl+Alt+F9	Run to the line where the caret is located, ignoring breakpoints. See <a href="#">Stepping Through the Program</a> .
Resume Program	F9	Resume program execution.
Stop Program	Shift+F2	Terminate a debugging session.
Evaluate Expression	Alt+F8	Evaluate an arbitrary expression.
Quick Evaluate Expression	Ctrl+Alt+F8	Evaluate an arbitrary expression without calling Evaluate Expression dialog.
Toggle Breakpoint	Ctrl+F8	Toggle breakpoint at the current line.
View Breakpoints	Ctrl+Shift+F8	View/manage all breakpoints.
Switch to another coverage suite.	Ctrl+Alt+F6	Open the Coverage Suites pop-up window and select the desired suite to run.

**FunctionShortcutUse this  
shortcut  
to...**

Close Active Tab	Ctrl+Shift+F4	Close an active tab in a tool window (for example, Find tool window).
Close Editor	Ctrl+F4	Close an active editor.
Edit Source	F4	Open an editor for the selected item or items and give focus to the last opened file.
Escape	Escape	Depending on the context: <ul style="list-style-type: none"><li>– In the editor: close pop-up windows, terminate search, or remove highlighting.</li><li>– In a tool window: return focus to the editor.</li></ul>
Export to Text File	Alt+O	Export contents of a tool window to a text file. This feature applies to the <a href="#">Version Control Tool Window</a> , <a href="#">Messages Tool Window</a> , and the other tool windows that provide the export button  on the window toolbar.
New...	Alt+Insert	Create a new class, interface, file or directory.
Save All	Ctrl+S	Save all files and settings.
Select Next Tab	Alt+Right	When several tabs are open in the editor or a view, open the next tab to the right (or first tab if the current one is the last).
Select Previous Tab	Alt+Left	When several tabs are open in the editor or a view, open the next tab to the left (or last tab if the current one is the first).
Show Intention Action	Alt+Enter	Display <a href="#">intention actions</a> (if any) for the code where the caret is currently located, or the selected GUI component in a form.
Synchronize	Ctrl+Alt+Y	Detect all externally changed files and reload them from disk.
View Source	Ctrl+Enter	Depending on the context: <ul style="list-style-type: none"><li>– In Tool Windows: Open an Editor tab or tabs for the selected item or items, respectively.</li><li>– In the editor: Intelligently split the current line into 2 lines, shifting quotes, etc. as necessary.</li><li>– On the context menus of the modules in the <a href="#">Project Tool Window</a> , <a href="#">Dependency Viewer</a> , and <a href="#">Module Dependencies tool window</a> : open the <a href="#">Modules structure</a> .</li></ul>

**FunctionShortcutUse this shortcut to...**

Select next component	Arrow	Move selection to the adjacent component.
Add to selection	Shift+Arrow	Add adjacent component to the selection.
Extend selection	Ctrl+W	Select successively increasing sets of components from the current component to its container. Compare to <a href="#">selecting text in the editor</a> .
	Ctrl+Shift+W	
Move component	Ctrl+Arrow	Move selected component to the adjacent valid container.
Expand component	Ctrl+Shift+Arrow	Expand component to the adjacent valid container.

**FunctionShortcutUse this shortcut to...**

Find		Initiate <a href="#">text search</a> .
Replace		Initiate <a href="#">text search and replace</a> .
Search for next/ previous occurrence	 	Navigate to the next/previous occurrence of a selected word in the editor.
Find Word at Caret		Search in the editor for the word where the caret is currently located.
Incremental Search		Initiate <a href="#">text search</a> .
Find in Path		Initiate <a href="#">search for a text string in the specified scope</a> .
Replace in Path		Initiate <a href="#">search and replace in the specified scope</a> .
Find Usages		Initiate <a href="#">search for usages of the selected symbol in the specified scope</a> .
Find Usages in File		Initiate <a href="#">search for usages of the selected symbol in the current file</a> .
Highlight Usages in File		<a href="#">Highlight usages of a symbol</a> at caret.
Show Usages		<a href="#">Show usages of a symbol</a> at caret in a pop-up window. Use list of found usages to jump to the desired location.
Find Action		Find an action, bypassing menus. See <a href="#">Finding Actions</a> .

**FunctionShortcutUse this shortcut to...**

---

Go to Bookmark <number>	Ctrl+Number	Navigate to a <a href="#">numbered bookmark</a> with the corresponding number.
Toggle Bookmark	F11	Turn anonymous bookmark on or off.
Toggle Bookmark with Mnemonic	Ctrl+F11	Turn bookmark with mnemonic on or off.
Show Bookmarks	Shift+F11	Open <a href="#">Bookmarks</a> dialog to manage existing bookmarks and navigate between them.

---

In this section you can find keyboard shortcuts for navigation between:

- [Views and Windows](#) .
- [Differences](#) .

## Views and Windows

**Function** **Shortcut** **Use this shortcut to...**

Select Target		Move focus from the current file, class, method or reference to a data source, to a view suggested in the Select Target pop-up menu. Refer to <a href="#">Navigating Between IDE Components</a> .
Collapse all		Collapse all nodes in a tree view.
Expand all		Expand all nodes in a tree view.
Switcher		Navigate between files opened in the editor, and tool windows.
Open tool window		Open a tool window with the specified number.
Hide Active Window		Hide the currently active tool window.
Jump to Last Window		Activate the last focused tool window.

## Differences

**Function** **Shortcut** **Use this shortcut to...**

Move to Next Difference		Navigate to the next difference in <a href="#">view</a> .
Move to Previous Difference		Navigate to the previous difference in <a href="#">view</a> .

**Function Shortcut** Use this shortcut to...

File Structure Pop-up	Ctrl+F12	Display the <a href="#">Structure pop-up window</a> for quick navigation through the current file.
Select target	Alt+F1	Move focus from the current file, class, method or reference to a data source table to a view suggested in the Select Target pop-up menu. See <a href="#">Navigating Between IDE Components</a> .
Recent Files	Ctrl+E	Show the list of <a href="#">recently opened files</a> .
Recently Changed Files	Ctrl+Shift+E	Show the list of <a href="#">recently updated files</a> .
Type Hierarchy	Ctrl+H	Browse hierarchy for the selected <a href="#">class</a> class .
Method Hierarchy	Ctrl+Shift+H	Browse hierarchy for the selected <a href="#">method</a> .
Call Hierarchy	Ctrl+Alt+H	Browse <a href="#">call hierarchy</a> for the selected method.
Navigate to Class	Ctrl+N	Navigate directly <a href="#">to a class in project</a> by specifying its name in a pop-up dialog box.
Navigate to File	Ctrl+Shift+N	Navigate directly <a href="#">to a file in project</a> by specifying its name in a pop-up dialog box.
Navigate to Recently Opened File	Ctrl+E	Show the list of <a href="#">recently opened files</a> .
Navigate to Recently Changed File	Ctrl+Shift+E	Show the list of <a href="#">recently updated files</a> .
Navigate to Line	Ctrl+G	Navigate <a href="#">to any line in the current file</a> by specifying its number.
Navigate to Declaration	Ctrl+B	Navigate <a href="#">to declaration</a> of a symbol at caret.
Navigate to Implementation	Ctrl+Alt+B	Navigate to implementation of the item at caret.
Navigate to Type Declaration	Ctrl+Shift+B	Navigate to a type declaration of a symbol at caret, the symbol being a variable or a method call.
Navigate to Super Method	Ctrl+U	Navigate to a super method declaration of a method under the caret.
Navigate to Test/Test Subject	Ctrl+Shift+T	Navigate to a test for the class at caret, if any, or navigate from a test to a test subject.
Navigate to Related Symbol	Ctrl+Alt+Home	Navigate between files with complicated relationships between them. For example, use this shortcut to navigate between the various web entities.
Navigate to Next Method	Alt+Down	Navigate to the next method declaration in the active editor tab.
Navigate to Previous Method	Alt+Up	Navigate to the previous method declaration in the active editor tab.
Navigate to Opening Brace	Ctrl+Open Bracket	Navigate to the start of the current code block.
Navigate to Closing Brace	Ctrl+Close Bracket	Navigate to the end of the current code block.
Back	Ctrl+Alt+Left	Undo last navigation operation. <b>Note</b> On a macOS computer, you can also use the three-finger right-to-left swipe gesture.
Forward	Ctrl+Alt+Right	Redo last undone navigation operation. <b>Note</b> On a macOS computer, you can also use the three-finger left-to-right swipe gesture.
Navigate to Previous Occurrence	Ctrl+Alt+Up	Navigate to a previous found item.
Navigate to Next Occurrence	Ctrl+Alt+Down	Navigate to a next found item.
Last Edit Location	Ctrl+Shift+Backspace	Move through the most recent change points.
Navigate to Next Highlighted Error	F2	Navigate to the next found error/warning.
Navigate to Previous Highlighted Error	Shift+F2	Navigate to the previous found error/warning.

**FunctionShortcutDescription**

Rename	Shift+F6	Rename the selected file, class, field, method, etc. and change all references to it accordingly.
Change Method Signature	Ctrl+F6	Change the signature of the selected method and update all the corresponding method calls.
Move	F6	Move the selected class, package or static member to another package or class and update all the corresponding references.
Copy	F5	Create a copy of the selected class, file or directory in the same or different directory or package.
Clone		Create a copy of the selected class in the same package.
Safe Delete	Alt+Delete	Delete the selected class, method or field checking its usages.
Extract Method	Ctrl+Alt+M	Turn the selected code fragment into a method.
Extract Variable	Ctrl+Alt+V	Create a new variable and use the selected expression as its value.
Extract Field	Ctrl+Alt+F	Create a new field and use the selected expression as its value.
Extract Constant	Ctrl+Alt+C	Create a new constant (static final field) and use the selected expression as its value.
Extract Parameter	Ctrl+Alt+P	Turn the selected expression into a new method parameter.
Inline	Ctrl+Alt+N	Inline the selected method or variable.

**ItemDescription**

Middle mouse button rotate	Scroll vertically
<b>Shift</b> + Middle mouse button rotate	Scroll horizontally
<b>Ctrl</b> + Middle mouse button rotate	Change font size
Middle mouse button click on a tab	Close tab
Right mouse button click	Show context menu

- [Shelve Changes Dialog](#)
- [Show History for File / Selection Dialog](#)
- [Show History for Folder Dialog](#)
- [Unshelve Changes Dialog](#)

In this part:

- [CVS Global Settings Dialog](#)
- [CVS Options Dialog](#)
- [CVS Tool Window](#)

Use this dialog box to set up CVS roots. The dialog box is available for files and directories that are under CVS version control.

## Common Options

### ItemDescription

	Click this button to configure a new CVS root.
	Click this button to remove the selected CVS root configuration from the list.
	Click this button to create a copy of the selected CVS root.
Global Settings	Click this button to open the <a href="#">Global CVS Settings</a> dialog box where you can set up CVS options at the global level.
CVS root	In this text box, specify the CVS repository string according to the following syntax:

```
[ :method: ][ [user] [ :password ] @ ] hostname [ : [port] ] / path / to / repository .
```

**Tip** Obtain the valid string from your system administrator or click the Edit by Field button to open the [Configure CVS Root Field by Field](#) dialog box where you can specify the mandatory connection parameters and have IntelliJ IDEA [assemble](#) them into a correct repository string.

Edit by Field	Click this button to open the <a href="#">Configure CVS Root Field by Field</a> dialog box where you can specify the mandatory connection parameters and have them assembled into a CVS root string automatically.
Use version	Use this section to specify the revision you want to synchronize your local working copy with. The available options are: <ul style="list-style-type: none"> <li>– HEAD revision : this option is suggested by default.</li> <li>– By tag : select this option to access the revision with a specific tag. Type the desired tag in the text box or click the Browse button  and select the desired tag from the list. The list shows all the tags available on the CVS server according to the specified CVS root.</li> <li>– By date : select this option to access the revision with a specific date and time stamp. Type the end date and time in the format <code>dd:mm:yy hh:mm:ss</code> or click the Browse button  and select the desired date from the calendar. This date and time are passed to the server with the GMT parameter.</li> </ul>

**Tip** The controls in the area are available only after the CVS root text box is filled in with valid data.

**Warning!** If you perform update or checkout from the CVS repository with the By tag or By date option selected, the resulting working copy will be permanently restricted to the specified tag or date, until you force the update operation to reset this sticky data .

Test connection	Click this button to check that the specified settings ensure successful connection to the CVS server.
-----------------	--

## Additional Connection Settings

In this area, specify additional settings to flexibly configure connection to the CVS server. The contents of the area depends on the [connection method](#) set in the CVS root text box.

- [pserver](#)
- [ext](#)
- [ssh](#)
- [local](#)

### pserver

**Warning!** The settings specified in this area affect all CVS roots that use the pserver connection method.

### ItemDescription

Password	In this text box, type the fully qualified path to the <code>.cvspass</code> file. Click the Browse button  to select the file in the <a href="#">corresponding dialog</a> .
Connection timeout	In this text box, type the connection timeout in seconds.
Proxy Settings	See the <a href="#">Proxy Settings</a> section below.

### ext

### ItemDescription

Use internal <code>ssh</code> implementation	Select this checkbox to access the <a href="#">ssh area</a> , where you can specify the SSH version to use, the port to listen to, and configure your private key and password. Clear this checkbox to access the Ext Protocol Settings area with the following controls available: <ul style="list-style-type: none"> <li>– Path to external rsh : in this text box, specify the location of the external <code>rsh</code> . If necessary, click the Browse button  to select the necessary location in the <a href="#">corresponding dialog</a> .</li> <li>– Path to private key file : in this text box, specify the location of the file with your private <code>ssh</code> key. If necessary, click the Browse button  to select the file in the <a href="#">corresponding dialog</a> .</li> <li>– Additional parameters : in this text box, specify additional connection parameters.</li> </ul>
--	---

## ssh

This area is also available when you have specified the [ext](#) connection method and selected the Use internal ssh implementation checkbox.

### ItemDescription

SSH version	In this area, specify the SSH version to use. The available options are: <ul style="list-style-type: none"><li>– Allow both</li><li>– Force SSH1</li><li>– Force SSH2</li></ul>
Port	In this text box, specify the <code>ssh</code> port to listen to.
Use Private key file	Select this checkbox, if you want to pass server authentication using a private <code>ssh</code> key. In the text box, specify the location of the file with your private <code>ssh</code> key. If necessary, click the Browse button  to select the file in the <a href="#">corresponding dialog</a> .
Change password	Click this button to open the SSH PAssword dialog box, where you can specify the password for the curent CVS root.
Proxy Settings	See <a href="#">Proxy Settings</a> section below.

## local

**Tip** IntelliJ IDEA does not provide the server functionality. If you want to use a local CVS client, you need to install CVS on your local host computer and configure it to work as a server.

### ItemDescription

Path to CVS client	In this text box, type the path to CVS client installed on the host computer and configured to work as a server. If necessary, click the Browse button  to select the necessary location in the <a href="#">corresponding dialog</a> .
Server command	In this text box, specify the server command.

## Proxy Settings

### ItemDescription

Use proxy	Select this checkbox to enable using the Proxy server and access the Login , Password , Proxy host , and Proxy port text boxes below. This checkbox is available only in two cases: <ul style="list-style-type: none"><li>– The connection method is <code>pserver</code> or <code>ssh</code>.</li><li>– The connection method is <code>ext</code> and the Use internal ssh implementation checkbox is selected.</li></ul>
Protocol	Select the protocol to use. The available options are: <ul style="list-style-type: none"><li>– HTTP</li><li>– Socks4</li><li>– Socks5</li></ul>
Login	In this text box, specify your user name.
Password	In this text box, specify the user password.
Proxy host	In this text box, specify the Proxy host name.
Proxy port	In this text box, specify the Proxy port number.

---

This tool window opens, when you browse a CVS repository, and enables you to view contents of the repository, check out files, browse changes, view annotations and navigate to source code.

**ItemDescription**

---

	Click this button to close the current tab.
	Click this button to open the selected file in the editor.
	Click this button to <a href="#">obtain a local copy</a> of the selected file or directory.
	Click this button to open selected file in the editor with the annotations turned on. See <a href="#">Viewing Annotations</a> .
	Click this button to see the changes that affect the selected file or directory, and that have been committed to the repository by a certain user, or during the specified period. The filtering information is entered in the Search Criteria dialog. Search results show in a dedicated tab of the <a href="#">Version Control tool window</a> .
	Click this button to show reference page.

Use this dialog to import a directory into the specified CVS repository.

## Select CVS Configuration

Use this page to select the target CVS root and change its configuration, if necessary.

## Select Directory to Import to

Use this page to select the target directory.

## Select Import Directory

Use this page to select the directory to be imported. If you are importing an IntelliJ IDEA project, make sure that the project file is located under that directory. Multiple selection is not available.

## Customize Keyboard Substitution

Use this page to specify the [keyword substitution rule](#) for the files imported into the repository.

## Import Settings

### ItemDescription

---

Name in repository	<p>In this field, specify the name that corresponds to the <code>module</code> argument.</p> <p><b>Tip</b> For import, <code>module</code> refers to the absolute location in the repository, not to a module name defined in the modules file.</p>
Vendor	<p>In this field, specify the name that corresponds to the <code>vendor-tag</code> argument. This tag is used as a branch tag. No checkouts will ever be done explicitly on it. Type a name that is relevant to the project, or just VENDOR.</p>
Release tag	<p>In this text box, specify the string that corresponds to the <code>release-tag</code> argument. The tag should refer to a version or a release number.</p> <p><b>Tip</b> A tag name cannot contain punctuation marks.</p> <p>For example: <code>-release-2.2</code> is wrong</p> <p><code>release-2-2</code> is correct.</p>
Log message	<p>In this field, specify the string that corresponds to the <code>-m</code> command-line argument. By default, the field shows the previous log message; you can accept default, or type a new comment.</p>
Checkout after import	<p>Select this option to have CVS checkout run after completing the import operation.</p>
Make checked out files read-only	<p>Select this option to mark the checked out files as read-only after import. This option is disabled if the Checkout after import option is cleared.</p>

The dialog consists of the following pages:

- [Select CS Configuration](#)
- [Select CVS Element to Check Out](#)
- [Select Checkout Location](#)
- [Check out to](#)

## Select CVS Configuration

### ItemDescription

List of available CVS configurations	Use this list to select the desired CVS configuration.
Configure	Click this button to define a new CVS configuration, or modify an existing one, in the CVS Roots dialog box.

## Select CVS Element to Check Out

Use this page to select elements of the repository to check out. Next button is only available when an element is selected.

## Select Checkout Location

Use this page to specify the target location for the artifacts to check out. All actions can be performed using the toolbar buttons, or context menu.

### ItemShortcut Description

		Jump to the user's home directory.
		Jump to the project root directory.
		Create a new directory where the files will be checked out to.
		Delete the selected directory.
		Synchronize with external changes.
	N/A	Show Hidden Files and Directories

## Check out to

Use this page to define CVS-specific checkout options.

### ItemDescription

List of local paths	Select the local path to which the module name should be added.
Make new files read-only	Check this option to set read-only attribute for the files that did not exist locally but were checked out from the repository.
Prune empty directories	Check this option to delete empty directories from the repository.
Change keyword substitution to	Check this option to enable keyword substitution, and select the desired substitution mode from the drop-down list.

---

This dialog box opens when you click the Edit by Field button in the CVS Roots dialog box. Use this dialog box to specify the parameters for connecting to the CVS server and have IntelliJ IDEA assemble them into a correct repository string according to the CVS root string syntax.

**ItemDescription**

---

Method	From this drop-down list, select the desired connection method. The available options are: <ul style="list-style-type: none"><li>- pserver</li><li>- ext</li><li>- ssh (internal implementation)</li><li>- local</li></ul>
User	In this text box, type your login to the CVS server.
Port	In this text box, specify the port to listen to on the CVS server host.
Host	In this text box, type the name of the host where the desired CVS server is located.
Repository	In this text box, type the path to the CVS repository relative to the host name.

In this section:

- [Menu commands according to file status](#) .
- [Effect of rolling back local changes](#) .

## Menu Commands According to File Status

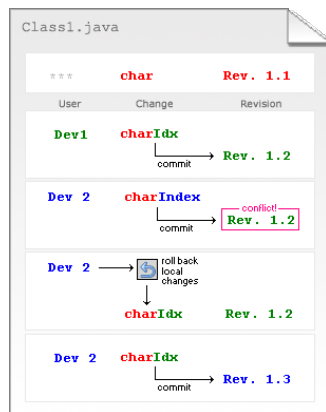

Depending on the file status, the Rollback Changes command will be *aliased* as shown in the following table:

File status	Rollback Command	Result
modified	Rollback Local Changes	all changes made in the file will be reverted, and the file will acquire the <i>up to date</i> status
deleted	Rollback Deletion	file will be restored both on the disk and in CVS with the <i>up to date</i> status
externally deleted	Rollback Deletion	file will be restored on the disk and assigned the <i>up to date</i> status
added	Rollback Creation	file will be deleted from disk
merged	Rollback Local Changes	all local changes will be dropped, changes from the repository will be accepted, and the file will be assigned the <i>up to date</i> status
merged with conflicts	Rollback Local Changes	all local changes will be dropped, changes from the repository will be accepted, and the file will be assigned the <i>up to date</i> status
unknown	Rollback Creation	file will be deleted from the disk

## Effect of rolling back local changes

The effect of Rollback Local Changes may not be what you intuitively expect in terms of the revision you have locally after running the command.

The image below represents a file in CVS and a sequence of actions by two developers. It shows a simple example of what happens in terms of the local copy's CVS revision after rolling back conflicting local changes.

Here's what happens:

- The developer *Dev1* takes Revision 1.1 from the repository, modifies it, and commits changes to CVS.
- The developer *Dev2* doesn't know about *Dev1*'s changes and modifies the same code in the local copy of Revision 1.1 . When *Dev2* commits these changes, he gets a message from CVS that the repository has changed. So he runs Update to synchronize, and his local copy is then updated to Revision 1.2 , and CVS sets the *Merged with Conflicts* status on the file.
- *Dev2* decides to roll back local changes. He is left with a local copy of Revision 1.2 .
- When *Dev2* commits the file to CVS, it becomes Revision 1.3 even though the content is identical to Revision 1.2 .

In these dialog boxes, configure synchronization of local files or folders with the repository.

#### ItemDescription

Branch Merging	<p>In this area, specify the repository branch to synchronize with.</p> <ul style="list-style-type: none"> <li>- Don't merge - select this option to synchronize with the counterpart of the current branch in the repository. This option is selected by default.</li> <li>- Merge with branch - select this option to have the local copy synchronized with a repository branch different from the counterpart of the current branch. In the first text box below, specify the branch to synchronize with. Type the branch name manually or click the Browse button  and select the desired branch from the list in the Select Tag dialog box that opens. This option is equivalent to the <code>-j</code> command-line option of the <code>update</code> command.</li> <li>- Merge two branches - select this option to have the local copy synchronized with the result of merging two repository branches different from the counterpart of the current branch. In the text boxes below, specify the branches to synchronize with. This option is equivalent to the <code>-j -j</code> command-line option of the <code>update</code> command.</li> </ul>
Use Version	<p>In this area, specify the version of repository file(s) or folder(s) to synchronize with.</p> <ul style="list-style-type: none"> <li>- Default - select this option to have the local copy synchronized with the latest repository version.</li> <li>- By tag - select this option to have the local copy synchronized with a particular repository version. In the text box, specify the desired version number or tag. Type the version number or tag manually or click the Browse button  and select the desired branch from the list in the Select Revision or Tag dialog box that opens. <ul style="list-style-type: none"> <li>- When updating a single file, you can specify its repository counterpart either through a version number or a tag.</li> <li>- When updating an entire folder, its repository counterpart can be specified only through a tag.</li> </ul> </li> </ul> <p>This option is equivalent to the <code>-r</code> command-line option of the <code>update</code> command.</p> <ul style="list-style-type: none"> <li>- By date - select this option to have the local copy synchronized with a repository version that was submitted on a particular date. Type the date manually or click the Calendar button  and select the desired date from the calendar pop-up window that opens with the current date selected by default. This option is equivalent to the <code>-D</code> command-line option of the <code>update</code> command.</li> </ul>
Reset sticky data	<p>Select this checkbox to remove the date or tag restriction from the local file(s) or folder(s) to be updated. Such restrictions are set on files and folders checked out or previously updated with the By tag or By date options. This option is equivalent to the <code>-A</code> command-line option of the <code>update</code> command.</p>
Prune empty directories	<p>Select this option while updating a directory to have IntelliJ IDEA remove the subfolders whose repository counterparts are empty. This option is equivalent to the <code>-P</code> command-line option of the <code>update</code> command.</p>
Change keyword substitution to	<p>Select this checkbox to have the <a href="#">default keyword expansion mode</a> changed. From the drop-down list, choose the relevant substitution. This option is equivalent to the <code>-k</code> command-line option of the <code>update</code> command.</p>
Create new directories	<p>Select this option while updating a directory to have IntelliJ IDEA create new local subfolders when any new subfolders have been created in the repository counterpart of the directory to be updated. This option is equivalent to the <code>-k</code> command-line option of the <code>update</code> command.</p> <p>By default, all the new subfolders will be picked including empty ones. To avoid creating empty subfolders, it is recommended that you select the Prune empty directories checkbox as well.</p>
Clean copy	<p>Select this checkbox to have IntelliJ IDEA backup the local changes and replace the changed file(s) with their counterparts from the repository. This option is equivalent to the <code>-C</code> command-line option of the <code>update</code> command.</p>
Do not show this dialog in the future	<p>Select this option to have the <code>update</code> operation performed <a href="#">silently</a> in the future. To have IntelliJ IDEA show this dialog box before <code>update</code> again:</p> <ol style="list-style-type: none"> <li>1. Open the <a href="#">Version Control - Confirmation</a> page of the <a href="#">Settings</a> dialog box.</li> <li>2. In the Display Option dialogs when these commands are invoked area, select the Update checkbox.</li> </ol>

In this part:

- [Merge Branches Dialog](#)
- [Rebase Branches Dialog](#)

---

Use this dialog box to specify arguments for merging branches in a local Git repository.

**ItemDescription**

---

Git Root	From this drop-down list, select the path to the local repository in which you want to merge branches.
Current Branch	This read-only field shows the name of the branch which is currently checked out in the selected local repository. This is the target branch, the changes from the selected source branches will be applied to it. The contents of the field depend on the selection in the Git Root drop-down list.
Branches to Merge	Use this list box to specify the source branches from which changes will be applied to the target branch. The list shows only those branches that contain applicable commits. Applicable commits are commits made after a branch separated from the target branch.
Strategy	From this drop-down list, select the <a href="#">merge strategy</a> . The available options are: <ul style="list-style-type: none"><li>– Default</li><li>– Resolve - select this option if you need to resolve two HEADs, one of which is the current branch and the other HEAD is the branch which you selected in the Branches to Merge list. When this option is selected, the 3-way merge algorithm is applied.</li><li>– Recursive - the default merge strategy for merging the current branch with one branch. Select this option if you need to resolve two HEADs by applying the 3-way merge algorithm and there are more than one common ancestor that can be used for 3-way merge.</li><li>– Octopus - the default merge strategy for merging the current branch with more than one branch. Merges that require resolving conflicts manually are not performed.</li><li>– Ours - select this option if you need to resolve several HEADs. The result of the merge is always the HEAD of the current branch.</li><li>– Subtree - a modified recursive strategy.</li></ul> <p>When two or more source branches are selected in the Branches to Merge list box, only the Octopus and Ours options are available.</p>
No Commit	Select this checkbox if you need to inspect and, if necessary, adjust the result of merging before committing the result. The merge is performed but is not committed automatically, as if it failed.
No Fast Forward	Select this checkbox to generate a merge commit even if the merge resolved as a <a href="#">fast-forward</a> .
Squash Commit	Select this checkbox to create a single commit on top of the current branch instead of merging one or more other branches. The working tree and index state are produced as if a real merge happened, but commit is not performed and the HEAD is not moved.
Add Log Information	Select this checkbox to have IntelliJ IDEA populate, in addition to branch names, a log message with one-line descriptions from the actual commits that are being merged.
Commit Message	In this text box, provide a description for the commit. The text box is available only if the No Commit checkbox is not selected.
Merge	Click this button to initiate merging the specified branches in the local repository according to the defined settings.

Use this dialog box to specify the branch to rebase, the new base, the rebasing mode, and configure the rebasing procedure.

#### ItemDescription

Git Root	From this drop-down list, select the path to the local repository in which you want to rebase a branch.
Branch	From this drop-down list, select the branch to rebase. By default, the current working branch is selected. If you specify another branch, it will be automatically checked out first.
Interactive	Select this checkbox to view and possibly edit a list of commits to be rebased.
Preserve Merges	Select this checkbox to have the possibility to recreate merges instead of ignoring them. The checkbox is available only when the Interactive checkbox is selected. <b>Warning!</b> When this checkbox is selected, Git does not support squashing commits.
Onto	Use this drop-down list to specify the new base for the selected branch. To specify the required commit, type its commit hash or use an expression, for example, of the following structure: <code>&lt;branch&gt;~&lt;number of commits backwards between the latest commit (HEAD) and the required commit&gt; .</code> Refer to the Git <a href="#">commit naming</a> conventions for details. If no commit is specified, the HEAD of the selected branch is used as the new base.
Validate	Click this button to check that the commit specified in the Onto field exists and view which files were affected in it.
From	Use this drop-down list to specify the commit starting from which you want to apply the branch to the new base. Type the required commit hash or use an expression, for example, of the following structure: <code>&lt;branch&gt;~&lt;number of commits backwards between the latest commit (HEAD) and the required commit&gt; .</code> Refer to the Git <a href="#">commit naming</a> conventions for details. To apply the entire branch, leave the field empty.
Validate	Click this button to check that the commit specified in the From field exists and view which files were affected in it.
Show Tags	Select this checkbox to have <a href="#">tagged commits</a> included in the Onto and From drop-down lists.
Show Remote Branches	Select this checkbox to have branches in the remote repository included in the Onto drop-down list.
Merge Strategy	From this drop-down list, select the <a href="#">merge strategy</a> . The available options are: <ul style="list-style-type: none"><li>- Default</li><li>- Resolve - select this option if you need to resolve two HEADs, one of which is the current branch and the other HEAD is the branch from which you pulled changes. When this option is selected, the 3-way merge algorithm is applied.</li><li>- Recursive - the default merge strategy for pulling one branch. Select this option if you need to resolve two HEADs by applying the 3-way merge algorithm and there are more than one common ancestor that can be used for 3-way merge.</li><li>- Octopus - the default merge strategy for pulling more than one branch. Merges that require resolving conflicts manually are not performed.</li><li>- Ours - select this option if you need to supersede old development history of side branches. By applying this strategy any number of HEADs can be resolved but the result of the merge is always the HEAD of the current branch.</li><li>- Subtree - a modified recursive strategy.</li></ul>
Do not use merge strategies	When this checkbox is selected, no merge strategy is applied during rebase.
Rebase	Click this button to initiate rebasing according to the defined settings.

In this part:

- [Clone Mercurial Repository Dialog](#)
- [Create Mercurial Repository Dialog](#)
- [Merge Dialog \(Mercurial\)](#)
- [New Bookmark Dialog](#)
- [Pull Dialog](#)
- [Switch Working Directory Dialog](#)
- [Tag Dialog \(Mercurial\)](#)
- [Update Project Dialog \(Mercurial\)](#)

Use the dialog box to set up a local repository by downloading the data from a remote repository.

**ItemDescription**

---

Mercurial Repository URL In this text box, type the URL of the remote repository which you want to clone.

---

Test Click this button to check that connection to the remote repository has been established successfully.

---

Parent Directory In this text box, specify the directory where you want IntelliJ IDEA to create a folder for your local Mercurial repository. Type the path manually or click the Browse button  and choose the desired directory in the [dialog that opens](#) .

---

Directory Name In this text box, type the name of the new folder into which the repository will be cloned.

**Warning!** The parent directory must not contain a folder with the specified name.

---

Clone Click this button to start cloning the specified repository.

Use this dialog box to create a local Mercurial repository in the folder of your choice.

**ItemDescription**

---

**Create repository for the whole project**      Select this option to have a repository initialized in the project root directory. This option is helpful if you want to put the entire project under Mercurial control.

---

**Select where to create repository**      Select this option to have a repository initialized in one of the folders below the project root. With this option, you can have folders of your project under control of different version control systems. In the text box below, specify the folder to create the repository in. Type the path manually or click the Browse button  and choose the desired folder in the [dialog that opens](#) .

context menu of the Editor - Mercurial | Merge

VCS | Mercurial | Branches - <branch name> - Merge

context menu of the Editor - Mercurial | Branches - <branch name> - Merge

Use this dialog box to merge the [current working directory](#) to a [named branch](#), [light-weight branch \(bookmark\)](#), or a specific [changeset](#) identified by a [tag](#), [hash](#), or [revision number](#).

By default, **Mercurial** requires that before merge the current working directory should be **clean**, that is, it should not contain any uncommitted changes. Otherwise the merge operation fails and IntelliJ IDEA shows the corresponding error message.

The message also recommends that you clean the current working directory by running the `hg merge <target branch, bookmark, or changeset> -C` to discard the uncommitted changes.

#### ItemDescription

Repository	From this drop-down list, choose the repository to run the merge in. The contents of the Branch, Tag, and Bookmark drop-down lists are updated to show the branches, tags, and bookmarks that are available in the selected repository.
------------	---

Merge with	<p>In this area, choose the branch, bookmark, or changeset to merge with.</p> <ul style="list-style-type: none"><li>– Branch: choose this option to switch to another line of development identified by a <a href="#">branch name</a> and merge to the <a href="#">branch head</a>. Choose the desired branch from the drop-down list which shows all the named branches available in the current repository.</li><li>– Tag: choose this option to merge to a <a href="#">changeset</a> to which you have previously assigned a <a href="#">tag identifier</a>. Choose the relevant tag from the drop-down list. The list shows both local tags (from <code>.hg/localtags</code>) and global tags (from <code>.hgtags</code>).</li><li>– Bookmark: choose this option to switch to another line of development which is identified by a <a href="#">bookmark</a> and merge to its <a href="#">head</a>. Choose the relevant bookmark from the drop-down list which shows all the available light-weight branches in the current repository.</li><li>– Revision: choose this option to merge to a specific changeset identified by its <a href="#">hash</a> or <a href="#">revision number</a>. In the text box, type the relevant revision number or paste the hash. To copy a hash, open the Log tab of the Version Control tool window, select the relevant branch and revision, and then choose Copy Hash on the context menu of the selection.</li></ul>
------------	--

---

Use this dialog box to establish a new light-weight Mercurial branch (bookmark). The bookmark will immediately appear in the Branches pop-up. You can create both **active** and **inactive** bookmarks. By default, IntelliJ IDEA creates an **active** bookmark, so you are immediately switched to the new bookmark and it is marked with a tick in the Branches pop-up. If you do not want to move your development to the new bookmark right now, you can create an **inactive** bookmark and switch to it later. Note that tracking and updating is available only for the bookmark that is currently active. You can have only one active bookmark. For details, see <http://mercurial.selenic.com/wiki/Bookmarks> and [Managing Mercurial Branches and Bookmarks](#).

---

**ItemDescription**

---

Bookmark Name	In this text box, type the name of the bookmark. This identifier will always point at the head of the new light-weight branch as you commit changes. You can use this name to identify the head of the relevant light-weight branch when during update or merge.
Inactive	<ul style="list-style-type: none"><li>– Clear this checkbox to activate the new bookmark and thus enable tracking and updating the light-weight branch the bookmark identifies. The checkbox is cleared by default.</li><li>– Select this checkbox to have an inactive bookmark created, that is, to remain in the current light-weight branch (bookmark) or named branch and switch to the new bookmark later.</li></ul>

Use this dialog box to specify parameters for fetching changes from a remote repository and applying them to a local repository.

**ItemDescription**

---

**Pull From**                      In this text box, specify the URL address of the remote repository to fetch the changes from.

Use this dialog box to update the [current working directory](#) to a [named branch](#) , [light-weight branch \(bookmark\)](#) , or a specific [changeset](#) identified by a [tag](#) , [hash](#) , or [revision number](#) .

By default, **Mercurial** requires that before update the current working directory should be **clean** , that is, it should not contain any uncommitted changes. Otherwise the update operation fails and IntelliJ IDEA shows the corresponding error message.

The message also recommends that you clean the current working directory by running the `hg update <target branch, bookmark, or changeset> -C` to discard the uncommitted changes.

#### ItemDescription

Repository	From this drop-down list, choose the repository to run the update in. The contents of the Branch , Tag , and Bookmark drop-down lists are updated to show the branches, tags, and bookmarks that are available in the selected repository.
Switch to	<p>In this area, choose the branch, bookmark, or changeset to switch to.</p> <ul style="list-style-type: none"> <li>- Branch: choose this option to switch to another line of development identified by a <a href="#">branch name</a> and update to the <a href="#">branch head</a> . Choose the desired branch from the drop-down list which shows all the named branches available in the current repository.</li> <li>- Tag: choose this option to update to a <a href="#">changeset</a> to which you have previously assigned a <a href="#">tag identifier</a> . Choose the relevant tag from the drop-down list. The list shows both local tags (from <code>.hg/localtags</code> ) and global tags (from <code>.hgtags</code> ).</li> <li>- Bookmark: choose this option to switch to another line of development which is identified by a <a href="#">bookmark</a> and update to its <a href="#">head</a> . Choose the relevant bookmark from the drop-down list which shows all the available light-weight branches in the current repository.</li> <li>- Revision: choose this option to update to a specific changeset identified by its <a href="#">hash</a> or <a href="#">revision number</a> . In the text box, type the relevant revision number or paste the hash. To copy a hash, open the Log tab of the Version Control tool window, select the relevant branch and revision, and then choose Copy Hash on the context menu of the selection.</li> </ul>
Overwrite locally modified files (no backup)	<p>If you are going to update to another branch, bookmark, or changeset and you have any uncommitted changes in the current line of development, technically there can be two ways to treat them. The uncommitted changes can be either committed before update or abandoned ( <a href="#">cleaned</a> ).</p> <p>By default, <b>Mercurial</b> requires that before update the current working directory should be <b>clean</b> , that is, it should not contain any uncommitted changes. Otherwise the update operation fails and IntelliJ IDEA shows the corresponding error message. The message also recommends that you clean the current working directory by running the <code>hg update &lt;target branch, bookmark, or changeset&gt; -C</code> to discard the uncommitted changes. Use the Overwrite locally modified files (no backup) checkbox to prevent failures during update when the current working copy is not clean.</p> <ul style="list-style-type: none"> <li>- Select the checkbox to abandon any uncommitted local changes.</li> <li>- Clear the checkbox if you are sure that the current working directory is clean.</li> </ul>

context menu of the Editor - Mercurial | Tag Repository

Use this dialog box to create a global tag that identifies the **tip** of a repository, which is the most recently changed **head** e in this repository. The created tag will be stored in the file `.hgtags` and tracked by Mercurial.

**ItemDescription**

---

**Select repository to tag** From this drop-down list, choose the repository whose **tip** you want to tag. The list shows the location of the repositories under the project root.

---

**Tag name** In this text box, type the name of the tag. By this name, you will be able to find the tag in the [Log Tab](#) of the Version Control tool window.

To access this dialog, click VCS in the main menu, and select Update Project from the popup. Alternatively, you can use the `Ctrl+T` shortcut.

In this dialog, select how you want to synchronize your local repository with the central storage.

#### OptionDescription

Pull	Select this option to pull new changesets from the remote repository to the local one. This option can be deselected if the pull operation is performed by other means, for example via a script. The result is identical with that of running the <code>hg pull</code> command.
Update Strategy	<p>In this section, select the synchronization method. This strategy will be applied to all Mercurial version control roots. The available options are:</p> <ul style="list-style-type: none"><li>– Only Update : select this option to apply the <a href="#">update</a> strategy. The local working directory will be updated to the latest available changeset. The result is identical with that of running the <code>hg update</code> command. It is recommended to select this option only if there are no conflicting changes or multiple heads, and if the latest changeset is a descendant or ancestor of the working directory's parent. Otherwise, the update operation will be aborted with errors.</li><li>– Merge : select this option to apply the <a href="#">merge</a> strategy. The latest changeset from the central repository will be incorporated into the current tip in your working directory. The result is identical with that of running the <code>hg merge</code> command.</li><li>– Commit after merge without conflicts : select this option if you want to commit the resulting changeset after the merge operation has completed successfully.</li><li>– Rebase : select this option to apply the <a href="#">rebase</a> strategy. Your local changes will be detached, the working directory will be synchronized with the central repository, and then the local changes will be appended on top of the new remote changes.</li></ul>

**Note** To be able to use this method, you need to enable the Rebase extension in the configuration file for your repository (for instructions on how to create configuration files, refer to [hgrc](#)).

Do not show this dialog in the future	<p>Select this option to have IntelliJ IDEA update your project silently in the future using the specified update strategy. To invoke this dialog before an update:</p> <ol style="list-style-type: none"><li>1. Open the <a href="#">Settings / Preferences Dialog</a> by pressing <code>Ctrl+Alt+S</code> or by choosing File   Settings for Windows and Linux or IntelliJ IDEA   Preferences for macOS, and click Confirmation under Version Control .</li><li>2. On the <a href="#">Confirmation</a> page that opens, select the Update checkbox in the Display option dialogs when these commands are invoked area.</li></ol>
---------------------------------------	--

This feature is only supported in the Ultimate edition.

In this part:

- [Edit Jobs Linked to Changelist Dialog](#)
- [Integrate File Dialog \(Perforce\)](#)
- [Link Job to Changelist Dialog](#)
- [Perforce Options Dialog](#)
- [Update Project Dialog \(Perforce\)](#)

This feature is only supported in the Ultimate edition.

VCS | Show Changes View - Local

View | Tool Windows | Changes - Local

VCS | Commit Changes

The dialog box opens in the following cases:

- When you select a changelist and then select Edit Associated Jobs from the context menu.
- When you click the  button in the Performe area of the [Commit Changes](#) dialog box.

Use the dialog box to search for Performe jobs, link jobs to the selected changelist, and detach currently linked jobs.

**ItemTooltip** **Description**  
**and**  
**Shortcut**

	Unlink selected jobs	Click this button to detach the selected job from the changelist.
	Search	Click this button to open the <a href="#">Link Job to Changelist</a> dialog box, where you can search for available jobs, view their details, and link the desired job to the changelist.
	Find and link job matching the pattern	Click this button to start quick search for the job that matches the pattern specified in the text box and attach the job to the changelist. In the text box, specify the exact name of the desired job or a search pattern according to the Performe jobs <a href="#">syntax rules</a> .

**Tip** If only one job matching the pattern is found, it is attached to the changelist automatically. Otherwise, to select a job among several available jobs, click  and find the desired job using the [Link Job to Changelist](#) dialog box.

Close

Click this button to save the specified settings and leave the dialog box.

Use this dialog box to integrate changelists from one branch spec to another.

**ItemDescription**

---

Branch Spec	Select the branch spec that will be used for change integration. Consider the following: <ul style="list-style-type: none"><li>- If the Reverse option is enabled, changes are integrated from the selected branch to the local copy.</li><li>- If the Reverse option is disabled, changes are integrated from the local copy to the selected branch.</li></ul>
Integrate changelist	Use this option to invoke the Changes Browser , where you can select the changelist that will be integrated into the current branch/local copy.
Store Changes To Changelist	Specify the changelist where the integrated changes should be stored.
Revert unchanged files before sync (p4 revert -a)	Select this option to revert unchanged files.
Run resolve automatically after the sync (p4 resolve -am)	Select this option to automatically resolve the files that can be resolved without conflicts.

This feature is only supported in the Ultimate edition.

The dialog box opens when you click the  button in the [Edit Jobs Linked to Changelist](#) dialog box.

Use this dialog box to search for available jobs, view their details, and link jobs to the changelist.

**Tip** When you need to attach only one job to a changelist, you can use the [quick search](#) functionality. This requires that you know the exact name of the job or at least can specify a search pattern for it.

## Specify search parameters

Use the controls in this area for specifying various criteria to limit the search output. Follow the [Perforce jobs syntax rules](#).

The specified values are joined in the generated command line query via the `AND` operation.

**Tip** At least one of the fields should be filled in.

### ItemDescription

**Job name pattern** In this text box, type the desired job name search pattern.

**Status** Use this drop-down list to specify the status of the job you are looking for. The available options are:

- \* - when this option is selected, all the jobs that match the remaining search criteria are displayed, regardless of their job statuses.

**Tip** If you specify Status as the only criterion and select this option, all the jobs that are currently present on the Perforce server will be retrieved.

- Open
- Closed
- Suspended

**User name pattern** In this text box, specify the search pattern or the exact name of the user who created the desired job.

**Date before/Data after** Use these text boxes to specify the time period the desired job is created in. The appropriate formats are `yyyy/mm/dd` or `yyyy/mm/dd:hh:mm:ss`.

**Description pattern** In this text box, type the desired job description search pattern.

**Search** Click this button to start searching for jobs that match the specified criteria.

## Search results

Use this area to view the details of found jobs, select the desired job, and attach it to the changelist.

### ItemDescription

**Search results** The list contains the jobs found according to the specified search criteria. When you select a job, the read-only area shows its details.

**OK** Click this button to link the selected job to the changelist.

This feature is only supported in the Ultimate edition.

File | Settings | Version Control | Configure | Perforce for Windows and Linux

IntelliJ IDEA | Preferences | Version Control | Configure | Perforce for macOS

Ctrl+Alt+S

In this dialog box, configure connection to the specified Perforce server.

#### ItemDescription

Perforce is online	Select this checkbox to enable establishing connection to the Perforce server. If there is a connection but the server does not respond (for example, because the server is backing up currently), you can disable such attempts by clearing this checkbox, or IntelliJ IDEA will suggest to do that after a timeout. After that the version control-specific operations will be disabled.
Use P4CONFIG or default connection	Use server information and user credentials from the P4CONFIG environment variable or default Perforce client connection. Otherwise, specify port, user, client, and password.
Charset	Select the charset corresponding to the one set on the server.
Dump Perforce commands to <i>IDEA_Home\bin\p4.output</i>	Log Perforce commands in the specified file.
Use login authentication	Toggle authentication.
Try to log in silently	Skip prompt dialog. This option works, when login authentication is required.
Use native Perforce API	Speed up connection to the server using a special library.
Path to P4 executable	Specify the path to the Perforce client executable file.
Test connection	Make sure that connection to the Perforce server is established.
Show branching history	See branches for files in the dialogs showing File History. When you work with several branches, it is recommended to enable this option so that the file branches are correctly displayed.

This feature is only supported in the Ultimate edition.

VCS | Update Project

Ctrl+T

Context menu of a file or directory | Perforce | Update File/Directory

VCS | Perforce | Update File/Directory

---

Use this dialog box to update the local working copy of a file, directory, or project with a revision from the repository.

**ItemDescription**

---

Revert unchanged files before sync (p4 revert -a)	Select this checkbox to discard changes made to open files. This option corresponds to the Perforce <code>revert</code> command. See <a href="#">p4 revert</a> reference for details.
Force sync (-f)	Select this checkbox to forcibly copy files from the depot into the workspace. This option corresponds to the Perforce <code>sync</code> command. See <a href="#">p4 sync</a> reference for details.
Run resolve automatically after the sync (p4 resolve -am)	Select this checkbox to resolve conflicts between file revisions. This option corresponds to the Perforce <code>resolve</code> command. See <a href="#">p4 resolve</a> reference for details.
Do not show this dialog in the future	If this checkbox is selected, the specified actions will be performed silently in future.

In this section:

- [Authentication Required](#)
- [Changes Browser](#)
- [Check Out From Subversion Dialog](#)
- [Configure Subversion Branches](#)
- [Create Branch or Tag Dialog \(Subversion\)](#)
- [Import into Subversion](#)
- [Integrate Project Dialog \(Subversion\)](#)
- [Integrate to Branch](#)

- [Subversion Working Copies Information Tab](#)
- [SVN Repositories](#)
- [Update Project Dialog \(Subversion\)](#)

Use this dialog to specify your credentials and gain access to the Subversion repository. The dialog is opened when you add a new repository location, or attempt to browse a repository.

**ItemDescription**

---

Authentication realm	This read-only area displays the repository name and URL.
User name	By default, this field shows the current user name. You can change the name as required.
Password	Type the password for your Subversion account.
Save credentials	Select this checkbox to preserve the specified user name and password.

This dialog opens when you select the Specified option in the [Integrate Project dialog](#) , and click the  button.

Use this dialog to select which revision to use in integration.

The Changes Browser dialog consists of the following areas:

- [Changes list](#)
- [Commit message](#)
- [Commit details](#)

## Changes list

This pane contains the list of all changes to your project. For each change, there is the revision number, the user who made the change, the date and the description. You can sort the list by this information by clicking the corresponding column header.

You can click the Older and Newer buttons to display the previous/next list of change.

## Commit message

This read-only area shows the commit message for the selected revision.

## Commit details

This pane shows a list of files that were modified in the selected revision.

## Toolbar

**ItemTooltip** **Description**  
and  
**Shortcut**

	<b>Show Differences</b>  	Click this button to open the <a href="#">Differences</a> dialog that points at the differences between the selected revision and the previous revision of the selected file.
	<b>Show Diff with Local</b>	Click this button to open the <a href="#">Differences</a> dialog that points at the differences between the selected file in the current revision and in your local working copy.
	<b>Edit Source</b>  	Click this button to open the source code of the selected file in the editor.
	<b>Open Repository Version</b>	Click this button to open the repository version of the selected file for editing.
	<b>Revert Selected Changes</b>	Click this button to roll back the changes in the selected file.
	<b>Compare Subversion Properties</b>	Click this button to view the differences in properties between the selected revision of the selected file and your local working copy.
	<b>Group by Directory</b>  	Click this button to transform a flat list of files into a tree of packages with files.
	<b>Expand All/Collapse All</b>  	Click this button to expand/collapse all nodes. Note that these buttons are only available only when tree-view is enabled.

Use this dialog box to create local working copies.

## Toolbar

**ItemTooltip** **Description**  
and  
**Shortcut**

	Add Repository Location	Click this button to <a href="#">configure a new repository location</a> .
	Edit Location URL	Click this button to edit the URL address of the selected repository.
	Discard Location	Click this button to discard selected repository location.
	Show/Hide Details	Click this button to display the details for each node below the repository location (changelist number, user name, date and time of the last change).
	Refresh	Click this button to refresh the view.
		
	Collapse All	Click this button to have all the nodes below all the repository locations collapsed.
		

## Repositories

In this area, manage the available repositories and select the locations to check out contents from.

**ItemDescription**

Repositories	Use this tree view to explore and manage the available repository locations. If necessary, right-click a node and choose the relevant item from its context menu.
Checkout	Click this button to check out the contents of the selected node to the specified location.

## Context Menu

**ItemDescription**

New	Select this menu item to configure a new <a href="#">repository location</a> , or a new remote folder in the selected repository location.
Checkout	Select this menu item to <a href="#">check out</a> the contents of the selected node.
Compare With	Select this menu item to <a href="#">compare</a> the selected node with the specified branch.
Browse Changes	Select this menu item to view changes that match the specified criteria (author, time range, and revision).
Import	Select this menu item to import a directory into the repository. You can select the directory you want to import from the Import Directory dialog that opens.
Export	Select this menu item to export the contents of the selected repository or folder to the specified destination. The exported contents are not under version control.
Branch or Tag	Select this menu item to create a branch or tag of the selected folder.
Move or Rename	Select this menu item to change name of the selected folder.
Delete	Select this menu item to delete the selected folder from the repository location.
	
Copy URL	Select this menu item to put the URL string to the clipboard.
	
Refresh	Select this menu item to synchronize to the repository.
Edit Location URL	Select this menu item to edit the selected repository location.
Discard Location	Select this menu item to discard the selected repository location.

This dialog appears when you have selected the repository you want to check out and the destination folder.

**ItemDescription**

---

Checkout	This read-only field shows the selected source repository.
Destination	From this list, select the directory to create the working copy in. Choose one of the available folders or click the Browse button  and select the relevant folder in the dialog box that opens.
Update / Switch to revision	In this area, specify the revision to check out. The available options are: <ul style="list-style-type: none"><li>- HEAD - select this option to have the latest revision checked out.</li><li>- Specified - select this option to have IntelliJ IDEA check out a specific earlier revision. Type the revision number in the text box or click the Browse button  and select the relevant revision from the Changes Browse that opens.</li></ul>
Depth	Use this drop-down list to specify the range of recursion into subdirectories. The available options are: <ul style="list-style-type: none"><li>- Empty : select this option to involve only the current file.</li><li>- Files : select this option to involve the files in the folder.</li><li>- Immediates : select this option to involve direct children of the current file.</li><li>- Infinity : select this option to enable full recursion.</li></ul>
Include external locations	Select this checkbox to have <a href="#">externals</a> included in the working copy.

Use this dialog box to compose a list of branches you work with.

**ItemDescription**

---

**Trunk location** In this text box, specify the URL address of the trunk in the repository. If necessary, click the Browse button  to open the Select Repository Location dialog box and select the required trunk in the repository structure tree.

---

**Branch locations** In this list, select the URL address of the folders in which the required branches are stored.

---

**Add** Click this button to add a branch to the list. The Select Repository Location dialog box opens where you can select the required branch in the repository structure tree.

---

**Remove** Click this button to remove the selected branch from the list.

---

In this dialog box, set the arguments for creating a branch or a tag on the basis of a local working copy or a repository version.

**ItemDescription**

---

Copy from	In this section, specify the source folder to create a branch or tag from. The source of the copy can be taken from the local working copy or from the repository.
Working Copy	Click this option to create a branch or tag on the basis of your local working copy. Type the path in the text box or click the Browse button  and select the desired directory in the <a href="#">dialog that opens</a> .
Repository Location	Click this option to create a branch or tag on the basis of the repository. Do one of the following: <ul style="list-style-type: none"><li>- Type the URL of the repository location in the text box.</li><li>- Click the browse button and select the source repository location.</li><li>- Click the  button to use the project home directory.</li></ul>
Revision	In this section, specify the source revision to create a branch or tag from. The available options are: <ul style="list-style-type: none"><li>- HEAD - select this option to have a branch or tag created on the basis of the HEAD revision.</li><li>- Specified - select this option to have a branch or tag created on the basis of a specific revision. Type the revision number in the text box manually or click the Browse button  and select the desired revision in the Changes Browser dialog box, that opens.</li></ul>
Copy to	Use this section to define the target folder for a branch or tag. The available options are: <ul style="list-style-type: none"><li>- Branch or Tag - select this option to have the selected revision copied to a specific branch or tag.</li></ul> <p>In the Base URL text box, specify the base URL of the branch or tag. In the Name text box, specify the name of the new branch.</p> <ul style="list-style-type: none"><li>- Any location - select this option to have to have the selected revision copied to a location of your choice. In the text box below, specify the URL of any valid location. Type the URL manually or click the Browse button  and specify the desired location in the Select Repository Location dialog box, that opens.</li></ul>
Comment	Type some meaningful description in the text area.

Use this dialog box to specify the options for importing data into Subversion.

## Toolbar buttons

**ItemTooltip  
and  
Shortcut**

	Add Repository Location	Click this button to configure a new <a href="#">repository location</a> .
	Edit Location URL	Click this button to edit the URL address of the selected repository.
	Discard Location URL	Click this button to discard the selected repository location and remove it from the list.
	Show/Hide Details	Click this button to display the details for each node below the repository location (changelist number, user name, date and time of the last change).
	Refresh	Click this button to refresh the view.  
	Collapse All	Click this button to have all the nodes below all the repository locations collapsed.  

## Main Controls

**ItemDescription**

Repositories	Use this tree view to explore and manage the available repository locations. Right-click nodes and examine context menus.
Import	Click this button and in the <a href="#">dialog that opens</a> , select the directory whose contents should be imported to the selected repository location.

## Context Menu

**ItemDescription**

New	Select this menu item to configure a new <a href="#">repository location</a> , or a new remote folder in the selected repository location.
Checkout	Select this menu item to <a href="#">check out</a> the contents of the selected node.
Compare With	Select this menu item to <a href="#">compare</a> the selected node with the specified branch.
Browse Changes	Select this menu item to view changes that match the specified criteria (author, time range, and revision).
Export	Select this menu item to export the contents of the selected repository or folder to the specified destination. The exported contents are not under version control.
Branch or Tag	Select this menu item to create a branch or tag of the selected folder.
Move or Rename	Select this menu item to change name of the selected folder.
Delete	Select this menu item to delete the selected folder from the repository location.
Copy URL	Select this menu item to put the URL string to the clipboard.  
Refresh	Select this menu item to synchronize to the repository.
Edit Location URL	Select this menu item to edit the selected repository location.
Discard Location	Select this menu item to discard the selected repository location.

Use this dialog box to integrate differences between two branches in the Subversion repository into a local working copy.

**ItemDescription**

Source 1	In this text box, specify the URL address of the first branch to compare. If necessary, click the Browse button <input type="button" value="..."/> and select the desired URL from the <a href="#">Select Repository Location</a> dialog box.
Source 2	In this text box, specify the URL address of the second branch to compare. If necessary, click the Browse button <input type="button" value="..."/> and select the desired URL from the <a href="#">Select Repository Location</a> dialog box.
Revision	For each source, specify the revision to use. The possible options are: <ul style="list-style-type: none"><li>- HEAD - select this option to use the Head revision of the source. The Head revision is suggested by default</li><li>- Specified - select this option to use a revision different from the Head revision. Specify the required revision in the text field. If necessary, click the <input type="button" value="..."/> button and select the revision from the Changes Browser dialog box.</li></ul>

**Tip** Based on the sources and revisions you specify, the difference between source 2 and source 1 is calculated and applied to the local working copy.

Use ancestry	Select this checkbox to take the ancestry of the Source1 and Source2 URLs into consideration when comparing revisions. If the checkbox is not selected, only the contents of the files are compared.
Try merge, but make no changes	Select this checkbox to enable the <code>--dry-run</code> switch of the <code>svn</code> command. If this checkbox is not selected, the sources are merged silently.
Depth	Use this drop-down list to specify the range of recursion into subdirectories. The available options are: <ul style="list-style-type: none"><li>- Empty - select this option to involve only the current file.</li><li>- Files - select this option to involve the files in the folder.</li><li>- Immediates - select this option to involve direct children of the current file.</li><li>- Infinity - select this option to enable full recursion.</li></ul>

Subversion | Integrate to Branch

---

Use this dialog to specify the options for integrating changes into a branch.

**ItemTooltipDescription**

---

Source branch URL	This read-only field shows the URL address of the source branch.
Target branch URL	This read-only field shows the URL address of the target branch.
Integrate into working copy	From this list, select the path to the local working copy into which the changes will be integrated.
Ignore whitespaces	Select this option if whitespaces are not important.
Try merge, but make no changes	Select this option to preview merge results by enabling the <code>--dry-run</code> switch of the <code>svn</code> command. If this option is unchecked, sources are merged silently.
	Add Click this button to add a working copy to the list.
	Remove Click this button to remove the selected working copy from the list.

Use this dialog box to lock file when it is necessary to avoid overwriting changes.

**ItemDescription**

---

Lock Comment	In this text box, describe the reason for locking the file and some additional comments, if necessary.
Steal existing lock	Select this checkbox to override the lock previously set on the desired file by someone else.
Do not show this dialog in the future	Select this checkbox to suppress displaying this dialog box and have files and folders locked silently. To have IntelliJ IDEA show this dialog box before locking files or folders again: <ol style="list-style-type: none"><li>1. Open the <a href="#">Version Control - Confirmation</a> page of the <a href="#">Settings</a> dialog box.</li><li>2. In the Display Option dialogs when these commands are invoked area, select the Checkout checkbox.</li></ol>

VCS | Subversion | Mark Resolved

Project tool window | context menu of a file | Subversion | Mark Resolved

Local Changes tab of the Version Control tool window | context menu of a file | Subversion | Mark Resolved

Project tool window | context menu of a file | Subversion | Mark Resolved

Version Control tool window - Merged with conflicts list | context menu of a file | Subversion | Mark Resolved

Use this dialog box to have IntelliJ IDEA consider conflicts in a file or directory resolved. This operation is most often required after merging text or property conflicts manually.

#### ItemDescription

---

Files and directories	The list shows all the files and directories where merge or updated resulted in conflicts that IntelliJ IDEA cannot resolve automatically. When you have examined the conflicts resolved them manually or considered irrelevant, you need to tell IntelliJ IDEA that these files are no longer conflicting. To appoint a file for marking as free from conflicts, select the checkbox next to it.
Select All	Click this button to have all the items in the list appointed for marking as resolved.
Deselect All	Click this button to clear the list of candidates for marking as resolved.
Mark Resolved	Click this button to have IntelliJ IDEA treat all the selected items as conflict free. The dialog box closes, whereupon the Local Changes tab of the Version Control tool window shows the affected files as updated and available for submitting to the server.

[Version Control tool window](#) | Repository Tab | Merge Info Pane - Browse

[Version Control tool window](#) | Subversion Working Copies Information Tab | Merge from

[Update Project/Directory dialog box](#) - Browse

---

The pop-up dialog box opens when you click the Browse button  or press `Shift+Enter` to select the path to the target branch.

Use this dialog box to select the relevant branch or working copy.

---

**ItemDescription**

Trunk	Choose this option to set the current trunk as the target branch or working copy.
Branches	Choose this option to select the relevant branch in the Branches list.
Tags	Choose this option to select the relevant tag in the Tags list.
Configure Branches	Choose this option to open the <a href="#">Configure Subversion Branches</a> dialog box and compose a list of branches you work with.

VCS | Subversion | Branch or Tag | Copy From | Repository location

VCS | Subversion | Branch or Tag | Copy To | Any location

**ItemDescription**

---

Repositories	Use this tree view to explore and manage the available repository locations. Right-click nodes and examine context menus.
--------------	---

---

Copy as	Specify the name under which the file or folder will be stored in branch.
---------	---

Use this dialog to define SVN-specific properties for the files and folders under SVN version control (ignore list, externals etc.)

**ItemDescription**

---

**Property name** Enter custom property name in the text field, or use the drop-down list to select one of the pre-defined properties.

---

**Set property value** Click this radio-button to set value for the specified property name in the text area. Properties that accept multiple values, such as an ignore list, can be entered on multiple lines.

---

**Delete property** Click this radio-button to remove selected property from the list.

---

**Update properties recursively** Check this option, if you want to apply the property to every file and directory under the selected directory.

**ItemDescription**

---

Use system default Subversion configuration directory	Store Subversion configuration files in the system default directory: <code>user_home\Application Data\Subversion</code>
Subversion configuration directory	Remove the content of the corresponding directory in the Subversion configuration directory. You may need to clear the authorization information from the configuration file, for example, when your credentials have changed.
Clear authentication cache	Remove the content of the corresponding directory in the Subversion configuration directory. You may need to clear the authorization information from the configuration file, for example, when your credentials have changed.

Use this tab to configure the format of your working copies.

**Tip** The tab is only available, when the current project sources are entirely or partially under Subversion control.

The tab displays a list of all detected directories under Subversion control supplied with information on the formats used.

**ItemDescription**

---

Refresh	Click this button to get the information on all the detected Subversion working copies up-to-date.
Root Path	This read-only field shows the full path to the directory.
URL	This read-only field shows the URL address of the remote directory the selected local copy is mapped to.
Format	This read-only field shows the actual Subversion format used in the selected directory.
Change	Click this link to open the Convert Working Copy Format dialog box, where you can select the desired format option.
Depth	This read-only field shows the range of recursion into subdirectories specified in the <a href="#">Update</a> dialog box.
Working Copy Root	This read-only field is displayed only if the directory in question is the root of a working copy.
Configure Branches	Click this link to open the <a href="#">Configure Subversion Branches</a> dialog box, where you can view and update the list of branches to work with.
Merge from	Click this link to open the <a href="#">Select Branch</a> pop-up dialog box and appoint the source of changes to merge to the current directory.

Use this tool window to view, add, and edit the location of SVN repositories.

**Item**  
**Tooltip**  
**and**  
**shortcut**

Item	Tooltip	Shortcut
	Add Repository Location	Click this button to configure a new <a href="#">repository location</a> . The New Repository Location dialog box opens, where you can select a repository URL in the drop-down list that contains previously added URL addresses.
	Edit Location Url	Click this button to edit the URL of the selected repository.
	Discard Location	Click this button to remove the selected repository from the list.
	Show/Hide Details	Click this button to display the details for each node under the repository location (changelist number, user name, date and time of the last change).
	Refresh	Click this button to refresh the view.
		
	Expand All/Collapse All	Click this button to expand/collapse all nodes.
		
	Close	Click this button to close the tool window.

## Context Menu

**Item**  
**Description**

New	Select this menu item to configure a new <a href="#">repository location</a> , or a new remote folder in the selected repository location. The New Repository Location dialog box opens where you can select a repository URL in the drop-down list that contains previously added URL addresses.
Show History	Select this item to open the <a href="#">Version Control</a> tool window with the history of the selected repository location.
Checkout	Select this menu item to <a href="#">check out</a> the contents of the selected node.
Compare with	Select this menu item to <a href="#">compare</a> the selected node with the specified branch.
Browse changes	Select this menu item to view changes that match the specified criteria (author, time range, and revision).
Export	Select this menu item to export the contents of the selected repository or folder to the specified destination. The exported contents are not under version control.
Branch or Tag	Select this menu item to create a branch or tag of the selected folder.
Move or Rename	Select this menu item to change name of the selected folder.
Delete	Select this menu item to delete the selected folder from the repository location.
Copy URL	Select this menu item to put the URL string to the clipboard.
Refresh	Select this menu item to synchronize to the repository.
Edit location Url	Select this menu item to edit the selected repository location.
Discard location	Select this menu item to discard the selected repository location.

Ctrl+T

Context menu of a file or directory | Subversion | Update File/Directory

VCS | Subversion | Update File/Directory

---

Use this dialog box to update the local working copy of a file, directory, or project with a revision from the repository.

**ItemDescription**

**Update/Switch to specific Uri**

- Select this checkbox to synchronize your local working copy with a specific repository. Specify the source repository either in the URL text box through its full Uri address or in the Use Branch text box through the branch name.
- Clear this checkbox to bring the changes from the repository that corresponds to the current working copy.

**Use Branch**

In this text box, specify the location of the required repository through its branch name. Click the Browse button  to choose the required branch in the [Select Branch](#) dialog box that opens.

**Note**

1. To use this method of specifying the required repository, you need to [configure a list of branches](#) you work with. If you have not done it yet, click [Configure Branches](#) in the [Select Branch](#) dialog box.
2. The text box is enabled only when the Update/Switch to specific Uri checkbox is selected.

**Url**

In this text box, specify the location of the required repository through its full URL address. Click the Browse button  to open the [Select Repository Location](#) dialog box.

The text box is enabled only when the Update/Switch to specific Uri checkbox is selected.

**Update/Switch to specific revision**

Select this checkbox to synchronize your local working copy with a specific revision different from the HEAD revision. The Update/Switch to specific revision text box becomes enabled.

In this text box, specify the number of the revision to be used. Click the Browse button  to open the [Changes Browser](#) dialog box. By default, IntelliJ IDEA suggests to update your local working copy the HEAD revision. This option corresponds to the  switch of the Subversion  command.

**Depth**

Use this drop-down list to specify the range of recursion into subdirectories. The available options are:

- Working copy - select this option to get files/directories from repository subtrees that have not been checked out yet.
- Empty: select this option to involve only the current file.
- Files: select this option to involve the files in the folder.
- Immediates: select this option to involve direct children of the current file.
- Infinity: select this option to enable full recursion.

**Force Update**

Select this checkbox to have local files replaced with the files from the repository even if the local files have modifications and thus abandon the local modifications.

**Update administrative**

This option only applies to working copies older than SVN 1.7 managed by SVNKit.

**information only in changed subtrees**

During synchronization with the server (update), SVN locks your working copy one subtree after another by creating empty `lock` files in the corresponding administrative `.svn` directories. After that, SVN starts comparing file hashes to detect which local files need to be synchronized.

When this option is selected, SVN first checks if any files from a subtree have been modified on the server, and locks this subtree (i.e. creates a `.svn/lock` file) only if such files are detected. This approach improves performance but may cause concurrency issues, for example, with antiviral software.

**Ignore Externals**

Select this checkbox if you do not want IntelliJ IDEA take into account [externals definitions](#) during update.

**Do not show this dialog in the future**

Select this checkbox to have IntelliJ IDEA perform future updates silently.

To have IntelliJ IDEA show this dialog box before update again:

1. Open the [Version Control - Confirmation](#) page of the [Settings](#) dialog box.
2. In the Display Option dialogs when these commands are invoked area, select the Update checkbox.

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS

Use this wizard to download the files from a TFS server according to the settings from a new or an existing [workspace](#) .

The menu item and the wizard are available only when the TFS Integration plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

In this part:

- [Checkout from TFS Wizard: Checkout Mode](#)
- [Checkout from TFS Wizard: Source Server](#)
- [Checkout from TFS Wizard: Choose Source and Destination Paths](#)
- [Checkout from TFS Wizard: Source Workspace](#)
- [Checkout from TFS Wizard: Choose Source Path](#)
- [Checkout from TFS Wizard: Summary](#)

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS

On this page, choose the way to map the files and folders on your server with their local copies. These mappings are referred to as [workspaces](#). You can either specify new mappings and have a new workspace generated or use mappings from an existing workspace.

Item	Description
<a href="#">Create workspace automatically</a>	Choose this option to have IntelliJ IDEA generate a workspace for you, with the folder mapping based on your <a href="#">choice of the local and remote paths</a> .
Workspace name	In this text box, type the name of the workspace to be generated.
<a href="#">Choose workspace manually</a>	Choose this option to have the data downloaded according to the mappings from an existing workspace.

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS - Create workspace automatically

On this page, choose the server to download the data from.

**ItemDescription**

Team servers	In this list box, manage the list of the servers you have access to and select the server to download the data from.
Add	Click this button to open the <a href="#">Add Team Foundation Server</a> dialog box, and specify the address of your TFS server and the credentials to connect to it.
Remove	Click this button to delete the selected server from the list.
TFS Proxy	Click this button to open the Set TFS proxy for server... dialog box where you can specify the parameters for accessing the selected server via Proxy.

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS - Create workspace automatically

The page opens when you select the server to download the data from on the [Source Server](#) page and click Next .

On this page, specify the remote folder to download the data from and map it to a local folder where the data will be downloaded to. The data is downloaded recursively, that is, the structure of subfolders under the selected source node is reproduced locally.

---

**ItemDescription**

---

Source Path	In this area, specify the folder on the server to download the data from. Select the folder in the tree, and Source Path read-only field displays the path to it relative to the server root.
Destination path	In this text box, specify the local folder to download the sources to. Type the path to the folder manually or click the Browse button  and select the folder in the dialog box, that opens. The data is downloaded recursively, that is, the structure of subfolders under the source node is repeated locally.

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS - Choose workspace manually

On this page, specify the workspace to add the imported files and folders to. The data will be downloaded according to the mappings defined in the selected workspace. The data is downloaded recursively, that is, the structure of subfolders under the selected source node is reproduced locally.

You can use an existing workspace as is, or update it as necessary, or even create an entirely new workspace manually.

#### ItemDescription

---

**Server/Workspace** This read-only field shows the URL addresses of TFS servers you have access to and workspaces available on these TFS servers.

---

**Workspace comment** This read-only field shows the descriptions of workspaces on the servers you have access to.

---

**Team Servers** Use the buttons in this area to manage the list of available servers and workspaces and configure access to them.

- Add: click this button to open the [Add Team Foundation Server](#) dialog box where you can specify the parameters for establishing connection to a TFS server. TFS uses [NTLM authentication](#), so native Windows applications (that is, [Microsoft Team Explorer](#)) authenticate silently with system credentials. IntelliJ IDEA users must always specify their username and password because of limitations posed by Java Runtime.
- Remove: click this button to remove the selected server from the list.
- Reload workspaces: click this button to have the list of available workspaces refreshed.
- TFS Proxy: click this button to open the Set TFS proxy for server... dialog box where you can specify the parameters for accessing the selected server via Proxy.
- Check-in Policies: click this button to open the [Edit Check-in Policies](#) dialog box where you can manage the list of check-in policies to be applied.

---

**Workspaces** Use the buttons in this area manage the list of available workspaces and update the workspaces, when applicable.

- Create: click this button to open the [Create Workspace](#) dialog box for creating a new workspace.
- Edit: click this button to open the [Edit Workspace](#) dialog box for editing the selected workspace.
- Delete: click this button to remove the selected workspace from the list.

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS - Choose workspace manually

The page opens when you choose an existing workspace on the [Source Workspace](#) page and click Next .

On this page, specify the folder on the server to download data from.

The page shows a tree of folders on the server that you have access to. When you select the required folder, \$product\$ tells you which local folder it is mapped to in the [current workspace](#) .

This feature is only supported in the Ultimate edition.

VCS | Checkout from Version Control | TFS - Create workspace automatically

VCS | Checkout from Version Control | TFS - Choose workspace manually

This last, read-only, page of the wizard shows the name of the workspace to be used or generated, the URL address of the server, the source folder to download data from, and the local folder to save the downloaded data in. Review the details and click Finish .

Use the dialog box to restore changes that were preserved in a patch file in the specified directory.

**Item Tooltip  
and  
Shortcut**

Patch file name		In this text box, specify the name of the *.patch file to be applied. Type the fully qualified name or click the Browse button  and locate the desired patch file using the Select Patch File dialog box, that opens.
	Group by Directory  	Use this button to toggle between the flat view and the directory tree view. Select the checkboxes next to the changes that you want to be applied.
	Expand All/Collapse All   	Use these buttons to expand/collapse all nodes
	Map base directory	In the <a href="#">dialog that opens</a> , select the directory relative to which file names in the patch file will be interpreted. You can map a base directory to a single file, directory, or to a selection.
	Show Differences  	Click this button to open the <a href="#">Differences Viewer for Files</a> that shows the differences between your local working copy, the repository version, and the patch. Use the buttons Compare Previous File  and Compare Next File  to have the files in patch compared in a chain.
<b>Tip</b> If the patch cannot be applied without conflicts, the lines with conflicts are highlighted with red.		
	Strip Directory	Use this button to apply the changes to files located in different directories from the ones specified in the patch. Clicking this button removes one slash in the path to the target file. Click the button as many times as many leading directories you need to strip. The number of removed slashes is indicated in square brackets.
	Restore Directory	Use this button to revert the last strip directory action. Click the button as many times as many previously stripped leading directories you need to restore.
	Reset Directories	Use this button to revert all strip directory actions in the selection.
	Remove Directories	Click this button to have all the leading directories stripped and have the changes applied to the file with the specified name in the base directory.
	Refresh	Click this button to synchronize the tree with the current state of the file system.
Summary	This section displays summary information for the currently selected changelist (the number of modified, new, and deleted files).	
Existing Changelist	Select this option to add the patched files to an existing changelist and select the desired changelist from the drop-down list.	
New Changelist	<p>Select this option to create a new changelist and add the patched files to it.</p> <ul style="list-style-type: none"> <li>- Name : in this text box, type the name of the new changelist. By default, it is the name of the current patch.</li> <li>- Comment : in this text box, type the comment to the new changelist.</li> <li>- Make this changelist active: select this checkbox to have IntelliJ IDEA automatically give the <i>active</i> status to the new change list immediately after the changes are restored in it. When this checkbox is cleared, the current active changelist remains active. See <a href="#">Changelist</a> for details.</li> <li>- Track Context : select this checkbox to have IntelliJ IDEA preserve the context of the task associated with the new changelist on its deactivation and restore the context when the changelist becomes active. See <a href="#">Managing tasks and contexts</a> for details.</li> </ul>	

Use this dialog box to generate a patch file for the specified changelist or files.

Use this dialog box to create a patch from the selected changelist or files.

This dialog box consists of several areas:

- [Modified files pane](#)
  - [Toolbar](#)
- [Commit Message pane](#)
  - [Toolbar](#)
- [Details pane](#)
  - [Toolbar](#)

## Modified files pane

This section contains a list of files that were modified since the last commit. All files in this list are selected by default.

Deselect the check-boxes next to the files that you want to exclude from the patch.

## Toolbar

Item Icon	Item Tooltip and Shortcut	Description	Available in
	Show Differences  Ctrl+D	Click this button to open the <a href="#">Differences</a> dialog box that highlights the differences between your local working copy of the selected file and its repository version.	All VCSs
	Refresh Changes  Ctrl+F5	Click this button to reload the Changed files tree view so it is up-to-date.	All VCSs
	Show Unversioned Files	Click this button if you want to see newly added files that have not been added to version control yet under the Unversioned Files node.	All VCSs
	Add to VCS  Ctrl+Alt+A	Click this button to move the files selected under the Unversioned Files node to the active changelist, so that they are added to your version control system during the commit.	All VCSs
	Move to Another Changelist  F6	Click this button to add the selected file(s) to another changelist. The Move to Another Changelist dialog box opens where you can select an existing changelist or create a new one.	All VCSs
	Delete	Click this button to delete the selected file.	
	Ignore	Click this button to leave the selected files unversioned.	All VCSs
	Revert	Click this button to revert all changes made to the local working copy of the selected files.	All VCSs
	Jump to source  F4	Click this button to open the source code of the selected file in the editor.	All VCSs
	Revert Unchanged Files	Click this button to revert the files that have not been modified locally.	Subversion Perforce
	Group by Directory  Ctrl+P	Click this button to toggle between the flat view and the directory tree view.	All VCSs
 	Expand or collapse all nodes  Ctrl+NumPad Plus  Ctrl+NumPad -	Click these buttons to expand or collapse all nodes in the directory tree. These buttons are not available in flat view.	All VCSs
Change list	N/A	From this drop-down list, select the changelist that contains the modified files to be checked in or included in the patch. The active changelist is selected by default.	All VCSs

The summary under the modified files pane shows statistics on the currently selected changelist, such as the number of

modified, new and deleted files. This area also shows how many files of each type are shown, and how many of them will be included in the patch.

## Commit Message pane

The comment you enter in this area will be used as the name of the patch file.

## Toolbar

Icon and Tooltip	Shortcut	Description
------------------	----------	-------------

	Ctrl+M	Click this icon to invoke the Commit Message History dialog that contains a list of your twenty-five last commits and the corresponding commit messages.
---	--------	--

## Details pane

The Details pane is hidden by default. To unfold it, click the arrow button  next to the pane title.

In this pane you can explore the differences between the base repository version of the selected file, and the version you want to include in the patch.

## Toolbar

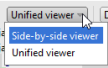

Item	Tooltip and Shortcut	Description
------	----------------------	-------------

	Previous Difference / Next Difference Shift+F7 F7	Use these buttons to jump to the next/previous difference. When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons  /  once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a> .
--	---	--

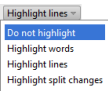

This behavior is supported only when the Differences Viewer is invoked from the [Version Control](#) tool window.

	Compare Previous/Next File Alt+Left Alt+Right	Click these buttons to compare the local copy of the previous/next file with its update from the server. <b>Tip</b> These buttons are only available when there is more than one file in the selected changelist.
---	---	--

	Jump to Source F4	Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer.
--	----------------------	---

Viewer type		Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only. Both types of viewers enable you to <ul style="list-style-type: none"><li>– Edit code. Note that one can change text only in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.</li><li>– Perform the Apply/Append/Revert actions.</li></ul>
-------------	---	--

Whitespace		Use this drop-down list to define how the differences viewer should treat white spaces in the text. <ul style="list-style-type: none"><li>– Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.</li><li>– Trim whitespaces : <code>("\\t", " ")</code>, if they appear in the end and in the beginning of a line.<ul style="list-style-type: none"><li>– If two lines differ in trailing whitespaces only, these lines are considered equal.</li><li>– If two lines are different, such trailing whitespaces are not highlighted in the <a href="#">By word</a> mode.</li></ul></li><li>– Ignore whitespaces : white spaces are not important, regardless of their location in the source code.</li><li>– Ignore whitespaces and empty lines : the following entities are ignored:<ul style="list-style-type: none"><li>– all whitespaces (as in the 'ignore whitespaces' option)</li><li>– all added or removed lines consisting of whitespaces only</li><li>– all changes consisting of splitting or joining lines without changes to non-whitespace parts.</li></ul></li></ul> <p>For example, changing <code>a b c</code> to <code>a \\n b c</code> is not highlighted in this mode.</p> <li>– Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).</li>
------------	---	--

Highlighting mode		Select the way differences granularity is highlighted.  The available options are: <ul style="list-style-type: none"><li>– Highlight words : the modified words are highlighted</li><li>– Highlight lines : the modified lines are highlighted</li></ul>
-------------------	---	--

- **Highlight split changes** : if this option is selected, big changes are split into smaller 'atomic' changes.

For example, `A \n B` vs. `A X \n B X` will be treated as two changes instead of one.

- **Do not highlight** : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.

	<b>Collapse unchanged fragments</b>	Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the Diff & Merge settings page.
	<b>Synchronize scrolling</b>	Click this button to scroll both differences panes simultaneously. If this button is released, each pane can be scrolled independently.
	<b>Disable editing</b>	Click this button to enable editing of the local copy of the selected file, which is disabled by default. When editing is enabled, you can make last-minute changes to the modified file before committing it.
	<b>Editor settings</b>	Click this button to open a drop-down list of available options. Select or clear these options to show or hide line numbers, indentation guides, white spaces, and soft wraps.
	<b>Show diff in external tool</b>	Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> settings page. This button only appears on the toolbar when the Use external diff tool option is enabled in the <a href="#">External Diff Tools</a> settings page.
	<b>Help</b>	Click this button to show the corresponding help page.

F1

Note that the options listed above are available for text files only. IntelliJ IDEA cannot compare binary files, so most commands will be unavailable for them.

After you've selected the files you want to commit, click the Create Patch button and specify the patch file options in the dialog that opens.

Use this dialog box to commit (check in) changes from the selected changelist to the repository and, optionally, to create a patch file.

This dialog box consists of several areas:

- [Modified files pane](#)
  - [Toolbar](#)
- [Commit Message pane](#)
  - [Toolbar](#)
- [VCS-specific controls](#)
- [Before Submit / Before Commit section](#)
- [After Submit / After Commit section](#)
- [Diff pane](#)
  - [Toolbar](#)
- [Submit / Commit button](#)

The options available in this dialog depend on the version control system you are using.

## Modified files pane

This section contains a list of files that have been modified since the last commit. Deselect the check-boxes next to the files that you want to exclude from current commit.

## Toolbar

Item and Shortcut	Description	Available in
	Show Differences  	Click this button to open the <a href="#">Differences</a> dialog box that highlights the differences between your local working copy of the selected file and its repository version.  All VCSs
	Refresh Changes  	Click this button to reload the Changed files tree view so it is up-to-date.  All VCSs
	Show Unversioned Files	Click this button if you want to see newly added files that have not been added to version control yet under the Unversioned Files node.  All VCSs
	Add to VCS  	Click this button to move the files selected under the Unversioned Files node to the active changelist, so that they are added to your version control system during the commit.  All VCSs
	Move to Another Changelist  	Click this button to add the selected file(s) to another changelist. The Move to Another Changelist dialog box opens where you can select an existing changelist or create a new one.  All VCSs
	Delete	Click this button to delete the selected file.
	Ignore	Click this button to leave the selected files unversioned.  All VCSs

 	Expand or collapse all nodes   	Click these buttons to expand or collapse all nodes in the directory tree. These buttons are not available in flat view.  All VCSs

Change list	N/A	From this drop-down list, select the changelist that contains the modified files to be checked in or included in the patch. The active changelist is selected by default.	All VCSs
-------------	-----	---	----------

The summary under the modified files pane shows statistics on the currently selected changelist, such as the number of modified, new, deleted and unversioned files. This area also shows how many files of each type are shown, and how many of them will be committed.

## Commit Message pane

In this area, enter a comment to the current commit. You cannot commit your changes until you enter some description in the Commit Message field.

This comment will also be used as the name of the patch file, if you decide to create a patch.

## Toolbar

<b>Icon and</b>	<b>Shortcut</b>	<b>Description</b>
<b>Tooltip</b>		

 Commit Message History	<b>Ctrl+M</b>	Click this icon to invoke the Commit Message History dialog that contains a list of your twenty-five last commits and the corresponding commit messages.
--	---------------	--

## VCS-specific controls

The controls in this section are located in the top-right part of the dialog, and contain the options that are specific for the version control system you are using.

Item	Description	Available for
Author	Use this drop-down list to select the author of the changes that you are going to commit. This may be useful when you are committing changes made by another person.	Git
Amend commit	Select this checkbox to replace the previous commit with the current changes (see <a href="#">Git Basics: Undoing Things</a> for details).	Git, Mercurial
Sign-off commit	Select this option if you want to sign off your commit, i.e. to certify that the changes you are about to check in have been made by you, or that you take the responsibility for the code in question. When this option is enabled, the following line is automatically added at the end of the commit message: <b>Signed off by: &lt;username&gt;</b>	Git
Keep files locked	Select this checkbox to keep the changed files <b>locked</b> after they are checked in.	Subversion
Jobs	<p>These controls are available only if you select the Enable Perforce Jobs Support checkbox on the <a href="#">Perforce settings page</a> .</p> <p>Use the controls in this area to search for <a href="#">Perforce jobs</a> , link jobs to the selected changelist, and detach the currently linked jobs.</p> <ul style="list-style-type: none"> <li>-  Unlink selected jobs : click this button to detach the selected job from the changelist.</li> <li>-  Edit associated jobs : click this button to open the <a href="#">Edit Jobs Linked to Changelist</a> dialog where you can search for available jobs, view their details, and link jobs to the selected changelist.</li> <li>-  Find and link job matching the pattern : click this button to start quick search for the job that matches the pattern specified in the text box and attach the job to the changelist.</li> </ul> <p>In the text box, specify the exact name of the job or a search pattern according to the Perforce jobs <a href="#">syntax rules</a> .</p> <div style="background-color: #ffff00; padding: 5px; border: 1px solid #ccc;"> <p><b>Tip</b> If only one job matching the pattern is found, it is attached to the changelist automatically. Otherwise, to select a job among several available jobs, click the  button and find the desired job using the <a href="#">Edit Jobs Linked to Changelist</a> dialog box.</p> </div> <p>The list box in the bottom of the area displays the jobs that are currently attached to the selected changelist.</p>	Perforce

## Before Submit / Before Commit section

Use the controls in this area to define which additional actions you want IntelliJ IDEA to perform before committing the selected files.

These controls are available for the following version control systems:

- Git
- CVS
- Subversion
- Perforce

## ItemDescription

Reformat code	Select this checkbox to perform code formatting according to the <a href="#">Project Code Style settings</a> .
Rearrange code	Select this checkbox to rearrange your code according to the <a href="#">arrangement rules preferences</a> .
Optimize imports	Select this checkbox to <a href="#">remove redundant import statements</a> .
Perform code analysis	Select this checkbox to run code inspection on the files you are about to commit.
Check TODO (<filter name>)	Select this checkbox to review the <a href="#">TODO items</a> matching the specified filter. Click the Configure link to choose an <a href="#">existing TODO filter</a> , or open the <a href="#">TODO settings page</a> and define a new filter to be applied.
Cleanup	Select this checkbox if you want to automatically apply the current inspection profile to the files you are going to commit.
Update copyright	Select this checkbox to <a href="#">add or update a copyright notice</a> according to the selected copyright profile - scope combination.
Revert unchanged files	Select this checkbox to revert the files that have not been modified. This option is only available for Perforce.

## After Submit / After Commit section

Use the controls in this area to define which additional actions you want IntelliJ IDEA to perform after committing the selected files.

Item	Description	Available for
Run tool	From this drop-down list, select the <a href="#">external tool</a> that you want IntelliJ IDEA to launch after the selected changes have been committed. You can select a tool from the list, or click the Browse button  and configure an external tool in the <a href="#">External Tools</a> dialog box that opens.	All VCSs
Upload files to	From this drop-down list, select the <a href="#">server access configuration</a> to use for uploading the committed files to a local or remote host, a mounted disk, or a directory. To suppress uploading, choose None . To add a server configuration to the list, click  and fill in the required fields in the Add Server dialog that opens.	All VCSs
Always use selected server	Select this checkbox to always upload files to the selected server access configuration. The drop-down list and the checkbox are only available if the Remote Hosts Access plugin is enabled.	All VCSs
Tag committed files	Select this checkbox to assign a tag to the committed files and type the name of the tag. To replace a previously assigned tag with a new one, select the Override existing tags option.	CVS
Auto-update after commit	Select this checkbox to automatically update your project after the commit. Enabling this option will help prevent your working copy against the <a href="#">mixed-revision state</a> . The mixed-revision state of a working copy may affect the <a href="#">Move</a> and <a href="#">Rename</a> refactoring applied to folders, in which case items in revisions different from the moved subtree root will be tracked separately, which can be confusing.  When the Auto-update after commit option is enabled: – Merge will fail with an error if the merge target is a mixed-revision working copy. – <a href="#">Your own changes</a> will never cause a 409 conflict.	Subversion

## Diff pane

The Diff pane is hidden by default. To unfold it, click the arrow button  next to the pane title.

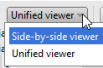

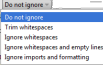

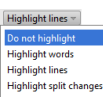

In this pane you can explore the differences between the base repository version of the selected file, and the version you are about to commit.

## Toolbar

### ItemTooltip Description and Shortcut

	Previous Difference / Next Difference Shift+F7 F7	Use these buttons to jump to the next/previous difference. When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons  /  once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a> .  This behavior is supported only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.
	Compare Previous/Next File	Click these buttons to compare the local copy of the previous/next file with its update from the server.  <b>Tip</b> These buttons are only available when there is more than one file in the selected changelist.

		
	<b>Jump to Source</b> 	Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer .
<b>Viewer type</b>		Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only. Both types of viewers enable you to <ul style="list-style-type: none"> <li>– Edit code. Note that one can change text <b>only</b> in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.</li> <li>– Perform the Apply/Append/Revert actions.</li> </ul>
<b>Whitespaces</b>		Use this drop-down list to define how the differences viewer should treat white spaces in the text. <ul style="list-style-type: none"> <li>– Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.</li> <li>– Trim whitespaces : (" \t", " ") , if they appear in the end and in the beginning of a line. <ul style="list-style-type: none"> <li>– If two lines differ in trailing whitespaces only, these lines are considered equal.</li> <li>– If two lines are different, such trailing whitespaces are not highlighted in the <b>By word</b> mode.</li> </ul> </li> <li>– Ignore whitespaces : white spaces are not important, regardless of their location in the source code.</li> <li>– Ignore whitespaces and empty lines : the following entities are ignored: <ul style="list-style-type: none"> <li>– all whitespaces (as in the 'ignore whitespaces' option)</li> <li>– all added or removed lines consisting of whitespaces only</li> <li>– all changes consisting of splitting or joining lines without changes to non-whitespace parts.</li> </ul> <p>For example, changing <code>a b c</code> to <code>a \n b c</code> is not highlighted in this mode.</p> </li> <li>– Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).</li> </ul>
<b>Highlighting mode</b>		Select the way differences granularity is highlighted. The available options are: <ul style="list-style-type: none"> <li>– Highlight words : the modified words are highlighted</li> <li>– Highlight lines : the modified lines are highlighted</li> <li>– Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.</li> </ul> <p>For example, <code>A \n B</code> vs. <code>A X \n B X</code> will be treated as two changes instead of one.</p> <ul style="list-style-type: none"> <li>– Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.</li> </ul>
	<b>Collapse unchanged fragments</b>	Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the Diff & Merge settings page.
	<b>Synchronize scrolling</b>	Click this button to scroll both differences panes simultaneously. If this button is released, each pane can be scrolled independently.
	<b>Disable editing</b>	Click this button to enable editing of the local copy of the selected file, which is disabled by default. When editing is enabled, you can make last-minute changes to the modified file before committing it.
	<b>Editor settings</b>	Click this button to open a drop-down list of available options. Select or clear these options to show or hide line numbers, indentation guides, white spaces, and soft wraps.
	<b>Show diff in external tool</b>	Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> settings page. This button only appears on the toolbar when the Use external diff tool option is enabled in the <a href="#">External Diff Tools</a> settings page.
	<b>Help</b> 	Click this button to show the corresponding help page.

Note that the options listed above are available for text files only. IntelliJ IDEA cannot compare binary files, so most commands will be unavailable for them.

## Submit / Commit button

Click this button to commit the selected files, or hover your mouse over this button to display one of the following available commit options:

- Commit and Push : select this option to push the changes to the remote repository immediately after the commit. This

option is available if you are using [Git](#) or [Mercurial](#) as a version control system.

- Create MQ Patch : select this option to create an MQ patch based on your changes. This option is only available if you are using Mercurial as a version control system.
- Create Patch : select this option if you want IntelliJ IDEA to generate a patch based on the changes you are about to commit. In the Create Patch dialog that opens, type the name of the patch file and specify whether you need a reverse patch.
- Remote Run : select this option to [run your personal build](#) . This option is only available when you are logged in to [TeamCity](#) . Refer to [TeamCity plugin documentation](#) for details.

Use this dialog to configure a list of files and directories that you do not want to put under version control. These can be file names associated with VCS administration, backup files, and any other artifacts that you want to remain unversioned. You can also specify patterns of files you want to ignore.

 You can only ignore unversioned files, i.e. files that have not yet been put under version control.

**Item**  
**Keyboard shortcut**

		Use this icon or shortcut to add an item to the list. The <a href="#">Ignore Unversioned Files</a> dialog box opens where you can type an exact path to a file or directory to be ignored or specify a pattern that defines the names of files and directories to be ignored.
		Use this icon or shortcut to edit the selected path or pattern in the <a href="#">Ignore Unversioned Files</a> dialog box.
		Use this icon or shortcut to remove the selected path or pattern from the list.

In this dialog box, choose one of the registered Version Control Systems to use in your project and assign it to the Project Root.

The dialog box and the menu item are available only if the project does not use any Version Control System.

**Item Description**

---

Select a version control system to associate with the project root	From this drop-down list, select one of the supported version control systems that you want to associate with the project root.
--	---

## Introduction

In IntelliJ IDEA each file has its own status marked with a specific color. The file status denotes correspondence of the actual file content with the one marked as 'current'.

In the editor, each line in a file is checked whether it corresponds to the state at the 'current' point and marked with a specific color at the left gutter area.

You can customize the default colors:

- For files - in the File Status page of the [Color Scheme](#) settings.
- For the lines in the editor - in the VCS page of the [Color Scheme](#) settings.

## File Status in views

### ColorFile Description Status

Black	Up to date	File is unchanged. <a href="#">PhantomsTest.java</a>
Gray	Deleted	File is scheduled for deletion from the repository. <a href="#">privatent.txt</a>
Blue	Modified	File has changed since the last synchronization. <a href="#">Advice.java</a>
Green	Added	File is scheduled for addition to the repository. <a href="#">ResultTest.java</a>
Violet	Merged	File is merged by your VCS as a result of an update. <a href="#">VcsHistoryDialog.java</a>
Brown	Unversioned	File exists locally, but is not in the repository, and is not scheduled for adding. <a href="#">Test.xml</a>
Olive	Ignored	File will be ignored in any VCS operation. <a href="#">Test.html</a>
Light brown	Hijacked	File is <a href="#">modified without checkout</a> . This status is valid for the files under Perforce, ClearCase and VSS. modified without checkout . <a href="#">HelpTOC.xml</a>
Red	Merged with conflicts	During the last update, file was merged with conflicts. <a href="#">HistoryTestCase.java</a>
Lilac	Externally deleted	File is deleted locally, but was not scheduled for deletion, and still exists in the CVS repository. <a href="#">test1.txt</a>
Dark cyan	Switched	The file is taken from a different branch than the whole project. This status is valid for CVS and SVN. <a href="#">test1.txt</a>

## Line Status in the editor

### Color File Description Status

	Modified	Denotes the lines modified since the last synchronization.
	Added	Denotes the lines added since the last synchronization.
	Deleted	Denotes the lines removed since the last synchronization.

Alt+Insert

---

Use this dialog box to create a new changelist.

**ItemDescription**

---

Name	Type the name of the new changelist.
Comment	Type optional comment. When the new changelist will be submitted to the repository, this comment will appear in the Comment text area of the <a href="#">Commit Changes</a> dialog box.
Make this changelist active	Select this check box to have IntelliJ IDEA automatically give the <b>active</b> status to the new change list immediately after the changes are restored in it. When this checkbox is cleared, the current active changelist remains active. See <a href="#">Changelist</a> for details.
Track context	Select this check box to have IntelliJ IDEA preserve the context of the task associated with the new changelist on its deactivation and restore the context when the changelist becomes active. See <a href="#">Managing tasks and contexts</a> for details.

Use this dialog to configure the patch file settings.

**ItemDescription**

Patch file	Specify the name of the patch file. By default, the text in the Commit Message section of the <a href="#">Create Patch dialog</a> is used as the file name. If the Commit Message section is empty, the default name is <code>unnamed.patch</code> .
Base path	Specify the path relative to which paths inside the patch file will be written. Normally, this is your project directory, but you may want to use a relative path, for example, if the modified files are stored inside your VCS repository.
Reverse patch	Select this option if you want to create a patch that reverts the changes you have made.
Encoding	Select the encoding for the patch file from the drop-down list.

This dialog is available for the following version control systems:

- Git
- Mercurial

The dialog consists of two panes (the Repositories pane and the Commit details pane) and the Push controls area:

- [Repositories pane](#)
- [Commit details pane](#)
- [Push controls](#)

## Repositories pane

The left pane shows a list of Git and/or Mercurial repositories (as well as which local branch/active bookmark will be pushed to which remote branch), and a list of commits performed in each repository.

- Hover the mouse over a commit: a tooltip is displayed showing the commit number, date and time, author, and the commit message. If the author of a commit is different from the current user, this commit is marked with an asterisk.
- Select the checkbox next to each repository to which you want to push.
  - If you have a multirooted project where repositories are not controlled synchronously, only the current repository is selected by default (or multiple repositories selected in the Project View ). For details on how to enable/disable synchronous repositories control, refer to the following sources:
    - for **Git**: [Version Control Settings: Git](#)
    - for **Mercurial**: [Version Control Settings: Mercurial](#)
- To modify the target branch where you want to push (it is highlighted in blue), click it. The label turns into a text field where you can specify the target branch. You can also switch into the editing mode by selecting the branch that you want to modify and pressing `Enter`.
- You can also edit the remote repository (if there are multiple ones) in the same way as the remote branch. Note that if no remotes have been specified, the Define remote link will appear instead of a remote name. Click it to add a remote.
- If there are no remotes in the repository, the Define remote link appears. Click this link and specify the remote name and URL in the dialog that opens.

## Commit details pane

The right pane shows which files are included in the selected commit. If you select multiple branches in the left pane, all corresponding commits will be shown.

The toolbar in this area provides the following options:

### ItemTooltip Description and shortcut

	<b>Show Diff</b> <code>Ctrl+D</code>	Click this button to open the <a href="#">Differences Viewer for Files</a> dialog that shows the differences between the committed version of the selected file and its previous version.
	<b>Edit Source</b> <code>F4</code>	Click this button to open the selected file in the editor.
	<b>Group by Directory</b> <code>Ctrl+P</code>	Click this button to toggle between the flat view and the directory view.
	<b>Collapse All / Expand All</b> <code>Ctrl+NumPad - /</code> <code>Ctrl+NumPad Plus</code>	Click these buttons to fold/unfold all nodes in the directory tree. These buttons are unavailable if the flat view is selected.

## Push controls

The controls in this area allow you to select the following push options:

### ItemDescription

Push Tags	<p>This option is only available if you are using Git.</p> <p>By default, when you perform the <code>push</code> operation, tags are not sent to the remote repositories. Select this option if you want to push tags with your commits.</p> <ul style="list-style-type: none"> <li>– Select All if you want to push all tags, including the tags that do not belong to the selected branches you are about to push (equivalent to <code>push --tags</code>).</li> <li>– Select Current Branch if you want to push only the tags that belong to the selected branches you are about to push (equivalent to <code>push --follow-tags</code> available since Git 1.8.3).</li> </ul>
-----------	---

Export Active  
Bookmarks

This option is only available if you are using Mercurial.

By default, when you perform the `push` operation, bookmarks are not sent to the remote repositories. Select this option if you want to push active bookmarks with your commits.

---

Push

Click this button and select which operation you want to perform from the drop-down menu: `push` or `push --force`.

For instructions on how to use the `push --force` command and where it may be useful, refer to:

- For Git: [Using Git integration](#)
- For Mercurial: [Pushing Changes to the Upstream \(Push\)](#)

**Note** For Git, these choice options are only available if the Allow force push option is enabled (see [Version Control Settings: Git](#)), otherwise, you can only perform the `push` operation.

Use this dialog box to roll back changes that have not yet been committed to the repository.

## Toolbar

### ItemTooltip Description and Shortcut

	<b>Show Differences</b> 	Click this button to open the Differences dialog box that points at the inconsistencies between your local working copy of the selected file and the file in the repository.
	<b>Move to Another Changelist</b> 	Click this button to add the selected file(s) to another changelist. The Choose Changelist dialog box opens where you can select an existing changelist or create a new one.
	<b>Group by Directory</b> 	Click this button to toggle between the flat view and the directory tree view.
	<b>Expand or collapse all nodes</b>  	Click these buttons to expand or collapse all nodes in the directory tree. These buttons are not available in flat view.
	<b>Select All</b> 	Click this button to select all the files in the list or directory tree.

## Controls

### ItemDescription

Changed files	This tree view displays the list of changed files. Select checkboxes next to the files to be reverted.
Change list	Use the drop-down list to select the change list that contains the modified files to be reverted. By default, the active change list is suggested.
Delete local copies of added files	Use this checkbox to revert added files as well as your changes in modified ones.

Use this dialog box to roll back changes from a certain change list.

#### ItemDescription

---

Existing Changelist	Choose this option restore the shelved changes in one of the existing changelists. Choose the target changelist from the drop-down list.
New Changelist	<p>Choose this option to create a new changelist and restore the changes from the shelf in it.</p> <ul style="list-style-type: none"><li>- Name: in this text box, type the name of the changelist to be created.</li><li>- Comment: in this text box, type an optional description of the new changelist.</li><li>- Make this changelist active: select this checkbox to have IntelliJ IDEA automatically give the <b>active</b> status to the new change list immediately after the changes are restored in it. When this checkbox is cleared, the current active changelist remains active. See <a href="#">Changelist</a> for details.</li><li>- Track context: select this checkbox to have IntelliJ IDEA preserve the context of the task associated with the new changelist on its deactivation and restore the context when the changelist becomes active. See <a href="#">Managing tasks and contexts</a> for details.</li></ul>
Remove successfully applied files from the shelf	<ul style="list-style-type: none"><li>- Clear this checkbox to have IntelliJ IDEA still display already unshelved changes in the Shelf tab so that you can apply them once more if necessary.</li><li>- When this checkbox is selected, the changes are not displayed in the Shelf tab after they are unshelved.</li></ul>

Use this dialog box to [shelve](#) the selected files or changelists.

This dialog consists of several areas:

- [Modified files pane](#)
  - [Toolbar](#)
- [Commit Message pane](#)
  - [Toolbar](#)
- [Before Submit / Before Commit section](#)
- [After Submit / After Commit section](#)
- [Diff pane](#)
  - [Toolbar](#)

## Modified files pane

This section contains a list of files that have been modified since the last commit. All files in the list are selected by default. Deselect the files that you do not want to shelve.

## Toolbar

**Icon****Tooltip** **Description**  
and  
**Shortcut**

	<b>Show Differences</b>	Click this button to open the <a href="#">Differences</a> dialog box that highlights the differences between your local working copy of the selected file and its repository version.	All VCSs
	<b>Refresh Changes</b>	Click this button to reload the Changed files tree view so it is up-to-date.	All VCSs
	<b>Move to Another Changelist</b>	Click this button to add the selected file(s) to another changelist. The Move to Another Changelist dialog box opens where you can select an existing changelist or create a new one.	All VCSs
	<b>Revert</b>	Click this button to revert all changes made to the local working copy of the selected files.	All VCSs
	<b>Jump to source</b>	Click this button to open the source code of the selected file in the editor.	All VCSs
	<b>Group by Directory</b>	Click this button to toggle between the flat view and the directory tree view.	All VCSs
	<b>Expand or collapse all nodes</b>	Click these buttons to expand or collapse all nodes in the directory tree. These buttons are not available in flat view.	All VCSs
	<b>Revert Unchanged Files</b>	Click this button to have unchanged files Perforce reverted.	Perforce

The summary under the modified files pane shows statistics on the currently selected changelist, such as the number of modified, new and deleted files. This area also shows how many files of each type are shown, and how many of them will be shelved.

## Commit Message pane

In this area, enter a string that will be used as the shelf name. When you unshelve your changes, a new changelist with the same name will be created in the [Local Changes tab](#) . If you leave this field empty, the shelf name will be generated using the following pattern: <number of files in the shelf>, <date and time when the shelf was created>:

## Toolbar

**Icon and** **Shortcut****Description**  
**Tooltip**

## Before Submit / Before Commit section

Use the controls in this area to define which additional actions you want IntelliJ IDEA to perform before putting the selected files to a shelf.

These controls are available for the following version control systems:

- Git
- CVS
- Subversion
- Perforce

### ItemDescription

Reformat code	Select this checkbox to perform code formatting according to the <a href="#">Project Code Style settings</a> .
Rearrange code	Select this checkbox to rearrange your code according to the <a href="#">arrangement rules preferences</a> .
Optimize imports	Select this checkbox to <a href="#">remove redundant import statements</a> .
Perform code analysis	Select this checkbox to run code inspection on the files you are about to commit.
Check TODO (<filter name>)	Select this checkbox to review the <a href="#">TODO items</a> matching the specified filter. Click the Configure link to choose an <a href="#">existing TODO filter</a> , or open the <a href="#">TODO settings page</a> and define a new filter to be applied.
Cleanup	Select this checkbox if you want to automatically apply the current inspection profile to the files you are going to commit.
Update copyright	Select this checkbox to <a href="#">add or update a copyright notice</a> according to the selected copyright profile - scope combination.
Revert unchanged files	Select this checkbox to revert the files that have not been modified. This option is only available for Perforce.

## After Submit / After Commit section

Use the controls in this area to define which additional actions you want IntelliJ IDEA to perform after putting the selected files to a shelf.

### ItemDescription

Upload files to	From this drop-down list, select the <a href="#">server access configuration</a> to use for uploading the selected files to a local or remote host, a mounted disk, or a directory. To suppress uploading, choose None . To add a server configuration to the list, click  and fill in the required fields in the Add Server dialog that opens.
Always use selected server	Select this checkbox to always upload files to the selected server access configuration. The drop-down list and the checkbox are only available if the Remote Hosts Access plugin is enabled.

## Diff pane

The Diff pane is hidden by default. To unfold it, click the arrow button  next to the pane title.

In this pane you can explore the differences between the base repository version of the selected file, and the version you are about to shelve.

## Toolbar

### ItemTooltip Description and Shortcut

	<p>Previous Difference / Next Difference</p> <p>Shift+F7</p> <p>F7</p>	<p>Use these buttons to jump to the next/previous difference.</p> <p>When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons  /  once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a> .</p> <p>This behavior is supported only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.</p>
	<p>Compare Previous/Next File</p> <p>Alt+Left</p> <p>Alt+Right</p>	<p>Click these buttons to compare the local copy of the previous/next file with its update from the server.</p> <p><b>Tip</b> These buttons are only available when there is more than one file in the selected changelist.</p>
	<p>Jump to Source</p> <p>F4</p>	<p>Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer .</p>

## Viewer type

Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only.

Both types of viewers enable you to

- Edit code. Note that one can change text **only** in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.
- Perform the Apply/Append/Revert actions.

## Whitespace

Use this drop-down list to define how the differences viewer should treat white spaces in the text.

- Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.
  - Trim whitespaces : (" \t", " ") , if they appear in the end and in the beginning of a line.
    - If two lines differ in trailing whitespaces only, these lines are considered equal.
    - If two lines are different, such trailing whitespaces are not highlighted in the **By word** mode.
  - Ignore whitespaces : white spaces are not important, regardless of their location in the source code.
  - Ignore whitespaces and empty lines : the following entities are ignored:
    - all whitespaces (as in the 'ignore whitespaces' option)
    - all added or removed lines consisting of whitespaces only
    - all changes consisting of splitting or joining lines without changes to non-whitespace parts.
- For example, changing `a b c` to `a \n b c` is not highlighted in this mode.
- Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).

## Highlighting mode

Select the way differences granularity is highlighted.

The available options are:

- Highlight words : the modified words are highlighted
  - Highlight lines : the modified lines are highlighted
  - Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.
- For example, `A \n B` vs. `A X \n B X` will be treated as two changes instead of one.
- Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.

	Collapse unchanged fragments	Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the Diff & Merge settings page.
	Synchronize scrolling	Click this button to scroll both differences panes simultaneously. If this button is released, each pane can be scrolled independently.
	Disable editing	Click this button to enable editing of the local copy of the selected file, which is disabled by default. When editing is enabled, you can make last-minute changes to the modified file before committing it.
	Editor settings	Click this button to open a drop-down list of available options. Select or clear these options to show or hide line numbers, indentation guides, white spaces, and soft wraps.
	Show diff in external tool	Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> settings page. This button only appears on the toolbar when the Use external diff tool option is enabled in the <a href="#">External Diff Tools</a> settings page.
	Help	Click this button to show the corresponding help page.

F1

Note that the options listed above are available for text files only. IntelliJ IDEA cannot compare binary files, so most commands will be unavailable for them.

Use this dialog to explore changes to a file, or selection. There are two views in this dialog:

- [History view](#) in the left-hand part
- [Differences view](#) in the right-hand part

**Tip** The same dialog boxes are available on the context menu of a file or selected text in the editor.

## History view

This view shows the list of revisions (states) of a file, with the date and time when the revision was stored. Some of the revisions are supplied with tags and labels.

Revisions are tagged automatically, for example, on opening a project, committing changes, or performing test. You can also [set your own labels](#) .

### ItemDescription

	Click this button to revert the selected action.
	Click this button to create a patch based on the selected local version.
	Click this button to open the corresponding help topic.

**Tip** The same actions are available on the context menu of each revision.

## Differences view

The Differences view is a powerful editor that supports [basic search and replace](#) , [undo/redo actions](#) , and [code completion](#) .

If a revision is selected in the [History view](#) , the left-hand pane of the Differences view shows this read-only revision, with the differences against the current revision which is displayed in the right-hand pane. The current revision can be edited.

### Item ShortcutDescription

		Click this button to copy the current line or the selected fragment to the clipboard.
	 	Click this button to initiate the <a href="#">finding and replacing text procedure</a> in the pane where the caret currently resides. Refer to the <a href="#">search options description</a> for details.
		Use these buttons to move to the next or previous difference.
Ignore whitespace		Use this drop-down list to define how the differences viewer should treat white spaces in the text. <ul style="list-style-type: none"> <li>- Do not ignore - when this option is selected, white spaces are considered unimportant and the differences are highlighted.</li> <li>- Leading and Trailing - select this option to have differences in the end and in the beginning of a line ignored.</li> <li>- All - when this option is selected, white spaces are considered unimportant regardless of their location in the source code.</li> </ul>
		Use these buttons to apply differences.
Legend		This area shows summary information about the encountered differences: the number of differences found and the color map. The color map for the Differences viewer is configured on the <a href="#">Colors and Fonts page</a> .

Use this dialog to explore changes to a folder. There are two views in this dialog:

- [History view](#) in the left-hand part
- [Changes view](#) in the right-hand part

**Tip** The same dialog box is available on the context menu of a folder.

## History view

The History view shows a list of folder revisions (states), each one being supplied with a time stamp, revision number, and an indication of the action that resulted in that state.

### ItemDescription

	Click this button to revert the selected action.
	Click this button to create a patch based on the selected local version.
	Click this button to open the corresponding help topic.

## Changes view

The Changes view shows the differences between the current state and the one selected in the [History view](#). The differences are shown as a tree of changed (new, modified and deleted) files and subfolders.

### ItemShortcutDescription

	<b>Ctrl+D</b>	Click this button to show the <a href="#">differences</a> between the current local version and the one selected in the History view. Alternatively, double-click the current local version in the Changes view.
		With a file selected in the Changes view, click this button to roll back the selected action.
	<b>Ctrl+P</b>	Click this button to show changed files as a tree view of folders. If this button is not pressed, the files are shown as a flat list.
	<b>Ctrl+NumPad Plus</b> or <b>Ctrl+NumPad -</b>	Click these buttons to have all nodes expanded or collapsed. These buttons are only available when the changed files are shown as a tree view.
	<b>Ctrl+A</b>	Click this button to select all the files in the list or a tree view.
	<b>Ctrl+F</b>	In this area, type the search string. Note also that <a href="#">speed search</a> is available in the Changes pane.
		Click this button to clear the search area.

**Tip** [Speed search](#) is available in the Version Control view.

Use this dialog box to restore shelved changes from a shelf to a changelist.

**ItemDescription**

---

Existing Changelist	Choose this option restore the shelved changes in one of the existing changelists. Choose the target changelist from the drop-down list.
New Changelist	Choose this option to create a new changelist and restore the changes from the shelf in it. <ul style="list-style-type: none"><li>- Name: in this text box, type the name of the changelist to be created.</li><li>- Comment: in this text box, type an optional description of the new changelist.</li><li>- Make this changelist active: select this checkbox to have IntelliJ IDEA automatically give the active status to the new change list immediately after the changes are restored in it. When this checkbox is cleared, the current active changelist remains active. See <a href="#">Changelist</a> for details.</li><li>- Track context: select this checkbox to have IntelliJ IDEA preserve the context of the task associated with the new changelist on its deactivation and restore the context when the changelist becomes active. See <a href="#">Managing tasks and contexts</a> for details.</li></ul>
Remove successfully applied files from the shelf	<ul style="list-style-type: none"><li>- Clear this checkbox to have IntelliJ IDEA still display already unshelved changes in the Shelf tab so that you can apply them once more if necessary.</li><li>- When this checkbox is selected, the changes are not displayed in the Shelf tab after they are unshelved.</li></ul>

- [XML-Java Binding Reference](#)

Use this dialog box to bring the beans created according to the EJB 1.x or EJB 2.0 specifications into compliance with the EJB 3.0 specification.

#### ItemDescription

EnterpriseBeans to apply EJB 3.0 style to	This table shows the list of Objects encountered in the selected module with EJB facet. Use the checkboxes in the left column of the table to include or exclude beans from refactoring. If a certain bean has a home interface, use the checkbox in the Retain Home interfaces column to convert home interfaces, rather than delete them.
Environment Access	Select the preferred mode of environment access: <ul style="list-style-type: none"><li>– Prefer resource injection : click this radio-button to force convert all environment access to resource injection.</li><li>– Prefer lookup : click this radio-button to force convert all environment access to context lookup.</li><li>– Leave as is if possible : click this radio-button to leave environment access as is in case it does not interfere with the converted code. If not, IntelliJ IDEA automatically selects the most appropriate method.</li></ul>
Replace JNDI lookup with EJB context lookup	If this checkbox is selected, the system resources will be retrieved using the <code>EJBContext.lookup()</code> . Otherwise, JNDI environment lookup will be used.
Inline injected fields	If this checkbox is selected, all usages of a context lookup will be replaced with a reference to an an injected field.
Copy metadata from XML descriptor	Select this checkbox to copy meta information to the <code>ejb-jar.xml</code> file.
Delete copied XML tags	Clear this checkbox to preserve duplicates.
Replace Entity beans with CMP to Persistence Unit	Select this checkbox, if you want to try to convert outdated entity beans to Container Managed Persistence. <b>Warning!</b> Select this option with extreme care because it can render your project incompatible.
Refactor	Click this button to perform refactoring, and close the dialog box.
Preview	Click this button to open tentative refactoring results in the dedicated tab of the <a href="#">Find Tool Window</a> , and close the dialog box.

Use the dialog box to [change properties](#) of existing beans.

**Tip** The contents of the dialog box are bean type-specific. See comments in the Available in column.

Item	Description	Available in
<ejb-name>	This read-only field shows the basic name used for generating the names of the EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> dialog box.	All bean types
Package	In this text box, specify the fully qualified path to the package where the bean resides or click the Browse button  and select the desired package in the module tree.	All bean types
EJB Class	This read-only field shows the name of the bean implementation class.	All bean types
Message Listener	In this text box, specify the message listener interface. Type a fully qualified name or click the Browse button  and select the message listener interface from the list of available interfaces.	Message beans
Primary key class	In this text box, specify the class that will be used to access the primary key of the <a href="#">data source</a> the entity bean is associated with.	Entity beans
CMP version	This read-only field shows the used CMP version.	Entity beans
	For BMP Entity beans, the field is read-only.	
Remote Interface	Select this checkbox if you want to configure a remote client view of the bean. <b>Tip</b> Selecting this checkbox enables the Home and Remote text boxes.	Entity beans
Home	In this text box, specify the implementation class for a remote home interface . If necessary, click the Browse button  to open the Choose EJB Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.	Entity beans
Remote	In this text box, specify the implementation class for a remote interface . If necessary, click the Browse button  to open the Choose EJB Remote Interface dialog box, where you can search for the desired interface by name or select it in the project tree.	Entity beans
Local Interface	Select this checkbox if you want to configure a local client view of the bean. <b>Tip</b> Selecting this checkbox enables the Local Home and Local text boxes.	Entity beans
Local Home	In this text box, specify the implementation class for a local home interface . If necessary, click the Browse button  to open the Choose EJB Local Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.	Entity beans
Local	In this text box, specify the implementation class for a local interface . If necessary, click the Browse button  to open the Choose EJB Local Interface dialog box, where you can search for the desired interface by name or select it in the project tree.	Entity beans

The dialog opens when you select a servlet in the Servlets Configured pane and click Change Class in the Servlet Initialization Params that opens.

Use this dialog to select the class that implements the selected servlet.

The dialog contains two tabs:

- [Search by Name](#)
- [Project](#)

## Search by Name Tab

Use the tab to search a relevant class to implement the servlet. Specify the class name or part of the name.

### ItemDescription

---

Search pattern area	The text field for typing a part of the name of the relevant class.
Search results area	Shows a list of classes that meet the search pattern. The contents of the area change dynamically as you type.
Include non-project classes	Involves classes outside the current project into the search.

## Project Tab

Use this tab to select the relevant class in the project tree.

This dialog box opens when you click the Add button  in the Entity Bean Specifics section.

Use the dialog box to create a CMP field for the current entity bean.

#### ItemDescription

Name	In this text box, specify the name of the CMP field.
Description	In this text box, provide a description of the CMP field.
	Click this button to open the Description dialog box and type s description of the CMP field there.
Type	From this drop-down list, select the required type for the CMP field. <b>Note</b> Actually, you select the class that implements the type.
	Click this button to open the Choose Class dialog box, where you can select a class that is not available in the Type drop-down list.
Primary Key	Select this checkbox to set the current CMP field as a primary key.
Generate getter in	Select the relevant checkbox to specify where the <code>getter</code> method of the entity bean will be generated. The available options are: <ul style="list-style-type: none"><li>- Local Interface</li><li>- Remote Interface</li></ul> <b>Note</b> If the bean does not have a local or remote interface, the corresponding checkbox is disabled and the remaining option is selected.
Generate setter in	Select the relevant checkbox to specify where the <code>setter</code> method of the entity bean will be generated. The available options are: <ul style="list-style-type: none"><li>- Local Interface</li><li>- Remote Interface</li></ul> <b>Note</b> If the bean does not have a local or remote interface, the corresponding checkbox is disabled and the remaining option is selected.

This dialog opens when you draw or double-click a link between entities on an entity-relationship diagram for a persistence unit or a session factory.

---

Specify the settings for the relationship.

The left-hand and the right-hand parts are for the two sides of the relationship. For a unidirectional relationship, specify the settings only in one of the parts.

**ItemDescription**

---

Attribute	The name of the field to be added to the corresponding entity and also the name of the relationship.
Multiplicity	The multiplicity on the corresponding side of the relationship.
Optional	Whether the relationship is optional.
Owner	The owner of the relationship.
Fetch Type	See <a href="#">FetchType</a> .
Cascade Type	See <a href="#">CascadeType</a> .

Ctrl+Alt+S , 1

The dialog opens when you click + (Alt+Insert) or (Enter) on the [File Sets tab](#) of the [Struts 2 Facet page](#).

Use this dialog to [configure a validation file set](#) by selecting the relevant files in the module tree.

---

**ItemDescription**

**File Set name** Use this field to edit the file set name.

**Locate** Use this button to add the files that are external to your module. (The [Select Path dialog](#) will open.)

The bean editor is accessible from the [EJB](#) tool window only. The editor consists of two tabs: General tab and Assembly Descriptor tab.

The General tab consists of a common part, and a bean specific part. The Assembly Descriptor tab is similar for all bean types.

In this part:

- [EJB Editor - General Tab - Entity Bean](#)
- [EJB Editor - General Tab - Message Bean](#)
- [EJB Editor - General Tab - Session Bean](#)
- [EJB Editor - Assembly Descriptor](#)
- [Assembly Descriptor Dialogs](#)
- [EJB Editor General Tab - Common](#)

This section describes the fields that are specific for the entity beans.

#### ItemShortcutDescription

---

Abstract Schema Name		In this text box, specify the bean reference name that can be used to call the bean from QL queries. This field is available for the CMP Entity Beans only.
Primary Key Class		In this field, specify the class that will be used to access primary key of a datasource the bean is associated with. This field is available for the CMP and BMP Entity Beans .
Reentrant		Select this checkbox if you need the bean to handle multiple simultaneous, interleaved, or nested invocations that do not interfere with each other. This field is available for the CMP and BMP Entity Beans .
CMP fields		These fields are available for CMP Entity Beans only.
		Click this button to <a href="#">create a new CMP field</a> .
		Click this button to <a href="#">change CMP field</a> .
		Click this button to delete selected field with its accessor methods and tags in the deployment descriptor.
		Click this button to show reference page.

This section describes the fields that are specific for Message beans .

**Item**    **Shortcut****Description**

---

Transaction Type	In this field, specify the object by which the transactions should be managed. The available options are: <ul style="list-style-type: none"><li>- Bean</li><li>- Bean container</li></ul>
------------------	---

---

Destination Type	In this field, specify the message queue class to which the bean should listen.
------------------	---

---

Activation Config	Use this section to define the bean behavior.
-------------------	---

---

	 Click this button to add activation configuration elements.
---	---

---

	 Click this button to delete selected activation configuration element.
---	--

---

	 Click this button to show reference page.
---	---

This section describes the fields that are specific for Session beans .

**ItemDescription**

---

Session Type	Select session type (stateful or stateless) depending on the conversational state the bean should have.
Transaction Type	Specify an object the transactions should be managed with. The possible options are a bean and its container.

Use this tab to define how the beans are deployed and configured at the target application server.

#### ItemShortcutDescription

		Click this button to create an element of the deployment descriptor.
		Click this button to change the selected element.
		Click this button to delete the selected element.

#### Configuration Parameters setting

EJB Environment Entry	<ul style="list-style-type: none"><li>- Name</li><li>- Value</li><li>- Type</li><li>- Description</li></ul>
EJB Local Reference	<ul style="list-style-type: none"><li>- Name</li><li>- EJB Home interface</li><li>- Link</li><li>- Type</li><li>- Remote interface</li><li>- Description</li></ul>
EJB Reference	<ul style="list-style-type: none"><li>- Name</li><li>- EJB Home interface</li><li>- Link</li><li>- Type</li><li>- Remote interface</li><li>- Description</li></ul>
Web Service Reference	<ul style="list-style-type: none"><li>- Name</li><li>- Type</li><li>- Service interface</li><li>- JAX-RPC mapping file</li><li>- WSDL name</li><li>- Service QName</li><li>- Description</li></ul>
EJB Resource Reference	<ul style="list-style-type: none"><li>- Name</li><li>- Type</li><li>- Aunentication</li><li>- Shareable</li><li>- Description</li></ul>
EJB Resource Environment Reference	<ul style="list-style-type: none"><li>- Name</li><li>- Type</li><li>- Description</li></ul>
Message Destination Reference	<ul style="list-style-type: none"><li>- Name</li><li>- Type</li><li>- Message destination usage</li><li>- Message destination line</li><li>- Description</li></ul>

The dialog boxes that open are specific for the various types of assembly descriptors.

The fields in the General section are available for all bean types.

#### ItemDescription

---

**Display name** Use this field to change the display name of a bean.

---

**Description** Use this field to type optional textual description of a bean.

---

**EJB Classes** These fields are available for all bean types.

---

**Change EJB Classes** Click this button to open the bean-specific [Change Bean dialog](#) , where you can define the classes that comprise a bean: bean class, local and remote interfaces, and primary key class.

---

**Rename EJB and Classes** Click this button to change the name of the bean and propagate this change to all the constituent classes of the bean. This renaming is performed as the [Rename Refactoring](#) .

An EJB ER diagram opens on a separate editor tab when you select ER Diagram in the context menu for a module in the [EJB tool window](#) .

Use this diagram to view entity beans defined in your module, and also to create and change relationships between them.

– [Toolbar](#)

– [Context menu](#)

## Toolbar

### ItemDescription

	Click this button to show grid in the diagram background.
	Click this button to align elements against the grid.
	Click this button to increase the scale of the diagram.
	Click this button to decrease the scale of the diagram.
	Click this button to restore the actual size of the diagram.
	Click this button to change the scale to make the contents fit into the current diagram size.
	Click this button to apply the current layout, selected on the context menu of the diagram.
	Click this button to save the diagram in an image file with the specified name and path. The possible formats are: <code>jpeg</code> , <code>png</code> and <code>gif</code> .
	Click this button to print the diagram.
	Click this button to open the diagram preview in a separate frame, where you can configure the page layout, scale, and headings information.

## Context menu

### ItemDescription

New	Use this node to add new EJBs to a module with the EJB facet and configure relationships between CMP Entity Beans.
Layout	Choose this command to select the desired layout from the list.
Show edge labels	Choose this command to show multiplicities of the relationship links in diagram.

The EJB Relationship Properties dialog opens when you draw a line between entity beans on an [EJB ER diagram](#). (In this way you create a relationship between the corresponding beans.)

Use this dialog to define the relationship properties, and also to add the corresponding elements to the deployment descriptor.

#### ItemDescription

Relationship Name	Type the name of a new relationship link.
Description	Type optional description. If the text is long, click the ellipsis button, and type the desired text in the editor dialog box.
Role 1,2	Use these sections of the dialog box to specify attributes of each side of a relationship link.
EJB	Select the source and target EJBs from the drop-down lists.
Role name	Type the names of the roles for each side of the relationship link.
Multiplicity	Select multiplicity from the drop-down list.
CMR Field	Select this checkbox, if you want to create a container-managed relation field <code>&lt;cmr-field &gt;</code> in the deployment descriptor. If this option is checked, specify following attributes.
Field name	Type the name of the new CMR field. The <code>&lt;cmr-field-name&gt;</code> element is generated in the deployment descriptor.
Field type	Select the type of the new CMR field. The <code>&lt;cmr-field-type&gt;</code> element is generated in the deployment descriptor.
Getter / Setter	If the checkboxes are selected, the getter and setter methods are generated in the bean implementation class.

Use the tabs in this editor to configure the [beans contained in a module](#) with an EJB facet, [method permissions](#) , and [transaction attributes](#) .

If the EJB module editor is invoked from the deployment descriptor, the [text editor](#) tab is also available.

Use this tab to configure the beans contained in a module with EJB facet.

**ItemDescription**

---

New	Click this button to add a new bean to a module with EJB facet. The bean type is selected from the submenu. Refer to the section <a href="#">Creating EJB</a> for the detailed description of procedure.
Remove	Click this button to delete the selected bean from the module.
Edit	Click this button to invoke the <a href="#">EJB editor</a> for the selected bean. Refer to the section <a href="#">Editing EJB</a> for the detailed description of procedure.
Help	Click this button to show reference page.

Use this tab to configure security roles and method permissions for a bean.

## Toolbar

### ItemShortcutDescription

		Click this button to define a custom security role by specifying the security role name and optional description in the Add Security Role dialog box. A column for a new security role is added to the table.
		Click this button to change the selected security role by choosing the desired role from the submenu, and changing the security role name and optional description in the Edit Security Role dialog box.
		Click this button to delete the selected security role.

## Table

### ItemDescription

Name	This column shows beans, their interfaces, and a list of methods that they implement.
Excluded	Select the checkboxes in this column for the methods, which you want to add to the list of excluded methods. The selected methods will be added to the <code>&lt;exclude-list &gt;</code> section of the deployment descriptor.
Unchecked	Select the checkboxes in this column for the methods with unchecked permissions. The selected methods will be marked as <code>&lt;unchecked/&gt;</code> in the deployment descriptor.
<code>&lt;security role &gt;</code>	Select the checkboxes for the methods to assign the selected security roles.

Use this tab to manage the transaction attributes that are used by the EJB container to control the transaction scope when the enterprise bean methods are invoked.

**ItemDescription**

---

<b>Name</b>	This column shows beans, their interfaces and the list of methods that they implement.
<b>Transaction Attribute</b>	This column displays the transaction attribute for a method, interface or bean. The possible values are: <ul style="list-style-type: none"><li>- Mandatory</li><li>- Never</li><li>- NotSupported</li><li>- Required</li><li>- RequiresNew</li><li>- Supports</li></ul>

Use this dialog box to view the compilation output of a GWT module.

**Item****Description**

---

GWT Module From this drop-down list, select the module to view the output of.

---

Generate Click this button to have a new report generated.

---

View Report Click this button to have the previous generated report opened in the browser.

 IntelliJ IDEA informs you how long ago a report was generated last.

From the [Persistence tool window](#) : Right-click a module, persistence unit or session factory, point to Generate Persistence Mapping and select the necessary option.

Specify the settings for generating entity classes and object/relational mappings for them. Depending on the option that you selected, one of the following is used as a source:

- A database schema represented by a [data source](#) .
- An EJB facet, if exists in the current project, or, to be more exact, the deployment descriptor file ejb-jar.xml associated with that facet. (Only the <entity> elements are processed.)
- Only for JPA: a Hibernate object/relational mapping file (.hbm.xml). The file should be within the current project.

- [General Settings](#)
- [Database Schema Mapping](#)
- [Generation Settings](#)

## General Settings

### ItemDescription

Choose Data Source	When importing a database schema: Specify the <a href="#">data source</a> to be used as a source of import.  opens the <a href="#">Data Sources and Drivers dialog</a> which lets you create a new data source.
Choose EJB Facet	When importing an EJB facet: Specify the EJB facet to be used as a source.  opens the dialog which lets you select the facet. (The EJB facets available in the current project are suggested.)
Choose Hibernate XML	When importing a Hibernate object/relational mapping file: Specify the <code>.hbm.xml</code> file to be used as a source.  opens the dialog which lets you select the file. (The corresponding file must be available in the current project.)
Package	The destination package for your entity classes.  opens the dialog which lets you select an existing package, or create a new one (  ).
Entity prefix	One or more characters to be used as a prefix for your entity class names.
Entity suffix	One or more characters to be used as a suffix for your entity class names.
Prefer primitive types	When importing a database schema: Prefer primitive field types to object types (e.g. when <code>int</code> and <code>java.lang.Integer</code> are the alternatives).
Show default relationships	When importing a database schema: If this checkbox is selected, IntelliJ IDEA analyzes the foreign keys in the tables and suggests to create corresponding relationships (e.g. one-to-one, one-to-many).

## Database Schema Mapping

This section is available only when importing a database schema.

Select the tables and columns to be mapped. Edit the names of the entity classes and their persistent fields (the Map As column). Adjust the field types (the Mapped Type column). Use the toolbar for working with relationships and performing other tasks.

### ItemDescription

	Create a new relationship between the entities. (The <a href="#">Add Relationship dialog</a> will open.)
	Edit the selected relationship. (The <a href="#">Edit Relationship dialog</a> will open.)
	Delete the selected relationship.
	Refresh the database schema.
	Select all the tables, fields and relationships.
	Deselect all the tables, fields and relationships.
	Expand all the nodes in the table.
	Collapse all the nodes in the table.

## Generation Settings

### ItemDescription

Add to Persistence Unit / Add to Session Factory	The persistence unit or session factory with which the generated entity classes will be associated. If the Generate Persistence Mapping command was called on a persistence unit or session factory, the info about the entity classes will be added to the current persistence unit or session factory (hibernate.cfg.xml). If the command was called on a module, you can select a target persistence unit or session factory. This may be an existing persistence unit or session factory (hibernate.cfg.xml), or a new one. To create a new persistence unit or session factory, click  . In the case of the persistence unit, just specify its name (a new <code>&lt;persistence-unit name="" /&gt;</code> element will be added to <code>persistence.xml</code> .) In the case of the session factory, a new Hibernate configuration file will be created. So, in the dialog that opens, select the destination folder, click  and specify the file name. <code>.xml</code> in the file name may be omitted.
Generate Column Properties	Select the checkbox for the column properties (e.g. <code>length</code> , <code>nullable</code> ) to be included.

Generate Single Mapping XML Store object/relational mappings for all the generated entity classes in one XML file.  
To define the target file:

1. Click  .
2. If suggested, select the target file format (Hibernate mapping or JPA mapping descriptor (JPA ORM)).
3. In the dialog that opens, select an existing mapping file or create a new one.  
To create a new file, select the destination directory, click  and specify the file name. `.xml` in the file name may be omitted.

---

Generate Separate XML per Entity Create an individual object/relational mapping file for all the generated entity classes. The file names will be `<ClassName>.xml` for JPA and `<ClassName>.hbm.xml` for Hibernate.

---

Generate JPA Annotations (Java 5) Add the mapping information to the source code of the generated entity classes as annotations.

From the [Import Database Schema dialog](#) :  or  in the Database Schema Mapping section.

---

Use this dialog to specify the settings for a relationship.

**ItemDescription**

---

Source / Target	Within the relationship, one of the entities (the left-hand one) is referred to as a source and the other one as a target.
Table	The corresponding database table.
Attribute name	The name of the field to be added to the corresponding entity and also the name of the relationship.
Type	The Java type for the corresponding field.
Map Key Column	Select the desired column name from the drop-down list.
Join Table	The join table if used.
Join Columns	Joined table columns for the relationship. Use  and  to manage the list.

EJB Tool Window | context menu of a module with an EJB facet | New - bean type

EJB Tool Window | context menu of a module with an EJB facet | Jump to Source | New - bean type

---

Use these dialog boxes to [create EJBs](#) of various types.

The contents of the dialog boxes are bean type-specific.

In this section:

- [New Session Bean Dialog](#)
- [New Message Bean Dialog](#)
- [New BMP Entity Bean Dialog](#)
- [New CMP Entity Bean Dialog](#)

Use this dialog box to [create Session Beans](#) .

**ItemDescription**

---

<ejb-name>	In this text box, type the basic name to be used for generating the names of the EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> dialog box.
Package	In this text box, specify the fully qualified path to the package where the bean resides. If necessary, click the Browse button  and select the desired package in the project tree.
EJB Class	In this text box, specify the name of the bean implementation class. If necessary, click the Browse button  to open the Choose EJB Class dialog box, where you can search for the desired class by name or select it in the project tree.

Use this dialog box to [create Message Beans](#) .

---

**ItemDescription**

---

<ejb-name>	In this text box, type the basic name to be used for generating the names of the EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> dialog box.
Package	In this text box, specify a fully qualified path to the package where the bean resides. If necessary, click the Browse button  and select the desired package in the project tree.
EJB Class	In this text box, specify the name of the bean implementation class. If necessary, click the Browse button  to open the Choose EJB Class dialog box, where you can search for the desired class by name or select it in the project tree.
Message Listener	In this text box, specify the message listener interface. Type a fully qualified name or click the Browse button  to open the Choose EJB Message Listener Interface dialog box, where you can search for the desired message listener interface by name or select it in the project tree.

Use this dialog box to [create Bean Managed Persistence \(BMP\) Entity Beans](#) .

**ItemDescription**

<ejb-name>	In this text box, type the basic name to be used for generating the names of the EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> dialog box.
Package	In this text box, specify a fully qualified path to the package where the bean resides. If necessary, click the Browse button  and select the desired package in the project tree.
EJB Class	In this text box, specify the name of the bean implementation class. If necessary, click the Browse button  to open the Choose EJB Class dialog box, where you can search for the desired class by name or select it in the project tree.
Primary Key Class	In this text box, specify the class to be used for accessing the primary key of the <a href="#">data source</a> the entity bean is associated with. If necessary, click the Browse button  to open the Choose EJB Primary Key Class dialog box, where you can search for the desired class by name or select it in the project tree.
CMP version	This read-only field shows the Container Managed Persistence (CMP) version used.
Remote Interface	Select this checkbox if you want to configure a remote client view of the bean. 
Home	In this text box, specify the implementation class for a remote home interface . If necessary, click the Browse button  to open the Choose EJB Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Remote	In this text box, specify the implementation class for a remote interface . If necessary, click the Browse button  to open the Choose EJB Remote Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Local Interface	Select this checkbox if you want to configure a local client view of the bean. 
Local Home	In this text box, specify the implementation class for a local home interface . If necessary, click the Browse button  to open the Choose EJB Local Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Local	In this text box, specify the implementation class for a local interface . If necessary, click the Browse button  to open the Choose EJB Local Interface dialog box, where you can search for the desired interface by name or select it in the project tree.

Use this dialog box to [create Container Managed Persistence \(CMP\) Entity Beans](#) .

#### ItemDescription

<ejb-name>	In this text box, type the basic name to be used for generating the names of the EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> dialog box.
Package	In this text box, specify a fully qualified path to the package where the bean resides. If necessary, click the Browse button  and select the desired package in the project tree.
EJB Class	In this text box, specify the name of the bean implementation class. If necessary, click the Browse button  to open the Choose EJB Class dialog box, where you can search for the desired class by name or select it in the project tree.
Primary Key Class	In this text box, specify the class to be used for accessing the primary key of the <a href="#">data source</a> the entity bean is associated with. If necessary, click the Browse button  to open the Choose EJB Primary Key Class dialog box, where you can search for the desired class by name or select it in the project tree.
CMP version	From this drop-down list, select the Container Managed Persistence (CMP) version to be used.
Remote Interface	<p>Select this checkbox if you want to configure a remote client view of the bean.</p> <p> Selecting this checkbox enables the Home and Remote text boxes.</p>
Home	In this text box, specify the implementation class for a remote home interface . If necessary, click the Browse button  to open the Choose EJB Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Remote	In this text box, specify the implementation class for a remote interface . If necessary, click the Browse button  to open the Choose EJB Remote Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Local Interface	<p>Select this checkbox if you want to configure a local client view of the bean.</p> <p> Selecting this checkbox enables the Local Home and Local text boxes.</p>
Local Home	In this text box, specify the implementation class for a local home interface . If necessary, click the Browse button  to open the Choose EJB Local Home Interface dialog box, where you can search for the desired interface by name or select it in the project tree.
Local	In this text box, specify the implementation class for a local interface . If necessary, click the Browse button  to open the Choose EJB Local Interface dialog box, where you can search for the desired interface by name or select it in the project tree.

---

Specify the settings for the new servlet.

**ItemDescription**

---

Name	<p>The "root part" of the servlet name.</p> <p>This name (along with its prefix and suffix) will be used either in the <code>&lt;servlet-name&gt;</code> element in <code>web.xml</code> or in the servlet class <code>@WebServlet</code> annotation.</p> <p>You can specify the servlet name prefix and suffix (the <code>&lt;servlet-name&gt;</code> tag Prefix and Suffix fields on the <a href="#">Java EE Names tab</a> of the Editor   Code Style   Java page in the Settings dialog). In that case, the prefix and the suffix are added before and after the specified name automatically.</p>
Package	<p>The name of the package in which the new servlet class should be created.</p> <p>Click . Then select an existing package or click  to create a new package.</p>
Class	<p>The fully qualified name of the servlet class.</p> <p>The default class name is generated using the package name, the class name prefix, the servlet name, and the class name suffix.</p> <p>The class name prefix and suffix are set in the Settings dialog. (The Servlet Class Prefix and Suffix fields on the <a href="#">Java EE Names tab</a> of the Editor   Code Style   Java page.)</p> <p>If you want to specify an existing class, click  and select the class in the dialog that opens.</p>
Create Java EE 6 annotated class	<p>If the checkbox is not selected, the servlet name - class mapping is added to <code>web.xml</code>.</p> <p>If the checkbox is selected, the new servlet class will be <code>@WebServlet</code> -annotated and no changes will be made to <code>web.xml</code>.</p> <p>If there is no <code>web.xml</code> in your project, the checkbox is selected by default, and you cannot deselect it.</p>

This dialog opens when you click  next to the Package field in the [New Servlet dialog](#) .

Select an existing package or click  to create a new package. The new servlet class will be created in the specified package.

---

Specify the settings for the new filter.

**ItemDescription**

---

Name	<p>The "root part" of the filter name.</p> <p>This name (along with its prefix and suffix) will be used either in the <code>&lt;filter-name&gt;</code> element in <code>web.xml</code> or in the filter class <code>@WebFilter</code> annotation.</p> <p>You can specify the filter name prefix and suffix (the <code>&lt;filter-name&gt;</code> tag Prefix and Suffix fields on the <a href="#">Java EE Names tab</a> of the Editor   Code Style   Java page in the Settings dialog). In that case, the prefix and the suffix are added before and after the specified name automatically.</p>
Package	<p>The name of the package in which the new filter class should be created.</p> <p>Click . Then select an existing package or click  to create a new package.</p>
Class	<p>The fully qualified name of the filter class.</p> <p>The default class name is generated using the package name, the class name prefix, the filter name, and the class name suffix.</p> <p>The class name prefix and suffix are set in the Settings dialog. (The Filter Class Prefix and Suffix fields on the <a href="#">Java EE Names tab</a> of the Editor   Code Style   Java page.)</p> <p>If you want to specify an existing class, click  and select the class in the dialog that opens.</p>
Create Java EE 6 annotated class	<p>If the checkbox is not selected, the filter name - class mapping is added to <code>web.xml</code>.</p> <p>If the checkbox is selected, the new filter class will be <code>@WebFilter</code>-annotated and no changes will be made to <code>web.xml</code>.</p> <p>If there is no <code>web.xml</code> in your project, the checkbox is selected by default, and you cannot deselect it.</p>

---

Specify the settings for the new listener.

**ItemDescription**

---

Name	The listener name. Used only to generate the default listener class name.
Package	The name of the package in which the new listener class should be created. Click <input type="button" value="..."/> . Then select an existing package or click <input type="button" value="New"/> to create a new package.
Class	The fully qualified name of the listener class. The default class name is generated using the package name, the class name prefix, the listener name, and the class name suffix.  The class name prefix and suffix are set in the Settings dialog. (The Listener Class Prefix and Suffix fields on the <a href="#">Java EE Names tab</a> of the Editor   Code Style   Java page.)  If you want to specify an existing class, click <input type="button" value="..."/> and select the class in the dialog that opens.
Create Java EE 6 annotated class	If the checkbox is not selected, a <code>&lt;listener-class&gt;</code> element for the listener class is added to <code>web.xml</code> . If the checkbox is selected, the new listener class will be <code>@WebListener</code> -annotated and no changes will be made to <code>web.xml</code> .  If there is no <code>web.xml</code> in your project, the checkbox is selected by default, and you cannot deselect it.

This dialog box opens when you click Rename EJB and Classes in the EJB Classes section.

Use the dialog box to rename an entity EJB and/or the classes that implement it.

---

**ItemDescription**

<ejb-name>	Type the basic name that will be used to generate the names of the entity EJB constituent classes. The rules for generating EJB names are configured in the <a href="#">Java EE Names</a> settings tab.
Abstract Schema Name	Type the name of the abstract scheme that CMP will use to map to the physical database.
Refactor	Click this button to update the EJB deployment descriptor <code>ejb-jar.xml</code> according to the changes made in the fields above. The Rename Entity Beans Classes dialog box opens where you can specify which of the EJB constituent classes must be renamed.
Preview	Click this button to open the <a href="#">Refactoring Preview</a> window with all the occurrences of the EJB constituent classes.

Use this dialog box to select methods to be included in a transfer object for an entity bean.

**ItemTooltipDescription**

		Use this button to have methods sorted in the ascending or in the descending order.
	Show Classes	If a bean refers to ancestor classes, clicking this button reveals these classes and their members. Otherwise, the button is not available. This functionality depends on the EJB specification.
	Expand All	Click this button to have all nodes expanded.
	Collapse All	Click this button to have all nodes collapsed.
List of members in the entity bean in question		From the list, select the desired methods. Use the  and  keys for multiple selection.
Transfer object class name		In this field, specify a name for a transfer object class that matches a certain pattern. Accept the name suggested by IntelliJ IDEA or change it as required.
Generate getter/setter in <class name> interface		Select these checkboxes to have accessor methods for the selected fields generated. You can accept the suggested names of the accessor methods or change them as required.
Copy JavaDoc		Select this checkbox to have a JavaDoc comment to the generated transfer object included, if any.

In this section:

- [Expose Class As Web Service Dialog](#)
- [Generate WSDL from Java Dialog](#)
- [Generate Java Code from WSDL or WADL Dialog](#)
- [Monitor SOAP Messages Dialog](#)
- [Show Deployed Web Services Dialog](#)

The dialog box is available only through a dedicated intention action. To invoke it, position the cursor at the class name and press **Alt+Enter** or click the yellow bulb icon .

Use the dialog box to configure Web service WSDL generation for an entire class, with all its methods exposed as Web service operations and deployed. The contents of the dialog box depend on the Web service type.

Item	Description	Web Service Type
Service Name	Use this drop-down list to specify the name of the service to be published (e.g. empty text for <code>ROOT</code> context or <code>mycontext</code> for <code>/mycontext</code> ).	Apache Axis
Service Class Name	In this text box, specify the class to expose as a Web service.	All
Service Namespace	In this text box, type the Web service namespace prefix.	Apache Axis
Service Style	Use this drop-down list to specify the style of the WSDL document to be generated. The available options are: - RPC - select this option to have an rpc WSDL generated. This option is selected by default. - Document - select this option to have a Document WSDL generated. - Wrapped - select this option to have a WSDL generated using the wrapped approach. If you select this option, Literal is automatically pre-selected in the Use Items in Bindings drop-down list.	Apache Axis
Use of Items	From this drop-down list, select how the generated WSDL document should be used. The available options are: - Literal - when this option is selected, the representation of the XML for the request is defined by the XML Schema. - Encoded - select this option to have the SOAP encoding specified in the generated WSDL.	Apache Axis
Target Module		All
Status	View the information in this read-only field to track and improve discrepancies.	All

Use the dialog box to configure Web service WSDL generation and select the methods to be exposed as Web service operations and deployed. The contents of the dialog box depend on the Web service type.

Item	Description	Web Service Type
Class to Generate WSDL For	This read-only field shows the name of the class	All
Web Service URL	In this text box, specify the URL address the Web service will be available at.	All
Methods for Operation	<p>In this area, specify which methods of the selected class you want to be deployed as Web service operations.</p> <ul style="list-style-type: none"> <li>– Method to Expose - this column shows a list of all the methods within the selected class.</li> <li>– Add to Deployment - select the checkbox next to the methods you want to be deployed as operations.</li> </ul> <p>If a method cannot be selected, a tooltip explains the reason.</p>	Apache Axis
Web Service Namespace	In this text box, type the Web service namespace prefix	Apache Axis
SOAP Action	<p>From this drop-down list, select the value for the <code>soapAction</code> attribute of the <code>&lt;wsdl:soap:operation /&gt;</code> field. The available options are:</p> <ul style="list-style-type: none"> <li>– Default - when this option is selected, the <code>soapAction</code> is set according to the operation's meta data (usually to "").</li> <li>– Operation - when this option is selected, the <code>soapAction</code> is set to the operation's name.</li> <li>– None - when this option is selected, the <code>soapAction</code> is set to "".</li> </ul>	Apache Axis
Binding Style	<p>Use this drop-down list to specify the style of the WSDL document to be generated. The available options are:</p> <ul style="list-style-type: none"> <li>– RPC - select this option to have an rpc WSDL generated. This option is selected by default.</li> <li>– Document - select this option to have a Document WSDL generated.</li> <li>– Wrapped - select this option to have a WSDL generated using the wrapped approach. If you select this option, Literal is automatically pre-selected in the Use Items in Bindings drop-down list.</li> </ul>	Apache Axis
Use Items in Bindings	<p>From this drop-down list, select how the generated WSDL document should be used. The available options are:</p> <ul style="list-style-type: none"> <li>– Literal - when this option is selected, the representation of the XML for the request is defined by the XML Schema.</li> <li>– Encoded - select this option to have the SOAP encoding specified in the generated WSDL.</li> </ul>	Apache Axis
Type Mapping Version	<p>Use this drop-down list to specify the default <a href="#">type mapping</a> registry for mapping the Java class to an XML qualified name, using a specified Serializer. The available options are:</p> <ul style="list-style-type: none"> <li>– 1.1 indicates SOAP 1.1 JAX-RPC compliant.</li> <li>– 1.2 indicates SOAP 1.1 encoded.</li> </ul>	Apache Axis
Status	This read-only field shows whether the specified URL address is correct.	All

The dialog box opens after you create a Java module and [enable Web services client development](#) in it. To access the dialog box at any time during the development, select the desired client module in the Project view and choose WebServices | Generate Java Code from Wsdl or Wadl on the context menu.

Use the dialog box to have the client-side XML-Java bindings generated based on the desired WSDL descriptor of the target Web service.

Technically, IntelliJ IDEA generates Java code from WSDL using third party libraries that are controlled through a command line. This command line is assembled of the data you enter in the fields of this dialog box.

Item	Description	Web Service Client Type
Web service wsdl url	Use this drop-down list to specify the location of the target Web service WSDL descriptor.	All
User Name and Password	In these text boxes, type the credentials for accessing the WSDL URL address. The fields are mandatory if the WSDL location requires authentication.	JAX-WS
Output Path	Use this drop-down list to specify the module source directory to place the generated files in.	All
Package Prefix	Use this drop-down list to specify the package for the compiled Java classes.	All
Output Mode	Use this drop-down list to specify whether you want to generate Java code only for the client side or for the server side as well.	Apache Axis
Type Mapping Version	Use this drop-down list to specify the default <a href="#">type mapping</a> registry for mapping an XML qualified name to a Java class, using a specified Deserializer. The available options are: <ul style="list-style-type: none"> <li>- 1.1</li> <li>- 1.2</li> </ul>	Apache Axis
Allow Extensions	Select this checkbox to have Java code generated for the <a href="#">extension points</a> contained in the WSDL file.	All
Generate TestCase	Select this checkbox to have an additional JUnit test case class generated for testing purposes.	Apache Axis
Generate Classes for Schema Arrays	Do one of the following: <ul style="list-style-type: none"> <li>- Select this checkbox to have classes generated for schema arrays.</li> <li>- Clear the checkbox to have Java arrays used.</li> </ul>	Apache Axis
Generate Unreferenced Elements	Select this checkbox to have Java code generated for unreferenced (declared in the schema but not used) elements as well.	Apache Axis
Support Wrapped Document/Literal Style	Use this checkbox to configure processing of "wrapped" document/literal, which is a document literal variation, that wraps parameters as children of the root element. <ul style="list-style-type: none"> <li>- When this checkbox is cleared, no special treatment is applied to "wrapped" document/literal style operations.</li> <li>- When the checkbox is selected, a set of conditions is considered to decide whether top level elements are "unwrapped" and each component of the element should be treated as an argument of the operation. The following conditions are considered: <ul style="list-style-type: none"> <li>- An input message consists of single part.</li> <li>- This single part is an element.</li> <li>- The element has the same name as the operation.</li> <li>- The element's complex type has no attributes.</li> </ul> </li> </ul> <p>By default, the checkbox is selected.</p>	Apache Axis
Status	View the information in this read-only field to track and improve discrepancies when configuring the code generation procedure.	All

Use this dialog box to monitor SOAP messages testing the client side of an Apache Axis Web service.

**ItemDescription**

---

Web context name	Use this drop-down list to specify the context name of the server that is used for running the Web module on your local Tomcat session.
Port Name	Use this drop-down list to specify the port of the SOAP TCP monitor servlet, which is retrieved from <code>web.xml</code> descriptor settings.

Use this dialog box to have a list of all Web services deployed at the current server host displayed.

**ItemDescription**

---

Context name	In this text box, type the <a href="#">application context</a> under which you want to see the deployed Web services.
Status	This read-only field shows information on the status of the target server and hints in the format of the data specified in the Context name text box.

In this section:

- [Generate Java from Xml Schema using JAXB Dialog](#)
- [Generate XML Schema From Java Using JAXB Dialog](#)
- [Generate Java Code from XML Schema using XmlBeans Dialog](#)
- [Generate Instance Document from Schema Dialog](#)
- [Generate Schema from Instance Document Dialog](#)

Use this dialog box to configure generation of Java code stubs based on an XML Schema via the [JAXB](#) data binder.

- This functionality is provided via the WebServices bundled plugin, which is enabled by default. If not, enable it as described in the section [Enabling and Disabling Plugins](#).
- The menu item and the dialog box are available when the file opened in the active editor tab contains an XML Schema.

---

**ItemDescription**

---

JAXB Schemas / wsdl / dtd path	In this field, specify the file to be used as the generation basis. By default, the field shows the full path to the current file. To use another Schema, click the Browse button  and choose the desired file in the Select XML Schema File for JAXB Generation dialog box, that opens.
Output path	From this drop-down list, select the module source directory to place the generated Java code stubs in.
Package prefix	Use this drop-down list to specify the package to place the generated Java files in.
Generate package level annotations	Do one of the following: <ul style="list-style-type: none"><li>– Select this checkbox to have a <code>package-info.java</code> with annotations generated.</li><li>– Clear this checkbox to have annotations internalized into other generated classes.</li></ul>
Mark generated code with 'generated' annotation	Select this checkbox to have generated code supplied with the <code>javax.annotation.Generated</code> annotations.
Make generated file read-only	Select this checkbox to force the XJC binding compiler to mark the generated Java source code as read-only.
Add necessary libraries in order for generated code compile and work	Select this checkbox to have additional JAXB client libraries automatically added to the classpath of the module where the generated source code will be placed. These are libraries the generated stubs code depend on.
Do not generate header	Select this checkbox to pass <code>no-header</code> parameter to the corresponding command.
Add external binding file/dir	Select this checkbox to specify an external binding file or an output directory where the generated file is located.
Status	View the information in this read-only field to track and improve discrepancies when configuring the generation procedure.

---

Use this dialog box to configure XML Schema generation based on the existing Java code.

**Note** This functionality is provided via the WebServices bundled plugin, which is enabled by default. If not, enable it as described in the section [Enabling and Disabling Plugins](#).

2. The menu item and the dialog box are available when a Java class is opened in the active editor tab.

#### ItemDescription

Class Name	This read-only field shows the name of the class to base the XML Schema generation on.
Include parameter and return type of the following methods	<ul style="list-style-type: none"><li>– When the checkbox is cleared, the parameter and return type of all the class methods will be reflected in the generated Schema.</li><li>– Select this checkbox to have a list of the class methods displayed and specify the methods to be involved in Schema generation.</li></ul> <p>Selecting this checkbox enables the Parameter / return type of the following method and the Add to JAXB generation controls.</p>
Parameter / return type of the following method	This read-only field shows a list of all the methods of the current class.
Add to JAXB generation	Select this check to have the parameter/return type of the corresponding method involved in Schema generation.
Status	View the information in this read-only field to track and improve discrepancies when configuring the Schema generation procedure.

---

Use this dialog box to configure generation of Java code stubs based on an XML Schema via the [XmlBeans](#) data binder.

## Getting access to the dialog box

1. This functionality is provided via the WebServices bundled plugin, which is enabled by default. If not, enable it as described in the section [Enabling and Disabling Plugins](#).
2. The menu item and the dialog box are available when the file opened in the active editor tab contains an XML Schema.

### ItemDescription

Schema path	In this field, specify the file to be used as the generation basis. By default, the field shows the full path to the current file. To use another Schema, click the Browse button  and choose the desired file in the Select XML Schema / Wsdl File for generation dialog box, that opens.
Output path	Use this field to specify the name of the <code>.jar</code> to place the generated and compiled Java code in. By default, IntelliJ IDEA suggests to create a new <code>types.jar</code> . To overwrite an existing <code>.jar</code> , click the Browse button  and choose the desired <code>.jar</code> in the <a href="#">dialog that opens</a> .
Add necessary libraries in order for generated code compile and work	Select this checkbox to have additional XmlBeans libraries automatically added to the classpath of the module where the generated source code will be placed. These are libraries the generated stubs depend on.
Status	View the information in this read-only field to track and improve discrepancies when configuring the generation procedure.

---

In this dialog box, specify the options for generating an XML file based on the XSD (XML Schema Definition) [Schema](#) that describes its structure.

The menu item and the dialog box are available when the file opened in the active editor tab contains an XML Schema.

#### ItemDescription

---

Schema path	<p>In this field, specify the location of the <code>.xsd</code> Schema file to be used as the basis for XML document generation.</p> <p>By default, the field shows the full path to the current file. To use another Schema, click the Browse button  and select the desired file in the <a href="#">dialog that opens</a> .</p>
Instance document name	<p>In this text box, specify the name of the output XML file to be generated. By default, the generated XML file will inherit the name of the source Schema and will have the <code>.xml</code> extension. If you type another name for the document to be generated, make sure the extension is correct.</p> <p>The default location for the generated document is the directory where the source <code>.xsd</code> Schema file resides. To specify another location, click the Browse button  and select the desired path in the <a href="#">dialog that opens</a> .</p>
Element name	<p>In this drop-down list, specify the local name of the global element to be used as the root of the generated document.</p>
Enable restriction check	<p>Select this checkbox to have IntelliJ IDEA take restriction particles into consideration (if the specified Schema uses any).</p>
Enable unique check	<p>Select this checkbox to have IntelliJ IDEA take uniqueness particles into consideration (if the specified Schema uses any).</p>
Status	<p>View the information in this read-only field to track and improve discrepancies when configuring the generation procedure.</p>

In this dialog box, specify the options for generating an XSD (XML Schema Definition) [Schema](#) that describes the structure of the desired XML file.

The menu item and the dialog box are available when an XML document is opened in the active editor tab.

#### ItemDescription

---

Instance document path	<p>In this text box, specify the full path to the XML document to be used as the basis for Schema generation.</p> <p>By default, the field shows the full path to the current file. To use another XML document, click the Browse button  and select the desired file in the <a href="#">dialog that opens</a> .</p>
Result Schema file name	<p>In this text box, specify the name of the output file for the Schema to be generated. By default, the generated XSD Schema file will inherit the name of the instance document used and will have the <code>.xsd</code> extension. If you type another name for the Schema to be generated, make sure the extension is correct.</p> <p>The default location for the generated Schema is the directory where the source XML instance document resides. To specify another location, click the Browse button  and select the desired path in the <a href="#">dialog that opens</a> .</p>
Design type	<p>Use this drop-down to specify how to declare elements and complex types. The available options are:</p> <ul style="list-style-type: none"><li>- Local elements / global complex types</li><li>- Local elements / types</li><li>- Global elements / local types</li></ul>
Detect simple content types	<p>From this drop-down list, choose the type to render leaf text, which should be distinguished from the text used. The available options are:</p> <ul style="list-style-type: none"><li>- String</li><li>- Smart</li></ul>
Detect enumeration limit	<p>In this text box, type the number of occurrences to cause the Schema enumeration appearance. To suppress Schema enumeration, specify 0.</p>

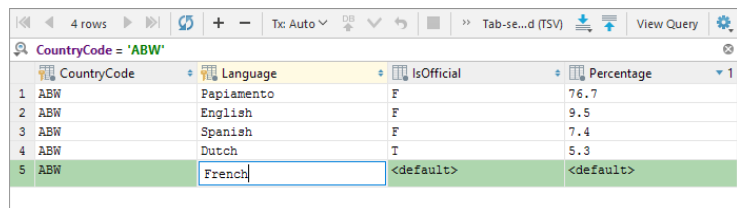

From the [Database tool window](#) (for any table within a DB data source):

-  on the toolbar (if the toolbar is not currently hidden)
- Open Editor from the context menu
- 

## Overview

The data editor provides a GUI for working with table data. It lets you sort, filter, add, edit and remove the data as well as perform other, associated tasks.

	CountryCode	Language	IsOfficial	Percentage
1	ABW	Papiamentu	F	76.7
2	ABW	English	F	9.5
3	ABW	Spanish	F	7.4
4	ABW	Dutch	T	5.3
5	ABW	French	<default>	<default>

## Toolbar controls, context menu commands for data cells and keyboard shortcuts

Most of the available functions are accessed by means of controls on the toolbar, context menu commands for the data cells, and associated keyboard shortcuts.

### ItemShortcutDescription

These icons and corresponding commands are for switching between the result set pages, i.e. the pages that show the table data. A fixed number of rows shown simultaneously is referred to as a [result set page](#). If this number is less than the number of rows in the table, only a subset of all the rows is shown at a time.

In such cases, you can use  to switch between the subsets. (If all the rows are currently shown, these icons and the corresponding commands are inactive.)

The result set page size is set on the [Database page](#) of the Settings dialog.

 First Page

Use this icon or command to switch to the first of the [result set pages](#) to see the first series of rows.

 Previous Page

Use this icon, command or shortcut to switch to the previous [result set page](#) to see the previous series of rows.

 Next Page

Use this icon, command or shortcut to switch to the next [result set page](#) to see the next series of rows.

 Last Page

Use this icon or command to switch to the last of the [result set pages](#) to see the last series of rows.

 Reload Page

Use this icon, command or shortcut to refresh the current table view. Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

 Add New Row

Use this icon, command or shortcut to add a new row to the table. Complete entering a value into a cell by pressing . To save the new row, select [Submit New Row](#) from the context menu or press .

See also, [Adding a row](#).

 Delete Rows

Use this icon, command or shortcut to delete the selected row or rows. Rows are selected by clicking the cells in the column where the row numbers are shown. To select more than one row, use mouse clicks in combination with the  key.

 Tx and Tx Isolation

Select the [isolation level](#) for database transactions and the way the transactions are committed.

- Auto. The current transaction is committed automatically when you submit your local changes to the database server.
- Manual. The changes submitted to the database server are accumulated in a transaction that can either be committed or rolled back.

 Submit

Submit local changes to the database server. See [Submitting and reverting changes](#).

 Commit

Commit the current transaction. See also, [Tx](#).

 Rollback

Roll back the current transaction. See also, [Tx](#).

 Cancel Query

Use this icon or shortcut to terminate execution of the current query.

 Compare With

Use this icon to compare the current table with another table. The tables open in the data editors and ones shown in the Database Console tool window are suggested for comparison.

Tab-se...d (TSV) Data  
Extractor:  
<current\_format>

Use this button or command to open a menu in which you can select an output format for your data.

In addition to output formats, there are also the following options and commands:

- Allow Transposition. For delimiter-separated values formats (TSV, CSV): If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. **Ctrl+C**), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). For SQL INSERTs and UPDATES: When copying or saving data (**Copy**, **Dump Data | To File**, **Dump Data | To Clipboard**), don't include auto-increment fields.
- Add Table Definition (SQL). For SQL INSERTs and UPDATES: When copying or saving data, add the table definition (CREATE TABLE).
- Configure CSV Formats. Open the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. Switch to the directory where the scripts that convert table data into various output formats are stored.

 **Dump Data | To Clipboard**

Use this command to copy the table data onto the clipboard.

 **Dump Data | To File**

Use this command to save the table data in a file. In the dialog that opens, specify the location and name of the file.

 **Export to Database**

Export the data to another table, schema or database. Select the target schema (a new table will be created) or table (the data will be added to the selected table). In the dialog that opens, specify the data mapping info and the settings for the target table.

**View Query**

Use this button to view the query which was used to generate the current table view. To close the pane where the query is shown, press **Escape**.

This icon provides access to the following commands:

- Transpose. Turn the transposed table view on or off. (In the transposed view, the rows and columns are interchanged. So, the rows are shown as columns and vice versa.)
- Reset View. Restore the initial table view after reordering or hiding the columns, or sorting the data.
- Sort via ORDER BY. Turn the corresponding option on or off.  
If the Sort via ORDER BY option is on, all the [sorting operations](#) that you perform are reflected in the corresponding **SELECT** statement (an **ORDER BY** clause is added or modified) which is executed immediately. As a result, the data for the whole table is sorted by the corresponding database system.

Don't turn this option on if you want to keep interactions with the database to a minimum (e.g. when the table is very big or the database connection is "slow").

If this option is off, the data is sorted "locally" by IntelliJ IDEA and only for the rows currently shown.

- Row Filter. Show or hide the [filter box](#).
- Settings. Open the [Database page](#) of the Settings dialog to view or edit the settings for your database, Hibernate and JPA consoles, data editors and the Database tool window.

 <Filter criteria>

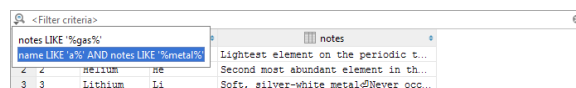

Specify filtering conditions for the table. (If the filter box is not currently shown, click  on the toolbar and select Row Filter.)

The filtering conditions are specified as in a **WHERE** clause but without the word **WHERE**, e.g. `name LIKE 'a%' AND notes LIKE '%metal%'`. Within the **LIKE** expressions, the SQL wildcards can be used: the percent sign (**%**) for zero or more characters and underscore (**\_**) for a single character.

To apply the conditions currently specified in the box, press **Enter**. To cancel filtering, click , or delete the contents of the filter box and press **Enter**.

To reapply a memorized filter, click  and select the filter in the list. See also, [Filter history size](#).

**Edit**

**F2**

Use this command or shortcut to start editing a value in the selected cell or cells. (Alternatively, you can double-click the cell or simply start typing.)

To open the value completion suggestion list, press **Ctrl+Space**. To enter the modified value, press **Enter**. To cancel editing, press **Escape**.

See also, [Modifying cell contents](#) and [Modifying values in a number of cells at once](#).

**Edit Maximized**

**F2**

Maximize the selected cell and start editing a value in it.

When working in a maximized cell, use **Enter** to start a new line and **Ctrl+Enter** to enter the value. To restore an initial value and quit the editing mode, press **Escape**.

See also, [Modifying cell contents](#) .

Set DEFAULT		If appropriate: Set the default value or values.
Set NULL		If appropriate: Replace the value or values with <code>null</code> .
Load File		If appropriate: Load a file into the field.
Revert		Revert the changes within the selection. See <a href="#">Submitting and reverting changes</a> .
Clone Row		Use this command or shortcut to create a copy of the selected row.
Quick Documentation		Use this command or shortcut to open the quick documentation view. To close the view, press  . For more information, see <a href="#">Using the quick documentation view</a> .
Transpose		Turn the transposed table view on or off. Alternatively, use    Transpose .
Go To   Row		Use this command or shortcut to switch to a specified row. In the dialog that opens, specify the row number to go to.
Go To   Related Data		Use this command or shortcut to switch to a related record. The command options are a combination of those for <a href="#">Go To   Referenced Data</a> and <a href="#">Go To   Referencing Data</a> . The command is not available if there are no related records.
Go To   Referenced Data		Use this command or shortcut to switch to a record that the current record references. If more than one record is referenced, select the target record in the pop-up that appears. The command is not available if there are no referenced records.
Go To   Referencing Data		Use this command or shortcut to see the records that reference the current record. In the pop-up that appears there are two categories for the target records: <ul style="list-style-type: none"><li>– First Referencing Row. All the rows in the corresponding table will be shown and the first of the rows that references the current row will be selected.</li><li>– All Referencing Rows. Only the rows that reference the current row will be shown.</li></ul> The command is not available if there are no records that reference the current one.
Filter by		Use this command to access quick filtering options. The options include those for the current column name and depend on the value in the current cell.
Copy		Copy the selection onto the clipboard. See also, <a href="#">Copying and pasting data: data types are converted if necessary</a> .
Paste		Paste the contents of the clipboard into the table. See also, <a href="#">Copying and pasting data: data types are converted if necessary</a> .
Save LOB		Use this command to save the large object (LOB ) currently selected in the table in a file.
	 ,  , 	See <a href="#">Selecting cells and ranges: using unobvious techniques</a> .

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  .

Finally, when you click the cell for the third time, the initial state is restored. That is, sorting by the corresponding column is canceled:  .

Here is an example of a table where data are sorted by two of its columns.

			
1	3	Dylan	brother
2	6	Jack	brother
3	1	Harry	father
4	2	Chloe	mother
5	5	Alice	sister
6	4	Emily	sister

To restore the initial "unsorted" state for the table, click  and select Reset View . See also, [Sort via ORDER BY](#) .

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row. To restore the initial order of columns, click  and select Reset View .

	member_id	relation	name
1	5	sister	Alice
2	1	mother	Chloe
3	3	brother	Dylan
4	4	sister	Emily
5	2	father	Harry

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

To show a hidden column:

1. Do one of the following:

- Right-click any of the cells in the header row and select Column List .
- Press `Ctrl+F12` .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	relation	name
1	5	<del>test.family</del>	Alice
2	1	<del>Chloe</del>	Chloe
3	3	<del>member_id int(11)</del>	Dylan
4	4	<del>name varchar(50) *1</del>	Emily
5	2	<del>relation varchar(50)</del>	Harry
6	6		Jack

2. Select (highlight) the column name of interest and press `Space` .
3. Press `Enter` or `Escape` to close the list.

To show all the columns, click  and select Reset View .

See also, [Using the Structure view to sort data, and hide and show columns](#) .

In this part:

- [Android Layout Preview Tool Window](#)
- [Choose Device Dialog](#)
- [Asset Studio](#)
- [Create Android Virtual Device Dialog](#)
- [Create Layout Dialog](#)
- [Designer Tool Window](#)
- [Generate Signed APK Wizard](#)
- [Inline Android Style Dialog](#)
- [New Android Component Dialog](#)
- [New Resource Directory Dialog](#)
- [New Resource File Dialog](#)

The tool window appears when you open a layout definition file for editing in the [manual mode](#) . It allows you to adjust the appearance of the layout preview and to emulate different configurations. This helps you adjust your application to different Android platforms, devices, orientations, dock modes, locales, etc.

In this section:

- [Toolbar](#)
- [Controls](#)

## Toolbar

Use the controls in this area to adjust the appearance of the layout preview.

### ItemTooltipDescription

	Zoom to Fit	Toggle this button to have IntelliJ IDEA compress or expand the preview so it fits the <a href="#">target screen size</a> .
	Reset Zoom to 100%	Click this button to have IntelliJ IDEA reset the zoom to preview the actual size.
	Zoom In	Click this button to have IntelliJ IDEA expand the preview.
	Zoom Out	Click this button to have IntelliJ IDEA compress the preview.
	Jump to Source	Click this button to switch to the Text tab where you can edit the application layout in the source <code>.xml</code> file.
	Refresh	Click this button to have IntelliJ IDEA update the preview so that it reflects on-the-fly changes to the current layout definition.
	Save Screenshot	Click this button to take a screenshot of the application preview. <b>Note</b> This button is only available from the Text tab of the layout preview window.
	Options	Click this button to configure the appearance and behavior of the tool window. <ul style="list-style-type: none"> <li>– Hide for non-layout files: select this option to have IntelliJ IDEA temporarily close the tool window when the focus in the editor switches to a non-layout file. As soon as the same or another layout definition file is in focus, the tool window re-appears automatically.</li> <li>– Include Device Frames (if available): select this option to make the preview look like it is going to appear on the actual device.</li> <li>– Show Lighting Effect: select this option to display lighting effects to make the preview look more natural.</li> </ul> <b>Note</b> This option is only available if the Include Device Frames option is selected.

## Controls

Use the controls in this area to preview your layout in different configurations.

### ItemTooltipDescription

	Configuration to render this layout in the IDE	From this drop-down list, select a layout configuration that you want to preview and edit, create a new layout configuration, or select different preview options. The available options are: <ul style="list-style-type: none"> <li>– Create Landscape Variation : select this option to create a landscape version of your layout. The corresponding layout definition file will be generated in the <code>res/layout-land</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-land option that opens the <code>layout-land&lt;layout_file_name&gt;.xml</code> file for editing.</li> <li>– Create layout-xlarge Variation : select this option to create a variation of your layout for an extra large screen size (at least 960x720 dp). The corresponding layout definition file will be generated in the <code>res/layout-xlarge</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-xlarge option that opens the <code>layout-xlarge&lt;layout_file_name&gt;.xml</code> file for editing.</li> <li>– Switch to layout : this option is only available if you have created multiple layout versions. Select it to return to the original layout definition file.</li> <li>– Create Other : select this option to create another variation of your layout. In the Select Layout Directory dialog that opens, specify the folder where the layout definition will be stored and select <a href="#">resource qualifiers</a> that determine a specific device configuration. Select the relevant qualifier and click <code>»</code> . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.</li> <li>– Preview Representative Sample select this option to display multiple device configurations and preview the layout on the most important screen sizes.</li> <li>– Preview All Screen Sizes : select this option to display multiple device configurations and preview the layout on all available screen sizes.</li> <li>– Preview All Locales : select this option to preview the layout in all locales where your application is going to be used.</li> <li>– Preview Right-to-Left Layout : select this option to preview the layout in both directions (left-to-right and right-to-left) side by side.</li> <li>– Preview Android Versions : select this option to preview the layout on all installed Android API versions.</li> <li>– Preview Included : select this option to preview your layout nested in another layout. This option is only available if the current layout is included into another layout.</li> <li>– Preview Layout Versions : select this option to display multiple device configurations and preview the layout in all available variations.</li> </ul>
---	--	--

- None : select this option to return to the default view.
- Toggle Layout Mode : select this option to switch between different preview options.

 Nexus 4+	The virtual device to render the layout with	From this drop-down list, select a virtual or a physical device to preview what your application will look like on this device. To add a new virtual device, select Add Device Definition and configure an emulator in the <b>Android Virtual Device (AVD) Manager</b> that opens (for instructions refer to <a href="#">Managing Virtual Devices</a> ).
	Go to next state	From this drop-down list, select the preview orientation ( <b>portrait</b> or <b>landscape</b> ), the UI mode ( <b>Normal</b> , <b>Car Dock</b> , <b>Desk Dock</b> , <b>Television</b> , <b>Appliance</b> ) and switch between the <b>Night</b> (dimmed screen) and <b>Not Night</b> (standard brightness) modes. For details on UI modes refer to <a href="#">UIModeManager</a> .
 Holo	Theme	Click this button to select a theme from the Select Theme dialog.
	N/A	Click this button to associate the layout with an activity. Select Associate with <activity_name> to associate it with the current activity, or Associate with Other Activity to display a list of available activities to select from.
	Locale to render layout with in the IDE	From this drop-down list, select an existing locale or add a locale for your application. A locale is a combination of the target country and language to have the dates and some other data presented in accordance with the local rules and preferences. You can also preview the layout in all available locales and in both directions (left-to-right and right-to-left).
	Android version to use when rendering layouts in the IDE	From this drop-down list, select an API version or use the Automatically Pick Best option to render the layout using the most suitable Android version. You can also preview the layout on all installed Android API versions.

Run | Run

Run | Debug

---

This dialog box opens when you start a run or a debug session with the manual selection of the target device specified in the run/debug configuration (i.e. the Show chooser dialog option is selected in the [Run/Debug Configuration: Android Application](#) dialog). It shows the list of all currently running devices, both physical and virtual.

Use this dialog box to appoint a running device, or to launch a virtual device.

---

**ItemDescription**

Choose a running device	Select this option to choose a running device from the list below. The following information is provided on each device: <ul style="list-style-type: none"><li>- Device : the device name.</li><li>- Serial Number : the device serial number assigned to it by the manufacturer.</li><li>- State : the device current state ( <b>Online</b> or <b>Offline</b> ).</li><li>- Compatible : shows whether the device is compatible with the application settings.</li></ul>
-------------------------	--

---

Launch emulator	Select this option to launch a virtual Android device. To create a new device, click the Browse button to launch the Android Virtual Device Manager.
-----------------	--

---

Use same device for future launches	Select this checkbox to use the selected device for the future run and debug sessions.
-------------------------------------	--

To access the Asset Studio wizard, in the [Project Tool Window](#) , right-click the `res` folder and select New | Image Asset from the popup menu.

The Asset Studio wizard is a convenient tool that allows you to create icons for your Android applications. It creates multiple icons for different screen resolutions and lets you see a live preview in the process of creating. You can create icons using your own images, clipart images, or text, configure the background shape, the colors, the fonts, etc.

– [Asset Studio. Page 1](#)

– [Asset Studio. Page 2](#)

Use this page to select the image source, adjust the original image to the icon size and aspect ratio, modify shapes and colors, etc.

#### ItemDescription

---

Asset Type	Select the type of icon you want to create from the drop-down list. The available options are: <ul style="list-style-type: none"><li>- Launcher Icons</li><li>- Action Bar and Tab Icons</li><li>- Notification Icons</li></ul>
Foreground	Select one of the following sources for your icon: <ul style="list-style-type: none"><li>- Image</li><li>- Clipart</li><li>- Text</li></ul>
Image file	This field is only available if Image is selected as the icon source. Specify the path to the image file, or click the Browse button  and select the image file in the dialog that opens.
Clipart	This control is only available if Clipart is selected as the icon source. Click the Choose button to select the foreground image from the clipart collection.
Text	This control is only available if Text is selected as the icon source. Enter the text and select the font from the Font drop-down list.
Trim surrounding blank space	Select this option if you want to contract the blank space around your image and adjust the foreground to the icon size.
Additional padding	Drag the slider if you want to increase/decrease the amount of blank space around the foreground image.
Foreground scaling	This control is only available if Launcher Icons is selected as the asset type. The image that serves as the source for your icon may not have the same aspect ratio as the icon itself. You can adjust it by selecting one of the following options: <ul style="list-style-type: none"><li>- Crop : the foreground image will be cropped so that it takes the full space of the parent element.</li><li>- Center : the foreground image will remain unchanged and will be placed in the middle of the parent element.</li></ul>
Shape	These controls are only available if Launcher Icons is selected as the asset type. Use these controls to add a shaped frame to your icon. The following options are available: <ul style="list-style-type: none"><li>- None</li><li>- Square</li><li>- Circle</li></ul>
Background color	This control is only available if Launcher Icons is selected as the asset type. Click the color block to open the Select Color dialog where you can choose the color that will fill the background if you have selected Square or Circle above as the icon shape.
Foreground color	This control is only available if Launcher Icons is selected as the asset type, and Clipart or Text is selected as the icon source. Click the color block to open the Select Color dialog where you can choose the color for the foreground image.
Theme	This control is only available if Action Bar and Tab Icons is selected as the asset type. Select a theme for your icon from the drop-down list.
Resource name	Enter the name for the new drawable resource.

Use this page to specify the target module for the new drawable resource.

**ItemDescription**

---

Res Directory      This field shows the path to your resource directory.

---

Output Directories      This pane shows the target folders for the new drawable resource in different output formats.

This dialog box opens when you first launch a Run/Debug session for an Android module, Emulator is selected as the target device on module creation, and you have no Android Virtual Devices configured.

Use this dialog box to create new emulators.

**ItemDescription**

Name	In this text box, type the name of the new emulator.
Target	From this drop-down list, select the Android platform to have the application built against.
Skin	From this drop-down list, choose a <a href="#">skin</a> to use for controlling screen dimensions (optional).
Abi Type	From this drop-down list, select the Application Binary Interface (ABI) type.
SDCard	If you want to simulate the presence of an SD card in the virtual device, you can create an SD card image by generating a dedicated file and specifying the virtual SD card size (optional).

The dialog box opens when you create a component of the **activity** or **fragment** type, and select the Create layout file checkbox.

In this dialog box, specify the layout name, its root element, and the set of qualifiers to be included in this layout.

---

#### ItemDescription

---

File name	In this text box, specify the name of the layout definition file associated with the new component. Only lowercase letters and numbers are supported.
Root element	In this text box, specify the root element of the layout. Press <code>Ctrl+Space</code> to get a list of available values. The value must be of the <a href="#">View</a> or <a href="#">ViewGroup</a> type, learn more at <a href="http://developer.android.com/guide/topics/resources/layout-resource.html">http://developer.android.com/guide/topics/resources/layout-resource.html</a> .
Directory name	<p>In this text box, specify the folder where the layout definition will be stored relative to the <code>res</code> folder.</p> <ul style="list-style-type: none"><li>– If your application does not need to be compatible with various Android devices and, therefore, no <a href="#">multiple screens</a> support is required, accept the default <code>layout</code> subfolder.</li><li>– To provide <a href="#">alternative resources</a>, specify the <a href="#">resource qualifiers</a> that determine a specific device configuration. Move the relevant qualifiers from the Available qualifiers list to the Chosen qualifiers list and specify their values. IntelliJ IDEA appends all the selected qualifiers to the Directory name field with a dash character as separator.</li></ul> <p>For details, see <a href="#">Creating Resources</a>.</p>
Available qualifiers	From this list, select the <a href="#">resource qualifiers</a> that determine a specific device configuration. Select the relevant qualifier and click <code>»</code> . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.

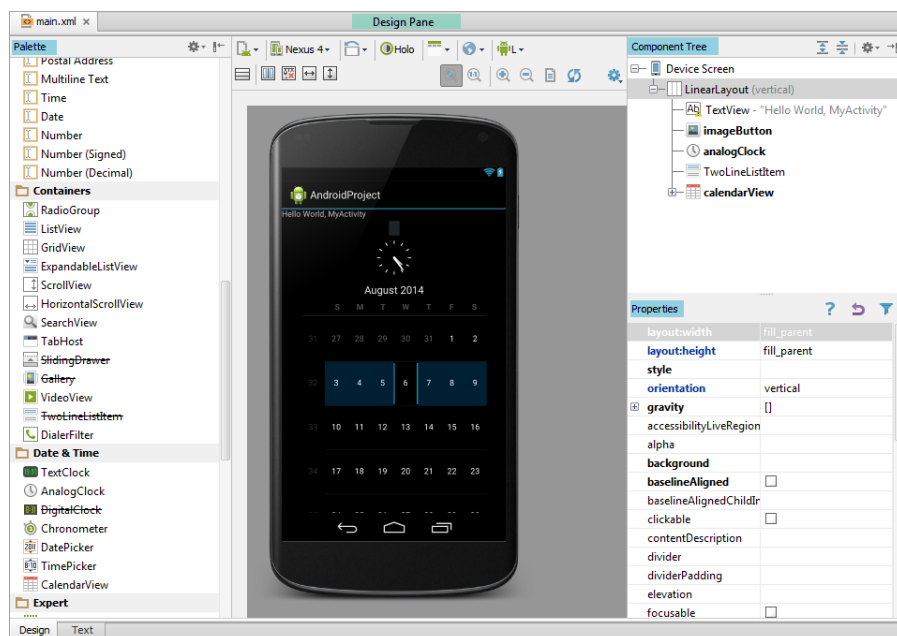

Use this dedicated tool window to build the design of your application without editing the layout definition files manually, and check how the application design is rendered in various target environments without running the application on any physical or virtual devices.

**Note** Alternatively, edit the layout definition files manually, possibly using the Android-specific refactoring provided by IntelliJ IDEA and [preview the changes](#) that are immediately reflected in the dedicated [Preview](#) tool window, where you can adjust the layout to various platforms and devices. To switch to the manual mode, click the Text tab or choose Go To Declaration from the [context menu](#) in the Design pane or in the Component Tree.

A **layout** defines the user interface of an **activity** or an **app widget** (fragment). Layouts are declared in XML **resource definition files**. See [Creating Resources](#) for instructions on how to create resource folders and resource definition files.

The Android UI designer consists of the following panes:

- [Design Pane](#)
- [Component Tree](#)
- [Properties](#)
- [Palette](#)

## Design Pane

The Design pane is located in the central part of the UI Designer (assuming the default tool window layout). When you open a layout definition file for editing, the pane appears in the editor tab by default. If you are editing the layout definition file manually and then switch to the visual mode by clicking the Design tab, the pane opens in the tab where the edited layout definition file is opened,

To toggle between the manual and visual editing modes, use the Text and Design tabs in the bottom of the pane/editor:

The pane shows a rectangular canvas that is synchronized with the current layout definition file and with the Component Tree view, so any changes to the canvas are reflected there accordingly.

To add a component to the canvas, do one of the following:

- Select the required element in the Palette pane and drag and drop it to the canvas in the Design pane.
- Click the required element in the Palette pane and then click an area on the canvas.

Every component added in either way is also added to the Component Tree and is declared in the layout definition file.

You can also specify the most essential properties for a component right in the canvas, without switching to the Properties pane. To do that, select the component in question, double click the selected area, and fill in the fields in the pop-up dialog box that opens.

The canvas has a [context menu](#) that provides access to the clipboard, layout actions, refactoring, and more.

You can view what the built layout will look like on various devices: [configure the target environment emulation](#) using the controls on the [Controls](#).

For details on different configuration options available from the Design pane, refer to the following sections:

- [Context Menu](#)
- [Toolbar](#)
- [Controls](#)

## Context Menu

The context menu is available from any area in the Design pane, both inside the canvas and outside it. All actions are synchronized with the Component Tree and the XML definition files, so all changes are immediately reflected in them. The same actions are also available from the context menu of the Component Tree pane.

### ItemShortcutDescription

Cut		Choose this option to cut the selected component.
Copy		Choose this option to copy the selected component to the clipboard.
Paste		Choose this option to insert the component from the clipboard inside the selected parent component in the canvas. <b>Note</b> This action is available only when a parent component is selected.
Delete		Choose this option to remove the selected component from the canvas and from the layout.
Select	N/A	Choose this option to select one of the following: <ul style="list-style-type: none"><li>– Select Parent : choose this option to select the parent component of the selected component.</li><li>– Select Siblings : choose this option to select the components located on the same level as the selected component.</li><li>– Select Same Type : choose this option to select the components of the same type as the selected component.</li><li>– Select All : choose this option to select all components on the canvas.</li><li>– Deselect All : choose this option to deselect all selected components.</li></ul>
Morphing	N/A	Choose this option to convert the selected component into a component of another type preserving the properties that are common for both types. When you choose this option, IntelliJ IDEA shows a list of compatible component types, that is, the types into which the selected component can be converted.
Save Screenshot	N/A	Choose this option to take a screenshot of the current layout.
Refactor	N/A	Choose this option to apply one of the available <a href="#">refactorings</a> to the current XML layout definition file. The XML code will be optimized while the layout itself will not be affected. The list of available refactorings depends on the type of the selected component.
Go To Declaration		Choose this option to navigate to the definition of the selected component in the XML layout definition file. <b>Note</b> Choosing this option automatically brings you to the <b>manual</b> layout editing mode. To return to the <b>design</b> mode, switch to the Design tab in the bottom of the editor.

## Toolbar

Use the controls in this area to adjust the appearance of the layout preview.

### ItemTooltipDescription

	Zoom to Fit	Toggle this button to have IntelliJ IDEA compress or expand the preview so it fits the <a href="#">target screen size</a> .
	Reset Zoom to 100%	Click this button to have IntelliJ IDEA reset the zoom to preview the actual size.
	Zoom In	Click this button to have IntelliJ IDEA expand the preview.
	Zoom Out	Click this button to have IntelliJ IDEA compress the preview.
	Jump to Source	Click this button to switch to the Text tab where you can edit the application layout in the source <code>.xml</code> file.
	Refresh	Click this button to have IntelliJ IDEA update the preview so that it reflects on-the-fly changes to the current layout definition.
	Save Screenshot	Click this button to take a screenshot of the application preview. <b>Note</b> This button is only available from the Text tab of the layout preview window.
	Options	Click this button to configure the appearance and behavior of the tool window. <ul style="list-style-type: none"><li>– Hide for non-layout files: select this option to have IntelliJ IDEA temporarily close the tool window when the focus in the editor switches to a non-layout file. As soon as the same or another layout definition file is in focus, the tool window re-appears automatically.</li><li>– Include Device Frames (if available): select this option to make the preview look like it is going to appear on the actual device.</li><li>– Show Lighting Effect: select this option to display lighting effects to make the preview look more natural.</li></ul> <b>Note</b> This option is only available if the Include Device Frames option is selected.

## Controls

Use the controls in this area to preview your layout in different configurations.

## ItemTooltipDescription

	Configuration to render this layout in the IDE	<p>From this drop-down list, select a layout configuration that you want to preview and edit, create a new layout configuration, or select different preview options. The available options are:</p> <ul style="list-style-type: none"><li>– Create Landscape Variation : select this option to create a landscape version of your layout. The corresponding layout definition file will be generated in the <code>res\layout-land</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-land option that opens the <code>layout-land\&lt;layout_file_name&gt;.xml</code> file for editing.</li><li>– Create layout-xlarge Variation : select this option to create a variation of your layout for an extra large screen size (at least 960x720 dp). The corresponding layout definition file will be generated in the <code>res\layout-xlarge</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-xlarge option that opens the <code>layout-xlarge\&lt;layout_file_name&gt;.xml</code> file for editing.</li><li>– Switch to layout : this option is only available if you have created multiple layout versions. Select it to return to the original layout definition file.</li><li>– Create Other : select this option to create another variation of your layout. In the Select Layout Directory dialog that opens, specify the folder where the layout definition will be stored and select <a href="#">resource qualifiers</a> that determine a specific device configuration. Select the relevant qualifier and click <b>»</b> . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.</li><li>– Preview Representative Sample select this option to display multiple device configurations and preview the layout on the most important screen sizes.</li><li>– Preview All Screen Sizes : select this option to display multiple device configurations and preview the layout on all available screen sizes.</li><li>– Preview All Locales : select this option to preview the layout in all locales where your application is going to be used.</li><li>– Preview Right-to-Left Layout : select this option to preview the layout in both directions (left-to-right and right-to-left) side by side.</li><li>– Preview Android Versions : select this option to preview the layout on all installed Android API versions.</li><li>– Preview Included : select this option to preview your layout nested in another layout. This option is only available if the current layout is included into another layout.</li><li>– Preview Layout Versions : select this option to display multiple device configurations and preview the layout in all available variations.</li><li>– None : select this option to return to the default view.</li><li>– Toggle Layout Mode : select this option to switch between different preview options.</li></ul>	
	Nexus 4+	The virtual device to render the layout with	From this drop-down list, select a virtual or a physical device to preview what your application will look like on this device. To add a new virtual device, select Add Device Definition and configure an emulator in the <a href="#">Android Virtual Device (AVD) Manager</a> that opens (for instructions refer to <a href="#">Managing Virtual Devices</a> ).
	Go to next state		From this drop-down list, select the preview orientation ( <code>portrait</code> or <code>landscape</code> ), the UI mode ( <code>Normal</code> , <code>Car Dock</code> , <code>Desk Dock</code> , <code>Television</code> , <code>Appliance</code> ) and switch between the <code>Night</code> (dimmed screen) and <code>Not Night</code> (standard brightness) modes. For details on UI modes refer to <a href="#">UIModeManager</a> .
	Holo	Theme	Click this button to select a theme from the Select Theme dialog.
	NA		Click this button to associate the layout with an activity. Select Associate with <code>&lt;activity_name&gt;</code> to associate it with the current activity, or Associate with Other Activity to display a list of available activities to select from.
	Locale to render layout with in the IDE		From this drop-down list, select an existing locale or add a locale for your application. A locale is a combination of the target country and language to have the dates and some other data presented in accordance with the local rules and preferences. You can also preview the layout in all available locales and in both directions (left-to-right and right-to-left).
	Android version to use when rendering layouts in the IDE		From this drop-down list, select an API version or use the Automatically Pick Best option to render the layout using the most suitable Android version. You can also preview the layout on all installed Android API versions.

## Component Tree

This pane shows a hierarchy of components in the current layout with the `Device Screen` root node. The pane is synchronized with the Design pane and the layout definition file, so any changes to them are reflected in the tree view on-the-fly.

For details on different configuration options available from the Component Tree , refer to the following sections:

- [Context Menu](#)
- [Toolbar](#)

### Context Menu

The context menu is available from any area in the Component Tree pane. All actions are synchronized with the Design Pane and the XML definition files, so all changes are immediately reflected in them. The actions available from the Component Tree context menu are identical with those of the [Design Pane context menu](#) .

### Toolbar

**ItemTooltip and Description**

## Shortcut

	<b>Expand All</b> Ctrl+NumPad Plus	Click this button to expand all nodes in the Component Tree view.
	<b>Collapse All</b> Ctrl+NumPad -	Click this button to collapse all nodes in the Component Tree view.
	N/A	Click this button to open the context menu and configure the pane <a href="#">viewing mode</a> .
	<b>Hide</b> Shift+Escape	Click this button to hide the pane.

## Properties

In this pane, specify property values of the component that is currently selected in the canvas or in the component tree view. The most frequently used properties are displayed in bold , "expert" properties are shown in *italic* , properties whose values have been updated are highlighted in blue.

## Toolbar

Item	Tooltip and Shortcut	Description
------	----------------------	-------------

	Show documentation	Click this button to have IntelliJ IDEA display a brief documentation for the selected property from the <a href="#">Android reference</a> .  Ctrl+Q
	Restore default value	For any newly added component, the default property values are set. After you edit a property value, this property is highlighted in blue. Click this button to discard the changes and restore the default value. When you edit the default value of an expert property, the property is also highlighted in blue and will remain in the list when the Show expert properties toggle button  is released.  <b>Note</b> The button is available only if you have re-defined the value of the selected property.
	Show expert properties	By default, the pane shows only a standard set of properties, and the most frequently used ones are displayed in bold . However, you can have IntelliJ IDEA display the entire set of properties for the selected component to enable advanced component configuration. <ul style="list-style-type: none"><li>– Click this button on to have the pane display all properties that are defined for the selected component according to the specification. All "expert" properties are displayed in <i>Italic</i> .</li><li>– Release this button to have only the standard set of properties displayed. If the value of an expert property has been updated, the property will still remain in the list.</li></ul>

## Palette

The Palette pane contains a number of pre-built UI elements that you can drag-and-drop to the canvas to design the layout of your application. For detailed instructions refer to [Designing Layout of Android Application](#) .

For details on different options available from the Palette pane, refer to the following sections:

- [Toolbar](#)
- [UI Components](#)

## Toolbar

Item	Tooltip and Shortcut	Description
------	----------------------	-------------

	N/A	Click this button to open the context menu and configure the pane <a href="#">viewing mode</a> .
	<b>Hide</b> Shift+Escape	Click this button to hide the pane.

## UI Components

This pane contains UI components which you can place in the canvas. The available components are grouped into categories. To hide/expand the contents of a group, click the group title. The following groups of UI components are available:

Components	Description
------------	-------------

---

Layouts	<a href="#">Android Layouts</a> define the visual structure of your application's interface. They are a class that determines the way its children appear on the screen.
Widgets	<a href="#">Android widgets</a> are interactive components in a user interface. You can select from a variety of widgets, such as buttons, checkboxes, text fields, etc.
Text Fields	A <a href="#">text field</a> allows the user to enter text into the application, such as name, password, number, etc.
Containers	Containers are composite views that are comprised of multiple other views.
Date & Time	This section provides predesigned UI elements related to date and time, such as different types of clocks, a date and time picker controls, etc.
Expert	This section contains extra predefined UI elements in addition to the most frequently used components.
Custom	<p>In this section, you can choose and add UI components defined either in your project, or in the Android SDK. You can insert elaborate combinations of widgets, or even embed entire layouts into the current layout. IntelliJ IDEA checks for a resource definition of the appropriate type in the project and in the Android SDK. The following options are available:</p> <ul style="list-style-type: none"><li>- include : click this item to choose the layout that you want to embed. In the Resources dialog box that opens, select the Project tab to pick a layout definition from within your project, or the System tab to search in the SDK.</li><li>- fragment : click this item to choose the fragment that you want to embed.</li><li>- requestFocus : click this item to include the <code>requestFocus</code> element in a <code>view</code> object. The <code>requestFocus</code> element gives its parent initial focus on the screen.</li><li>- CustomView : click this item to choose a <a href="#">user-defined view</a> that you want to embed.</li></ul>

---

To deploy and run an Android Application package ([.apk file](#)) on physical devices, you need to [sign](#) it with your personal signature (certificate). Based on this signature, the Android system identifies the author of every deployed application. You do not need to apply for a personal signature to any authority, a signature generated by IntelliJ IDEA is quite sufficient.

Use the **Generate Signed APK Wizard** to have IntelliJ IDEA [digitally sign](#) Android Packages (`.apk` files) during package extraction. You can use previously created signature keys, create new ones in existing keystores, or create new keystores.

Alternatively, you can configure the `.apk` file as an [artifact](#) by creating an [artifact definition](#) of the **Android application** type with the Release signed package mode turned on. When IntelliJ IDEA builds the package in accordance with this definition, it signs the package automatically.

**Note** An **unsigned package** is used when you want to test your application on an emulator. Unsigned packages can be extracted only through artifact definitions with the Release unsigned package mode turned on.

You can also extract and sign **debug** packages. This is sufficient for testing and debugging applications but does not allow publishing them. Signing packages in the debug mode is available only through an artifact with the Debug package mode turned on.

In this section:

- [Generate Signed APK Wizard. Specify Key and Keystore](#)
- [New Key Store Dialog](#)
- [Generate Signed APK Wizard. Specify APK Location](#)

On this page of the Wizard, specify the key store file that contains the digital key to sign the package with. You can use an existing key, or create a new one in an existing keystore, or create a new keystore.

---

**ItemDescription**

---

**Key store path** In this text box, specify the location of the file where the key will be stored. Type the path manually or click the **Choose existing** button to choose the relevant file in the [dialog that opens](#) .

---

**Create new** Click this button to open the [New Key Store Dialog](#) and configure a new key store and/or a release key to be generated.

---

**Choose existing** Click this button to have your package signed with a key from an existing key store file. Choose the relevant key store file in the [dialog that opens](#) .

 Later you can choose to use an existing key from this key store, or to have a new key generated in it.

---

**Key store password** In this text box, type the password for the selected key store.

---

**Key alias** In this text box, specify the alias to address the key to be used.

---

**Key password** In this text box, specify the password to access the selected key.

---

**Remember passwords** Select this checkbox to have IntelliJ IDEA automatically use the specified passwords to access the key store and the key.

This dialog box opens when you click the Create new button on the [Generate Signed APK Wizard. Specify Key and Keystore](#) page, or in the [Android](#) tab of the Artifact page.

In this dialog box, specify the data required for generating new keys and key stores.

#### ItemDescription

---

Key store path	In this text box, specify the location of the file where the new key will be stored. Type the path manually, or click the Browse button to choose the file in the <a href="#">dialog that opens</a> .
----------------	---

---

Password	In this text box, enter the password that will be used to access the key store.
----------	---

---

Confirm	Re-type the password.
---------	-----------------------

---

Alias	In this text box, specify the alias to address the new key.
-------	---

---

Password	In this text box, enter the password that will be used to access the new key.
----------	---

---

Confirm	Re-type the password.
---------	-----------------------

---

Validity (years)	Use this spin box to specify how long the new key will be valid.
------------------	--

**Tip** Set the validity period in accordance with the [expected lifespan of your application](#) .

---

Certificate	In this area, specify the following personal data:
-------------	--

- First and Last Name
- Organizational Unit
- Organization
- City or Locality
- State or Province
- Country Code

On this, last, page of the Wizard, specify the output directory for the generated Android Package. Optionally, have IntelliJ IDEA obfuscate the application through integration with the [ProGuard](#) built-in tool.

---

**ItemDescription**

---

Destination APK path	In this text box, specify the path where the generated <code>.apk</code> file will be stored. Type the path manually, or click the Browse button to choose the path in the <a href="#">dialog that opens</a> .
Run ProGuard	Select this checkbox to have IntelliJ IDEA <a href="#">obfuscate the application</a> through integration with the built-in <a href="#">ProGuard</a> tool. If this option is selected, the default paths to the configuration files that are created automatically are displayed. For Android SDK tools revision 17 and higher, this option is selected by default. For already existing projects, this checkbox is cleared.

<context menu of a selection> | Refactor | Inline Style

Ctrl+Alt+N

Use this dialog box to configure the **Inline Style**. This refactoring is opposite to the **Extract Style** refactoring and results in adding all attributes defined in a style to one or all components where this style is applied. This refactoring is also used when you need to merge a [parent style with its inheritor](#).

#### ItemDescription

---

**Inline all references and remove the style** Select this option to have IntelliJ IDEA convert the attributes of the style into XML tags, add them to the definitions of all components where the style is used, and remove the style definition.

---

**Inline this usage and keep the style** Select this option to have the refactoring applied to the current component only.

**Note** When the refactoring is invoked from the style definition file, only the Inline all references and remove the style option is available and selected by default.

---

**Refactor** Click this button to apply the changes immediately.

---

**Preview** Click this button to [preview the changes before applying](#) in the [Find tool window](#).

In this dialog, specify the class that implements the new Android component, the component type, and the title to be displayed to the user.

#### ItemDescription

Name	In this text box, type the name of the class that implements the component.
Kind	<p>In this drop-down list, specify the component type. The available options are:</p> <ul style="list-style-type: none"><li>- <a href="#">AIDL</a> : an Android Interface Definition Language (AIDL) interface used for interprocess communication.</li><li>- <a href="#">Activity</a> : implements a window where you place your UI to interact with the user.</li><li>- <a href="#">Android Auto</a> : lets you extend your application for use in vehicles. You can add either Media Service or Messaging Service activity.</li><li>- <a href="#">Folder</a> : creates a source root based on the activity you have selected for this component.</li><li>- <a href="#">Fragment</a> : represents a behavior or a part of user interface in an activity.</li><li>- <a href="#">Google</a> : lets you create an activity for Google maps and <a href="#">AdMob Ads</a> activities.</li><li>- <a href="#">Application</a> : an Android package, i.e. an <code>.apk</code> archive that contains the contents of an Android app and the installer.</li><li>- <a href="#">Service</a> : represents an application's desire either to perform an operation without interacting with the user, or to supply functionality for other applications.</li><li>- <a href="#">Other</a> : lets you add the following components to your application:<ul style="list-style-type: none"><li>- <a href="#">Android Manifest File</a></li><li>- <a href="#">Broadcast Receiver</a></li><li>- <a href="#">Content Provider</a></li><li>- <a href="#">Daydream</a></li></ul></li><li>- <a href="#">UI Component</a> : lets you add custom views to you application.</li><li>- <a href="#">Wear</a> : lets you extend your application for use in Android wear.</li><li>- <a href="#">Widget</a> : lets you add different types of widgets for your application.</li><li>- <a href="#">XML</a> : lets you add different types <code>.xml</code> files for Android layouts and values.</li></ul>
Label	<p>In this text box, type the title that will be displayed to the user.</p> <ul style="list-style-type: none"><li>- If no title is specified, the label assigned to the entire application will be displayed.</li><li>- No label is specified for the Remote Interface component.</li></ul>
Mark as startup Activity	<p>Select this checkbox to have the new component of the Activity type displayed by default when the application starts.</p> <p><b>Note</b> The checkbox is available only when the Activity component type is specified in the Kind drop-down list.</p>
Create layout file	<ul style="list-style-type: none"><li>- Select this checkbox to have IntelliJ IDEA generate a stub of the related layout definition file, that is, the content view of the new activity or fragment.</li><li>- If the checkbox is cleared, you will have to create a content view of the new activity or fragment manually.</li></ul> <p><b>Note</b> The checkbox is available only for the <code>activity</code> or <code>fragment</code> component types.</p>

Use this dialog box to create a resource directory for your Android project.

**ItemDescription**

---

Directory name In this text box, specify the name for the new resource directory.

---

Resource type From this drop-down list, select the application resource [type](#) that the new directory will contain.

---

Available qualifiers From this list, select the [resource qualifiers](#) that determine a specific device configuration. Select the relevant qualifier and click . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.

Use this dialog box to create a resource file for your Android project.

#### ItemDescription

---

**File name** In this text box, specify the name for the new resource definition file.

---

**Resource type** From this drop-down list, select the application resource [type](#) .

**Tip** You can scroll through the list of resource types right from the File name text box by using the Up and Down keyboard keys.

---

**Root element** This field is populated automatically depending on the selected resource type.

---

**Directory name** In this text box, specify the folder where application resources will be stored.

**Tip** IntelliJ IDEA can automatically compose folder name based on the resource type and the qualifier you select. For details, refer to [Creating Resources](#) .

---

**Available qualifiers** From this list, select the [resource qualifiers](#) that determine a specific device configuration. Select the relevant qualifier and click » . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.

In this section:

- [Create AIR Descriptor Template Dialog](#)
- [Create HTML Wrapper Template Dialog](#)
- [New ActionScript Class dialog](#)
- [New MXML Component dialog](#)
- [Package AIR Application Dialog](#)
- [Runtime-Loaded Modules dialog](#)

Use this dialog to configure and create an [application descriptor](#) template for your AIR (Desktop or Mobile) application.

During the compilation or packaging, the text in the `<content>` element of the template will be replaced with the name and extension ( `.swf` ) of the application file.

- [AIR application descriptor](#)
- [Application properties](#)
- [Mobile options](#)
- [Android tab](#)
- [iOS tab](#)

## AIR application descriptor

### ItemDescription

File name	Specify the name of the descriptor template <code>.xml</code> file to be generated.
Folder	Specify the folder in which the generated descriptor template should be stored. Use <code>...</code> ( <code>Shift+Enter</code> ) to select the folder in the <a href="#">corresponding dialog</a> .
AIR version	Specify (select or type) the target AIR version.

## Application properties

### ItemDescription

ID	Specify the application ID.
Name	Specify the application name, that is, the text to be displayed as the application title.
Version	Specify the application version in the <code>x.x.x</code> format. Note that this isn't the <a href="#">AIR version</a> .

## Mobile options

### ItemDescription

Mobile platform	Select which platform (Android or iOS) the application descriptor is intended for.
Common options	Select or deselect the following <a href="#">screen options</a> : <ul style="list-style-type: none"><li>- Auto-orient. If selected, corresponds to <code>&lt;autoOrients&gt;true&lt;/autoOrients&gt;</code> .</li><li>- Full screen. If selected, corresponds to <code>&lt;fullScreen&gt;true&lt;/fullScreen&gt;</code> .</li></ul>

## Android tab

### ItemDescription

Permissions	Use the checkboxes to enable or disable the corresponding <a href="#">Android permissions</a> .
-------------	---

## iOS tab

### ItemDescription

Devices	Select the supported device family. If iPhone/iPod Touch and iPad are supported, select All .
High resolution	Select this option if your application should use the high screen resolution mode.

Use this dialog to configure and create an [HTML wrapper](#) template for your Web-targeted ActionScript or Flex application.

The generated template ( `index.template.html` ) will contain a set of tokens, such as `${title}` , `${swf}` , etc. During the compilation, these tokens will be replaced with the appropriate values. For example, `${swf}` will be replaced with the `.swf` file name. The resulting `.html` wrapper file will have the same name as the `.swf` file.

See also, [Using the SWF metadata tag to control HTML wrapper properties](#) .

#### ItemDescription

Create HTML wrapper template in the following folder	Specify the folder in which the HTML wrapper template files should be created. Use  ( <code>Shift+Enter</code> ) to select the folder in the <a href="#">corresponding dialog</a> .
Enable integration with browser navigation	Select this option to enable deep linking. Deep linking lets users navigate their interactions with the application by using the Back and Forward buttons in their browser.
Check Flash player version	If you select this option, the compiled application will check for the correct version of Flash Player.
Express install	If you select this option, the application will run an SWF file in the existing Flash Player to upgrade users to the latest version of the player.

Use this dialog to specify the settings for an ActionScript [class](#) or [interface](#) to be created. You can also create a new [package](#) if you specify the package that doesn't yet exist.

#### ItemDescription

Name	<p>Specify the name of the class or interface.</p> <p>When the cursor is in this field, you can use the <b>Up</b> and <b>Down</b> arrow keys to browse the contents of the <a href="#">Template list</a>.</p>
Package	<p>Specify the fully qualified name of the package in which the class or interface should be created. To do that, you can:</p> <ul style="list-style-type: none"> <li>– Select the package from the list.</li> <li>– Click <b>[...]</b> (<b>Shift+Enter</b>) and select the package in the Choose Destination Package dialog that opens.</li> <li>– Type in the field. To enable package name completion, press <b>Ctrl+Space</b>.</li> </ul> <p>This field may be left blank. In this case, the class or interface will be created in the default root package (usually corresponds to the <code>src</code> folder).</p> <p>If you type the name of a package that doesn't yet exist (the name in this case is shown red), the corresponding package will be created.</p> <p>You can create more than one package at once. For example, if you type <code>myPackage.mySubpackage</code> and none of these packages currently exists, both these packages (<code>myPackage</code> and <code>mySubpackage</code>) will be created.</p>
Template	<p>Select the <a href="#">file template</a> to be used.</p> <ul style="list-style-type: none"> <li>– Class. Select this template to create a class that doesn't extend another class or implement an interface.</li> <li>– Class with Supers. Select this template to create a class that extends another class and/or implements one or more interfaces.</li> <li>– Interface. Select this template to create an interface.</li> </ul> <p>To edit an existing file template or to create a new one, click <b>[...]</b> (<b>Shift+Enter</b>). The <a href="#">File Templates dialog</a> will open.</p> <p>If the selected template contains variables whose values are undefined, the Next button appears in the dialog instead of the Create button. In such a case, if you click Next, an additional dialog opens in which you can set the variable values. (This may happen if a <a href="#">custom template</a> that contains <a href="#">custom variables</a> is used.)</p> <p>See also, <a href="#">Predefined file template variables for ActionScript and Flex</a> and <a href="#">An example of creating a custom file template for an MXML component</a>.</p>
Superclass	<p>For the Class with Supers template: specify the class that the class you are creating should extend. To do that, you can:</p> <ul style="list-style-type: none"> <li>– Click <b>[...]</b> (<b>Shift+Enter</b>) and select the class in the Choose Superclass dialog that opens.</li> <li>– Type in the field. To enable class name completion, press <b>Ctrl+Space</b>.</li> </ul>
Interfaces	<p>For the Class with Supers template: specify the interface or interfaces that the class you are creating should implement.</p> <p>To add an interface to the list, point to &gt;&gt; and click <b>+</b> (<b>Alt+Insert</b>). Select the interface in the Choose Super Interface dialog that opens.</p> <p>To remove unnecessary interfaces from the list, select them and click <b>-</b> (<b>Alt+Delete</b>).</p>

Use this dialog to specify the settings for an [MXML component](#) to be created. You can also create a new package if you specify the package that doesn't yet exist.

#### ItemDescription

Name	<p>Specify the name of the component. This is the name of the <code>.mxml</code> file which will be created.</p> <p>When the cursor is in this field, you can use the <code>Up</code> and <code>Down</code> arrow keys to browse the contents of the <a href="#">Template list</a>.</p>
Package	<p>Specify the fully qualified name of the package in which the component should be created. To do that, you can:</p> <ul style="list-style-type: none"> <li>– Select the package from the list.</li> <li>– Click <code>[...]</code> (<code>Shift+Enter</code>) and select the package in the Choose Destination Package dialog that opens.</li> <li>– Type in the field. To enable package name completion, press <code>Ctrl+Space</code>.</li> </ul> <p>This field may be left blank. In this case, the component will be created in the default root package (usually corresponds to the <code>src</code> folder).</p> <p>If you type the name of a package that doesn't yet exist (the name in this case is shown red), the corresponding package will be created.</p> <p>You can create more than one package at once. For example, if you type <code>myPackage.mySubpackage</code> and none of these packages currently exists, both these packages (<code>myPackage</code> and <code>mySubpackage</code>) will be created.</p>
Template	<p>Select the <a href="#">file template</a> to be used.</p> <p>Initially, there is only one choice which is different depending on the Flex SDK version associated with the <a href="#">active build configuration</a> (MXML 4 Component for Flex SDK 4 or MXML 3 Component for Flex SDK 3).</p> <ul style="list-style-type: none"> <li>– Class. Select this template to create a class that doesn't extend another class or implement an interface.</li> <li>– Class with Supers. Select this template to create a class that extends another class and/or implements one or more interfaces.</li> <li>– Interface. Select this template to create an interface.</li> </ul> <p>To edit an existing file template or to create a new one, click <code>[...]</code> (<code>Shift+Enter</code>). The <a href="#">File Templates dialog</a> will open.</p> <p>If the selected template contains variables whose values are undefined, the Next button appears in the dialog instead of the Create button. In such a case, if you click Next, an additional dialog opens in which you can set the variable values. (This may happen if a <a href="#">custom template</a> that contains <a href="#">custom variables</a> is used.)</p> <p>See also, <a href="#">Predefined file template variables for ActionScript and Flex</a> and <a href="#">An example of creating a custom file template for an MXML component</a>.</p>
Parent component	<p>Specify a parent component for the component that you are creating. The parent component defines the root tag of the new MXML component, e.g. <code>&lt;s:Application&gt;</code>, <code>&lt;s:Module&gt;</code>, <code>&lt;s:ComboBox&gt;</code>.</p> <p>To specify the parent component, you can:</p> <ul style="list-style-type: none"> <li>– Click <code>[...]</code> (<code>Shift+Enter</code>) and select the component in the Choose Superclass dialog that opens.</li> <li>– Type in the field. To enable component name completion, press <code>Ctrl+Space</code>.</li> </ul>

Use this dialog to specify packaging options and to package your AIR applications (Desktop and Mobile) according to the specified options.

- [The upper part of the dialog](#)
- [Packaging options](#)

## The upper part of the dialog

Use the available checkboxes to select the [build configurations](#) for which you want to create the application packages.

Included in the list are the Desktop and Mobile-targeted build configurations whose output type is Application.

The build configurations are grouped by Flash modules.

## Packaging options

Select the packaging options for Desktop and Mobile (Android and iOS) applications, and click Package .

Note that the availabilities of the options depend on the selected build configurations and their settings (e.g. on whether packaging for Android and iOS is enabled in the selected Mobile-targeted build configurations).

### ItemDescription

---

Desktop application package	<p>Select one of the following:</p> <ul style="list-style-type: none"><li>- installer (*.air). Select this option to create a digitally-signed installer file or a number of such files (one for each of the selected Desktop-targeted build configurations).</li><li>- native installer. Select this option to create a <a href="#">native application installer</a> or a number of native installers for the operating system that you are using.</li><li>- captive runtime bundle. Select this option to create a <a href="#">captive runtime bundle</a> or a number of bundles for the operating system that you are using.</li><li>- unsigned package (*.airi). Select this option to create an unsigned AIR intermediate file or a number of such files.</li></ul>
Android package type (*.apk)	<p>Select one of the following <a href="#">target types for the Android package</a> or packages:</p> <ul style="list-style-type: none"><li>- release. For the AIR runtime to be packaged, select the Captive runtime option. See the discussion of the <a href="#">captive runtime</a> option.</li><li>- debug over USB port. If necessary, change the port suggested by IntelliJ IDEA.</li><li>- debug over network.</li></ul>
iOS package type (*.ipa)	<p>Select one of the following <a href="#">target types for the iOS package</a> or packages:</p> <ul style="list-style-type: none"><li>- test without debugging. If necessary, select the Fast packaging option. If this option is selected, the ActionScript bytecode is interpreted and not translated to machine code. As a result, packaging is performed faster but code execution is slower.</li></ul> <p>In technical terms, the <code>ipa-test-interpreter</code> target is used instead of <code>ipa-test</code> .</p> <p>See the discussion of the corresponding targets in <a href="#">Adobe AIR documentation</a> .</p> <ul style="list-style-type: none"><li>- debug over network. If necessary, select the Fast packaging option. (The <code>ipa-debug-interpreter</code> target will be used instead of <code>ipa-debug</code> .)</li><li>- ad hoc distribution.</li><li>- Apple App Store distribution.</li></ul>
Package	<p>Click this button to package your applications.</p>

Use this dialog to manage dependencies on runtime-loaded modules (RLMs). The RLMs are identified by their main classes.

To add a dependency, click  ( `Alt+Insert` ) and select the main class of the corresponding RLM in the Choose Main Class of Runtime-Loaded Module dialog that opens.

To optimize (reduce) the size of compiled RLM file, select the Optimize checkbox.

For more information, see the following table.

#### ItemDescription

 or <code>Alt+Insert</code>	Use this icon or shortcut to add a dependency. Select the main class of the corresponding RLM in the Choose Main Class of Runtime-Loaded Module dialog that opens.
 or <code>Alt+Delete</code>	Use this icon or shortcut to remove the selected RLMs from the list of dependencies.
Main Class	In this column, the fully qualified names of the main RLM classes are shown. To replace a class with a different one, click the corresponding field (table cell) and click  that appears in the field ( <code>Shift+Enter</code> ). Then select the necessary class in the Choose Main Class of Runtime-Loaded Module dialog that opens.
Output File	In this column, paths to RLM SWF files to be generated are shown (readonly). All the paths are relative to the build configuration output folder.
Optimize	Select the checkbox for the corresponding RLM SWF file size to be optimized (reduced).

This section provides important information that is common for all types of diagrams used in IntelliJ IDEA. A diagram enables you to visually explore the dependencies, navigation rules, relationships etc. for the various types of applications.

In this section:

- [Diagram Toolbar and Context Menu](#)
- [Diagram Preview](#)
- [General Techniques of Using Diagrams](#)
- [Class Diagram Toolbar, Context Menu and Legend](#)

In this section:

- [Toolbar](#)
- [Context menu](#)

## Toolbar

### ItemDescription

	Click this button to show primary key columns in diagram.
	Click this button to show columns in diagram.
	Click this button to increase the scale of the diagram. Alternatively, press <code>NumPad+</code> .
	Click this button to decrease the scale of the diagram. Alternatively, press <code>NumPad-</code> .
	Click this button to restore the actual size of the diagram.
	Click this button to make the contents fit into the current diagram size.
	Click this button to apply the current layout, selected on the context menu of the diagram.
	Click this button to save the current diagram in the specified location as <code>xml</code> file.
	Click this button to save the diagram in an image file with the specified name and path. The possible formats are: <code>jpeg</code> , <code>png</code> , <code>svg</code> , <code>svgz</code> , or <code>gif</code> .
	Click this button to print the diagram.
	Click this button to open the diagram preview in a separate frame, where you can configure the page layout, scale, and headings information.

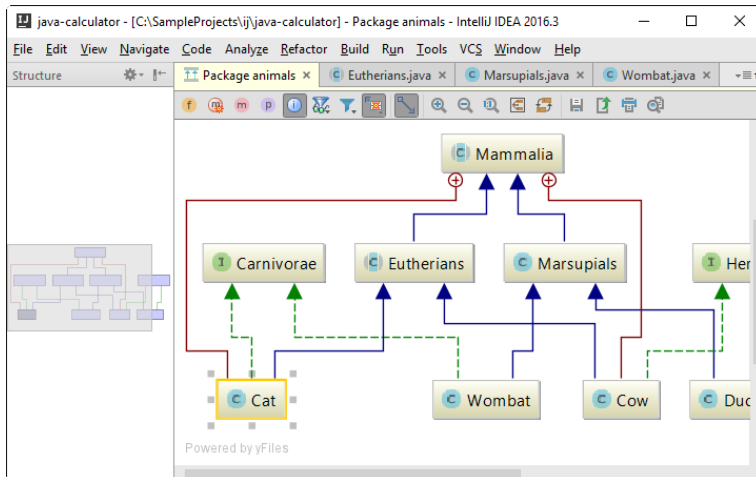

## Context menu

The table below contains commands that are not available from the toolbar.

### ItemDescription

New	Use this node to add new elements to a diagram.
Analyze	This node contains <a href="#">analysis</a> commands, enabled in the current context.
Refactor	This node contains refactoring commands, enabled in the current context.
Jump to Source	Choose this command to open the selected diagram node element in the editor.
Find Usages	Choose this command to <a href="#">search for usages</a> of the selected node element.
Layout	Select the desired diagram layout from the submenu.
Show Edge Labels	Check this command to show multiplicities in diagram.

Use the [Structure view](#) as a Preview, that allows you to get a "10,000-feet" look on a diagram. The shadow area represents the visible part of a diagram. As you zoom in or out, or change the shape of the IntelliJ IDEA windows, the size of the shadow area changes accordingly.

### To enable the diagram preview

- Open the Structure tool window.

### In the Preview pane, the following actions are available:

- Keeping the mouse button pressed, move the shadow area to obtain the desired view.
- Select one or more nodes in the diagram, and the corresponding nodes in the Preview are marked dark gray.

This section describes some general techniques applicable to the various types of diagrams (Hibernate and JPA ER diagrams, Seam navigation rules, Grails domain classes dependencies etc.)

In this section:

- [Selecting elements in diagram](#) .
- [Managing diagram layout](#) .
- [Zooming in and out](#) .
- [Using the magnifier tool](#) .
- [Navigating to source code](#) .
- [Invoking refactoring commands](#) .
- [Finding usages of the selected node element](#) .
- [Drawing links between node elements](#) .

## To select elements in diagram

- To select an element, just click it in diagram.
- To select multiple adjacent elements, keep **Shift** pressed and click the desired elements, or just drag a lasso around the elements to be selected.
- To select multiple non-adjacent elements, keep **Ctrl+Shift** pressed and click the desired elements.
- To select a member of a node element, double-click the node element, and then use the arrow keys, or the mouse pointer.

## To manage diagram layout

- Right-click the diagram background, and choose Layout command of the diagram context menu. Next, select the desired layout from the submenu.
- Use Drag-and-drop technique to lay out entities in diagram manually.
- Apply the current layout selected on the context menu of the diagram, by clicking  .

## To zoom in and out, do one of the following

- Use the  and  toolbar buttons.
- Keeping **Ctrl** key pressed, rotate your mouse wheel up or down.
- Press **NumPad+** or **NumPad-** .

**Tip** As you zoom in or out, the size of the shadow area in the diagram preview changes accordingly.

## To use the magnifier tool

- Keep the **Alt** key pressed, and hover your mouse pointer over the most interesting, or problematic areas of the diagram.

## To jump from an element in diagram to the underlying source code

1. Select an element in diagram.
2. Do one of the following:
  - On the context menu of the diagram, choose Jump to Source
  - Press **F4** .
  - Double-click selected element.

The source code of the corresponding source file opens in a separate tab in the editor.

## To draw a link between nodes

- Click the source node, and drag a link to the target node. This technique slightly differs for the various types of diagrams. Refer to the corresponding procedures for details.

In this section:

- [Toolbar](#)
- [Context Menu](#)
- [Legend of a Class Diagram](#)

## Toolbar

### ItemDescription

	Click this button to show methods in the class nodes.
	Click this button to show fields in the class nodes.
	Click this button to show constructors in the class nodes.
	Click this button to show properties in the class nodes.
	Click this button to show inner classes in the class nodes.
	Click this button to reveal the combo box, and select visibility level of the elements to be displayed in diagram.
	Click this button to reveal the combo box, and select the desired scope of elements to be displayed in diagram, for example, project or non-project files. The elements out of the selected scope will be hidden.
	Click this button to enable creating extends or implements links between node elements. If this button is not pressed, links cannot be drawn.
	Click this button to show dependencies of the selected class or package.
	Click this button to increase the scale of the diagram, or press <code>NumPad+</code> .
	Click this button to decrease the scale of the diagram, or press <code>NumPad-</code> .
	Click this button to restore the actual size of the diagram.
	Click this button to make the contents fit into the current diagram size.
	Click this button to apply the current layout, selected on the context menu of the diagram, or press <code>F5</code> .
	Click this button to save the current diagram as a <code>*.uml</code> file.
	Click this button to save the diagram in an image file with the specified name and path. The possible formats are: <code>jpeg</code> , <code>png</code> , <code>svg</code> , <code>svgz</code> , or <code>gif</code> .
	Click this button to print the diagram.
	Click this button to open the diagram preview in a separate frame, where you can configure the page layout, scale, and headings information.

## Context Menu

This section describes only those context menu commands that are not available from the toolbar.

### Item ShortcutDescription

Add class to diagram	<code>Space</code>	Choose this command to <a href="#">add existing class</a> to the diagram background.
Collapse nodes	<code>C</code>	Choose this command to show the containing package of the selected node.
Expand nodes	<code>E</code>	Choose this command to show class diagram of the selected package.
New	<code>Alt+Insert</code>	Choose this command to create a new node element or member.
Refactor		Point to this node to select one of the refactoring commands available in this context.
Analyze		Point to this node to select one of the code analysis commands available in this context.

## Legend of a Class Diagram

### ItemDescription

	The green arrow corresponds to the <code>implements</code> clause in a class declaration.
	The blue arrow corresponds to the <code>extends</code> clause in a class declaration .
	This sign appears for the inner classes.

This part provides miscellaneous information related to the GUI Designer, including the tour of the UI, properties reference and dialog descriptions:

- [Components of the GUI Designer](#)
- [Components Properties](#)
- [Components Treeview](#)
- [Data Binding Wizard](#)
- [Form Workspace](#)
- [Inspector](#)
- [Palette](#)
- [Add/Edit Palette Component](#)

The GUI Designer occupies the same space in the IntelliJ IDEA main window as the Editor. Each GUI form opens in a separate tab. (For information on how to create and open forms, see [Building GUI Forms](#) ). The GUI Designer consists of the following main components:

- [Components Treeview](#)
- [Properties Inspector](#)
- [Components Palette](#)
- [Form Workspace](#)

The gray shaded section of the [Inspector](#) provides a set of properties that are proprietary to the GUI Designer and used by its code generation and other processes.

When a component is added to a form, [it can be created as a component or as a container](#) . In the latter case, such component acquires certain properties that are specific to the containers only. In the tables below the properties that pertain to the containers are specially noted.

In this section you will find descriptions of the following groups of properties:

- [Code Binding Properties](#)
- [Component Sizing Properties](#)
- [Layout and Alignment Properties](#)
- [Other Properties](#)

Properties are layout-specific. Some of the properties can be missing for certain layout managers.

## Code Binding Properties

The properties covered in this section are related to binding of GUI forms and components to source code.

### PropertyDescription

bind to class	<p>This is a property of Forms only. It specifies the name of a class that contains the logic to make the form work. When this property is set to a valid class, we say the Form is <a href="#">bound to the class</a> .</p> <p>If no target class exists yet, you can still type in the name of this <i>future</i> class. IntelliJ IDEA will offer a Quick Fix to create a class of the specified name for you whenever the property is focused. You can use the Quick Fix to create the class whenever you are ready.</p> <p>See sections <a href="#">Binding Form to Existing Class</a> and <a href="#">Binding Form to a New Class</a> .</p>
field name	<p>This is a property of components. It specifies the name of the field in the parent form's class to which the component is bound. For most components, a default field name is automatically entered, and a corresponding declaration is written to the Form's bound source file. You can change the default field name in the Inspector if you wish, and the source will be updated automatically. You can optionally <a href="#">change the field name</a> in the source file, and the change will reflect in the Inspector when you return to the GUI Designer.</p>
Custom Create	<p>This is a property of components. If the option is checked, it means that you want to call a non-default constructor for the component, rather than have the GUI Designer generate a default constructor during the runtime build of the GUI. Code generation will ignore the component and assume you have written a constructor method. See <a href="#">Creating Form Initialization Code</a> .</p> <p>If a non-default constructor does not yet exist, IntelliJ IDEA will show you a Quick Fix whenever the Custom Create property is focused in the Inspector. You can use this to create the constructor in the source file bound to the parent Form.</p>

## Component Sizing Properties

The properties described in this section affect how components are sized at design time and/or runtime.

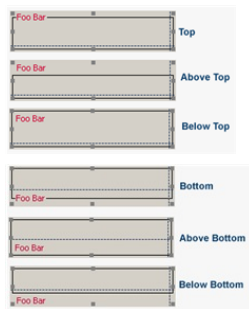

### PropertySubpropertyDescription

Horizontal Size Policy	These properties define how dimensions of a component are affected by resizing of its container along the horizontal axis and vertical axis respectively. This property applies to the <code>GridLayoutManager</code> (IntelliJ) and has the following subproperties:
Vertical Size Policy	
	<code>canShrink</code> The element size can be diminished (less than the preferred size) when the pane is resized.
	<code>canGrow</code> The element size can be enlarged when the pane is resized.
	<code>wantGrow</code> The element size is enlarged when the pane is resized. This flag takes precedence over <code>canGrow</code> .
	These options can be set simultaneously.
Same Size Horizontally	This is the property of a container that wraps the component. When the option is checked, all columns in the layout grid are always sized equally. Applicable only to the <code>GridLayoutManager</code> (IntelliJ).
Same Size Vertically	This is the property of a container that wraps the component. When the option is checked, all rows in the layout grid are always sized equally. Applicable only in the <code>GridLayoutManager</code> (IntelliJ).
Minimum Size	For the Swing layout managers, these properties are the same as in Java SDK.
Preferred Size	For the layout managers <code>GridLayoutManager</code> (IntelliJ) and <code>FormLayout</code> , these properties are different from those used in the Java SDK. To be more specific, they are not actual properties but a part of constraints with which a component is added to a container.
Maximum Size	Such feature enables you to set a size value only for 1 dimension.
	For instance, if you set Preferred Size values as <code>200; -1</code> - it means that the component height will be calculated dynamically and the width value will be used as the preferred size. In effect it is like the Java statement:
	<pre>getPreferredSize().height();</pre>

## Layout and Alignment Properties

The properties described in this section control various aspects of component layout and/or alignment.

### PropertySubpropertyDescription

Layout Manager		This is a property of container type components only (e.g. JPanel, JScrollPane). The setting controls which layout manager the container uses. The setting affects both design-time and runtime. Find the list of supported layout managers in the section <a href="#">GUI Designer Options</a> of the Settings dialog.
border		Defines how the component border and (optional) title will look. Applies to container type components only, and includes the following subproperties:
	type	Specifies the bevel characteristics of the element border. <ul style="list-style-type: none"><li>– None. No border. If <i>title</i> is specified, it will be hidden.</li><li>– Empty. No border properties specified.</li><li>– Bevel Lowered. Border bevel will make container look lowered.</li><li>– Bevel Raised. Border bevel will make container look raised.</li><li>– Etched. The container appears flat with an etched or 3D border.</li></ul>
	title	Optionally specify a string to appear as the container's title at runtime. You can enter a string literal directly in the edit field, or click the ellipsis button to open a dialog where you can either hardcode a string value, or specify the identifier of a resource.
	title justification	Controls how the text of <i>title</i> is justified. <ul style="list-style-type: none"><li>– Default. The justification is determined at compile-time.</li><li>– Left. Force left-justified text.</li><li>– Center. Force centered text.</li><li>– Right. Force right-justified text.</li><li>– Leading. For use with locales requiring leading justification.</li><li>– Trailing. For locales requiring trailing justification.</li></ul>
	title position	Controls where the title is positioned with respect to the container border. Horizontal position of the text is controlled by title justification setting. Default, Above Top, Top, Below Top, Above Bottom, Bottom, Below Bottom, as shown on the following images: 
	title font	Controls the font used for displaying the text of the title.
	title color	Controls the color of the font used for displaying the text of the title. The ellipsis button launches a color picker dialog, where you can choose a color from one of several palettes (AWT, Swing, System), or specify an RGB or HSB color value, or select a color from a graphical set of color Swatches.
margins		This property of JPanel controls the amount of spacing between the outer border of the container, and its contents. Applies to FormLayout and GridLayoutManager(IntelliJ).
	Top	Each attribute controls the spacing at the respective edge of the pane. The value of each attribute is an integer which specifies the number of pixels in the respective spacing. Zero means no space.
	Right	
	Bottom	
	Left	
Horizontal Gap		This is a property of JPanel only and has effect only when the pane uses a grid type layout manager such as the default GridLayoutManager. The property defines the pixel dimension of a space inset between the edge of a grid cell in the pane, and the edge of a contained component (a JRadiobutton, for example).
Vertical Gap		The default value is -1, which indicates the default spacing. You can enter zero or any positive integer value and see the result at design time.  For Vertical Gap to have any effect, the layout grid should have at least 2 rows.
Horizontal Align		This property determines the relative horizontal position of a component within its container. Select a value from the drop-down list: <ul style="list-style-type: none"><li>– Left. The left-hand edge of the component snaps to the left border of its container.</li><li>– Center. The component is centered horizontally within its container.</li><li>– Right. The right-hand edge of the component snaps to the right border of its container.</li></ul>

- Fill. The component fills its container's horizontal space entirely.

---

#### Vertical Align

This property determines the relative vertical position of a component within its container. Select a value from the drop-down list:

- Top. The top edge of the component snaps to the top border of its container.
- Center. The component is centered vertically within its container.
- Bottom. The bottom edge of the component snaps to the bottom border of its container.
- Fill. The component fills its container's vertical space entirely.

---

#### Indent

This property is only applicable for GridLayoutManager. Valid values are zero or any positive integer. The selected component is shifted to the right by the specified number of pixels times ten. For example, if you enter 12, the indent will be 120 pixels ( $12 * 10$ ).

---

#### Align Grid with Parent

This is a property of panes and applicable with grid type layout managers. When checked, it means that grid columns and rows in a child (nested) container always align with the rows and columns of the parent container. If not checked, the grid columns and rows of a child container may be aligned independently:

## Other Properties

This section describes other GUI Designer properties that are not classified any other way.

#### ItemDescription

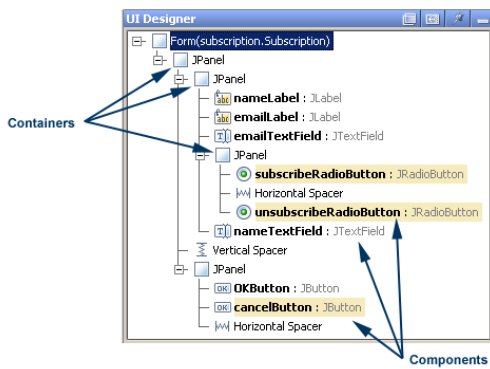

---

Client Properties	This is a property with configurable sub-properties. If you develop your own components, you can configure a Custom Property in the GUI Designer to support it. Refer to the section <a href="#">Customizing Client Properties</a> .
-------------------	--

This treewiew displays the components contained in the design form and enables you to navigate to and select one or more components. Selection of one or more components here is reflected in parallel on the design form and vice versa as shown in the following figure:

The treewiew hierarchy represents containment. Expandable nodes represent some type of container. Sub-nodes of containers represent UI components (including nested containers). The root node represents the Form, which is, in effect, the top-level container for the GUI you are building with the GUI Designer. When you create a new Form, a JPanel component is automatically added to the Form Workspace and it appears as a child of the Form in the Component Treewiew. This JPanel is the top of the UI component hierarchy (in the Java sense) for the current Form. All other Swing or other UI components are contained by it, as the next figure illustrates:

It is possible to move components from one container to another using drag-and-drop operation in the Component Treewiew:

---

Use this dialog box to generate `getData` and `setData` methods for the fields in a UI class that are bound to components in a GUI form.

---

**ItemDescription**

---

Page 1

Create new bean	Click this radio button to bind components to data in a new bean class. If this option is selected, specify the name of the new bean class, and the package where it will be created.
-----------------	---

Bind to existing bean	Click this radio button to bind components to data in an existing bean class. If this option is selected, specify the name of the desired bean class.
-----------------------	---

---

Page 2

Form Field	This column displays the list of components of the GUI Form that can be bound to data.
------------	--

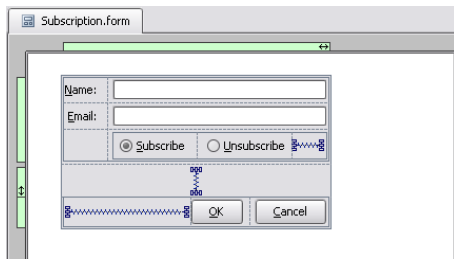

Bean Property	Use this column to specify the name of the bean property that will be created in the specified bean class.
---------------	--

<code>getData()</code>	If this option is checked, the method <code>getData()</code> is generated in the bound class of the GUI form.
------------------------	---

<code>setData()</code>	If this option is checked, the method <code>setData()</code> is generated in the bound class of the GUI form.
------------------------	---

<code>isModified()</code>	If this option is checked, the method <code>isModified()</code> is generated in the bound class of the GUI form.
---------------------------	--

The Form Workspace occupies the center part of the frame (assuming the default tool window layout and visibility). The background is white by default. When you create a new Form, a JPanel component is added to the workspace which appears as a gray rectangle. You can place components from the Component Palette into this container by first clicking on the component in the Palette, and then clicking within the pane in the Form Workspace. The form workspace has a [context menu](#) that provides access to the Clipboard, layout actions and more.

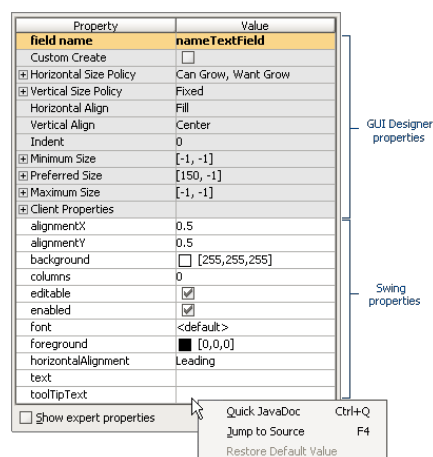

#### ItemDescription

Preview	Show the form as it should look at runtime. See <a href="#">Previewing Forms</a> .
Data Binding Wizard	Generate <code>getData()</code> , <code>isModified()</code> and <code>isModified()</code> methods for the fields bound to data. The corresponding class should already exist. See <a href="#">Generating Accessor Methods for Fields Bound to Data</a>
Cut, Copy, Paste	Perform usual Clipboard operations.
Pack	Choose this command to compress the current form to its minimal size, defined by the layout manager. This command is only available for the top level container in a form.
Show Grid	If this option is checked, the form displays grid lines.
Show Component Tags	This option toggles display of the name of a field associated with the selected component. This feature is available for the components that exceed certain pre-defined dimensions.
Create Component	Choose this command to display the list of available components and insert the selected one in the current location.
Jump to Source	Open the bound class in the editor, and place the caret to the field associated with the selected component. For the whole form, the caret rests at the class declaration.
Expand/Shrink Selection	Select successively increasing sets of components from the current one to its container. Compare to <a href="#">selecting text in the editor</a> .
Duplicate	Clone the selected component.
Morph Component	Create a component of a different type with the same properties. See <a href="#">Morphing Components</a> .
Create Listener	<a href="#">Create listener for the selected component</a> .
Go To Listener	<a href="#">Navigate to the source code of the selected listener.</a>
Surround With	Display the list of available containers, and place in one or more selected components into the container of your choice. See section <a href="#">Wrapping/Unwrapping Components</a>
Flatten	Unwrap components from a container. See section <a href="#">Wrapping/Unwrapping Components</a> .
Local history	Access the commands of the <a href="#">local version control</a> .
Add to Favorites	<a href="#">Add selected component to favorites</a> .

The Property Inspector window shows properties for the component currently selected in the form workspace, or the form itself if no components exist or none are selected.

In this section you will find information about the groups of properties, context menu commands, and types of editors.

The Inspector has two groups of properties, as shown in the following figure:

### ItemDescription

**Upper group** The shaded properties at the top of the Inspector are proprietary to IntelliJ IDEA; they are mainly used to control the layout constraints of the components for the given layout. These properties are layout-specific and depend on the layout of the container where the component is placed.

**Lower group** This group is not shaded and contains properties of the selected Swing component. There are two levels of properties: *Basic* and *Expert*. The Expert level can be toggled on and off using the Show Expert Properties checkbox in the bottom line of the Inspector. Refer to [Sun documentation for the Swing libraries](#).

The context menu of each property provides the following commands:

### ItemKeyboardDescription

#### Shortcut

Quick Javadoc	<input type="checkbox"/> <b>Ctrl+Q</b>	Opens related API documentation for the selected property, provided that the necessary paths are added to the API docs in the Project Settings.
Jump to Source	<input type="checkbox"/> <b>F4</b>	Opens in the editor the source code of the class that contains the selected property.
Restore Default Value		This command is enabled for the modified properties only.

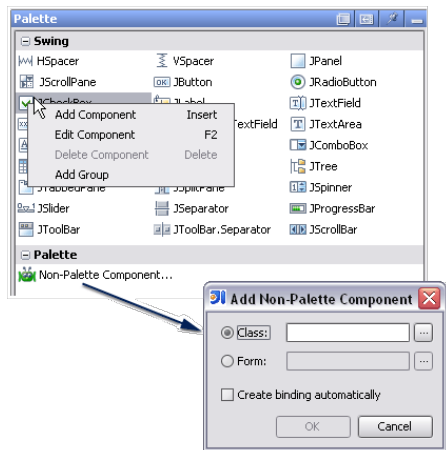

Several types of property editors appear in the Value column of the inspector:

- Text field : Type a value.
- Pick list : Pick a value from a drop-down list of valid choices.
- Checkbox : Set value for Boolean type properties.
- Dialog : Presents an ellipsis button which opens a dialog box.

The Component Palette is a tool window which appears by default at the right side of the frame next to the Form Workspace. It contains UI components which you can visually place on a Form. The default Group of the Palette contains a set of Swing user interface components that you can arrange on forms as needed. The Swing group also has horizontal and vertical Spacers that you can place on the form to define space between components. (These can behave differently depending on the setting in the Layout Manager property of the container into which a spacer is placed.) You can customize the Component Palette to contain additional groups, and your own and/or third-party GUI components (see [Customizing the Palette](#) ).

The context menu of the Palette tool window provides functions for managing components and groupings. Two groups are present by default:

- Swing : contains components from the Swing component library.
- Palette : contains a single component labeled *Non-Palette component* . When you select this *component* and add it to a Form, a dialog appears in which you can select any component class accessible to your project, or any other existing Form. This is useful in cases where you want to use a component without adding it to the Component Palette.

If you have your own custom components, or if you reuse components from third-party libraries, you can add them to the Component Palette via the context menu, which also enables you to add component groups. For more information, see [Customizing the Component Palette](#) .

Use this dialog to create a new component in the [Palette](#) , or change an existing one.

**ItemDescription**

**Class** Click this radio-button to add a component from a class library. You can enter a fully qualified class name in the text field, or click the ellipsis button, and select the desired class from the libraries, or project. Note that code completion is available in the text field.

**Form** Click this radio-button to add an existing GUI form. You can enter a fully qualified form name in the text field, or click the ellipsis button, and select the desired form from the libraries, or project.

**Icon** Specify the fully-qualified name of the icon file, or click the ellipsis button, and select the desired icon file from the libraries, or project.

**Group** Select the target group where the new component will be added.

**Tip** This field is available for the Add Component dialog only.

**Horizontal / Vertical Size Policy** The sizing policies define the behavior of the component, when its parent container is being resized.

**Can shrink** If this option is checked, the size of the component can reduce, when the container is resized.

**Can grow** If this option is checked, the size of the component can increase, when the container is resized.

**Want grow** If this option is checked, the size of the component can increase, when the container is resized. This option has a higher priority, when competing with the cells of the other components.

**Is container** If this option is checked, the component can accommodate nested components, and acquires some properties that pertain to the containers.

**Create binding automatically** If this option is checked, the field for the component is automatically added to the [bound class](#) .

**Can have attached label** If this option is checked, the component of this type appears in the `labelFor` field of a `JLabel` component in the [Inspector](#) . It is important to note that Can have attached label option affects all components of this type on a GUI form. For example, if you check this option for `JButton` and `JCheckBox` Palette components, all instances of these components (already existing and newly added) appear in the `labelFor` field:

- File Types Recognized by IntelliJ IDEA
- Symbols

IntelliJ IDEA recognizes numerous file types. Each file type is denoted with a special icon. Custom files types are also allowed. Each file type is associated with one or more extensions that match a certain pattern.

The file types and their extensions are configurable in the [File Types](#) dialog.

**Note** "Recognized" does not mean "supported with extensive support". For example, `.php` files are recognized in the Community Edition and marked with the corresponding icon, although the edition does not provide PHP development support.

**Note** The file recognized types depend on the installed plugins.

The default types include:

File Type	Icon	Recognized in
<a href="#">ActionScript files</a>		Ultimate Edition
Active Server Pages files		Ultimate Edition
<a href="#">Android files</a>		Ultimate Edition: all Android-related file types; Community Edition: Android IDL files, Android renderscript files

## Common

### IconDescription

	Class
	Abstract class
	Groovy class
	Annotation
	Enumeration
	Exception
	Final Java class
	Interface
	Java class that contains declaration of the <code>main()</code> method.
	Test case
	Java class located out of the source root. Refer to the section <a href="#">Configuring projects</a> for details.
	Java class <a href="#">excluded from compilation</a> .
	<a href="#">PHP trait</a>
	Method
	Abstract method
	Field
	Variable
	Property
	Parameter
	Element
	Directory
	Module
	Group of modules
	Package
	<a href="#">Source root</a>
	<a href="#">Test root</a>
	<a href="#">Excluded root</a>
	<a href="#">Resources</a>
	<a href="#">Test resources</a>
	<a href="#">Generated source roots</a>
	<a href="#">Generated test source roots</a>

### Visibility modifiers

	Read-only class, e.g. from a jar of an external library.
	private
	protected
	package protected
	static
	public

## Data Sources

### IconDescription

	DB data source. Also, DBMS-specific icons are used: <ul style="list-style-type: none"><li>-  <a href="#">Amazon Redshift</a></li><li>-  <a href="#">DB2</a></li><li>-  <a href="#">Derby</a></li><li>-  <a href="#">H2</a></li><li>-  <a href="#">HSQLDB</a></li><li>-  <a href="#">Microsoft Azure</a></li><li>-  <a href="#">MySQL</a></li><li>-  <a href="#">Oracle</a></li></ul>
---	--

-  PostgreSQL
-  SQL Server
-  SQLite
-  Sybase

	DB data source with the read-only status, e.g.  for Derby.
	DDL data source
	Database
	Schema
	Table
	View
	Column
	A <code>NOT NULL</code> column
	Column with a primary key
	Column with a foreign key
	Column with an index
	Primary key
	Foreign key
	Index
	Trigger
	Stored procedure or function

This section provides a brief summary of regexp syntax that can be helpful for creating search and issue navigation patterns.

## RegEx syntax reference

### CharacterDescription

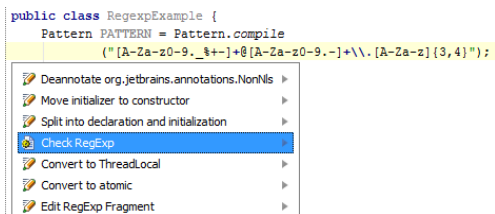

<code>\</code>	Marks the next character as either a special character or a literal. For example: <ul style="list-style-type: none"><li>- <code>n</code> matches the character <code>n</code>. <code>"n"</code> matches a newline character.</li><li>- The sequence <code>\\</code> matches <code>\</code> and <code>\(</code> matches <code>(</code>.</li></ul>
<code>^</code>	Matches the beginning of input.
<code>\$</code>	Matches the end of input.
<code>*</code>	Matches the preceding character zero or more times. For example, <code>"zo*"</code> matches either <code>z</code> or <code>zoo</code> .
<code>+</code>	Matches the preceding character one or more times. For example, <code>"zo+"</code> matches <code>zoo</code> but not <code>z</code> .
<code>?</code>	Matches the preceding character zero or one time. For example, <code>a?ve?</code> matches the <code>ve</code> in <code>never</code> .
<code>.</code>	Matches any single character except a newline character.
<code>( subexpression )</code>	Matches <i>subexpression</i> and remembers the match. If a part of a regular expression is enclosed in parentheses, that part of the regular expression is grouped together. Thus a regex operator can be applied to the entire group. <ul style="list-style-type: none"><li>- If you need to use the matched substring within the same regular expression, you can retrieve it using the backreference <code>( \num )</code>, where <code>num = 1..n</code>.</li><li>- If you need to refer the matched substring somewhere outside the current regular expression (for example, in another regular expression as a replacement string), you can retrieve it using the dollar sign <code>( \$num )</code>, where <code>num = 1..n</code>.</li><li>- If you need to include the parentheses characters into a <i>subexpression</i>, use <code>\(</code> or <code>\)</code>.</li></ul>
<code>x   y</code>	Matches either <code>x</code> or <code>y</code> . For example, <code>z wood</code> matches <code>z</code> or <code>wood</code> . <code>(z w)oo</code> matches <code>zoo</code> or <code>wood</code> .
<code>{ n }</code>	<code>n</code> is a nonnegative integer. Matches <b>exactly</b> <code>n</code> times. For example, <code>o{2}</code> does not match the <code>o</code> in <code>Bob</code> , but matches the first two <code>o</code> 's in <code>foooood</code> .
<code>{ n , }</code>	<code>n</code> is a nonnegative integer. Matches <b>at least</b> <code>n</code> times. For example, <code>o{2,}</code> does not match the <code>o</code> in <code>Bob</code> and matches all the <code>o</code> 's in <code>foooood</code> .  <code>o{1,}</code> is equivalent to <code>o+</code> . <code>o{0,}</code> is equivalent to <code>o*</code> .
<code>{ n , m }</code>	<code>m</code> and <code>n</code> are nonnegative integers. Matches <b>at least</b> <code>n</code> and <b>at most</b> <code>m</code> times. For example, <code>o{1,3}</code> matches the first three <code>o</code> 's in <code>foooood</code> . <code>o{0,1}</code> is equivalent to <code>o?</code> .
<code>[ xyz ]</code>	A character set. Matches any one of the enclosed characters. For example, <code>[abc]</code> matches the <code>a</code> in <code>plain</code> .
<code>[^ xyz ]</code>	A negative character set. Matches any character not enclosed. For example, <code>[^abc]</code> matches the <code>p</code> in <code>plain</code> .
<code>[ a-z ]</code>	A range of characters. Matches any character in the specified range. For example, <code>"[a-z]"</code> matches any lowercase alphabetic character in the range <code>a</code> through <code>z</code> .
<code>[^ m-z ]</code>	A negative range characters. Matches any character not in the specified range. For example, <code>[^m-z]</code> matches any character not in the range <code>m</code> through <code>z</code> .
<code>\b</code>	Matches a word boundary, that is, the position between a word and a space. For example, <code>er\b</code> matches the <code>er</code> in <code>never</code> but not the <code>er</code> in <code>verb</code> .
<code>\B</code>	Matches a non-word boundary. <code>ea*r\b</code> matches the <code>ear</code> in <code>never early</code> .
<code>\d</code>	Matches a digit character. Equivalent to <code>[0-9]</code> .
<code>\D</code>	Matches a non-digit character. Equivalent to <code>[^0-9]</code> .
<code>\f</code>	Matches a form-feed character.
<code>\n</code>	Matches a newline character.
<code>\r</code>	Matches a carriage return character.
<code>\s</code>	Matches any white space including space, tab, form-feed, etc. Equivalent to <code>[ \f\n\r\t\v ]</code> .
<code>\S</code>	Matches any nonwhite space character. Equivalent to <code>[ ^\f\n\r\t\v ]</code> .
<code>\t</code>	Matches a tab character.
<code>\v</code>	Matches a vertical tab character.
<code>\w</code>	Matches any word character including underscore. Equivalent to <code>[A-Za-z0-9_]</code> .
<code>\W</code>	Matches any non-word character. Equivalent to <code>[^A-Za-z0-9_]</code> .
<code>\ num</code>	Matches <code>num</code> , where <code>num</code> is a positive integer, denoting a reference back to remembered matches. For example, <code>(.)1</code> matches two consecutive identical characters.
<code>\ n</code>	Matches <code>n</code> , where <code>n</code> is an octal escape value. Octal escape values should be 1, 2, or 3 digits long. For example, <code>\11</code> and <code>\011</code> both match a tab character.  <code>\0011</code> is the equivalent of <code>\001</code> & <code>1</code> .  Octal escape values should not exceed 256. If they do, only the first two digits comprise the expression. Allows ASCII codes to be used in regular expressions.

<code>\x n</code>	Matches <i>n</i> , where <i>n</i> is a hexadecimal escape value. Hexadecimal escape values must be exactly two digits long. For example, <code>\x41</code> matches <code>A</code> . <code>\x041</code> is equivalent to <code>\x04 &amp; 1</code> .  Allows ASCII codes to be used in regular expressions.
<code>\\\$</code>	Escapes <code>\$</code> .
<code>\l</code>	Changes the case of the next character to the lower case.
<code>\u</code>	Changes the case of the next character to the upper case.
<code>\L</code>	Changes the case of all the subsequent characters up to <code>\E</code> to the lower case.
<code>\U</code>	Changes the case of all the subsequent characters up to <code>\E</code> to the upper case.

## Tips and Tricks

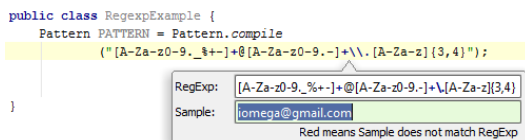

IntelliJ IDEA provides intention actions to check validity of the regular expressions, and edit regular expressions in a scratchpad. Place the caret at a regular expression, and press `Alt+Enter`. The suggestion list of intention actions, available in this context, appears:

```
public class RegexpExample {
    Pattern PATTERN = Pattern.compile
        ("[A-Za-z0-9._%+]+@[A-Za-z0-9.-]+\.[A-Za-z]{3,4}");
}
```

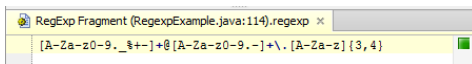

- Choose `Check RegExp`, and press `Enter`. The dialog box that pops up, shows the current regular expression in the upper pane. In the lower pane, type the string to which this expression should match. If the regular expression matches the entered string, the background becomes green. If the regular expression doesn't match, then the background is red.

```
public class RegexpExample {
    Pattern PATTERN = Pattern.compile
        ("[A-Za-z0-9._%+]+@[A-Za-z0-9.-]+\.[A-Za-z]{3,4}");
}
```

- Choose `Edit RegExp Fragment`, and press `Enter`. The regular expression opens for editing in a separate tab in the editor. However, this is but a scratchpad, and no file is physically created:

As you type in the scratchpad, all changes are synchronized with the original regular expression. Press `Escape` to close the editor tab.

The **scopes language** is used in specifying project **scopes** involved in the various kinds of analysis.

## Sets of classes

- Single class is defined by a class name, i.e. `com.intellij.openapi.MyClass`
- Set of all classes in a package, not recursing into subpackages, is defined by an asterisk after dot, for example:  
`com.intellij.openapi.*`
- Set of all classes in a package including contents of subpackages, is defined by an asterisk after double dot, for example  
`com.intellij.openapi..*`

## Sets of files

- Single file is defined by a file name, i.e. `MyDir/MyFile.txt`
- Set of all files in a directory, not recursing into subdirectories, is defined by an asterisk after slash, for example:  
`file:src/main/myDir/*`
- Set of all files in a directory including contents of subdirectories, is defined by an asterisk after double slash, for example  
`file:src/main/myDir/**`

## Modifiers

### Location modifiers

help you specify whether the desired set is located in the source files, library classes or test code in the form of location modifiers `src:`, `lib:`, `file:`, or `test:`.

For example, the following scope

```
src:com.intellij.openapi.*
```

implies all classes under the source root in the `com.intellij.openapi` package, excluding subpackages.

The default location is the module root.

### Module modifiers

help you narrow down the scope by specifying the name of the related module in one of the following ways:

```
src[module name]:<E>
lib[module name]:<E>
test[module name]:<E>
```

For example, the following scope

```
src[MyModule]:com.intellij.openapi.*
```

implies all classes under the source folders related to the module `MyModule` in the package `com.intellij.openapi`, excluding subpackages.

### Group modifier

help you narrow down the scope by specifying the name of the related module group (several modules can be joined into a group in the [Project Structure dialog](#)).

The group modifier has the following format:

```
[group:<group name>]
```

For example, the following scope

```
file[group:mygroup]:**/*
```

denotes a scope of all files in the group of modules with the specified name.

## Logical operators

The scope language allows you to use common logical operators:

&& for AND  
|| for OR  
! for NOT

Besides that, the parentheses can be used to join the logical operators into groups. For example, the following scope

```
(<a>||<b>)&&<c>
```

implies either <a> and <c>, or <b> and <c>.

Another example

```
file[*web*]:src/main/java/**
```

denotes a scope of all modules whose name contains `web`, and all the files recursively in the directory `src/main/java`.

## Defining scopes

Scopes are defined in the [Scopes](#) dialog box in the following ways:

- Manually
- With the pointing device

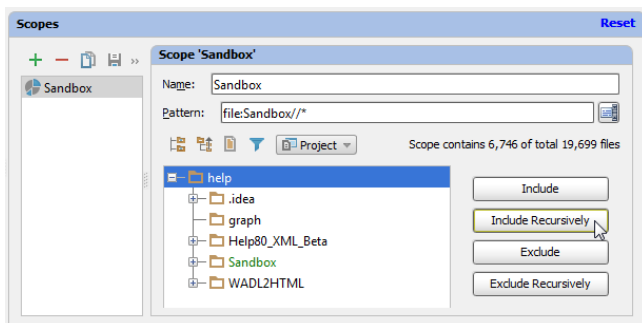

Manually

Specify file masks in the Pattern text box, or click  and type the pattern in the editor.

Using the Mouse Pointer

Select files and folders in the project tree view and click the buttons Include, Include Recursively, Exclude, and Exclude Recursively. For information about the controls, refer to [Scope](#) page description.

Based on the inclusion/exclusion of file and directories, IntelliJ IDEA creates an expression and displays it in the Pattern field.

## Examples

- `file[MyMod]:src/main/java/com/example/my_package/**` - include in a project all the files from module "MyMod", located in the specified directory and all subdirectories.
- `src[MyMod]:com.example.my_package.*` - recursively include all classes in a package in the source directories of the module.
- `lib:com.company.*|com.company.*` - recursively include all classes in a package from both project and libraries.
- `test:com.company.*` - include all test classes in a package, but not in subpackages.
- `[MyMod]:com.company.util.*` - include all classes and test classes in the package of the specified module.
- `file:*.js||file:*.coffee` - include all JavaScript and CoffeeScript files.
- `file:*js&&!file:*.min.*` - include all JavaScript files except those that were generated through **minification**, which is indicated by the `min` extension.

IntelliJ IDEA menu structure doesn't align with IntelliJ IDEA help structure. This page lists IntelliJ IDEA menu items, linked to the corresponding help topics.

**Warning!** – This table corresponds to the Windows and Linux platforms. Commands specific for macOS have special notes.  
– Any additional plugins and external tools make changes to the main menu.

## File

**Menu Keyboard Description**  
**item shortcut**

New...	Project	Use this command to <a href="#">create a new project</a> .
	Project from Existing Source	Use this command to <a href="#">create a new project from existing source</a> .
	Project from Version Control	Use this command to check out a project from a version control system.
	Module	Use this command to add a new module to an existing project.
	Module from Existing Sources	Use this command to create a <a href="#">new module</a> from existing sources.
	<File type>	Use this command to <a href="#">create a new element in a project</a> .
Open...	Use this command to open the specified directory, or an existing IntelliJ IDEA project. A directory that contains a project is marked with  icon. This command is duplicated with  icon on the main toolbar.	
Open Recent	Use this command to open one of the recent projects.	
Close Project	Use this command to close the current project .	
Settings... (on Windows/*NIX)/IntelliJ IDEA Preferences (on macOS)		Use this command to change the project and IDE configurations in the <a href="#">Settings/Preferences dialog</a> . See also the section <a href="#">Configuring Project and IDE Settings</a> . This command is duplicated with  icon on the main toolbar.  This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu and has the name Preferences .
Project Structure		Use this command to open the Project Structure dialog to configure SDKs, libraries, content roots, etc.
Other Settings	Point to this node to reveal the submenu of the default configuration commands (Default Settings, Configure Plugins, Default Project Structure)	
Import Settings...	Choose this command to <a href="#">import settings from an archive</a> .	
Export Settings...	Choose this command to <a href="#">export settings to an archive</a> .	
Export to Eclipse	Choose this command to invoke <a href="#">Export to Eclipse Dialog</a> . As a result, two Eclipse files  are added to the exported project: <code>.classpath</code> and <code>.project</code> .  If in <a href="#">Export to Eclipse Dialog</a> the checkbox Switch selected module to Eclipse-compatible format is selected, the file <code>&lt;module name&gt;.eml</code> is created.  If in <a href="#">Export to Eclipse Dialog</a> the checkbox Export non-module libraries is selected, the file <code>&lt;module name&gt;.userlibraries</code> is created.  Refer to the section <a href="#">Exporting an IntelliJ IDEA Project to Eclipse</a> for details.	
Settings Repository...	Choose this command to invoke the <a href="#">Settings Repository</a> dialog.	

Save All		Choose this command to <a href="#">save all changes</a> , when editing is over. This command is duplicated with  icon on the main toolbar.
Synchronize		Choose this command to check the IntelliJ IDEA caches and bring them up-to-date by keeping in sync with external changes. This command is duplicated with  icon on the main toolbar.
Invalidate Caches/Restart...		Choose this command to clean the system cache .
Export to HTML...		Use this command results to <a href="#">save selected files in HTML format</a> .
Print...		Choose this command to print selected file on the default printer. Refer to the <a href="#">Print dialog</a> description.
Add to Favorites		Use this command to <a href="#">add the selected files to the list of Favorites</a> . Click the right arrow to select the list of favorites you want to be modified. Refer to the description of the <a href="#">Favorites tool window</a> .
File Encoding		Use this command to <a href="#">change encoding of an individual file</a> . See also the section <a href="#">Encoding</a> .
Line Separators		Use this command to select the desired line separator style. Refer to the section <a href="#">Configuring Line Separators</a> .
Make File Read-Only / Make File Writable		Use these toggle commands to change read-only status of a file selected in the Project tool window, or currently active in the editor. If a file is made read-only, it is marked with  , and doesn't allow editing. You can also toggle read-only attribute of a file in the <a href="#">Status bar</a> .
Power Save Mode		Use this mode if you are working with a laptop. If Power-Save mode is on, then the background processes are turned off, to minimize the power consumption. You can also turn this mode on or off by clicking  in the <a href="#">Status bar</a> .
Exit		Choose this command to quit IntelliJ IDEA. This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu and has the name Quit IntelliJ IDEA .

## Edit

### MenuKeyboardDescription item shortcut

Undo <action>		Use this command to <a href="#">roll actions back</a> . This command is duplicated with  icon on the main toolbar.
Redo <action>		Use this command to <a href="#">repeat the last actions</a> . This command is duplicated with  icon on the main toolbar.
Cut		Choose this command to take the selected characters to the clipboard and delete them. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> . This command is duplicated with  icon on the main toolbar.
Copy		Choose this command to take the selected characters to the clipboard. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> . This command is duplicated with  icon on the main toolbar.
Copy Path		Choose this command to take the path to the selected symbol to the clipboard. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> .
Copy as Plain Text		Choose this command to take the selected fragment to the clipboard without formatting. Refer to the section <a href="#">Settings/Preferences   Editor   General</a> .
Copy Relative Path		Choose this command to take a reference to a symbol to the clipboard. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> .
Paste		Choose this command to place the latest entry from the Clipboard at the insertion point. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> . This command is duplicated with  icon on the main toolbar.
Paste from History...		Choose this command to place at the insertion point the selected entry from the Clipboard. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> .
Paste Simple		Choose this command to place the last entry from the Clipboard at the insertion point as plain text. Refer to the section <a href="#">Cutting, Copying, and Pasting</a> .
Delete		Choose this command to delete the selected files, or folder from the project tool window, or selected fragment of text from the active editor.
Find		Point to this node to reveal the sub-menu of search commands:  Find/Replace  /  <a href="#">Find or replace text in a current file</a> . These commands are duplicated by  and  icons on the main toolbar.

Find Next/Find Previous (Move to Next/Previous Occurrence)	F3 / Shift+F3	Use these commands to navigate through the search results in a file. See <a href="#">Finding and replacing text in a file</a> .
Find Word at Caret	Ctrl+F3	Use this command to jump to the next occurrence of the word where the caret rests. See <a href="#">Finding and replacing text in a file</a> .
Select All Occurrences	Ctrl+Shift+Alt+J	Use this command to find and select all the occurrences of an item.
Add Selection for Next Occurrence	Alt+J	Use this command to select the next occurrence of an item.
Unselect Occurrence	Shift+Alt+J	Use this command to remove selection from the last selected occurrence of an item.
Find in Path/Replace in Path	Ctrl+Shift+F / Ctrl+Shift+R	Use these commands to search for, and replace a text fragment in a whole project. Refer to the section <a href="#">Finding and Replacing text in Project</a> .
Search/Replace Structurally		Use these commands to perform structural search or replace. Refer to the section <a href="#">Structural Search and Replace</a> for details.
Find Usages	Alt+F7	Use this command to search for the usages of a symbol across an entire project. Refer to the section <a href="#">Finding Usages in Project</a> .
Find Usages Settings	Ctrl+Shift+Alt+F7	Use this command to search for the usages of a symbol across an entire project, after setting the desired search options. Refer to the section <a href="#">Finding Usages in Project</a> .
Show Usages	Ctrl+Alt+F7	Use this command to bring up a list of the usages of a symbol across the whole project. Refer to the section <a href="#">Viewing Usages of a Symbol</a> .
Find Usages in a File	Ctrl+F7	Refer to the section <a href="#">Finding Usages in the Current File</a> .
Highlight Usages in a File	Ctrl+Shift+F7	Use this command to visualize usage of a symbol in the current file. Refer to the section <a href="#">Highlighting Usages</a> .
Recent Find Usages	Ctrl+E	Choose this command to view the recent search results. Refer to <a href="#">Viewing Recent Find Usages</a> .
Evaluate XPath...	Ctrl+Alt+X, E	Use this command to <a href="#">evaluate an XPath expression</a> . Refer to <a href="#">XPath and XSLT Support</a> .
Find by XPath...	Ctrl+Alt+X, F	Use this command to find occurrences of certain XPath expressions in all XML files in a specific scope. Refer to <a href="#">XPath and XSLT Support</a> .

Macros		Point to this node to reveal the sub-menu of the macros-related commands. Refer to the section <a href="#">Using Macros in the Editor</a> .
Column Selection Mode	Shift+Alt+Insert	Use this command to toggle between column selection and line selection modes. Refer to the section <a href="#">Selecting Text in the Editor</a> .
Select All	Ctrl+A	Choose this command to select all contents of the current file. Refer to the section <a href="#">Selecting Text in the Editor</a> .
Extend Selection	Ctrl+W	Choose this command to select the current word. Use this command successively to extend selection. Refer to the section <a href="#">Selecting Text in the Editor</a> .
Shrink Selection	Ctrl+Shift+W	Choose this command to unselect the currently selected word. Use this command successively to shrink selection. Refer to the section <a href="#">Selecting Text in the Editor</a> .
Join Lines	Ctrl+Shift+J	Choose this command to <a href="#">join lines or literals</a> .
Fill Paragraph		Choose this command to create soft wraps in a paragraph.
Duplicate Lines	Ctrl+D	Choose this command to duplicate a line or fragment of text. Refer to <a href="#">Adding, Deleting and Moving Code Elements</a> .
Indent Selection/Unindent Selection	Tab / Shift+Tab	Choose this command to change indentation of the line at caret. Refer to the section <a href="#">Changing Indentation</a> .

Toggle Case	<b>Ctrl+Shift+U</b>	Choose this command to change case of the selection. See <a href="#">Toggling Case</a> .
Convert Indents		Point to this node to reveal the sub-menu of the possible indentation and toggle indentation style. Refer to <a href="#">Changing Indentation</a> .
Encode XML/HTML Special Characters		Choose this command to convert the selected special character to its HTML name in the format <code>&amp;char;</code> .
Edit as Table		Choose this command to invoke the <a href="#">table editor</a> for the current documents.

## View

### MenuKeyboardDescription item shortcut

Tool Windows		Point to this node to reveal the list of the available tool windows. Refer to the section <a href="#">Manipulating the Tool Windows</a> .
Quick Definition	<b>Ctrl+Shift+I</b>	Choose this command to open the quick definition popup. Refer to the section <a href="#">Viewing Definition</a> .
Quick Documentation	<b>Ctrl+Q</b>	Choose this command to <a href="#">view quick documentation</a> popup window.
Show Bytecode		Choose this command to show the byte code of the current <code>.java</code> class in the Byte Code Viewer popup window.
Parameter Info	<b>Ctrl+P</b>	Choose this command to <a href="#">view method parameter information</a> .
Context Info	<b>Alt+Q</b>	Choose this command to <a href="#">show the current cursor position</a> , if it runs out of the visible editor pane.
Jump to Source	<b>F4</b>	Choose this command to edit a file selected in a tool window. The file opens in the editor.
Recent Files	<b>Ctrl+E</b>	Choose this command to show the pop-up list of <a href="#">recently opened files</a> and tool windows, and navigate to them.
Recently Changed Files	<b>Ctrl+Shift+E</b>	Choose this command to show the pop-up list of <a href="#">recently changed files and navigate to them</a> .
Recent Changes	<b>Shift+Alt+C</b>	Choose this command to open the pop-up list of <a href="#">recent changes</a> .
Compare with Clipboard		Choose this command to compare the file currently opened in the editor with the contents of the system clipboard. See <a href="#">Comparing Files</a> .
Quick Switch Scheme	<b>Ctrl+Back Quote</b>	Choose this command to <a href="#">switch between schemes</a> .
Toolbar		Select or clear this check command to show or hide the <a href="#">main toolbar</a> .
Tool Buttons		Select or clear this check command to show or hide the <a href="#">tool window buttons</a> .
Status Bar		Select or clear this check command to show or hide the <a href="#">Status toolbar</a> .
Navigation Bar		Select or clear this check command to show or hide the <a href="#">Navigation bar</a> .
Active Editor		Point to this node to reveal the list of nested check commands. These commands apply to the <a href="#">active editor</a> and is only available when it exists.
	Show Whitespaces	Select or clear this check command to show or hide the whitespaces in the text.
	Show Line Numbers	Select or clear this check command to show or hide line numbers.
	Show Gutter	Select or clear this check command to show or hide the icons in the left gutter.
	Icons Show Indent	Select or clear this check command to show or hide vertical indent markers.
	Guides Use Soft Wraps	Select or clear this check command to show or hide soft wrap markers in the text.
	Show Import Popups	Select or clear this check command to show or hide import popups.
BiDi Text Direction		Point to this node to select the direction of text in the string literals containing RTL strings and tokens. Refer to the page <a href="#">Text Direction</a> .
Enter/Exit Presentation Mode		Choose this command to <a href="#">enter or exit presentation mode</a> .
Enter/Exit Distraction Free Mode		Choose this command to <a href="#">enter or exit distraction-free mode</a> .

## Navigate

### MenuKeyboardDescription

#### item shortcut

Class/File/Symbol	<a href="#">Ctrl+N</a> / <a href="#">Ctrl+Shift+N</a> <a href="#">Ctrl+Shift+Alt+N</a>	Choose these commands to find and jump to a <a href="#">class, file, or symbol by name</a> .
Custom Folding...	<a href="#">Ctrl+Alt+Period</a>	Choose this command to <a href="#">navigate between custom regions</a> .
Line...	<a href="#">Ctrl+G</a>	Choose this command to <a href="#">navigate to the specified line of code</a> .
Back/Forward	<a href="#">Ctrl+Alt+Left</a> / <a href="#">Ctrl+Alt+Right</a>	Choose these commands to <a href="#">go through the history of the recently navigated items</a> . These commands are duplicated with <a href="#">↶</a> and <a href="#">↷</a> buttons on the main toolbar.
Last/Next Edit Location	<a href="#">Ctrl+Shift+Backspace</a>	Choose these commands to jump to the <a href="#">latest edit location</a> and back.
Bookmarks		Point to this node to reveal the sub-menu of commands related to <a href="#">using bookmarks</a> .
Select In...	<a href="#">Alt+F1</a>	Choose this command to <a href="#">select the desired component from the pop-up list of possible targets</a> .
Jump to Navigation Bar	<a href="#">Alt+Home</a>	Choose this command to navigate across your project <a href="#">using the Navigation Bar</a> .
Declaration	<a href="#">Ctrl+B</a>	Choose this command to <a href="#">jump to a declaration of a symbol</a> .
Implementation(s)	<a href="#">Ctrl+Alt+B</a>	Choose this command to <a href="#">jump to an implementation of a method</a> .
Type Declaration	<a href="#">Ctrl+Shift+B</a>	Choose this command to <a href="#">jump to the type declaration of a symbol</a> .
Super Method	<a href="#">Ctrl+U</a>	Choose this command to <a href="#">jump to a super method</a> of the method at caret.
Test	<a href="#">Ctrl+Shift+T</a>	Choose this command to navigate to an existing test, or create a test. See section <a href="#">Creating Tests</a> .
Related Symbol...	<a href="#">Ctrl+Alt+Home</a>	.
File Structure	<a href="#">Ctrl+F12</a>	Choose this command to <a href="#">navigate through the source code using the File Structure view</a> .
File Path	<a href="#">Ctrl+Alt+F12</a>	See <a href="#">Navigating to File Path</a> .
Type/Method/Call Hierarchy	<a href="#">Ctrl+H</a> / <a href="#">Ctrl+Shift+H</a> / <a href="#">Ctrl+Alt+H</a>	Choose these commands to navigate using the hierarchy views. Refer to the sections <a href="#">Viewing Structure and Hierarchy of the Source Code</a> .
Next/Previous Highlighted Error	<a href="#">F2</a> <a href="#">Shift+F2</a>	Choose these commands to <a href="#">navigate through the highlighted errors</a> .
Next/Previous Emmet Edit Point	<a href="#">Shift+Alt+Close Bracket</a> / <a href="#">Shift+Alt+Open Bracket</a>	Refer to the section <a href="#">Emmet</a> for details.
Next/Previous Change	<a href="#">Ctrl+Shift+Alt+Down</a> <a href="#">Ctrl+Shift+Alt+Up</a>	Choose these commands to navigate through the change markers (when VCS integration is <a href="#">enabled</a> ) .
Next/Previous Method	<a href="#">Alt+Down</a> <a href="#">Alt+Up</a>	Choose these commands to <a href="#">go up and down through the methods and tags</a> .

## Code

### MenuKeyboardDescription

#### item shortcut

Override Methods...	<a href="#">Ctrl+O</a>	Choose this command to override a method. See <a href="#">Overriding Methods of a Superclass</a> .
Implement Methods...	<a href="#">Ctrl+I</a>	Choose this command to implement a method. See <a href="#">Implementing Methods of an Interface</a> .
Generate...	<a href="#">Alt+Insert</a>	Choose this command to create a new element.
Surround With...	<a href="#">Ctrl+Alt+T</a>	Choose this command to <a href="#">surround a logical fragment with code construct</a> .
Unwrap/Remove...	<a href="#">Ctrl+Shift+Delete</a>	Choose this command to <a href="#">unwrap an expression from enclosing statements</a> .
Completion		Point to this node to reveal the nested <a href="#">auto-completion</a> commands.
Folding		Point to this node to reveal the nested <a href="#">folding</a> commands.
Insert Live Template...	<a href="#">Ctrl+J</a>	Choose this command to <a href="#">create code constructs by live templates</a> .
Surround with Live Template...	<a href="#">Ctrl+Alt+J</a>	Choose this command to <a href="#">create code constructs using surround templates</a> .
Comment with Line Comment	<a href="#">Ctrl+Slash</a>	Choose this command to comment an entire line of code. See <a href="#">Commenting and Uncommenting Blocks of Code</a> .

Comment with Block Comment	Ctrl+Shift+Slash	Choose this command to comment out a block of code. See <a href="#">Commenting and Uncommenting Blocks of Code</a> .
Reformat Code...	Ctrl+Alt+L	Choose this command to perform code reformatting. See <a href="#">Reformatting Source Code</a> .
Auto-Indent Lines	Ctrl+Alt+I	Choose this command to <a href="#">change indentation</a> .
Optimize Imports...	Ctrl+Alt+O	Choose this command to optimize import statements. See <a href="#">Optimizing Imports</a> .
Rearrange Code		Choose this command to rearrange code according to the arrangement rules. See <a href="#">Rearranging Code Using Arrangement Rules</a> .
Move Statement Up/Down	Ctrl+Shift+Up / Ctrl+Shift+Down	Choose this command to <a href="#">move a statement up or down</a> .
Move Element Left/Right	Ctrl+Shift+Alt+Left / Ctrl+Shift+Alt+Right	Choose this command to move element at caret left or right.
Move Line Up/Down	Shift+Alt+Up / Shift+Alt+Down	Choose this command to <a href="#">move a line at caret up or down</a> .

## Analyze

### Menu Keyboard Description item shortcut

Inspect Code...		Choose this command to <a href="#">run an inspection</a> .
Code Cleanup		Choose this command to open the dialog <a href="#">Specify Code Cleanup Scope Dialog</a> .
Run Inspection by Name...	Ctrl+Shift+Alt+I	Choose this command to <a href="#">run the specified inspection</a> .
Configure Current File Analysis...	Ctrl+Shift+Alt+H	Choose this command to <a href="#">change highlighting level of the current file</a> .
View Offline Inspection Results...		Choose this command to see inspection results stored on your computer. See <a href="#">Viewing Offline Inspections Results</a> .
Locate Duplicates...		Choose this command to find code duplicates. Refer to <a href="#">Analyzing Duplicates</a> .
Analyze Stacktrace...		Choose this command to <a href="#">analyze external stacktrace</a> .

## Refactor

Note that the composition of this menu item depends upon the current context.

### Menu Keyboard Description item shortcut

Refactor This...	Ctrl+Shift+Alt+T	Choose this command to open a popup menu of the refactorings available in the current context. Refer to the section <a href="#">Refactoring Source Code</a> .
Rename...	Shift+F6	Choose this command to <a href="#">rename an element</a> .
Change Signature...	Ctrl+F6	Choose this command to perform the change signature refactoring. See <a href="#">Change Signature</a> and <a href="#">Change Signature for JavaScript</a> for details.
Move...	F6	Choose this command to <a href="#">move</a> a symbol to the specified location.
Copy...	Ctrl+C	Choose this command to create a copy of an element in the specified location. See <a href="#">Copy</a> for details.
Safe Delete	Alt+Delete	Choose this command to <a href="#">delete a symbol</a> , performing search for its usages.
Extract		Choose this command to perform one of the <a href="#">extract</a> refactorings. See <a href="#">Extract Refactorings</a> for details.
Inline...	Ctrl+Alt+N	Choose this command to perform <a href="#">inline refactoring</a> .
Pull Members Up...		Choose this command to perform <a href="#">pull members up refactoring</a> .
Push Members Down		Choose this command to perform <a href="#">push members down refactoring</a> .
Invert Boolean		Choose this command to perform <a href="#">invert boolean refactoring</a> .
XML Refactorings		Point to this node to reveal the sub-menu of XML-related refactorings, available in the current context.

## Build

Refer to the section [Compiler and Builder](#) for details.

### Menu Keyboard Description item shortcut

Build Project	Ctrl+F9	Choose this command to <a href="#">build a project</a> .
Build Module <name>		Choose this command to <a href="#">build a module</a> .
Rebuild <name>	Ctrl+Shift+F9	Choose this command to <a href="#">compile the specified target</a> .

Rebuild Project		Choose this command to <a href="#">rebuild your project</a> .
Generate Ant Build		Choose this command to <a href="#">generate an Ant build file</a> .
Build Artifacts		Choose this command to <a href="#">Package a module into a JAR file</a> .
Generate Signed APK		Choose this command to <a href="#">Generate a signed Android application package</a> .
Run Ant Target		Choose this command to <a href="#">execute an Ant target</a> .

## Run

### MenuKeyboardDescription item shortcut

Run <current run/debug configuration>		Choose this command to <a href="#">run</a> the current class with the <code>main()</code> method with the corresponding temporary run/debug configuration. This command is duplicated with  icon on the main toolbar.
Debug <current run/debug configuration>		Choose this command to <a href="#">debug</a> the current class with the <code>main()</code> method with the corresponding temporary run/debug configuration. This command is duplicated with  icon on the main toolbar.
Run <current run/debug configuration> with Coverage		Choose this command to <a href="#">run with coverage</a> the current class with the <code>main()</code> method with the corresponding temporary run/debug configuration. This command is duplicated with  icon on the main toolbar.
Run...		Choose this command to select the desired run/debug configuration, and then launch it. Refer to the section <a href="#">Creating and Editing Run/Debug Configurations</a> .
Debug...		Choose this command to select the desired run/debug configuration, and then launch it in debugging mode. Refer to the section <a href="#">Creating and Editing Run/Debug Configurations</a> .
Edit Configurations...		Choose this command to change run/debug configuration. Refer to the section <a href="#">Creating and Editing Run/Debug Configurations</a> .
Import Test Results		Choose this command to import test results from a file.
Stop		Choose this command to <a href="#">terminate execution of a run/debug configuration</a> . This command is duplicated with  icon in the toolboxes of the <a href="#">Run</a> and <a href="#">Debug</a> tool windows.
Show Running List		Choose this command to display a popup that lists all currently running/debugging applications. Refer to the section <a href="#">Viewing Running Processes</a> .
Stepping Commands		These commands become enabled with the debugger session on. Refer to the section <a href="#">Stepping Through the Program</a> . See also descriptions of the stepping toolbar buttons in the <a href="#">Debug</a> tool window reference.
Pause Program		Choose this command to pause output of the current run or <a href="#">debug</a> session. This command is duplicated with  icon in the toolboxes of the <a href="#">Run</a> and <a href="#">Debug</a> tool windows. Note that the button is not available for <a href="#">Run/Debug Configuration: Node.js</a> , <a href="#">Run/Debug Configuration: Attach to Node.js/Chrome</a> , and <a href="#">Run/Debug Configuration: NUnit</a> .
Resume Program		Choose this command to <a href="#">resume the debugger session</a> with the selected run/debug configuration. This command is duplicated with  icon in the toolbox of the <a href="#">Debug</a> tool windows.
Evaluate Expression		Choose this command to <a href="#">evaluate expression</a> during the debug session.
Quick Evaluate Expression		Choose this command to perform <a href="#">quick evaluation</a> of an expression in the editor during the debug session.
Show Execution Point		Choose this command to <a href="#">show execution point</a> during the debug session.
Toggle Line Breakpoint		Choose this command to turn on or off a line breakpoint. Refer to the section <a href="#">Creating Line Breakpoints</a> .
Toggle Temporary Line Breakpoint		Choose this command to turn on or off a temporary line breakpoint. Refer to the section <a href="#">Creating Line Breakpoints</a> .
View Breakpoints...		Choose this command to <a href="#">show all available breakpoints and change them</a> in the <a href="#">Breakpoints dialog</a> .

## Tools

Note that composition of the menu Tools depends on the enabled [plugins](#) and [external tools](#) .

### MenuKeyboardDescription item shortcut

Tasks and Contexts		Point to this node to reveal the sub-menu of commands related to <a href="#">tasks and contexts management</a> .
Save File as Template...		The current file is saved as a <a href="#">file template</a> and appears in the Files tab of the <a href="#">File and Code Templates</a> page of the editor settings.
Save Project as		The the current project or any its module is saved as a template project.

Template...	
Save File as Template	Choose this command to save the current file as a <a href="#">template file</a> .
IDE Scripting Console	Choose this command to launch the interactive scripting console.
XML Actions	Point to this node to reveal the sub-menu of <a href="#">XML-related commands</a> .
Capture Memory Snapshot	Choose this command to get the memory state of the profiled application.
Vim Emulator	Select this check command to enable or disable Vim emulation. This command only appears when Vim plugin is installed and enabled. Refer to the tutorial <a href="#">Configuring IntelliJ IDEA to work as a Vim editor</a> .
Reconfigure Vim Keymap	This command is only visible, when Vim Emulator is checked. Choose it to select a different base keymap for the Vim emulator.
Deployment	Point to this node to reveal the sub-menu of deployment-related commands. Refer to the section <a href="#">Deploying you application</a> .
Open terminal	Choose this command to run the <a href="#">embedded local terminal</a> .
Start SSH Session	Choose this command to launch a terminal on a remote SSH server. Refer to the section <a href="#">Running SSH Terminal</a> .
Test RESTful Web Service	Choose this command to compose and run requests to a RESTful web service. Refer to the section <a href="#">Testing RESTful Web Services</a> .
Kotlin	Point to this node to reveal the sub-menu of <a href="#">Kotlin-related commands</a> . See also the Kotlin page <a href="https://kotlinlang.org/">https://kotlinlang.org/</a> .

## VCS

Note that the VCS menu contains different commands, depending on the enabled version control system. The following table shows the menu commands available when no version control integration is enabled.

### MenuKeyboardDescription item shortcut

Local History	Point to this node to reveal the list of commands related to <a href="#">working with the Local History</a> .
Enable Version Control Integration...	Choose this command to <a href="#">associate a project root</a> with one of the supported version control systems.
VCS Operations Popup	 Choose this command to <a href="#">invoke the popup list of the most popular VCS actions</a> .
Apply Patch...	Choose this command to <a href="#">apply a patch</a> .
Checkout from Version Control	Point to this node to reveal the sub-menu of the checkout commands, specific for the supported version control systems. With no version control integration enabled, it is possible to check out from <a href="#">SVN</a> , <a href="#">Mercurial</a> , <a href="#">Git</a> , GitHub, and <a href="#">CVS</a> .
Import into Version Control	Point to this node to reveal the sub-menu of the import commands, specific for the supported version control systems. With no version control integration enabled, it is possible to import to <a href="#">SVN</a> , <a href="#">Mercurial</a> , <a href="#">Git</a> , GitHub, and <a href="#">CVS</a> .
Browse VCS Repository	Point to this node to reveal the sub-menu of the browse commands, specific for the supported version control systems. With no version control integration enabled, it is possible to browse <a href="#">Subversion</a> , <a href="#">Git</a> , and <a href="#">CVS</a> repositories that are not associated with the currently opened project. <ul style="list-style-type: none"> <li>– Browse CVS Repository: when you choose this option IntelliJ IDEA opens the Select CVS Root Configuration dialog, where you can select the relevant CVS root, see <a href="#">Configuring CVS Roots</a> and <a href="#">Browsing CVS Repository</a> .</li> <li>– Browse Git Repository Log: choose this option to view the log for a local Git repository that is associated with another project. When you select the relevant repository in the Select Path dialog box, IntelliJ IDEA adds a new Log tab to the Version Control tool window and shows the log for the selected repository. The name of the project associated with the selected repository is displayed in the tab title, when you hover the mouse over this tab, the full path to the repository is shown in a tooltip.</li> <li>– Browse Subversion Repository: when you choose this option IntelliJ IDEA opens the <a href="#">SVN Repositories</a> tool window where you can view, add, and edit location of <a href="#">SVN</a> repositories, see <a href="#">Browsing Subversion Repository</a> and <a href="#">Browsing Contents of the Repository</a> .</li> </ul>

It is important to note that with VCS integration enabled, the composition of the VCS menu is different. Refer to the following help sections for details:

- [Version Control concepts](#)
- [Common VCS procedures](#)
- [VCS-specific procedures](#)
- [Version Control reference](#)

## Window

### MenuKeyboardDescription item shortcut

Store Current Layout as Default	Choose this command to <a href="#">save the current way the tool windows are arranged</a> .
Restore Default Layout	 Choose this command to <a href="#">restore the initial way the tool windows are</a>

arranged .

Active Tool Window	Choose this command to reveal the sub-menu of commands, related to the <a href="#">active tool window</a> . Refer to the sections <a href="#">Tool Windows</a> , <a href="#">Manipulating the Tool Windows</a> , <a href="#">Specifying the Appearance Settings for Tool Windows</a> , <a href="#">Viewing Modes</a> .
Editor Tabs	Choose this command to reveal the sub-menu of commands, related to the editor tabs. Refer to the section <a href="#">Managing Editor Tabs</a> . Note that these commands can also be found on the context menu of an editor tab.
Background Tasks	Choose this command to reveal the sub-menu of commands, related to performing tasks in background.
Next Project Window / Previous Project Window	<a href="#">Ctrl+Alt+Close Bracket</a> Choose this command to switch between currently opened projects. See <a href="#">Configuring projects</a> . <a href="#">Ctrl+Alt+Open Bracket</a>
<project>	Select project to be shown in the active window. See <a href="#">Configuring projects</a> .

## Help

### MenuKeyboardDescription item shortcut

Find Action	<a href="#">Ctrl+Shift+A</a> Choose this command to <a href="#">invoke an action by its name</a> .
Keymap Reference	Choose this command to see the IntelliJ IDEA shortcuts map in PDF format.
Demos and Screencasts	Choose this command to see the IntelliJ IDEA demo <a href="#">videos and screencasts on YouTube</a> .
Help	Choose this command to visit IntelliJ IDEA online Help topics.
Tip of the Day	Choose this command to show an arbitrary tip. Refer to the section <a href="#">Using Tips of the Day</a> .
Productivity Guide	Choose this command to <a href="#">show productivity guide</a> .
Support Center	Choose this command to open <a href="#">JetBrains Support</a> page.
Submit Feedback	Choose this command to report your overall impression of IntelliJ IDEA to the support service. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> .
Show Log in Explorer/Finder	Choose this command to find IntelliJ IDEA's log. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> for details.
Edit Custom Properties	Choose this command to open the custom file <code>idea.properties</code> , located under the user home. If this file does not exist, IntelliJ IDEA suggests to create it. Refer to the section <a href="#">Tuning IntelliJ IDEA</a> for details.
Edit Custom VM Options	Choose this command to open the custom file <code>*.vmoptions</code> , located under the user home. If this file does not exist, IntelliJ IDEA suggests to create it. Refer to the section <a href="#">Tuning IntelliJ IDEA</a> for details.
Debug Log Settings	Choose this command to change logging level for a category. Choosing this command leads to opening the Custom Debug Log Configuration dialog box, where you have to type the log categories names, separated with new lines. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> .
What's New in IntelliJ IDEA	Choose this command to open the <a href="#">What's New page</a> .
Licences	Choose this command to show the legal information.
Register...	Choose this command to <a href="#">register</a> IntelliJ IDEA.
Check for Updates...	Choose this command to obtain information about the current version, and the availability of newer versions of IntelliJ IDEA. Refer to <a href="#">Updates</a> page. This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu.
About	Choose this command to obtain information about the current version of IntelliJ IDEA, current build, etc. Press <a href="#">Escape</a> to close the popup window. This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu.

Besides working from within IntelliJ IDEA, it is possible to perform certain actions "offline", without actually launching the IDE.

This way you can:

- Inspect code
- View differences
- Open files
- Format files

**Note**

- [Opening a file in the editor](#)
- [Examples](#)
  - [Windows](#)
  - [macOS](#)
  - [Linux](#)

## Opening a file in the editor

IntelliJ IDEA helps opening a file for editing so that the caret rests at the specified line.

### To open a file for editing

- In the command line, type the following:

```
<IntelliJ IDEA> <path1> --line <number> <path2>
```

where:

- `<IntelliJ IDEA>` is the platform-specific product launcher
- `<path1>` is the path to the project that contains the desired file
- `<number>` is the number of the line, where the caret should rest
- `<path2>` is the path to the file to be opened

## Examples

### Windows

```
IntelliJ IDEA.exe C:\SamplesProjects\MetersToInchesConverter --line 3 C:\SamplesProjects\MetersToInchesC
```

### macOS

```
/Applications/IntelliJ IDEA.app/Contents/MacOS/idea ~/IntelliJ IDEAProjects/untitled45 --line 1 ~/Intell
```

### Linux

```
~/jetbrains/IntelliJ IDEA-2017.2.1/bin/idea.sh ~/IntelliJ IDEAProjects/test_project/ --line 2 ~/IntelliJ
```

## Launching a code inspection from the command line

### To launch a code inspection from the command line

- Specify the following command line arguments:
  - Path to the launcher : specify the **full path** to one of the following launchers (which reside under the `bin` directory of your IntelliJ IDEA installation):
    - For Windows : `inspect.bat`
    - For UNIX and macOS : `inspect.sh`
  - Project file path is the **full path** to the directory that contains the project to be inspected.
  - Inspection profile path is the **full path** to the profile, against which the project should be inspected. The inspection profiles are stored under `USER_HOME\IntelliJ IDEAXX\config\inspection`
  - Output path is the **full path** to an existing directory where the report will be stored.
- Options . You can specify:
  - The directory to be inspected `-d <full path to the subdirectory>`
  - The verbosity level of output `-vX` , where X is 0 for quiet, 1 for noisy and 2 for extra noisy.

**Warning!** Please note that you have to specify full paths. Relative paths are not accepted!

**Tip** If SDK is not defined, the inspection will fail. The SDK descriptions should be stored in `config\options\jdk.table.xml` . Learn how to configure SDK [here](#) .

## Examples

### Windows

```
"C:\Program Files (x86)\JetBrains\IntelliJ IDEA home\bin\inspect.bat" E:\SampleProjects\MetersToInches
```

Note that your paths should be adjusted to your particular local system.

### macOS

```
/Applications/IntelliJ IDEA.app/Contents/bin/inspect.sh ~/IntelliJ IDEAProjects/MyTestProject ~/Library/
```

## Viewing the results of an offline inspection

If you have performed an offline inspection and exported the inspection results to a directory in the XML format you can always download and view these results.

### To view the results of an offline inspection, follow these steps

1. Open the project against which the inspection was performed.
2. On the main menu, choose Analyze | View Offline Inspection Results .
3. In the Select Path dialog box that opens, navigate to the directory that contains inspection results in XML format.
4. Click OK . Inspection results display in the Offline View tab in the [Inspection Results Tool Window](#) .

**Tip** Alternatively, you can open the relevant XML file in IntelliJ IDEA or in any other text processor without opening the inspected project.

Command-line source code formatter is a special functionality within IntelliJ IDEA that lets you format arbitrary files outside a project.

**Note** To be able to format files, make sure that the corresponding plugins that support the required file types are installed and enabled.

The script is `format.bat/format.sh` located in the `<IntelliJ IDEA_HOME>/bin` home directory. The script launches IntelliJ IDEA which formats the specified files and quits:

```
format [-h] [-r|-R] [-s|-settings settingsPath] [-m|-mask masks] [path1 [path2]...]
```

You can launch the script with the following options:

#### ParameterDescription

<code>-h</code>	Shows help and quits.
<code>-r -R</code>	Scans directories specified in <code>path1,path2...</code> recursively.
<code>-s -settings settingsPath</code>	<code>settingsPath</code> is a path to the file with the code style settings. You can use one of the following: <ul style="list-style-type: none"><li>– A file with exported code style settings: in the Settings/Preferences dialog ( <code>Ctrl+Alt+S</code> ), open the Editor   Code Style settings page and click Export under EditorConfig .</li><li>– The <code>.idea/codeStyleSettings.xml</code> file stored in your project directory (for IntelliJ IDEA version 2017.2 and below).</li><li>– The <code>.idea/codeStyles/Project.xml</code> file stored in your project directory (for IntelliJ IDEA version 2017.3 and above).</li></ul>

**Note** If this parameter is omitted, the default code style settings are used.

<code>-m -mask masks</code>	A comma-separated list of file masks which defines the files to be processed. Wildcards <code>*</code> (any string) and <code>?</code> (any single character) are supported.
<code>pathN</code>	The path to a file or directory to be processed.

## Example

1. Format all files in `C:\Data\src` directory including all subdirectories using the default code style settings:

```
format -r C:\Data\src
```

2. Non-recursively format all `.java` and `.html` files in the `C:\Data\src` directory using code style settings from `C:\Data\settings.xml` :

```
format -s C:\Data\settings.xml -m *.java,*.html C:\Data\src
```

## Viewing differences

### To view differences using command line diff tool

– In the command line, type the following:

```
<IntelliJ IDEA> diff <path1> <path2>
```

where:

- <IntelliJ IDEA> is the platform-specific product launcher
- <path1>, <path2> are full paths to the files to be compared.

## Examples

### Windows

```
IntelliJ IDEA.exe diff C:\SamplesProjects\MetersToInchesConverter\src\javascript\numbers.js  
C:\SamplesProjects\MetersToInchesConverter\src\coffeescript\numbers.coffee
```

### macOS

```
/Applications/IntelliJ IDEA.app/Contents/MacOS/idea diff ~/Documents/file1.txt ~/Documents/file2.txt
```

In this section:

- [Overview](#)
- [Enabling invocation of IntelliJ IDEA operations from the command line](#)
- [Comparing files using IntelliJ IDEA as a command line tool](#)
- [Merging files using IntelliJ IDEA as a command line tool](#)
  - [Passing three arguments to merge tool](#)

## Overview

Besides using IntelliJ IDEA as an Integrated Development Environment, you can use it as a command line tool for comparing and merging files.

IntelliJ IDEA executable is platform-dependent:

- **Windows** : `IntelliJ\IdeaXX\bin\idea.exe` / `IdeaICXX\bin\idea.exe` or `IntelliJ\IdeaXX\bin\idea.bat` / `IdeaICXX\bin\idea.bat`
- **UNIX** : `IntelliJ\IdeaXX/bin/idea.sh` / `IdeaICXX/bin/idea.sh`
- **macOS** : `/Applications/IntelliJ\IdeaXX.app/Contents/MacOS/idea` / `/Applications/IdeaICXX.app/Contents/MacOS/idea`  
To add the launcher to your path, add its containing directory `/Applications/IntelliJ IDEA.app/Contents/MacOS`.

However, for macOS and UNIX, one should create a wrapper script, since this helps avoid some drawbacks related to the usage of IntelliJ IDEA launcher.

## Enabling invocation of IntelliJ IDEA operations from the command line

For macOS and UNIX platforms, we recommend creating the wrapper script, or the command line launcher to integrate IntelliJ IDEA with your shell. Then, you need to ensure that the created launcher script is within the search path of your shell.

On Windows, we recommend you add the path to IntelliJ IDEA to the environment variable `Path`. Everything is done outside of IntelliJ IDEA, with the IntelliJ IDEA executable.

Note that if you have specified location of the IntelliJ IDEA executable as a `Path` environment variable, the command will work no matter which directory you are currently in.

### To enable invoking IntelliJ IDEA operations from the command line, follow these steps

- On macOS or UNIX :
  1. Make sure IntelliJ IDEA is running.
  2. On the main menu, choose Tools | Create Command-line Launcher. The dialog box Create Launcher Script opens, with the suggested path and name of the launcher script. You can accept default, or specify your own path.  
Make notice of it, as you'll need it later.
  3. Outside of IntelliJ IDEA, add the path and name of the launcher script to your path.
- On Windows :
  - Specify the location of the IntelliJ IDEA executable in the `Path` system environment variable. In this case, you will be able to invoke the IntelliJ IDEA executable and other IntelliJ IDEA commands from any directory.

## Comparing files using IntelliJ IDEA as a command line tool

### To compare two files using IntelliJ IDEA as a diff command line tool

1. [Enable invoking IntelliJ IDEA operations from the command line](#).
2. Type the following command at the command prompt:

```
<IntelliJ IDEA launcher(Windows) or wrapper script (MacOS or UNIX)> diff <path to file1> <p
```

where `file1` is your local copy, `file2` is the repository version.

For example:

```
idea diff README.md.bak README.md
```

## Merging files using IntelliJ IDEA as a command line tool

Most often you need to merge three versions of the same file: your local version, the version in the repository or in the upstream, and the base revision, which is the origin for the two diverged versions.

## To merge files using IntelliJ IDEA as a command line tool

1. [Enable invoking IntelliJ IDEA operations from the command line](#) .

2. Type the following command at the command prompt:

```
<IntelliJ IDEA launcher(Windows) or wrapper script (MacOS or UNIX)>  
merge <path to file1> <path to file2> <path to file3> <path to output>
```

where `file1` is your local copy, `file2` is the repository version, `file3` is the base revision for `file1` and `file2` , and `output` is the file to save the merge results in (optional).

## Passing three arguments to merge tool

It is possible to pass just three arguments to the merge tool:

```
<path to file1> <path to file2> <path to output> .
```

In this case, the contents of the output will be taken as the base revision:

```
<IntelliJ IDEA launcher> merge <path to file1> <path to file2> <path to output> <path to output>
```

See the example in this [blog](#) to learn how to use IntelliJ IDEA diff and merge tool with Git.
