

# IntelliJ IDEA 2017.3 Help

---

## For beginners

- [Discover IntelliJ IDEA](#) provides an overview of IntelliJ IDEA main features.
- [Getting Started with Java](#) helps you create and run your application.
- Popular tutorials:
  - [Getting Started with Java EE](#)
  - [Getting Started with Android Development](#)
  - [Getting Started with Grails](#)
  - [Getting Started with Groovy](#)
  - [Getting Started with Gradle](#)
  - [Getting Started with Scala](#)
  - [More...](#)

## For advanced users

- [Language and Framework - Specific Guidelines](#) provide information on how to create and run an application using one of the many supported frameworks and languages.
- [IntelliJ IDEA Pro Tips Guide](#) provides more advanced information about IntelliJ IDEA.

## Migration guides

- [Eclipse](#)
- [NetBeans](#)

## Installation requirements

### Hardware requirements

- 1 GB RAM minimum, 2 GB RAM recommended
- 1.5 GB hard disk space + at least 1 GB for caches
- 1024x768 minimum screen resolution

### Software requirements

JRE 1.8 is bundled with the IntelliJ IDEA distribution. You do not need to install Java on your computer to run IntelliJ IDEA.

A standalone JDK is required for Java development.

#### WindowsmacOSLinux

Microsoft Windows 10/8/7/Vista/2003/XP  (32 or 64 bit)	macOS 10.8 or later  (only 64-bit systems are supported)	- OS Linux (note that a 32-bit JDK is not bundled, so a 64-bit system is recommended) - KDE, Gnome or Unity DE desktop
---	--	---

## Download and install IntelliJ IDEA

IntelliJ IDEA is available in two editions: Ultimate and Community . The Community edition is an open-source project and is free, but it has less features. The Ultimate edition is commercial, and provides an outstanding set of tools and features. For details, see the [editions comparison matrix](#) .

To install IntelliJ IDEA

1. [Download IntelliJ IDEA](#) for your operating system.
2. Do the following depending on your operating system:
  - Windows :
    1. Run the `ideaIC.exe` or the `ideaIU.exe` file you have downloaded.
    2. Follow the instructions in the installation wizard.
  - macOS :
    1. Double-click the `ideaIC.dmg` or `ideaIU.dmg` file you have downloaded to mount the macOS disk image.
    2. Copy IntelliJ IDEA to the Applications folder.
  - Linux :
    1. Unpack the `ideaIC.gz` or `ideaIU.gz` file you have downloaded to a different folder if your current Downloads folder doesn't support file execution:

```
tar xzf ideaIC.tar.gz or ideaIU.tar.gz. <new_archive_folder>
```

The recommended install location according to the filesystem hierarchy standard (FHS) is `/opt` . For example, it's possible to enter the following command:

```
sudo tar xf -*.tar.gz -C /opt/
```

      2. Switch to the `bin` directory, for example:

```
cd opt/~/bin
```
      3. Run `idea.sh` from the `bin` subdirectory.

**Note** JRE for 32-bit systems is not bundled with IntelliJ IDEA. If you are using a 32-bit version of Windows, select the Download and install JRE x86 by JetBrains checkbox in the installation wizard to automatically download and install JRE.

**Note** A new instance must not be extracted over an existing one. The target folder must be empty.

## Run IntelliJ IDEA for the first time

### Import IntelliJ IDEA settings

When you start IntelliJ IDEA for the first time, or after you have upgraded it from a previous version, the Complete Installation dialog opens where you can select whether you want to import the IDE settings:

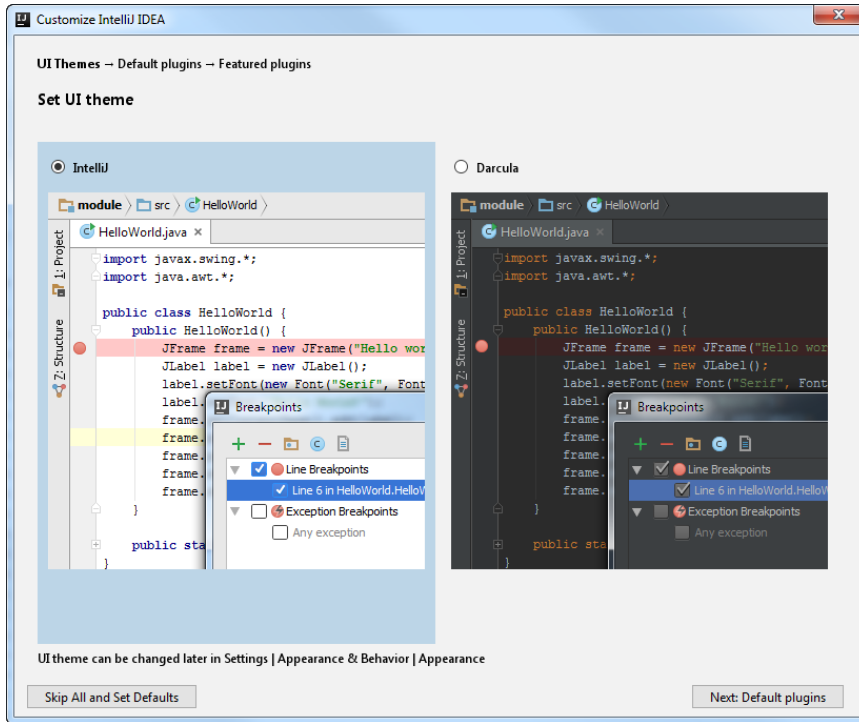

If this is your first instance of IntelliJ IDEA, choose the Do not import settings option.

**Note** You can [import and export settings](#) manually at a later point using the File | Import Settings and File | Export Settings commands on the main menu.

## Select the user interface theme

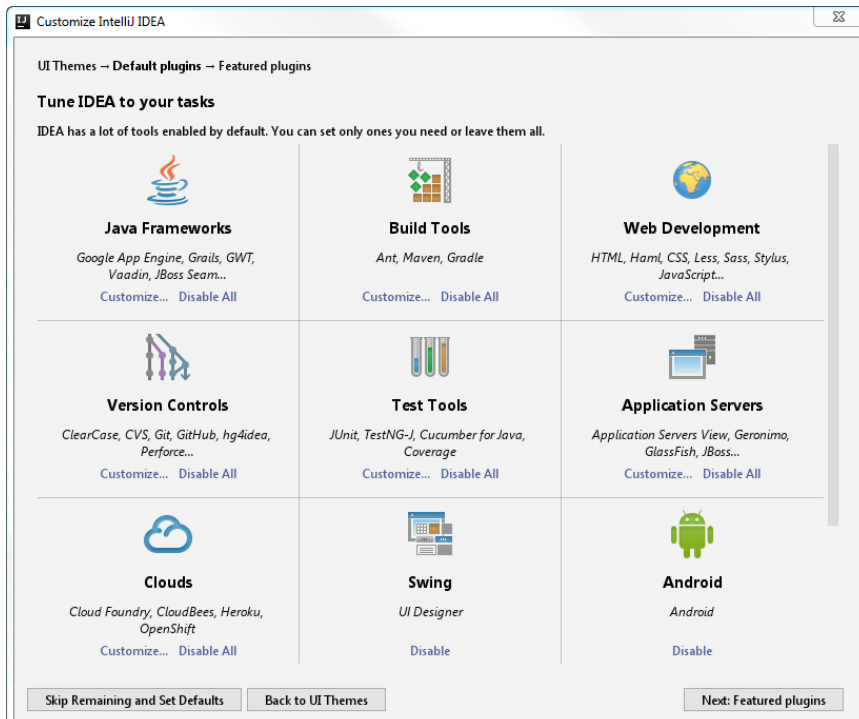

Next, you will be prompted to select the UI theme. You can choose between the Default and the Darcula themes:

## Disable the unnecessary plugins

IntelliJ IDEA is shipped with a variety of plugins that provide integration with different version control systems and application servers, add support for various frameworks and development technologies, etc.

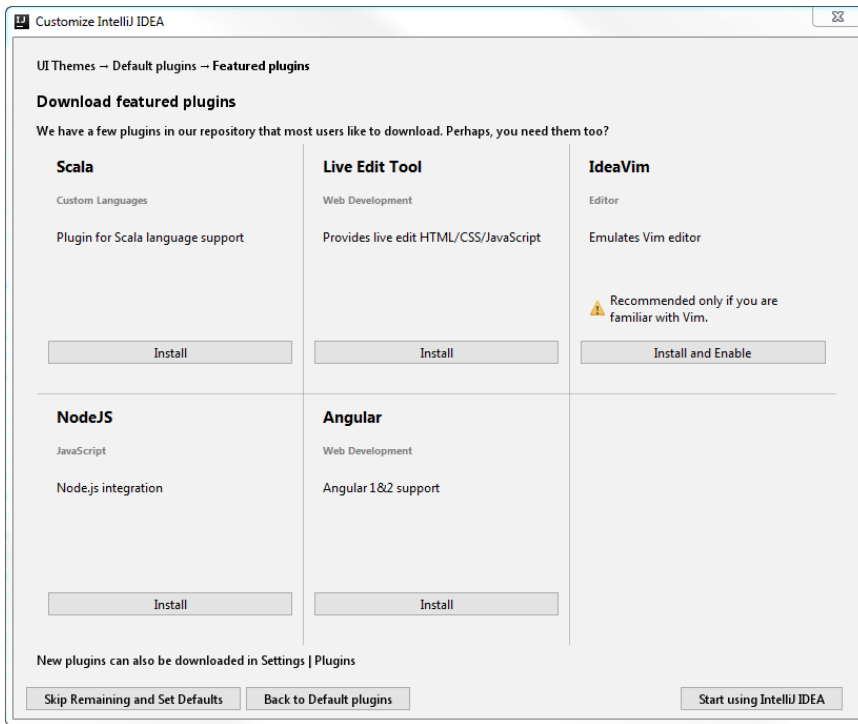

On the next step you can disable the plugins you do not need to increase IntelliJ IDEA performance. If necessary, you can re-enable them later in the Settings dialog ( `Ctrl+Alt+S` ) under Plugins ).

You can click the Disable All link for each group of plugins to disable them all, or Customize to disable individual plugins.

## Download and install additional plugins

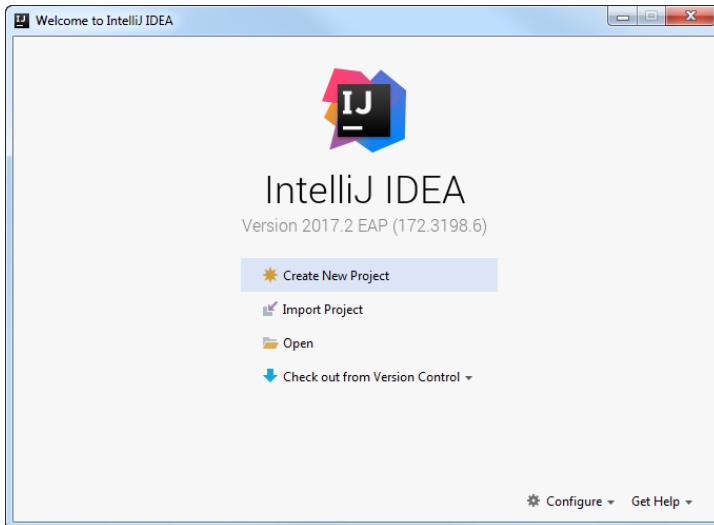

On the next step, you are prompted to download additional plugins that are not bundled with the IDE from the [IntelliJ IDEA plugins repository](#) :

## Start a project in IntelliJ IDEA

After you have completed initial IntelliJ IDEA configuration, the Welcome screen will be displayed. It allows you to:

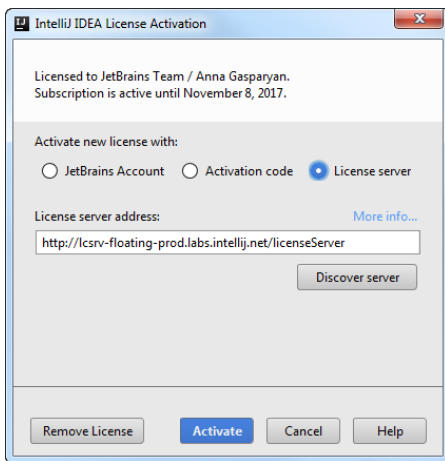

- [create a new project](#)
- or [check out an existing project from a version control system \(clone from a remote repository\)](#)

## Register IntelliJ IDEA

To try and evaluate IntelliJ IDEA, you can download and install its trial version for free. The trial version is available for 30 days, whereupon you need to obtain and register a license.

1. Do one of the following:
  - On the Welcome screen, click [Configure | Manage License](#)
  - Select [Help | Register](#) from the main menu

2. Select how you want to register IntelliJ IDEA:

- JetBrains Account : select this option if you have a [JetBrains Account](#) that allows you to access your purchases and manage licenses (see [What is JetBrains Account?](#) to learn more).
- Activation code : select this option if you have an activation code for IntelliJ IDEA, and paste it to the text area.
- License server : select this option to register IntelliJ IDEA through the [License Server](#) web application that allows you to manage floating licenses and issue licenses to users who do not have direct internet access.

**Note** IntelliJ IDEA builds that can be downloaded as part of the [Early Access Program](#) do not require any registration and are shipped with a 30-days license.

## Update IntelliJ IDEA

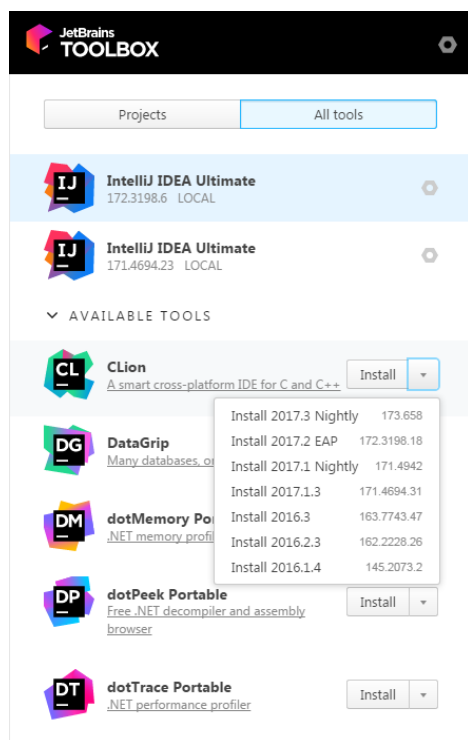

1. [Download](#) the latest version of IntelliJ IDEA.
2. Launch the setup as described in [Download and install IntelliJ IDEA](#) .
3. Choose whether you want to uninstall the existing IntelliJ IDEA version together with its settings, caches and local history and follow the instructions of the installation wizard.

## Manage IntelliJ IDEA through Toolbox App

Toolbox App is a control panel that allows you to manage all JetBrains developer tools, including IntelliJ IDEA, as well as your projects, from a single point of access. It lets you maintain different versions of the same tool, install updates and roll them back if needed. It also remembers your JetBrains Account and uses it to automatically log you in when you install and register new tools.

1. [Download](#) Toolbox App .
2. Launch the setup file.
3. When the installation is complete, accept the JetBrains privacy policy and sign in to your JetBrains Account.

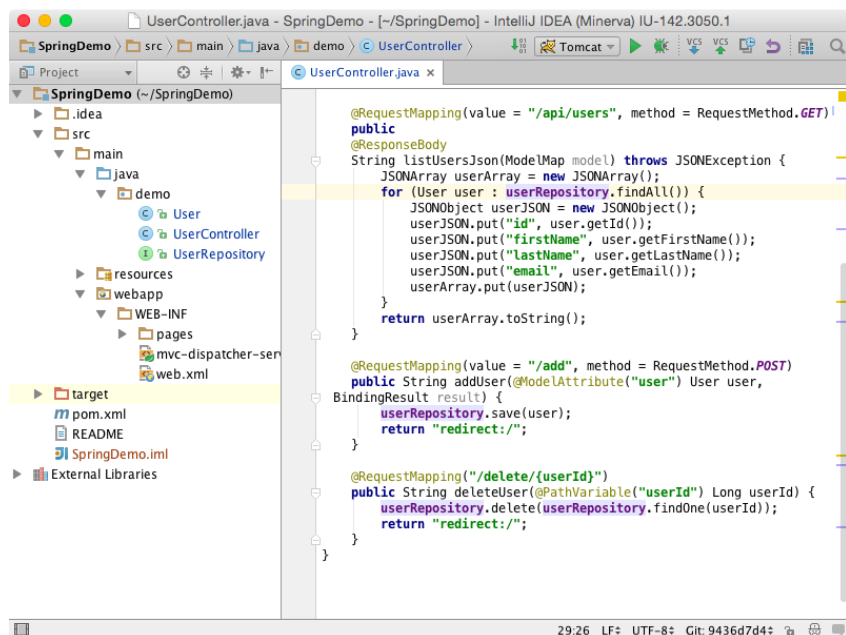

Now you can manage existing tools, install new tools and download updates:

This guide is intended to help you become more productive with IntelliJ IDEA, and provides an overview of the most important features, together with tips, tricks, and the hottest shortcuts.

## User interface

The IntelliJ IDEA [Editor](#) is special in a number of ways, most notable being is that you can invoke almost any IDE feature without leaving it, which allows you to organize a layout where you have more screen space because auxiliary controls like toolbars and windows are hidden.

Accessing a tool window via its shortcut moves the input focus to it, so you can use all keyboard commands in its context. When you need to go back to the editor, press `Escape`.

Below is a list of shortcuts that invoke the tool windows you will most often need:

Tool Window	Shortcut
Project	<code>Alt+1</code>
Version Control	<code>Alt+9</code>
Run	<code>Alt+4</code>
Debug	<code>Alt+5</code>
Terminal	<code>Alt+F12</code>
Editor	<code>Escape</code>

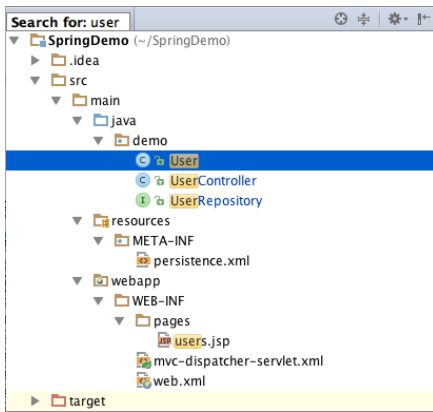

When you want to focus on the code, try the [Distraction Free Mode](#). It removes all toolbars, tool windows, and editor tabs. To switch to this mode, on the main menu select `View | Enter Distraction Free Mode`.

An alternative to the Distraction Free Mode may be hiding all tool windows by pressing `Ctrl+Shift+F12`. You can restore the layout to its default by pressing this shortcut once again.

The [Navigation Bar](#) is a compact alternative to the [Project Tool Window](#). To access the Navigation Bar, press `Alt+Home`.

Most components in IntelliJ IDEA (both tool windows and pop-ups) provide [speed search](#). This feature allows you to filter a list, or navigate to a particular item by using a search query.

**Tip** When you don't know the shortcut for an action, try using the Find action feature by pressing `Ctrl+Shift+A`. Start typing to find an action by its name, see its shortcut or call it.

For more details, refer to [Guided Tour around the User Interface](#), [Editor](#), and [Tool Windows](#).

## Editor basics

Since in IntelliJ IDEA you can undo refactorings and revert changes from [Local History](#), it makes no sense to ask you to save your changes every time.

The most useful Editor shortcuts are:

Action	Description
Move the current line of code	<code>Ctrl+Shift+Up</code> <code>Ctrl+Shift+Down</code>
Duplicate a line of code	<code>Ctrl+D</code>
Remove a line of code	<code>Ctrl+Y</code>
Comment or uncomment a line of code	<code>Ctrl+Slash</code>
Comment a block of code	<code>Ctrl+Shift+Slash</code>
Find in the currently opened file	<code>Ctrl+F</code>
Find and replace in the current file	<code>Ctrl+R</code>
Next occurrence	<code>F3</code>
Previous occurrence	<code>Shift+F3</code>
Navigate between opened tabs	<code>Alt+Right</code> <code>Alt+Left</code>
Navigate back/forward	<code>Ctrl+Alt+Left</code> <code>Ctrl+Alt+Right</code>
Expand or collapse a code block in the editor	<code>Ctrl+NumPad Plus</code> <code>Ctrl+NumPad -</code>
Create new...	<code>Alt+Insert</code>
Surround with	<code>Ctrl+Alt+T</code>
Highlight usages of a symbol	<code>Ctrl+F7</code>

To expand a selection based on grammar, press `Ctrl+W`. To shrink it, press `Ctrl+Shift+W`.

IntelliJ IDEA can select more than one piece of code at a time. You can select/deselect any piece of code via `Alt+J`, or by clicking a code selection and pressing `Shift+Alt+J`.

For more details, refer to [Editor](#).

## Code completion

When you access [Basic Completion](#) by pressing `Ctrl+Space`, you get basic suggestions for variables, types, methods, expressions, and so on. When you call [Basic Completion](#) twice, it shows you more results, including private members and non-imported static members.

The [Smart Completion](#) feature is aware of the expected type and data flow, and offers the options relevant to the context. To call [Smart Completion](#), press `Ctrl+Shift+Space`. When you call [Smart Completion](#) twice, it shows you more results, including chains.

**Tip** To overwrite the identifier at the caret, instead of just inserting the suggestion, press `Tab`. This is helpful if you're editing part of an identifier, such as a file name.

To let IntelliJ IDEA complete a statement for you, press `N/A`. [Statement Completion](#) will automatically add the missing parentheses, brackets, braces and the necessary formatting.

If you want to see the suggested parameters for any method or constructor, press `Ctrl+P`. IntelliJ IDEA shows the parameter info for each overloaded method or constructor, and highlights the best match for the parameters already typed.

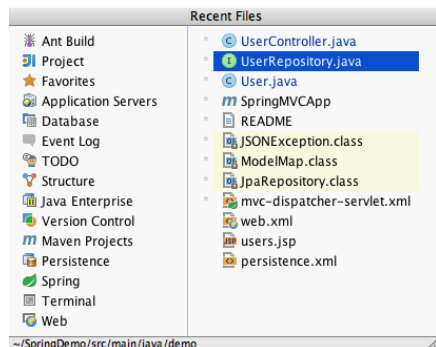

The [Postfix Completion](#) feature lets you transform an already typed expression to another one, based on the postfix you type after a dot.

For more details, refer to [Auto-Completing Code](#).

## Navigation

### Recent files

Most of the time you work with a finite set of files, and need to switch between them quickly. A real time-saver here is an action called **Recent Files** invoked by pressing `(Ctrl+E)`. By default, the focus is on the last accessed file. Note that you can also open any tool window through this action:

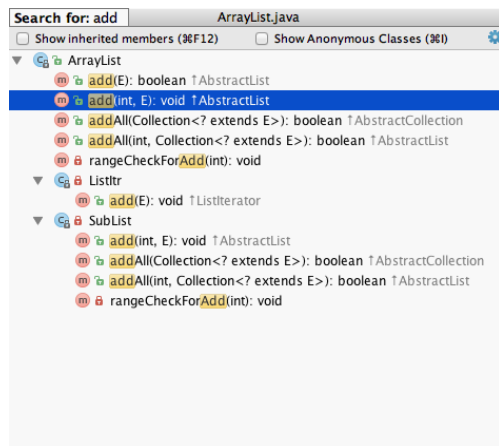

**Navigate to Class** is available by pressing `(Ctrl+N)` and supports sophisticated expressions, including camel humps, paths, line navigate to, middle name matching, and many more. If you call it twice, it shows you the results out of the project classes.

**Navigate to File** works similarly by pressing `(Ctrl+Shift+N)`, but is used for files and folders. To navigate to a folder, end your expression with the `(Slash)` character.

**Navigate to Symbol** is available by pressing `(Ctrl+Shift+Alt+N)` and allows you to find a method or a field by its name.

### Structure

When you are not switching between files, you are most probably navigating within a file. The simplest way to do it is to press `(Ctrl+F12)`. The pop-up shows you the structure of a file, and allows you to quickly navigate to any of them:

### Select in

If you need to open a file in a particular tool window (or Finder/Explorer), you can do so via the **Select In** action by pressing

`(Alt+F1)`:

Navigation shortcuts include:

## Action Shortcut

Search everywhere	Double Shift
Navigate to class	Ctrl+N
Navigate to file	Ctrl+Shift+N
Navigate to symbol	Ctrl+Shift+Alt+N
Recent files	Ctrl+E
File structure	Ctrl+F12
Select in	Alt+F1
Navigate to declaration	Ctrl+B
Navigate to type hierarchy	Ctrl+H
Show UML pop-up	Ctrl+Alt+U

For more details, refer to [Navigating Through the Source Code](#) .

## Quick pop-ups

**Quick Pop-ups** are helpful for checking additional information related to the symbol at the caret. Below is a list of pop-ups you should know if you want to be more productive:

## Action Shortcut

Documentation	Ctrl+Q
Quick definition	Ctrl+Shift+I
Show usages	Ctrl+Alt+F7
Show implementation	Ctrl+Alt+B

**Tip** Quick Pop-ups are available for symbols in the editor, however, they are also available for items in any other list via the same shortcuts.

## Refactoring basics

IntelliJ IDEA offers a comprehensive set of automated code refactorings that lead to significant productivity gains when used correctly. Firstly, don't bother selecting anything before you apply a refactoring. IntelliJ IDEA is smart enough to figure out what statement you're going to refactor, and only asks for confirmation if several choices are possible.

**Tip** To undo the last refactoring, switch the focus to the [Project Tool Window](#) and press `Ctrl+Z` .

## Action Shortcut

Rename	Shift+F6
Extract variable	Ctrl+Alt+V
Extract field	Ctrl+Alt+F
Extract a constant	Ctrl+Alt+C
Extract a method	Ctrl+Alt+M
Extract a parameter	Ctrl+Alt+P
Inline	Ctrl+Alt+N
Copy	F5
Move	F6
Refactor this	Ctrl+Shift+Alt+T

**Tip** A real time-saver is the ability to extract part of a string expression with the help of the **Extract** refactorings. Just select a string fragment and apply a refactoring to replace all of the selected fragment usages with the introduced constant or variable.

For more details, refer to [Refactoring Source Code](#) .

## Finding usages

**Find Usages** helps you quickly find all pieces of code referencing the symbol at the caret (cursor), no matter if the symbol is a class, method, field, parameter, or another statement. Just press `Alt+F7` and get a list of references grouped by usage type, module, and file.

If you want to set custom options for the **Find Usages** algorithm, press `Ctrl+Shift+Alt+F7` , or click the first button on the right panel with search results.

If what you're looking for is plain text, use **Find in Path** by pressing `Ctrl+Shift+F` .

For more details, refer to [Finding Usages](#) .

## Inspections

**Inspections** are built-in static code analysis tools that help you find probable bugs, locate dead code, detect performance issues, and improve the overall code structure.

Most inspections not only tell you where a problem is, but also provide quick fixes to deal with it right away. Press

`Alt+Enter` to choose a quick fix.

**Tip** The editor lets you quickly navigate between the highlighted problems via keyboard shortcuts. Press `F2` to go to the next problem, and `Shift+F2` to go to the previous one.

Inspections that are too complex to be run on-the-fly are available when you perform code analysis for the entire project. You can do this in one of the following two ways: by selecting `Analyze | Inspect Code` from the main menu, or by selecting `Analyze | Run Inspection by Name` to run an inspection by its name.

Note that while inspections provide quick-fixes for code that has potential problems, intentions help you apply automatic changes to code that is correct. To get a list of intentions applicable to the code at the caret, press `Alt+Enter`.

For more details, refer to [Code Inspection](#).

## Code style and formatting

IntelliJ IDEA automatically applies a code style you've configured in the [Code Style settings](#) as you edit, and in most cases you don't need to call the **Reformat Code** action explicitly.

Useful formatting shortcuts:

Action	Shortcut
Reformat code	<code>Ctrl+Alt+L</code>
Auto-indent lines	<code>Ctrl+Alt+I</code>
Optimize imports	<code>Ctrl+Alt+O</code>

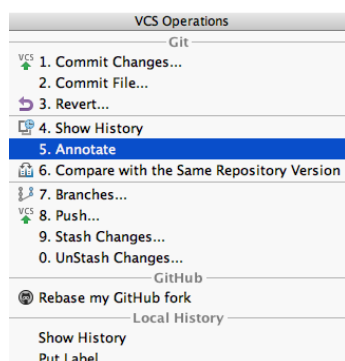

Note that by default, IntelliJ IDEA uses regular spaces for indents instead of tabs. If you have files with lots of indents, you may want to optimize their size by enabling the Use tab character option in the [Java code style settings](#).

For more details, refer to [Reformatting Source Code](#).

## Version control basics

To check out a project from a Version Control System (VCS), click Checkout from Version Control on the [Welcome Screen](#), or in the main VCS menu.

To quickly perform a VCS operation on the current file, directory, or an entire project, use the [VCS operations pop-up](#) by pressing `Alt+Back Quote`.

Once you've configured the VCS settings, you'll see the [Version Control tool window](#). You can switch to it anytime by pressing `Alt+9`.

The [Local Changes](#) tab of the Version Control tool window shows your local changes: both staged and unstaged.

Useful VCS shortcuts:

Action	Shortcut
Version Control tool window	<code>Alt+9</code>
VCS operations pop-up	<code>Alt+Back Quote</code>
Commit changes	<code>Ctrl+K</code>
Update project	<code>Ctrl+T</code>
Push commits	<code>Ctrl+Shift+K</code>

**Tip** **Annotation** (available from both the quick list, the main and the context menus) allows you to see who and when changed a line of code for any file.

For more details, refer to [Version Control with IntelliJ IDEA](#) .

## Branches

To perform an operation on a branch, either select Branches from the VCS main or context menu, the VCS operations pop-up , or the widget on the right of the status bar.

Note that for multiple repositories, IntelliJ IDEA performs all VCS operations on all branches simultaneously, so you don't need to switch between them manually.

[Shelves](#) , [stashes](#) and [patches](#) help you when you need to store some of the local changes without committing them to the repository. You can then switch to the repository versions of the files, and then come back to your changes later.

For more details, refer to [Manage branches](#) .

## Make

By default, IntelliJ IDEA doesn't automatically compile projects on saving. To compile a project, select Build | Make Project from the main menu, or press [\(Ctrl+F9\)](#) .

For more details, refer to [Compiling Applications](#) .

## Running and debugging

Once you've created a [Run/Debug configuration](#) by selecting Run | Edit Configurations from the main menu, you are able to run and debug your code.

### Action Shortcut

Run	<a href="#">(Shift+F10)</a>
Debug	<a href="#">(Shift+F9)</a>

When in the debug mode, you can [evaluate any expression](#) by using the **Evaluate expression** tool, which is accessed by pressing [\(Alt+F8\)](#) . This tool provides code completion in the same way as in the editor, so it's easy to enter any expression.

Sometimes, you may want to step into a particular method, but not the first one which will be invoked. In this case, use **Smart step into** by pressing [\(Shift+F7\)](#) to choose a particular method.

### Action Shortcut

Toggle breakpoint	<a href="#">(Ctrl+F8)</a>
Step into	<a href="#">(F7)</a>
Smart step into	<a href="#">(Shift+F7)</a>
Step over	<a href="#">(F8)</a>
Step out	<a href="#">(Shift+F8)</a>
Resume	<a href="#">(F9)</a>
Evaluate expression	<a href="#">(Alt+F8)</a>

If you want to "rewind" while debugging, you can do it via the **Drop Frame** action. This is particularly helpful if you mistakenly stepped too far. This will no revert the global state of your application, but will at least let you revert to a previous stack frame.

**Tip** Any breakpoint can be quickly disabled by clicking on the gutter while holding [\(Alt\)](#) . To change breakpoint details (e.g. conditions), press [\(Ctrl+Shift+F8\)](#) .

For more details, refer to [Running and Debugging](#) .

## Reloading changes and hot swapping

Sometimes, you need to insert minor changes into your code without shutting down the process. Since the Java VM has a HotSwap feature, IntelliJ IDEA handles these cases automatically when you call Make .

## Application servers

To deploy your application to a server:

1. Configure your artifacts by selecting File | Project Structure | Artifacts (done automatically for Maven and Gradle projects).
2. Configure an application server by clicking the Application Servers page of the Settings/Preferences dialog.
3. Configure a run configuration by selecting Run | Edit Configurations , then specify the artifacts to deploy and the server to deploy them to.

You can always tell IntelliJ IDEA to build/rebuild your artifacts (once they have been configured) by selecting Build | Build Artifacts .

**Tip** When you need to apply changes in the code to a running application, in addition to **Make** , you can use the Update action by pressing [\(Ctrl+F10\)](#) . This action is only available for the **Exploded artifact type**. Based on your choice, it can update resources or update classes and resources. When the **Update** action is applied in the **Debug mode**, it uses **HotSwap** ; otherwise, it uses **Hot redeployment** .

---

For more details, refer to [Working with Application Servers](#) .

## Working with build tools (Maven/Gradle)

Once you've imported/created your Maven/Gradle project, you are free to edit its `pom.xml` or `build.gradle` files directly in the editor. Any changes to the underlying build configuration will eventually need to be synced with the project model in IntelliJ IDEA.

If you want the IDE to synchronize your changes immediately, do the following:

- For `pom.xml`, enable the Import Maven projects automatically option in File | Settings | Build, Execution, Deployment | Build Tools | Maven | Importing (Windows and Linux) or IntelliJ IDEA | Preferences | Build, Execution, Deployment | Build Tools | Maven | Importing (macOS).
- For `build.gradle`, enable the Use auto-import option in Build, Execution, Deployment | Build Tools | Gradle of the Settings/Preferences dialog.

For manual synchronization, use the corresponding action on the Maven/Gradle tool window toolbar: .

Note that any goal or task can be attached to be run before a run configuration.

For more details, refer to [Build Tools](#) .

## Migrating from Eclipse or NetBeans

If you are considering the possibility to migrate from Eclipse or NetBeans to IntelliJ IDEA, refer to the migration guide for [Eclipse](#) or [NetBeans](#) .

## What's next

We strongly advise you to read the documentation. Also you might find it useful to refer to the Java tutorials under [Java SE](#) , and also to the tutorial on [Java EE](#) .

IntelliJ IDEA has keyboard shortcuts for most of its commands related to editing, navigation, refactoring, debugging, and other tasks. Memorizing these hotkeys can help you stay more productive by keeping your hands on the keyboard.

**Warning!** Use a keyboard with English layout. IntelliJ IDEA may not detect some of the shortcuts correctly for other national layouts.

## Choose the right keymap

To view the keymap configuration, open the Settings / Preferences dialog (`Ctrl+Alt+S`) and select Keymap.

**Warning!** Enable function keys and check for possible conflicts with global OS shortcuts

### – Use a predefined keymap

IntelliJ IDEA automatically selects a predefined keymap based on your environment. Make sure that it matches the OS you are using or select one that matches shortcuts from another IDE you are used to (for example, Eclipse or NetBeans).

### – Tune your keymap

You can modify a copy of any predefined keymap to assign your own shortcuts for commands that you use frequently.

### – Import custom keymap

If you have a customized keymap that you are used to, you can transfer it to your installation.

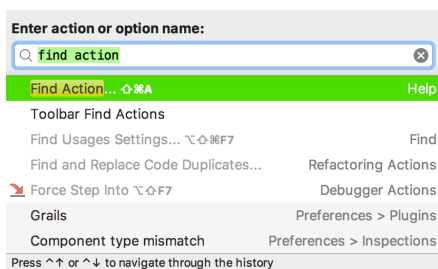

**Tip!** For macOS, select the Mac OS X 10.5+ keymap instead of Mac OS X

## Learn shortcuts as you work

IntelliJ IDEA provides several possibilities to learn shortcuts:

- **Find Action** is the most important command that enables you to search for commands and settings across all menus and tools.

Press `Ctrl+Shift+A` and start typing to get a list of suggested actions.

You can select the necessary command and press `Enter` to execute it.

- **Key Promoter X** is a plugin that shows the corresponding keyboard shortcut whenever a command is executed using the mouse and suggests to create a shortcut for commands that are executed frequently.
- If you are using one of the predefined keymaps for your OS, you can print the [default keymap reference card](#) and keep it on your desk to consult it if necessary. This cheat sheet is also available under Help | Keymap Reference. Full reference is documented in [Keyboard Shortcuts and Mouse Reference](#).

The following table lists some of the most useful shortcuts to learn.

### ShortcutAction

<code>Ctrl+Shift+A</code>	<a href="#">Find Action</a> Use keywords to search for a command and execute it.
<code>Ctrl+N</code>	<a href="#">Find class, file, or symbol</a>
<code>Ctrl+Shift+N</code>	Use keywords to find and jump to the desired class, file, or symbol.
<code>Ctrl+Shift+Alt+N</code>	
<code>Ctrl+E</code>	<a href="#">View recent files</a> Select a recently opened file from the list.
<code>Alt+Enter</code>	<a href="#">Show intention actions</a> Improve or optimize a code construct.
<code>Ctrl+Space</code>	<a href="#">Basic code completion</a> Complete names of classes, methods, fields, and keywords within the visibility scope.
<code>Ctrl+Shift+Space</code>	<a href="#">Smart code completion</a>

Complete code based on the type applicable to the current context.

Ctrl+Shift+Enter

Smart statement completion

Complete a statement with a syntactically correct code construct.

Ctrl+W

Extending or shrinking selection

Ctrl+Shift+W

Increase or decrease the scope of selection according to specific code constructs.

Ctrl+Slash

Add/remove line or block comment

Ctrl+Shift+Slash

Comment out a line or block of code.

Ctrl+Shift+F7

Highlight usages in file

Visualize all occurrences of the selected fragment in the current file.

## Use advanced features

You can further improve your productivity with the following useful features:

### – Quick Lists

If there is a group of actions that you often use, create a quick list to access them using a custom shortcut. For example, you can try using the following predefined quick lists:

– Refactor this `Ctrl+Shift+Alt+T`

– VCS Operations `Alt+Back Quote`

### – Smart Keys

IntelliJ IDEA provides various aids, such as automatically adding paired tags and quotes, and detecting *CamelHump* words.

### – Speed search

When the focus is on a tool window with a tree, list, or table, start typing to see matching items.

### – Press twice

Many actions in IntelliJ IDEA provide more results when you execute them multiple times. For example, when you invoke [basic code completion](#) with `Ctrl+Space` on a part of a field, parameter, or variable declaration, it suggests names depending on the item type within the current scope. If you invoke it again, it will include classes available through module dependencies. When invoked for the third time in a row, the list of suggestions will include the whole project.

### – Resize tool windows

You can adjust the size of tool windows without a mouse:

– To resize a vertical tool window, use `Ctrl+Shift+Left` and `Ctrl+Shift+Right`

– To resize a horizontal tool window, use `Ctrl+Shift+Up` and `Ctrl+Shift+Down`

This guide targets IntelliJ IDEA users who are already familiar with its basic features and would like to learn more. If you're relatively new to IntelliJ IDEA, we recommend that you read the [Discover IntelliJ IDEA guide](#) before delving into this one.

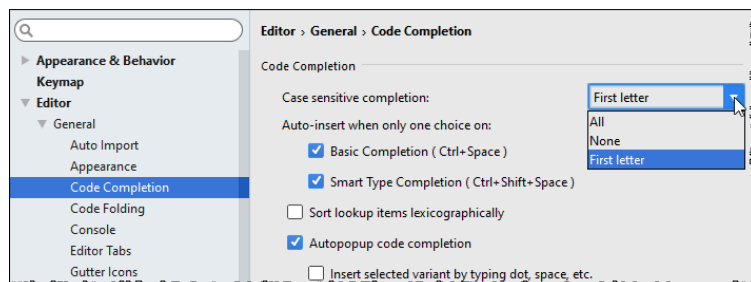

## Coding assistance

### Type info

If you want more information about a symbol at caret, e.g. where it comes from or what its type is, the [Quick Documentation](#) is your friend. Press `Ctrl+Q` to invoke it and you will see a popup with these details. If you don't need the full info, then use the Type Info action instead: it only shows the type of a selected expression, but doesn't take up that much of screen space.

### Code completion case sensitivity

By default IntelliJ IDEA code completion case sensitivity only affects the first letter you type. This strategy can be changed in the Settings/Preferences dialog, Editor | General | Code Completion, so you can make to either make the IDE sensitive to all letters or make it insensitive to the case at all, based on what better fits your preferences.

**Hot tip:** Here you can also turn off the Autopopup code completion option. This makes sense if you want the code completion popup to show up only when you explicitly call it.

### Disable highlighting usages of element at caret

Talking about the defaults you may want to change after learning IntelliJ IDEA better, we can't miss the Highlight usages of element at caret option in the Editor | General page of the Settings/Preferences dialog. If you know the `Ctrl+Shift+F7` shortcut and don't like the highlighting in the editor to appear and disappear each time you simply move the caret, you don't need this option.

### CamelHumps

By default, when you select anything in the editor, IntelliJ IDEA isn't sensitive to the case of the words. If you prefer to select words according to CamelCase, e.g. instead of selecting the whole word, select a part of it, you can enable this in Editor | General | Smart Keys of the Settings/Preferences dialog.

### Hippie completion

IntelliJ IDEA provides [Basic completion](#) via `Ctrl+Space`, [Smart completion](#) via `Ctrl+Shift+Space`, and [Statement completion](#) via `Ctrl+Shift+Enter`. All these features are based on the actual understanding of the code structure. However, sometimes you may need a more trivial, yet flexible logic that would suggest the words used earlier in the current file or even project regardless to their context. This feature is called [Hippie completion](#) and is available via `Alt+Slash`.

```
reportArray(((PatternSet) robj).getExcludePatterns(getProject()));
System.out.println();
System.out.println("Include patterns: ");
reportArray(((PatternSet) robj).getIncludePatterns(getProject()));
getExcludePatterns|

static String[] convertMetersToInches (String metersToConvertString) {
    String[] conversionResult = new String[2];
    double conversionFactor = 39.37;
    try {
        double metersToConvertDouble = Double.parseDouble(metersToConvertString);
        double
```

## Refactorings

### Undo refactorings

With IntelliJ IDEA you don't need to worry about consequences when refactoring code, because you can always undo anything by invoking [Undo](#) via the convenient `Ctrl+Z` shortcut.

### Extract string fragments

IntelliJ IDEA is capable of refactoring not only executable code, but also string literals. Select any fragment of a string, call [Extract](#) variable/constant/field/parameter to extract it as a constant and replace its usages throughout the code.

### Type migration

When you refactor, you usually rename symbols, or extract and move statements in the code. However, there's more to refactoring than just that. For example, [Type Migration](#) (available via `Ctrl+Shift+F6`) lets you change the type for a variable, field, parameter or a method's return value (`int → String`, `int → Long`, etc), update the dependant code, and resolve possible conflicts.

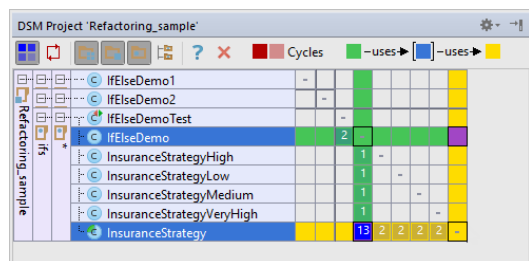

### Invert boolean

If IntelliJ IDEA can automate type migration, why not do the same with semantics? To invert all usages of a boolean symbol, just use the [Invert Boolean refactoring](#).

## Code analysis

### Dependency structure matrix

IntelliJ IDEA lets you analyze how tightly components in your code depend on each other, and you need to keep an eye on that because when there's too much dependencies, it's likely to cause various [problems](#). [Dependency Structure Matrix action](#) (available via the Analyze menu) will help you visualize and explore dependencies between modules, packages and classes.

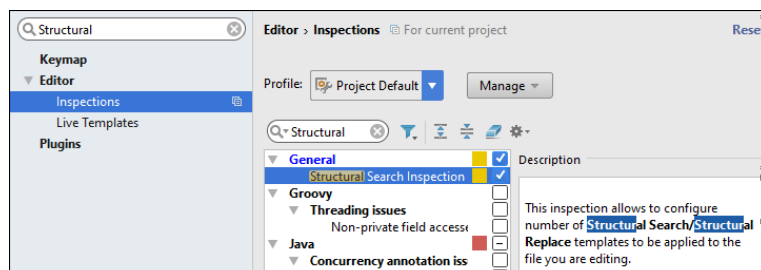

Despite its complex looks, it's a very easy-to-use tool. Just select a class or package and see where it's used and what it uses.

### Structural search and replace

[Structural Search and Replace, or SSR](#), is quite powerful (after you learn to use it right), and can be used for static code analysis and refactoring automation. In a nutshell, it lets you search for specific patterns in your code and replace them with parametrized templates. For that, it's equipped with its own language for defining code patterns that is described in more detail in this [article](#).

To access this feature, use the Edit | Find | Search/Replace Structurally... If you want to create your templates or patterns, go to Settings/Preferences dialog, click the page [Editor | Inspections](#), and enable Structural Search Inspection under the General node:

## User interface

### Disable breadcrumbs and tag tree highlighting

If you work with lots of HTML and XML and would like to avoid unnecessary distraction, you may want to disable breadcrumbs and tag tree highlighting in [Editor | General | Appearance](#).

### Disable unnecessary gutter icons

Gutter, the leftmost editor column, typically displays useful information related to the code you're editing. If you feel that sometimes it's just too much, you can configure what you want to see in the Settings/Preferences dialog: [Editor | General | Gutter Icons](#).

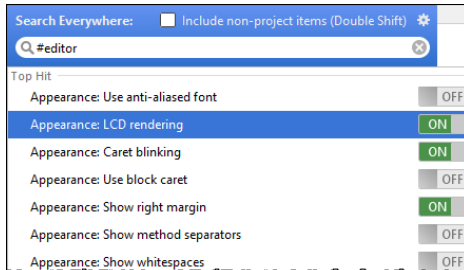

## Disable annoying intention light bulb

One more thing that might be annoying is the [intention bulb](#) that appears in the editor every time there is an intention available at the caret. Disabling that is a little bit more difficult: you need to manually edit your `<IntelliJ IDEA preferences folder>/options/editor.xml`, and add the following line:

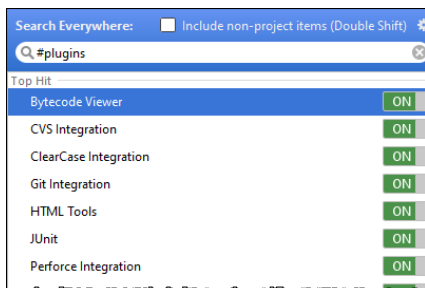

```
<option name="SHOW_INTENTION_BULB" value="false" />
```

## Using from Search everywhere

With [Search Everywhere](#) you can find arbitrary text fragments literally everywhere: in the code, libraries, parts of the UI, settings (by prepending the settings name with `#`), or even action names. If you're using this feature a lot, it's worth knowing that you can access IntelliJ IDEA settings by just pressing `Enter` right in its popup. For example, here we're accessing the editor settings:

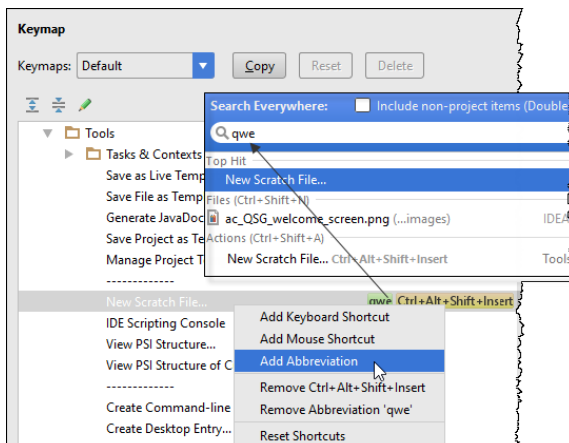

If you start your search query with `#plugins`, you'll be able to turn them on and off:

Other tags include `#appearance`, `#system`, `#inspections`, `#registry`, `#intentions`, `#templates`, and `#vcs`.

Another interesting fact is that Search Everywhere supports abbreviations. You can use [Keymap page](#) of the Settings/Preferences dialog to assign a short text to any action, and then have this action called from Search Everywhere by entering this text:

## Hide editor tabs

When you need to close all editor tabs except the current one, click the close icon `x` on the current tab holding `Alt`:

If you don't want to see the editor tabs at all, go to the [Editor Tabs](#) page of the Editor Settings/Preferences and under the Placement drop-down select None.

## Open file in new window

A feature that is not that easy to find, yet comes in handy, is opening a file in a new window by selecting it in the [Project Tool Window](#) and clicking `Shift+Enter`.

## Use path completion

Path completion helps you speed up the selection of files, folders, etc. This is useful when adding a new SDK in the Project Structure dialog, or specifying an application server home directory.

When you start typing a path, press `Ctrl+Space` to invoke the suggestions list:

## Add stop and resume buttons to the toolbar

It might be convenient to add Stop and Resume buttons to the toolbar of the [Navigation Bar](#). You can do it via the [Appearance and Behavior | Menus and Toolbars](#) page of the Settings/Preferences dialog.

If you prefer to use the mouse rather than keyboard shortcuts, this way you won't need to open the Debug tool window to manage your current debugging session.

## Editor

### Compare with clipboard

IntelliJ IDEA has a built-in Diff viewers for code, jar files, revisions and even images. To invoke it, select any pair of files and press `Ctrl+D`.

If you have selected a single file, the IDE will prompt you to select the one to compare to. To quickly compare active editor with Clipboard, choose `View | Compare with Clipboard`.

### Paste from history

Speaking of Clipboard, IntelliJ IDEA keeps track of everything you put there. Anytime you want to paste one of the previously copied items, press `Ctrl+Shift+V`.

### Multiple selections

[Multiple selection](#) is a relatively new, very powerful editor feature, which lets you quickly select and edit multiple (adjacent or not) pieces of code at once.

In a nutshell, here's what happens. You either start with pressing `Alt+J` (and then IntelliJ IDEA selects a symbol at caret), or you can just select something as you normally would.

Then, press `Alt+J` and IntelliJ IDEA will search the current file forward until it finds a matching piece of text, which it adds to the selection. You can press `Alt+J` again to go forward, or `Shift+Alt+J` to go back, but note that when search reaches the end of file, it will start over from the beginning of the file.

```
<procedure title="To select multiple words" alternative-title="Using #
  <step...>
</procedure>
<anchor name="column_selection"/>
<procedure title="To toggle between the line and the column selection
<anchor name="altdrag"/>
<procedure title="To make selection in the Column Selection Mode"
```

After selection is complete, you can start editing all the fragments as if they were one.

**Hot tip**: One more way to clone caret is to press `Ctrl` (`Alt` for macOS) twice, and then move the caret up or down with arrows or simply with mouse.

### Emmet

In case you didn't know, [Emmet](#) is a great way to write HTML, XML and CSS code. IntelliJ IDEA supports it [out of the box](#): simply write an Emmet expression and press `Tab` to expand it.

Use the Emmet preview action (which is available via Find Action or Search Everywhere - so make sure to assign it to a handy shortcut) to see a preview of the resulting code.

```

html | body
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <title>Title</title>
</head>
<body>
  <table>
    <tr>
      <td>
        <table id="users">
          <tr class="user">
            <td></td>
          </tr>
        </table>
      </td>
    </tr>
  </table>
</body>
</html>

```

## Regex

Regular expressions are powerful and widely used, but sometimes it's just too hard to write them properly. IntelliJ IDEA will help you check any Regex in your code: just place caret in it and press `Alt+Enter` to use the [Check Regex](#) intention:

```

public class RegexpExample {
    Pattern PATTERN = Pattern.compile(
        "[A-Za-z0-9._%+-]+@[A-Za-z0-9.-]+\\.[A-Za-z]{3,4}");
}

```

## Find and replace with Regex groups

Another place where IntelliJ IDEA helps with Regex is the [Find and Replace](#) feature. It's worth knowing that it supports captured groups in replacement expressions.

```

<code>title="Multiline search and replace in the current file" /&gt;
</code>

```

Find and replace also lets you exclude comments and literals from search: to do that, use the Gear icon .

## Bytecode viewer

Sometimes seeing the actual bytecode your program generates is very [insightful](#).

In IntelliJ IDEA you can always do that via `View | Show Bytecode`.

## Version control

### Amend changes

In the [Commit Changes](#) dialog IntelliJ IDEA offers to perform a variety of operations. One of them is Amend commit, which is useful when you want to change your last commit and join your current change to it.

### Shelves and patches

[Shelves](#) is an IDE feature similar to [Git Stash](#), but that works for all VCS: it helps when you need to pause your current work and pull something from the repository to fix it asap, and then resume working on whatever it was you were working on. This feature takes care of locally changed files without committing them, so no more lost changes or hastily made merge commits.

Refer to the page [Git Stash](#) and to the section [Stashing and Unstashing](#) for more detail.

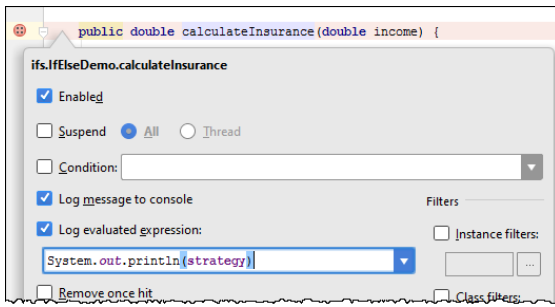

[Patches](#) allow you to save a set of changes to a text file that can be transferred via email (or any other ancient medium), and then applied to the code. It's super helpful when you really need to commit something after your plane crash landed on a desert island, or you somehow else got yourself in a situation without reliable broadband connection.

Refer to the section [Using Patches](#) for more detail.

## Debugging

### Action, or method breakpoints

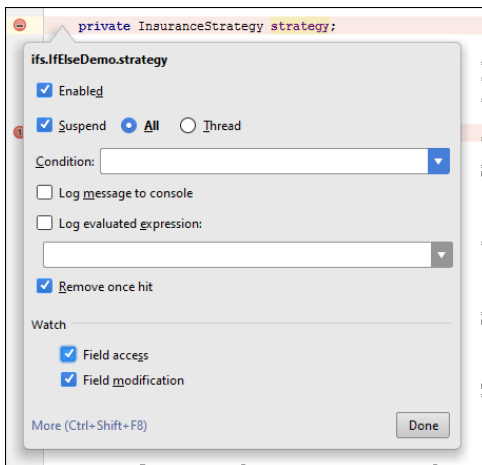

Sometimes you may want to evaluate something at a particular line of code without actually making a stop. You can do that by using a [Method breakpoint](#). To create one, just click the gutter holding `Shift`.

This way you can print any expression to the output without changing the code. This is especially useful when you debug libraries or a remote application.

## Field breakpoints or field watchpoints

In addition to the action breakpoints mentioned above, you can also use [Field watchpoints](#). This breakpoint will stop execution when a field associated with it is accessed. To create field watchpoints, just click the gutter holding `Alt` (`Ctrl+Cmd` for macOS).

## Object markers

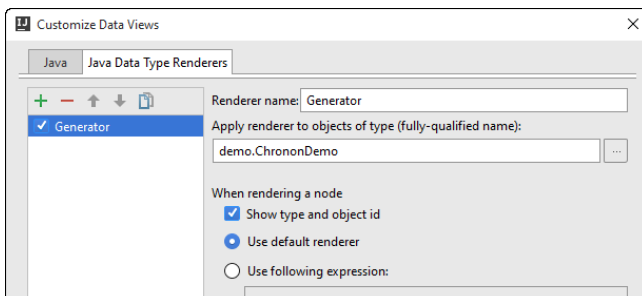

When you're debugging an application, IntelliJ IDEA lets you mark particular instances of arbitrary objects with colored labels for easier identification via the [Mark Object](#) action (available in the [Evaluate Expression](#), [Variables](#) or [Watches](#) views.)

And if you have any instance marked with a label, you can use it in the condition expression as well:

## Custom data renderers

[Evaluate Expression](#), [Variables](#), [Watches](#) and [inline debugger](#) all use a standard way to render variable values, mostly based on `toString` implementation of classes. Not everyone knows that you can define your own custom renderers for any class. For that, select [Customize Data Views](#) from the context menu in the [Debug](#) tool window.

This is especially useful when some of the classes in the libraries you're using do not provide a meaningful `toString` implementation—so you can define it yourself outside of the library.

## Drop frame

In case you want to "go back in time" while debugging you can do it via the [Drop Frame](#) action. This is a great help if you mistakenly stepped too far. This will not revert the global state of your application but at least will get you back by stack of

frames.

## Force return

The way around, if you want to jump to the future, and force the return from the current method without executing any more instructions from it, use the Force Return action (to invoke it, press `Ctrl+Shift+A` and type the action name). If the method returns a value, you'll have to specify it.

## DCEVM

Sometimes when you're making quick changes to code, you want to immediately see how they will behave in a working application. Unfortunately, the Java HotSwap VM has lots of limitations: you can't, say, add a new method or a field to a class and perform the hot swapping; the only thing you can actually change during the hot swapping is the method bodies.

Refer to the sections [Reloading Classes](#) and [HotSwap](#) for details.

Luckily, there is a way to amend this situation with the new open-source project Dynamic Code Evolution VM, a modification of Java HotSwap VM with unlimited support for reloading classes at runtime.

Using it in IntelliJ IDEA is easy with the dedicated [plugin](#). When you enable the plugin, the IDE will offer you to download DCEVM JRE for your environment. Then you'll have to choose it in the list of alternative JREs.

## Update application

If you are running your application on an application server (e.g. Tomcat, JBoss, etc), can you reload changed classes and resources using the Update application action via `Ctrl+F10`.

Refer to the section [Updating Applications on Application Servers](#) for details.

## Tools

### External tools

IntelliJ IDEA has many developer tools integrated and working out of the box. If a tool you need is not integrated, but you'd like to use it via a shortcut, go to Settings/Preferences | Tools | [External Tools](#), and configure how to run this tool. Then you'll be able to run this tool via the Tools | External Tools main menu.

Refer to the section [Configuring Third-Party Tools](#).

There are a lot of ways to obtain information about IntelliJ IDEA and its features, report issues and get support.

In this section:

- Getting Help
  - [Overview](#)
  - [Menu commands](#)
- [Using Help Topics](#)
- [Using Tips of the Day](#)
- [Using Online Resources](#)
- [Using Productivity Guide](#)
- [Reporting Issues and Sharing Your Feedback](#)
- [Keymap Reference](#)

## Overview

Use the Help menu commands:

## Menu commands

**Menu**  
**Keyboard**  
**Description**

**item** **shortcut**

Menu item	Keyboard shortcut	Description
Find Action	Ctrl+Shift+A	Choose this command to invoke an action by its name .
Keymap Reference		Choose this command to see the IntelliJ IDEA shortcuts map in PDF format.
Demos and Screencasts		Choose this command to see the IntelliJ IDEA demo <a href="#">videos and screencasts on YouTube</a> .
Help		Choose this command to visit IntelliJ IDEA online Help topics.
Tip of the Day		Choose this command to show an arbitrary tip. Refer to the section <a href="#">Using Tips of the Day</a> .
Productivity Guide		Choose this command to <a href="#">show productivity guide</a> .
Support Center		Choose this command to open <a href="#">JetBrains Support</a> page.
Submit Feedback		Choose this command to report your overall impression of IntelliJ IDEA to the support service. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> .
Show Log in Explorer/Finder		Choose this command to find IntelliJ IDEA's log. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> for details.
Edit Custom Properties		Choose this command to open the custom file <code>idea.properties</code> , located under the user home. If this file does not exist, IntelliJ IDEA suggests to create it. Refer to the section <a href="#">Tuning IntelliJ IDEA</a> for details.
Edit Custom VM Options		Choose this command to open the custom file <code>*.vmoptions</code> , located under the user home. If this file does not exist, IntelliJ IDEA suggests to create it. Refer to the section <a href="#">Tuning IntelliJ IDEA</a> for details.
Debug Log Settings		Choose this command to change logging level for a category. Choosing this command leads to opening the Custom Debug Log Configuration dialog box, where you have to type the log categories names, separated with new lines. Refer to the section <a href="#">Reporting Issues and Sharing Your Feedback</a> .
What's New in IntelliJ IDEA		Choose this command to open the <a href="#">What's New page</a> .
Licences		Choose this command to show the legal information.
Register...		Choose this command to <a href="#">register</a> IntelliJ IDEA.

Check for Updates...

Choose this command to obtain information about the current version, and the availability of newer versions of IntelliJ IDEA. Refer to [Updates](#) page. This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu.

---

About

Choose this command to obtain information about the current version of IntelliJ IDEA, current build, etc. Press  to close the popup window. This command is available on Windows/Linux. On Mac OS it appears on the IntelliJ IDEA menu.

In this section:

- [Documentation structure](#)
- [Built-in documentation](#)

This type of documentation is available for Ultimate edition only.

- [Online documentation](#)

This type of documentation is available for both Ultimate and Community editions.

## Documentation structure

IntelliJ IDEA documentation has the following structure:

Meet IntelliJ IDEA

This part contains system requirements and installation information, quick start guide that helps you get a grip of IntelliJ IDEA, the section [Discover IntelliJ IDEA](#) that outlines the main features of IntelliJ IDEA, the section [Java SE](#) with the tutorials that help you perform the most basic actions - create and run your first application.

Migration Guides

[This part](#) is intended for Eclipse and NetBeans users, who are about to move to IntelliJ IDEA.

How to

This contains information related to the platform features (such as, for example, [using the IntelliJ IDEA editor](#) , [tool windows](#) , or [version control](#) ) and [language- and framework-specific guidelines](#) .

Reference

This part contains the miscellaneous information, which includes the [basic concepts, or essentials](#) , [dialogs reference](#) , [icons reference](#) , and more.

## Using built-in documentation

Built-in documentation enables you to browse through the topics using the table of contents, find occurrences in the Search tab, or use the detailed Index that contains all keywords from all topics.

### To bring up help contents, do one of the following

- On the main menu, choose Help | Help Topics .
- Press [F1](#) .
- Click ? button, if it is available.

### To find a particular piece of information

1. Click the Search tab of the help viewer.
2. In the search field, type the search string and press [Enter](#) .
3. In the list of topics that contain occurrences of the search string, select the desired one. Occurrences are highlighted in the right pane of the help viewer.

### To find a keyword in the Index tab

1. Click the Index tab of the help viewer.
2. In the search field, type the desired keyword and press [Enter](#) . The caret rests at the first occurrence of the keyword. Every time you press [Enter](#) , the caret moves to the next occurrence of the keyword. To see the information about a keyword, select one of its sub-entries.

## Online documentation

On the IntelliJ IDEA site, find online documentation:

[IntelliJ IDEA web help](#)

The online version makes it possible to find entries in the table of contents, browse documentation with the table of contents, rate topics and express your opinion. The layout of online documentation consists of:

Table of contents pane

This pane shows the table of contents.

- Use this pane to browse through the topics.
- Click  button to show or hide this pane.
- If for some reason your browser fails to show actual table of contents, refresh the page.

Topics pane

This pane shows the topic that is currently selected in the table of contents.

- In the Keymap drop-down list, choose the platform you want to view keyboard shortcuts in (Windows/Linux, macOS)

etc.)

## Finding a piece of information in the table of contents

1. Switch to the Table of contents pane.
2. In the Search IntelliJ IDEA help field, type your query.
3. Press **Enter**.

The table contents shrinks to show the search results. Click the desired entry to show the corresponding page in the Topic pane.

Tips of the Day provide a collection of useful and interesting hints. They show up every time you start IntelliJ IDEA.

### **To show Tips of the Day**

- Choose Help | Tip of the Day on the main menu.

### **To navigate through the collection of tips**

- Use the Previous and Next buttons.

### **To suppress Tips of the Day**

- In the Tips of the Day window, clear the checkbox Show Tips on Startup .

If built-in documentation fails to answer your questions, you can find more information on the web. The following resources are available:

- [Official JetBrains home page](#)
- [IntelliJ IDEA community](#)
- [Blog](#)
- [Online version of documentation](#) contains the latest updates.
- Collection of [articles, white papers etc.](#)

Finally, do not miss the JetBrains TV ( [Help | JetBrains TV](#) ). On the [JetBrains TV](#) page, choose the IntelliJ IDEA channel, and watch screencasts.

IntelliJ IDEA smartly analyzes features you use during your development sessions and reminds you of the features you might have missed.

The [Productivity Guide](#) dialog, available in [Help | Productivity Guide](#), displays the list of features with usage statistics and tips.

Besides analysing your personal usage of features, you can discover similar features that you've never used. One of the ways to do so is to sort features by Group, and look for unused features that are next to the frequently used ones. You can quickly check how to use the feature by selecting it and studying the corresponding tip that opens.

IntelliJ IDEA provides various means to report problems and seek for assistance. In this section:

- [Locating IntelliJ IDEA log](#)
- [Configuring IntelliJ IDEA log settings](#)
- [Reporting issues](#)
- [Sharing feedback](#)
- [Seeking assistance](#)

## Locating IntelliJ IDEA log

On certain occasions, you will be required to attach the IntelliJ IDEA log to an email to the support service. You can easily locate the log file as described below.

- On the main menu, choose Help | Show Log in Explorer (Windows and Linux), or Help | Show Log in Finder (macOS). The Explorer/Finder opens, with the log file selected.

## Configuring IntelliJ IDEA log settings

To avoid editing the `log.xml` file itself, IntelliJ IDEA suggests a handy dialog box to change logging level for a category. This file resides under the `bin` directory of IntelliJ IDEA installation.

1. On the main menu, choose Help | Debug Log Settings... .
2. In the dialog box that opens, type the log categories names, separated with new lines.

While editing `log.xml` , keep in mind the following:

- It is not recommended to change `log.xml` , because from time to time it causes problems with patches.
- Editing `log.xml` should be done in tight contact with the support service. The reason is that the users might be unaware of the modules names to be specified, while the support service can suggest modules for the better diagnostics.

## Reporting issues

1. Open the IntelliJ IDEA tracking system at <https://youtrack.jetbrains.com/> .  
If you are not yet registered, do it.
2. Click Create issue .
3. On the page that opens, choose IntelliJ IDEA from the Project drop-down list.
4. Describe your problem and provide a brief summary of it in the Description and Summary fields respectively.
5. If necessary, attach a screenshot that illustrates your problem.
6. Click Create issue when ready.

## Sharing feedback

To share your feedback, do one of the following:

- Choose Help | Submit Feedback , which redirects you to the online feedback form.  
This form enables you to create a IntelliJ IDEA-specific [YouTrack](#) issue.

## Seeking assistance

To find assistance, do one of the following:

- Apply to the [JetBrains Support](#)
- Write to the support service. Use the following address:
  - [intellij-support@jetbrains.com](mailto:intellij-support@jetbrains.com)
  - [idea-support@jetbrains.com](mailto:idea-support@jetbrains.com)

If necessary, attach the source code and the [IntelliJ IDEA log](#) .

- Ask the [IntelliJ IDEA Community](#) .

IntelliJ IDEA provides the default keymap reference for Windows/Linux and for macOS in the [pdf](#) format.

To view the built-in keymap reference, choose Help | Keymap Reference from the main menu.

Alternatively, see the [web-version](#).

Project settings refer to a set of preferences related to resources, file colors, version control options, code styles, etc.  
Project settings are stored with each specific project as a set of `xml` files under the `.idea` folder.

You can configure project settings on the two possible levels:

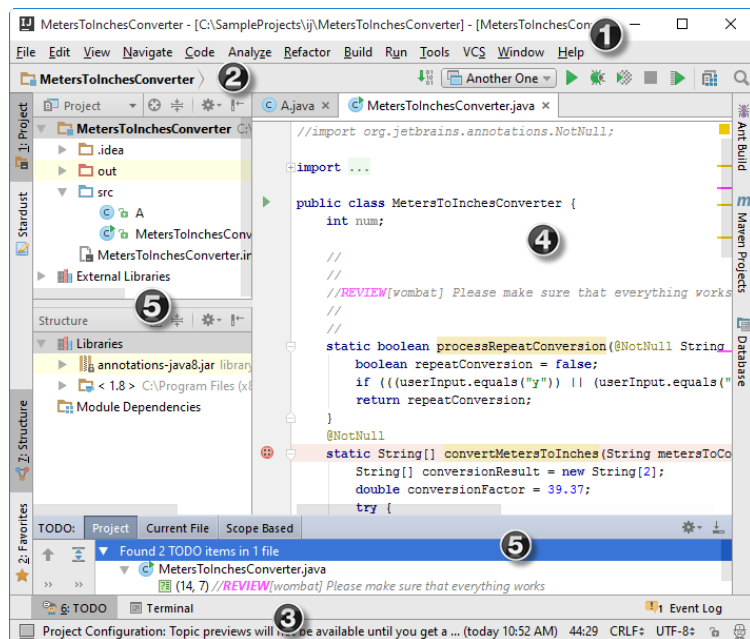

- The level of a template project . The settings defined for a template project, apply to any project you create.
- The project level . The settings defined on this level apply to the current project only.

Here you can learn how IntelliJ IDEA user interface is organized to help you find your way through your working environment.

**Tip** This page outlines the default (out-of-the-box) IDE interface layout. Note that [plugins](#) you are installing may change the way your IDE looks and behaves, for example there can be extra command buttons or menu items.

When you first run IntelliJ IDEA, or have no open project, IntelliJ IDEA displays the [Welcome screen](#) which enables quick access to the major entry points. When a project is opened, IntelliJ IDEA displays the main window.

IntelliJ IDEA's main window consists of logical areas, which are shown on the picture below, marked with numeric labels.

1. Main menu and toolbar — contain commands that affect the entire project or large portions of it, such as opening, creating project, refactoring the code, running and debugging applications, keeping files under version control and more.

The main toolbar duplicates the main menu's essential commands for quicker access. By default, the main toolbar is hidden. To show it, select View | Toolbar from the main menu.

2. Navigation bar — a quick alternative to the [Project view](#) . Use it to [navigate](#) your project and [open files for editing](#) .

Use View | Navigation Bar to hide or show the navigation bar; press `Alt+Home` to bring the application focus to the navigation bar.

3. **Status bar** — indicates the status of your project, the entire IDE, and shows various warning and information messages.

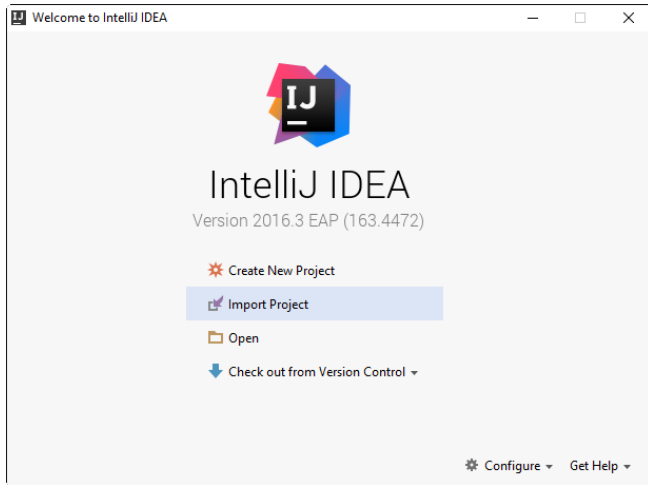

4. **Editor** — here you can read, create, and modify your code.

5. **Tool windows** — secondary windows that provide access to various specific tasks (project management, search, running and debugging, integration with version control systems, etc.).

## Overview

IntelliJ IDEA displays the Welcome screen when no project is open. From this screen, you can quickly access the major starting points of IntelliJ IDEA. The Welcome screen appears when you close the current project in the only instance of IntelliJ IDEA. If you are working with multiple projects, usually closing a project results in closing the IntelliJ IDEA window in which it was running, except for the last project, closing this will show the Welcome screen.

The Welcome screen is divided into the following sections: Quick Start and Recent Projects (if any).

**Tip** Use the **Tab** key to navigate through the Welcome screen.

## Quick start

Use the links of this section to [create a new project](#) , [open](#) or [check out](#) a project from version control.

Also, use the drop-down arrows (▾) Configure to [configure your working environment](#) and [default project](#) , and Get Help to open help topics, tips of the day, and default keymap document.

## Recent projects

If appropriate, the left-hand pane shows a list of projects you've recently been working with. Click a project to reopen it.

To find a project of interest, start typing its name.

To delete a recent project from the list, follow these steps:

1. Use the **Tab** key to move focus into the list of Recent projects.
2. Use arrows keys to select the project you'd like to remove, or find it, as shows above.
3. Do one of the following:
  - Press Delete on your keyboard and confirm deletion in the Remove Recent Project dialog box that opens.
  - To remove the selected recent project silently, click **X** or choose Remove Selected from Welcome Screen on the context menu of the selection.

On this page:

- [Overview](#)
- [Main elements of IntelliJ IDEA window](#)
- [Tips and tricks](#)

## Overview

IntelliJ IDEA menus and toolbars let you carry out various commands. The main menu and toolbar contain commands that affect the entire project or large portions of it. Additionally, context-sensitive pop-up menus let you perform the commands, which are specific to a part of a project, like source file, class, etc. Almost each of the commands has an associated keyboard shortcut to enable quicker access to it.

Use the check commands of the View menu to show or hide the main elements of the IntelliJ IDEA window. For example, if you want to show the main toolbar, make sure that the check command `Toolbar` is selected.

## Main elements of IntelliJ IDEA window

### 1. Main menu

The main menu contains commands for opening, creating projects, refactoring the code, running and debugging applications, keeping files under version control and more.

### 2. Main toolbar

The main toolbar contains buttons that duplicate the essential commands for quicker access. You can hide the main toolbar, using the checked command on the toolbar context menu.

By default, the main toolbar is hidden. To show it, select the check command `View | Toolbar` on the main menu.

### 3. Navigation bar

[Navigation bar](#) is a quick alternative to the Project tool window.

By default, the Navigation bar is shown. To hide it, clear the check command `View | Toolbar` on the main menu.

### 4. Context menus

These menus, available with right-click, contain commands applicable to the current context.

### 5. Pop-up menus

These menus, available with `Alt+Insert`, contain commands applicable to the current context.

## Tips and tricks

- Show or hide the main elements of IntelliJ IDEA UI using the View menu.
- Descriptions of the actions from all the menus and toolbar buttons are displayed in the left side of the Status bar.
- If you know which action you want to perform, but do not know where to find the appropriate command, just press `Ctrl+Shift+A`, type some part of the name of action you want to perform, and select the desired action from the suggestion list.

On this page:

- [Introduction](#)
- [Toggling the Navigation Bar](#)
- [Tips and tricks](#)

## Introduction

Navigation Bar is a quick alternative to the [Project view](#) . Use this tool to [navigate](#) through the project and [open files for editing](#) .

## Toggling the Navigation Bar

### To show the Navigation Bar, do one of the following

- On the View menu, select the check command Navigation Bar .
- Press `Alt+Home` .

### To hide the Navigation Bar

- On the View menu, clear the check command Navigation Bar .

## Tips and tricks

Please note the following:

- When the [main toolbar](#) is hidden, the Navigation Bar shows the run/debug configuration selector, run  and debug  , project structure  , version control buttons (if version control integration is enabled) and [search everywhere](#) magnifying glass  .
- When the Navigation bar is hidden, press `Alt+Home` to open it floating.
- Pressing `Escape` returns focus to the editor.

## Introduction

IntelliJ IDEA Status Bar indicates the current IDE state and lets you carry out certain environment maintenance tasks.

## Status Bar icons

### IconDescription

	Click to toggle showing or hiding tool window bars. Also double press and hold  (for macOS) or  (for Windows or *NIX) to show hidden tool window bars. Refer to the <a href="#">procedure description</a> .
	This section of the Status bar shows description of a command, currently selected on the main menu, context menu, or a toolbar.
	Click this icon to invoke the <a href="#">Background Tasks manager</a> . Visibility of this icon in the Status bar depends on a launched background task.
	The first two numbers denote the current caret position in the editor(line and column). If a selection is made in the editor, IntelliJ IDEA shows the length of the current selection after slash.
	This Lock icon indicates the <a href="#">read-only</a> or <a href="#">writable</a> attribute of the current file in the editor. To toggle the file attribute, click the Lock icon or use the File   Make File Writable/Read-only command on the main menu.
	View and change <a href="#">line endings</a> of the current file in the editor.
	View and change <a href="#">encoding</a> of the current file in the editor.
	Click this icon to navigate to the pending source control changelists in the <a href="#">Incoming tab</a> of the Version Control tool window.
	Hovering your mouse pointer over the icon shows the current <a href="#">code inspection</a> profile at the tooltip.  Clicking the Hector icon results in showing a dialog box with the following functions: <ul style="list-style-type: none"><li>– <a href="#">Highlighting level</a> . Use the slider to <a href="#">change highlighting level</a> for the current file , or <a href="#">configure inspection profile</a> . Depending on the highlighting level selected by the slider, Hector keeps an eye on the code  (Inspection level), turns half face  (Syntax), or averts his face from the code  (None).</li><li>– <a href="#">Power Save Mode</a> . Select this checkbox to minimize power consumption of your computer on account of eliminating the background operations. To indicate that the mode is on, Hector fades  . When Power Save Mode is on, IntelliJ IDEA reduces its functionality to the one of a text editor, by not executing expensive background activities that drain laptop battery. These activities include error highlighting and on-the-fly inspections, autopup code completion , and automatic incremental background compilation .  You can also toggle Power Save Mode through the File   Power Save Mode command on the main menu.</li><li>– <a href="#">Import popup</a> . Use this checkbox to enable or disable <a href="#">auto-import</a> for the current file. You can turn auto-import off for the whole product in the <a href="#">Auto Import</a> page of the Settings/Preferences dialog.</li></ul>
	Indicates that there are unattended notifications. Click this icon to see the notification descriptions in the Event Log tool window.
	Alternatively, when the icon is empty, there are no new notifications.
	This blinking icon indicates that internal IDE errors have occurred. Click to view the error descriptions and submit reports.
	Shows the current heap level and memory usage. Visibility of this section in the Status bar is defined by the Show memory indicator check box in the <a href="#">Appearance</a> page of the Settings/Preferences dialog. It is not shown by default. Click the memory indicator to run the garbage collector.

**Note** More icons appear in the Status Bar as you download and install plugins.

## Basics

IntelliJ IDEA provides special view modes:

- **Full Screen mode** allows you to use the entire screen for coding. This removes all menus from view, as well as the operating system controls. However, you can use context menus and keyboard shortcuts. The main menu is also available when you hover the mouse pointer over the top of the screen.
- **Presentation mode** is similar to the **Full Screen mode**, but it is designed for making presentations that involve coding with IntelliJ IDEA. In this mode, IntelliJ IDEA increases the font size and hides everything except the editor. If necessary, tool windows can also be displayed in this view using the corresponding items in the View | Tool Windows menu.
- **Distraction-free mode** shows no toolbars, no tool windows, no editor tabs; the code is center-aligned, etc.

These actions are available only through the View menu. By default they are not mapped to any shortcuts but you can create your own shortcuts as described in [Configuring Keyboard Shortcuts](#).

### Toggling the full screen mode

Besides [manipulating the tool windows](#) (show/hide or resize them), IntelliJ IDEA makes it possible to maximize the entire product window, hiding the main menu.

- To switch to the full screen mode, choose View | Enter Full Screen on the main menu.
- To exit the full screen mode, choose View | Exit Full Screen on the main menu.

### Toggling the presentation mode

In the presentation mode, the editor occupies the entire screen, while all the other IntelliJ IDEA components are hidden.

Besides that, the font size in this mode is larger than usual. You can define the font size for the presentation mode in the [Appearance page](#) of the Settings/Preferences dialog.

- To switch to the presentation mode, choose View | Enter Presentation Mode on the main menu.
- To exit the presentation mode, choose View | Exit Presentation Mode on the main menu.

### Toggling the distraction-free mode

In the distraction-free mode, the editor occupies the entire IntelliJ IDEA frame, without any editor tabs and tool-window buttons. The code is center-aligned.

- To switch to the distraction-free mode, choose View | Enter Distraction-Free Mode on the main menu.
- To exit the distraction-free mode, choose View | Exit Distraction-Free Mode.

### Toggling the viewing modes in the Switch pop-up list

1. Press `Ctrl+Back Quote` or choose View | Quick Switch Scheme on the main menu.
2. In the Switch pop-up list that opens, choose View mode.
3. On the context menu, choose the required mode. The contents of the menu depend on your current mode:
  - Enter Presentation Mode / Exit Presentation Mode
  - Enter Distraction Free Mode / Exit Distraction Free Mode
  - Enter Full Screen / Exit Full Screen

IntelliJ IDEA allows you to define any image as a background. So doing, you can set a background image for the current project only, or for any project you open or create anew.

This feature has no keyboard shortcut (you can easily create a shortcut as described in the section [Configuring Keyboard Shortcuts](#) ).

## To set a background image

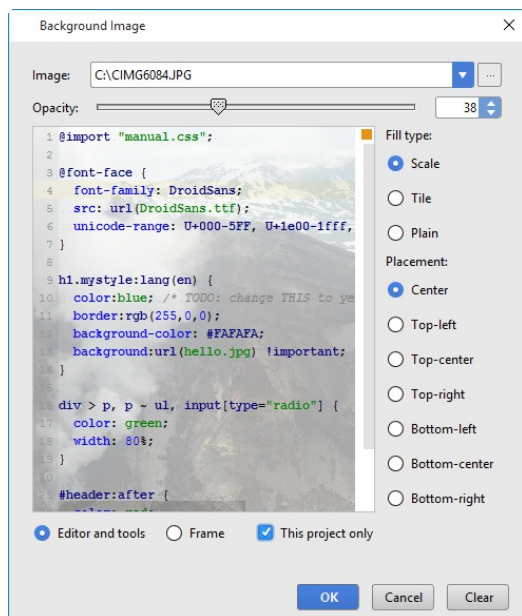

1. Do one of the following:

- Press **Shift** twice (see [Searching Everywhere](#) ).
- Press **Ctrl+Shift+A** (see [Navigating to Action](#) ).

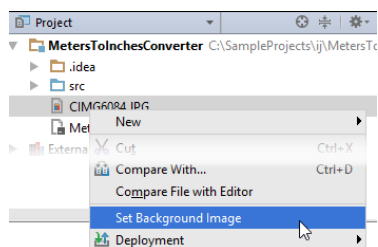

2. In the dialog box that opens, specify the image you want to use as the background, its opacity, filling and placement options. Besides that, you can choose to show background in the editor and tool windows, or in the IntelliJ IDEA frame.

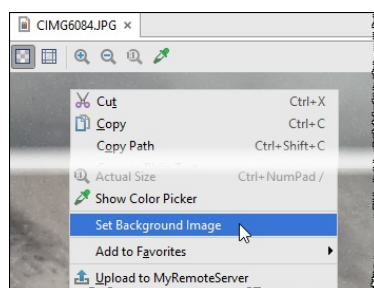

Also, select the checkbox **This project only** to show background in the current project, and ignore this background in the other projects.

If an image is already selected in a IntelliJ IDEA project, this action is also available from the context menu of the Project tool window:

and in the image editor

IntelliJ IDEA helps define settings and structure of a default project. These settings are used as defaults every time you create a new project.

On this page:

- [Accessing default project settings](#)
- [Accessing the default project structure](#)

### **To access default project settings**

1. On the main menu, choose File | Other Settings | Default Settings .
2. Define the desired settings in the [Settings/Preferences](#) dialog box that opens.

### **To access the default project structure**

- On the main menu, choose File | Other Settings | Default Project Structure .
- Define the desired settings in the [Project Structure](#) dialog box that opens.

On this page:

- [Introduction](#)
- [Opening the Settings / Preferences dialog](#)
- [Finding an option or setting](#)
- [Finding an option or setting using Search Everywhere or Find Action](#)

## Introduction

This section describes simple steps required to access the Settings/Preferences dialog. Note that the settings that pertain to the current project, are marked with  icon.

## Opening the Settings / Preferences dialog

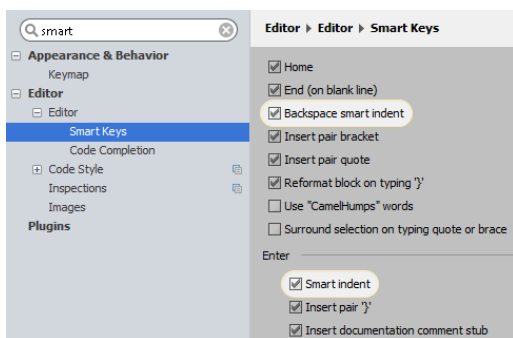

Do one of the following:

- Press `Ctrl+Alt+S`.
- On the main toolbar, click .
- On the main menu, choose File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS
- Press `Ctrl+Shift+A`, type `settings` and press `Enter`. See [Navigating to Action](#).
- Click  in the upper-right corner of the IntelliJ IDEA window, and type `#`.

Refer to [Finding an option or setting](#) using Search Everywhere or Find Action below.

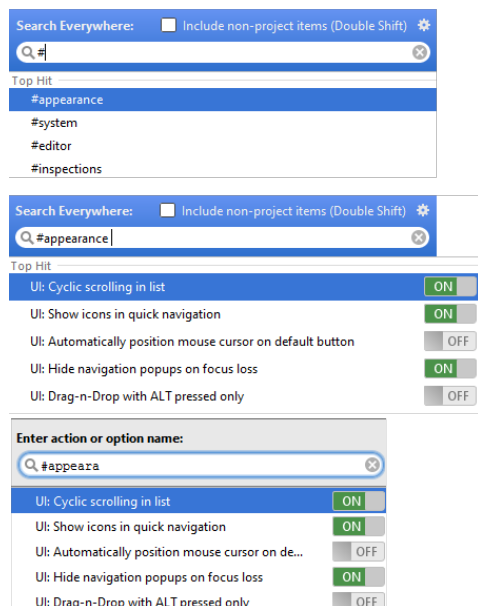

## Finding an option or setting

1. Open the [Settings / Preferences dialog](#).
2. In the search field, start typing the text that you expect to find in the name of the setting. As soon as the specified text is found, the matching element is highlighted and the corresponding page is displayed.

## Finding an option or setting using Search Everywhere or Find Action

You can also use [Searching Everywhere](#) or [Find Action](#). To find an option or setting, first type `#` character, and then choose one of the suggested categories:

On this page:

- [Basics and definitions](#)
- [Configuring code style for a language](#)
- [Copying code style settings from other languages](#)
- [Applying framework-specific pre-configured coding standards](#)
- [Configuring the code style for a project using EditorConfig](#)

## Basics and definitions

If certain coding guidelines exist in a company, one has to follow these guidelines when creating source code. IntelliJ IDEA helps maintain the required code style.

Code styles are defined at the project level and at the IDE level (global).

- At the **Project** level, settings are grouped under the Project scheme, which is predefined and is marked in bold. The **Project** style scheme is applied to the current project only.  
You can copy the Project scheme to the IDE level, using the Copy to IDE... command.
- At the **IDE** level, settings are grouped under the predefined Default scheme (marked in bold), and any other scheme created by the user by the Duplicate command (marked as plain text). Global settings are used when the user doesn't want to keep code style settings with the project and share them.  
You can copy the IDE scheme to the current project, using the Copy to Project... command.

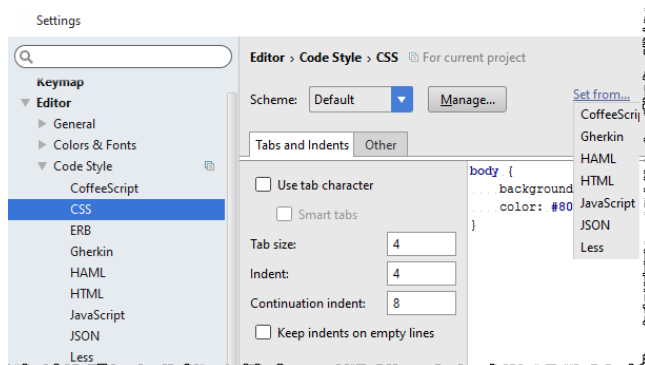

## Configuring code style for a language

1. In the Settings/Preferences dialog, click [Code Style](#), and then click the language in question.
2. Choose the code style scheme to be used as the base for your custom coding style for the selected language.
3. Browse through the tabs of the selected language page, and configure code style preferences for it.

## Copying code style settings from other languages

For most of the supported languages, you can copy code style settings from other languages or frameworks.

1. In the Settings/Preferences dialog, click [Code Style](#), and then click the language in question.
2. Click the link Set From in the upper-right corner. This link appears for those languages only, where defining settings on the base of the other languages is applicable.
3. In the drop-down list that appears, click the language to copy the code style from:

## Applying framework-specific pre-configured coding standards

For PHP files, you can have framework-specific pre-configured coding standards applied.

1. In the Settings/Preferences dialog, click [Code Style](#), and then click the language in question.
2. Click the Set from link, choose Predefined, then choose the relevant pre-configured standard.

## Configuring the code style for a project using EditorConfig

Before you start working with EditorConfig, make sure that the EditorConfig plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

Make sure that the checkbox Enable EditorConfig Support is selected in Editor | Code Style.

For more information, see [EditorConfig Website](#).

To configure the code style for a project using EditorConfig:

1. In the project tree, right-click a directory where you want to create the EditorConfig settings file and select New | File.
2. In the dialog that opens, enter `.editorconfig` and click OK.  
IntelliJ IDEA creates an EditorConfig settings file and displays a [notification](#) in the pop-up window.

Every time you open a file, the EditorConfig plugin looks for a file named `.editorconfig` in the directory of the opened file and in every parent directory. A search for `.editorconfig` files will stop if the root file path is reached or an EditorConfig file with `root = true` is found. Therefore, if you want to use the IDE settings instead of the EditorConfig settings, clear the Enable EditorConfig Support checkbox in Editor | Code Style that is selected by default.

3. Start defining your code style settings. Save( Ctrl+S ) your file. Every time you modify the `.editorconfig` file, save the file to apply changes to your project.

The EditorConfig code style configuration overrides the code style configuration in the IDE settings.

On this page:

- [Introduction](#)
- [Configuring colors and fonts](#)
- [Changing the language defaults](#)
- [Changing font for JavaScript](#)
- [Semantic highlighting](#)

## Introduction

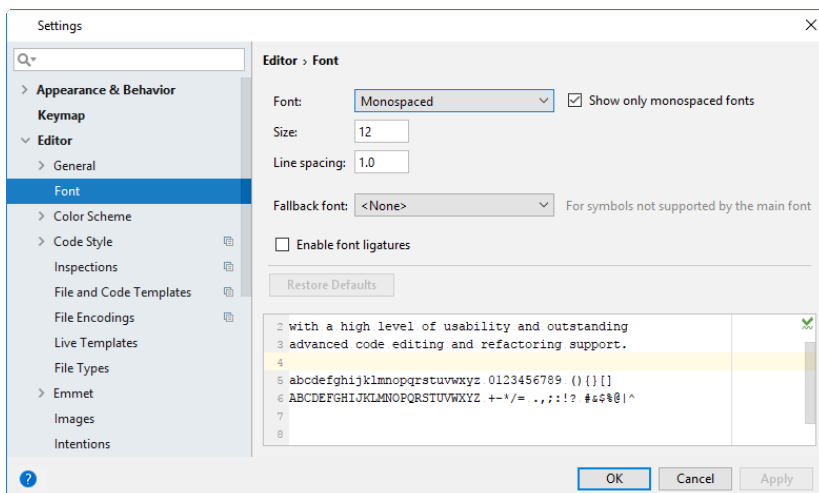

With IntelliJ IDEA, you can maintain your preferable colors and fonts layout for syntax and error highlighting in the editor, search results, Debugger and consoles via font and color schemes.

IntelliJ IDEA comes with a number of pre-defined color schemes. You can select one of them, or create your own one, and configure its settings to your taste.

It's important to mention the node Language Defaults - it contains the settings that are common for all the supported languages. It's enough to change one of the settings there, and then inherit this setting from the defaults.

## Configuring colors and fonts

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click Fonts under the Editor node.
2. Select the desired scheme from the Scheme name drop-down list.
3. Under the **Color Scheme** node, define the **font families** used in the editor and in the console. When you open the Font page, or Console Fonts under the **Color Scheme** node, IntelliJ IDEA displays the Editor Font area where you can configure the primary and secondary fonts, their size and line spacing.

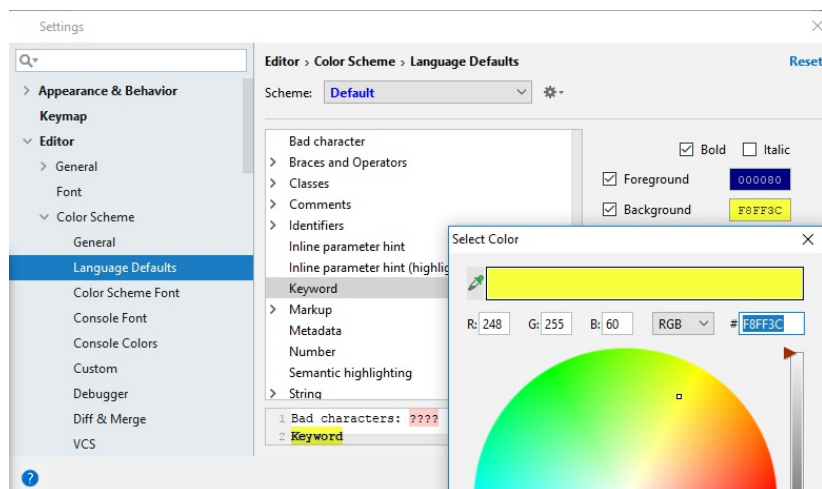

4. Under the **Color Scheme** node, open the corresponding pages to configure specific **color preferences** for the supported languages and IntelliJ IDEA components.

## Changing the language defaults

The node Language Defaults is actually language-agnostic. It contains the settings that are common to the majority of the supported languages (keywords, dots, commas, parenthesis etc.)

Select the node Language Defaults, and in the list of textual components, select the component Keyword. The background of the keywords is white; let's make it yellow.

To do that, select the checkbox to the left of the field name Background, and then click the white swatch. The **Color Picker** opens — all you need to do is to select the desired color and click OK:

So far, the changes to the language defaults are made; now let's look how they can be inherited.

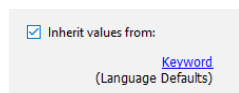

## Changing font for JavaScript

Click JavaScript node.

In the list of language components select Keyword , and see that the keywords now have the yellow background:

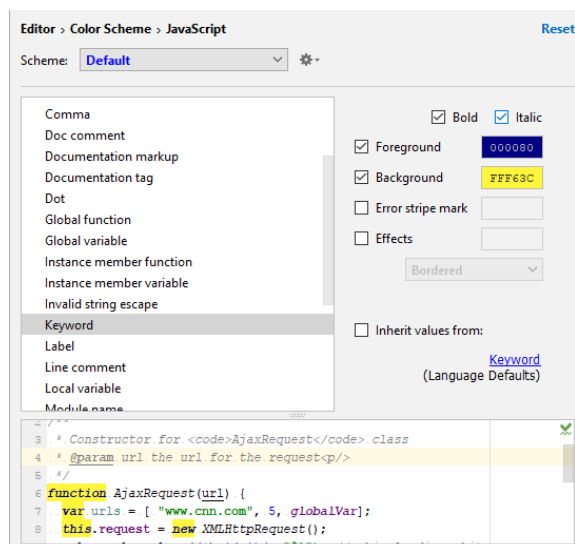

It's important to note that the checkbox Inherit values from is selected!

Clicking the link below this checkbox leads you to the respective page under Colors Scheme node, in this case to Language Defaults .

Next, clear the checkbox Inherit values from , and define the desired font type using the Bold and Italic checkboxes. In this case, these textual components will change for the selected language only!

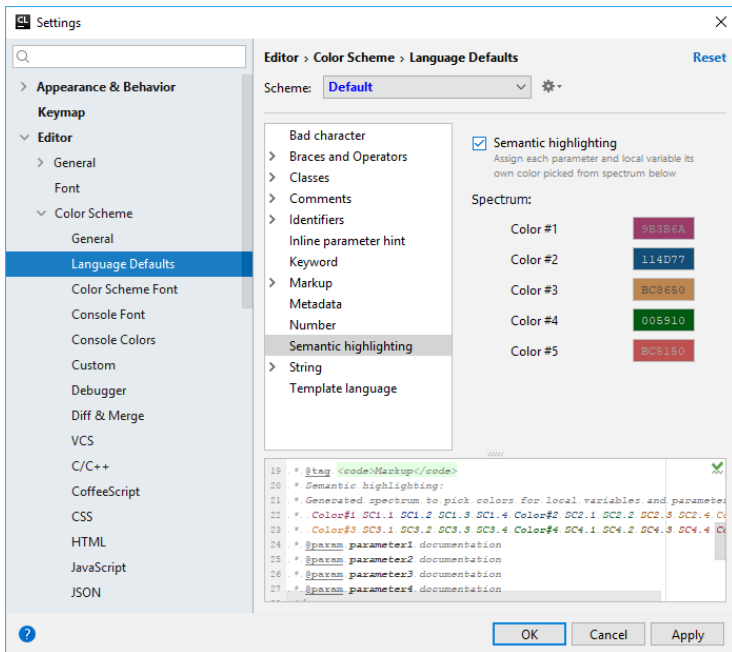

Observe results in the preview pane.

## Semantic highlighting

What happens if there is a function/method with a long list of uniformly highlighted parameters? One can easily make IntelliJ IDEA distinguish each parameter from the others using the semantic highlighting .

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click [Color Scheme](#) , and then click the Language Defaults page.
2. In the list of the supported Java components, choose Semantic highlighting .
3. In the right-hand pane, select the Semantic highlighting checkbox:

After that, all the parameters in a lengthy list will get the colors from the suggested swatches. If one is not happy with the suggested colors, [click on a swatch](#) to choose the suitable color.

On this page:

- [Predefined keymaps](#)
- [Configuring keyboard shortcuts and mouse shortcuts](#)
- [Avoiding conflicts with global OS shortcuts](#)
- [Location of user-defined keymaps](#)

IntelliJ IDEA is a keyboard-centric IDE. Most of its actions (navigation, refactoring, debugging, etc.) can be carried out without using a mouse, which lets dramatically increase coding speed.

**Tip** Even if you do not know the shortcut for specific action, you can still use the keyboard—the only shortcut you have to remember is `Ctrl+Shift+A`. After pressing it, start typing the name of the desired action and then press `Enter` to invoke it.

## Predefined keymaps

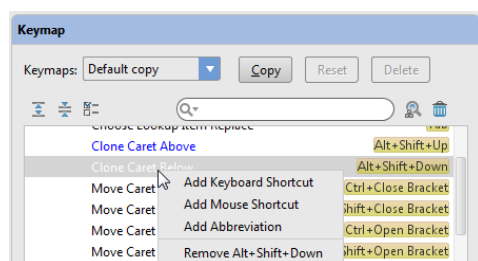

If you have used another IDE for a while and memorized your favorite keyboard shortcuts, you can choose one of the IntelliJ IDEA's predefined keymaps that matches key bindings of that IDE.

You can choose the keymap either on the first start of IntelliJ IDEA or anytime later on the Keymap page of IntelliJ IDEA settings (`Ctrl+Alt+S`).

If you are starting from scratch, without experience in other IDEs, we recommend using the Default keymap.

## Configuring keyboard shortcuts and mouse shortcuts

Predefined keymaps are not editable. When you add or modify any shortcut, a copy of the currently selected predefined keymap is created automatically.

### To configure keyboard shortcuts and mouse shortcuts

1. Select one of the pre-configured Keymaps, which you want to use as the base for the new one, and click `Copy`. Accept the default name, or change it as required.
2. In the content pane of actions, select the desired action.

To find an action by name, type the name in the search field `in`. As you type, the content pane shows actions with the matching names.

To find an action by shortcut, click `Find Shortcut`, then, when the Find Shortcut dialog opens, start pressing keys. The content pane will show only the actions with the matching shortcuts. Click your mouse somewhere outside the Find Shortcut dialog to close it.

3. Configure keyboard shortcuts. To do that, follow these steps:
  1. Right-click the selected action, and choose `Add Keyboard Shortcut`.
  2. In the dialog that opens, press the keys to be used as shortcuts. The keystrokes are immediately reflected in the First Stroke field. Optionally, select the checkbox next to Second Stroke and press keys to be used as alternative keyboard shortcuts.

As you press the keys, the Preview field displays the suggested combination of keystrokes, and the Conflicts field displays warnings, if some of the keystrokes are already assigned to the other actions.

3. Click `OK` with the mouse pointer to create a shortcut and bind it with an action.

It is important to use the mouse pointer, because when you press any keystroke while this dialog is open, the keystroke is interpreted as the shortcut.

4. Configure mouse shortcuts. To do that, follow these steps:
  1. Right-click the selected action, and choose `Add Mouse Shortcut` on the context menu. Enter Mouse Shortcut dialog box opens.
  2. In the Click Count section, click a radio button to choose a Single Click or Double Click.
  3. Hover your mouse pointer over the section Click Pad and click the desired mouse button. Use `Alt`, `Ctrl`, and `Shift` modifiers for diversity. As you click, the Shortcut Preview field displays the suggested shortcut, and the Conflicts field displays warnings, if some of the shortcuts are already assigned to the other actions.
  4. Click `OK` or Press `Enter` to create a shortcut and bind it with an action.

If a conflict is reported, a warning message appears. You can choose one of the following options:

- Remove to remove all other bindings and preserve the new one.
- Leave to preserve all bindings including the new one.
- Cancel to return to the keymap definition.

Although you can ignore conflict and bind a shortcut with several actions, it is strictly recommended to avoid binding two actions with the same shortcut, because the order of performing such actions is not defined.

## Avoiding conflicts with global OS shortcuts

Predefined keymaps do not cover every possible platform, version, and configuration. Try out the key combinations that you use and make necessary adjustments. Also, make sure that function keys are enabled on your system and check the following:

OS	Shortcut	System action	IntelliJ IDEA action
macOS		Show Spotlight search	Basic code completion
		Select the previous input source	
Ubuntu		Shade window	Settings
		Lock screen	Reformat Code
		Launch Terminal	Surround With
		Switch between Workspaces	Undo/redo navigation operations
			
		Move window	Find Usages
		Resize window	Evaluate Expression

## Location of user-defined keymaps

All user-defined keymaps are stored in separate configuration files under the `config/keymaps` subdirectory in the IntelliJ IDEA profile directory:

- Windows and \*NIX systems: `<User home>/IntelliJ IDEA<xx>/config/keymaps`
- macOS: `~/Library/Preferences/IntelliJ IDEA<xx>/keymaps/`

Each keymap file contains only differences between the current and the parent keymaps.

IntelliJ IDEA makes it possible to set up line separators (line endings) for the newly created files, and change line separator style for the existing files.

On this page:

- [Setting up line separators for newly created files](#)
- [Viewing line ending style for the current file](#)
- [Changing line separator for a file](#)
- [Changing line separator for a selection in the Project view](#)
- [Tips and tricks](#)

## Setting up line separators for newly created files

### To set up line separators for new files

1. In Settings, click [Code Style](#).
2. From the Line separator (for new files) drop-down list, select the desired line separator style:

3. Apply changes and close the dialog.

## Viewing line ending style for the current file

### To view line ending style for the current file

1. Open the desired file in the editor, as described in the section [Opening and Reopening Files](#).
2. View the [Status bar](#): the current line endings style is denoted by the dedicated icon with the specified style, for example, CRLF = .

## Changing line separator for a file

### To change line separator for a file, currently opened in the editor

1. Open the desired file in the editor, as described in the section [Opening and Reopening Files](#).
2. Do one of the following:
  - Click the line separator spin box in the [Status bar](#), and choose the desired line ending style from the pop-up menu:

- Choose File | Line Separators on the main menu, and then choose the desired line ending style from the sub-menu.

## Changing line separator for a selection in the Project view

### To change line separator for a file or directory, selected in the Project view

1. Select a file or directory in the [Project Tool Window](#).  
Note that if a directory is selected, the line ending style applies to all nested files recursively.
2. Choose File | Line Separators on the main menu, and then select the desired line ending style from the sub-menu.

## Tips and tricks

- Use multiple selection in the Project view.
- Changing line separator is reflected in the [Local history](#) of a file.
- [Run the inspection 'Inconsistent line separators'](#) to find out, which files use line separator different from project's default.

You can customize menu and toolbar command lists to regroup features or make your favorites easier to access.

## To customize menus and toolbars

1. Open Settings/Preferences dialog, and click [Menus and Toolbars](#) . Alternatively, right-click the main toolbar, and choose Customize Menus and Toolbars on the context menu.

2. In the list of available menus and bars, expand the node you want to customize and select the desired item.

3. Customize the list of items in the selected menu or bar using the buttons on the right from the list:

- To add a new command, select the desired location in the list and click the Add After button. In the [Choose Action To Add](#) dialog box that opens, select the desired action.

Optionally associate the action with an icon using the Icon Path text box. In this text box, specify the location of the file with the icon you want to assign to the selected action. If necessary, use the Browse button  to select the file in the [corresponding dialog](#) .

**Tip** The image file should have [.png](#) extension.  
– The size of the toolbar icons should be 16x16.

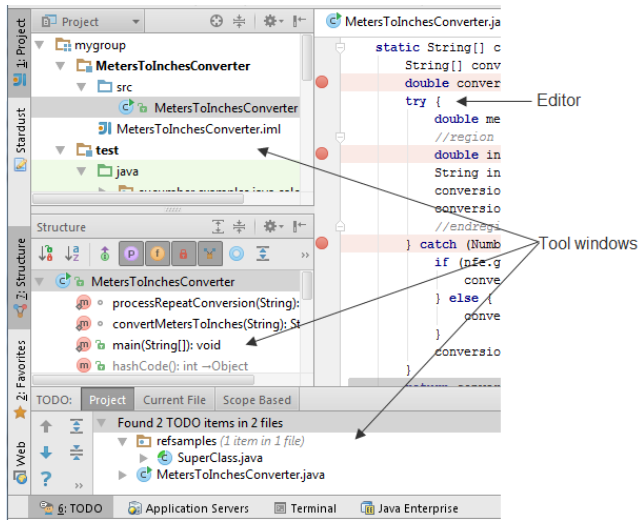

- To change the icon associated with a command, select the desired command in the list and click the Edit Action Icon button. In the Choose Actions Icon Path dialog box that opens, specify the location of the desired image. If necessary, use the Browse button  to select the image in the [Select Path Dialog](#) .
- To delete an item from the list, select it and click the Remove button.
- To have logical groups of commands separated from each other by a separator, select the desired location in the list and click the Add Separator button.
- To change the order in which commands appear in the selected menu or on the selected bar, use the Move Up and Move Down buttons.

4. To abandon the changes and return to the default settings, click the Restore Default button.

## Overview

Attached to the bottom and sides of the workspace are IntelliJ IDEA tool windows. These secondary windows let you look at your project from different perspectives and provide access to typical development tasks. These include project management, source code search and navigation, running and debugging, integration with version control systems, and many other specific tasks.

Certain tool windows are available always, that is, in any project irrespective of the project nature, contents, and configuration. Other tool windows are available only if the corresponding plugins and/or facets are enabled. There are also tool windows that only appear when certain actions are performed. For example, to invoke Find tool window you need to initialize a search.

## Tool window quick access

In the lower left corner of the workspace, there is a button which initially looks like this .

If you hover the mouse cursor over this button, a menu opens that provides quick access to tool windows:

If you click this button, tool window bars and buttons are shown. At the same time the button appearance toggles to . If you click the button again, the tool window bars and buttons are hidden again.

## Tool window bars and buttons

When visible, the tool window button bars (or just tool window bars) are around the tool windows (or the editor area if the tool windows are hidden). These bars contain the buttons for showing or hiding the tool windows (tool window buttons).

The tool window buttons also provide access to tool window context menus displayed if you right-click a tool window button:

The context menus let you control the tool window viewing modes and other aspects of the tool window appearance.

Initially, there are three button bars, two at the sides of the main window and one at the bottom. You can show or hide all button bars at once by clicking  in the bottom-left corner of the workspace.

Each tool window button has the name of the corresponding tool window on it. On certain buttons, the window name may be preceded by a number, for example, 1: Project. This means that the keyboard shortcut `Alt+<number>`

$\text{⌘}+\langle\text{number}\rangle$  is available for showing or hiding the window. You can, for example, show or hide the Project tool window by pressing  $\text{Alt}+1$   $\text{⌘}+1$ .

You can turn showing the window access numbers on the buttons on and off in the [Appearance settings](#).

The buttons for visible tool windows and for hidden ones are shown differently.

You can rearrange the tool windows by dragging-and-dropping the tool window buttons onto a different tool window bar (or to a different corner of the same bar). As a result, the tool window becomes attached to the bar you've moved the window button to.

## General tool window layout

Generally, all tool windows are organized in a similar way.

At the top of the window is a title bar. When you right-click the title bar, a menu for managing the window appearance and contents is shown.

The title bar contains two buttons in its right-hand part. The first of these buttons ( $\text{⚙}$ ) opens a menu for managing the tool window [viewing modes](#). Note that the menu options are a subset of the title bar context menu.

The second of the buttons ( $\text{⌵}$ ) is for hiding the tool window. When used in combination with the  $\text{Alt}+\text{⌵}$  key, clicking this button hides all the windows attached to the same tool window bar.

Underneath the title bar are the toolbar and content pane. Depending on the window, the toolbar may be above or to the left of the content pane.

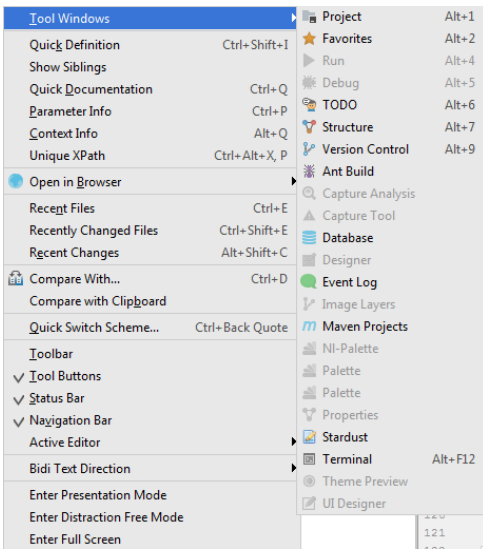

The toolbar buttons, generally, are window-specific. However, the windows with similar purposes may contain similar controls on their toolbars.

In most cases, a function associated with a toolbar button may also be accessed from the main or context menu, or may have a keyboard equivalent.

The content panes may be plain or contain two or more "layers" (views) represented, for example, by tabs. There are also tool windows with the content pane part shown on a separate tab in the editor area.

## Accessing tool window menus

– Use the [View | Tool Windows](#) menu to show or hide the tool windows.

**Note** Some of the tool windows (for example, **Find** or **Hierarchy** tool window) appear in the View menu **ONLY** when an action has been performed for the first time. So, unless you do something, say, find, or build a hierarchy, these tool windows are not visible in the View menu.

Same happens with the **Messages** and **Problems** tool windows. For example, the **Messages** tool window shows warnings from the compiler or the status after finishing a task, etc. Similarly, the **Problems** tool window appears only if auto make option is enabled and your code contains a compilation error.

- Use the Window | Active Tool Window menu to perform operations related to an active tool window. These include hiding the active and other windows, changing the **viewing modes** for the active tool window, and more.

You can manipulate the [tool windows](#) in various ways to adjust IntelliJ IDEA workspace to your needs.

- [Showing a tool window](#)
- [Hiding an individual tool window](#)
- [Hiding all tool windows attached to the same tool window bar](#)
- [Hiding all tool windows](#)
- [Switching to the last active tool window](#)
- [Hiding or showing the tool window bars](#)
- [Hiding tool window buttons](#)
- [Attaching a tool window to a different tool window bar](#)
- [Resizing a tool window](#)
- [Increasing the number of tool windows shown at a time](#)
- [Saving and restoring the arrangement of the tool windows](#)

## Showing a tool window

Do one of the following:

- In the lower left corner of the workspace, point to  and select the tool window in the menu that is shown.
- Click the corresponding tool window button on the [tool window bar](#).
- Choose View | Tool Windows | <tool window> in the main menu.
- If the tool window has an associated quick access number, press  (for Windows and Linux users) or  (for macOS users) key (for example, for the Project tool window, press  (for Windows or Linux users), or  (for macOS users)).

## Hiding an individual tool window

Do one of the following:

- Click the corresponding tool window button on the [tool window bar](#).
- Click  on the tool window title bar.
- Right-click the corresponding tool window button and select Hide from the context menu.
- Right-click the tool window title bar and select Hide from the context menu.
- Choose View | Tool Windows | <tool window> in the main menu.
- If the tool window has an associated quick access number, press  (for Windows and Linux users) or  (for macOS users) key (for example, for the Project tool window, press  (for Windows or Linux users), or  (for macOS users)).
- If the tool window you are going to hide is currently active, press .

## Hiding all tool windows attached to the same tool window bar

Do one of the following:

- Press and hold the  (for Windows and Linux users) or  (for macOS users) key, and click  on the title bar of any of the tool windows attached to the corresponding tool window bar.
- Choose Window | Active Tool Window | Hide Side Tool Windows in the main menu. This command hides all the tool windows attached to same tool window bar as the active tool window or the last of the active tool windows.

## Hiding all tool windows

Do one of the following:

- Choose Window | Active Tool Window | Hide All Windows in the main menu.
- Press .

## Switching to the last active tool window

Do one of the following:

- Choose Window | Active Tool Window | Jump to Last Tool Window in the main menu.
- Press .

If all the tool windows are currently hidden, the last active tool window will be shown and made active.

## Hiding or showing the tool window bars

You can hide all the tool window bars if you need more space in the IntelliJ IDEA window:

- In the lower left corner of the workspace, click .

If the tool window bars are hidden, you can bring them back onto the screen either permanently or for a short period of time:

- To restore the tool window bars, click  in the lower left corner of the workspace.
- To see the tool window bars for a short period of time, double-press and hold the  (for Windows and Linux users) or  (for macOS users) key. The tool window bars appear on the screen making the tool window buttons accessible. The tool window bars are hidden again when you release the key.

## Hiding tool window buttons

IntelliJ IDEA makes it possible to hide individual tool window buttons, without actually uninstalling the corresponding plugins.

To remove a tool window button from view:

1. Make sure that the [tool window bars are visible](#) .
2. Right-click the tool window button you want to hide.
3. Choose Remove from Sidebar

To restore the hidden tool window button, choose View | Tool Windows on the main menu, and then click the window with the hidden toolbar button.

## Attaching a tool window to a different tool window bar

Do one of the following:

- Drag the corresponding tool window button onto the desired tool window bar (top, left, bottom or right).

- Right-click the corresponding tool window button or the tool window title bar to open the context menu. Choose Move to and then select the destination tool window bar ( Top , Left , Bottom or Right ).

## Resizing a tool window

- Hover the mouse pointer over the tool window border. When the pointer becomes a double-headed arrow, drag the border in the required direction.

- You can also resize a tool window by moving its border to left or right, or up or down in steps. The following alternatives are available for doing that:

- Right-click the corresponding tool window button or title bar and select **Resize** . Then select one of the available **Stretch** to options.
- Make the tool window of interest active and do one of the following:
  - Choose **Window | Active Tool Window | Resize** , and then select the necessary **Stretch** to option.
  - Press **Ctrl+Shift** in combination with the corresponding arrow key.

## Increasing the number of tool windows shown at a time

To increase the number of tool windows to be shown at a time, you should appropriately set the [viewing modes](#) for different tool windows. Consider the following:

- Generally, for a tool window to be visible always (i.e. even when inactive), the tool window should be [pinned](#) .
- There are no limiting factors for the number of visible [floating](#) windows and ones in the windowed mode. Note that the [windowed](#) mode is not available if you are using macOS.
- To be able to see two windows [docked](#) to the same tool window bar at a time (rather than one), one of the windows should have the [split mode](#) off and the other one on.
- Initially, three (out of four) tool window bars are used. You can "activate" the fourth tool window bar (the top one) by [moving](#) certain tool windows to it.

## Saving and restoring the arrangement of the tool windows

You can save the way the tool windows are currently arranged by choosing Window | Store Current Layout as Default in the main menu.

At a later time, you can return to the saved workspace layout by choosing Window | Restore Default Layout ( `Shift+F12` ).

- Introduction
- Ways to control the viewing modes
- Docked / undocked mode
- Fixed / floating / windowed mode
- Pinned / unpinned mode
- Split mode
- Group Tabs option
- Wide screen support

## Introduction

IntelliJ IDEA provides various viewing modes that let you control the way the tool windows are shown and behave. These modes help you keep a proper balance between quick, easy access to tool windows and maximum screen space for editing your code.

The viewing modes are set separately for each of the tool windows.

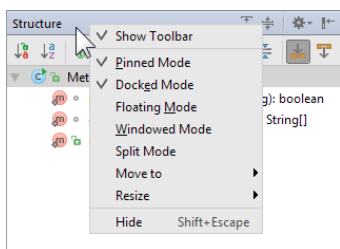

## Ways to control the viewing modes

The viewing modes are set by turning the corresponding viewing options on or off. To access these options, you can use:

-  on the title bar of a tool window.

- Context menus. The context menus are accessed by right-clicking the tool window buttons or the tool window title bars.

- For an active tool window: the Window | Active Tool Window menu.

## Docked / undocked mode

A tool window in the **fixed mode** may be docked or undocked .

In the docked mode, all the sides of a tool window are attached to surrounding elements (the editor, other tool windows, etc.) Thus, the tool window and the adjacent elements share the space available in the main window.

When a docked tool window becomes inactive, it stays visible or is hidden depending on whether the window is **pinned** or **unpinned** .

Initially, all the tool windows are in the docked mode (i.e. the docked mode is on).

When undocked, all the sides of a tool window (except the one at the tool window bar) are detached from surrounding elements. The window moves to the "upper layer" covering the elements it used to share the space with. In one of the directions (along the tool window bar), the window stretches and takes all the available space. In the other direction, one of the window borders becomes loose and can be moved without affecting the sizes of other, underlying elements.

When an undocked tool window becomes inactive, it is automatically hidden.

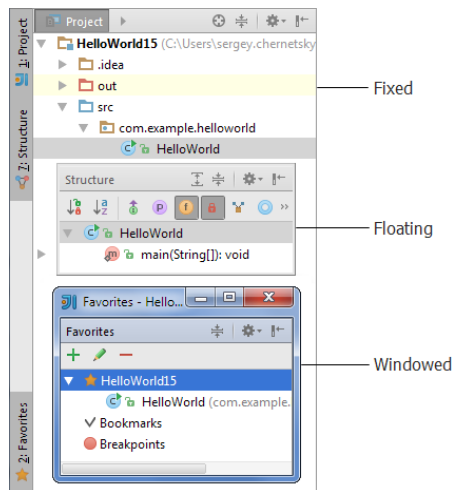

To switch between the docked and undocked mode, turn the Docked Mode option on or off. See [Ways to control the viewing modes](#) .

## Fixed / floating / windowed mode

A tool window may be **fixed** . In that case, it stays within the main window.

Alternatively, a tool window may be in the **floating** or in the **windowed** mode. Note that the **windowed** mode is not available if

you are using macOS.

When in the fixed mode, one side of the tool window is attached to one of the tool window bars. The behavior of the opposite side depends on whether the window is [docked or undocked](#) .

Initially, all the tool windows are in the fixed mode (i.e. the floating and windowed modes are off).

In the floating and in the windowed modes, a tool window may be moved around the screen to any place.

To switch to the floating or the windowed mode, turn on the Floating Mode or the Windowed Mode option. To bring a tool window back to the fixed mode, turn the Floating Mode and the Windowed Mode options off. See [Ways to control the viewing modes](#) .

Note that for the tool windows in the windowed mode, the Window menu command Hide Active Tool Window is disabled.

## Pinned / unpinned mode

Pinned tool windows, generally, stay visible when becoming inactive. Unpinned tool windows in such cases are automatically hidden.

Initially, all the tool windows are pinned (i.e. the pinned mode is on).

There may be slight differences in behavior depending on the other viewing modes:

- [Undocked](#) tool windows are always hidden when inactive. (In the undocked mode, the tool windows are effectively unpinned.)
- [Floating](#) pinned tool windows, when inactive, may become semi-transparent.

To switch between the pinned and unpinned mode, turn the Pinned Mode option on or off. See [Ways to control the viewing modes](#) .

## Split mode

This mode has to do with how many windows [docked](#) to the same tool window bar may be shown at a time (one or two).

Generally, the space along a tool window bar is shared between two groups of docked tool windows.

In one of the groups are the tool windows for which the split mode is off; in the other group are the ones with this mode on.

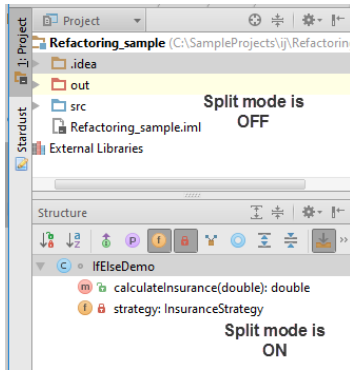

At each moment of time, only one window from each of the groups may be visible.

Thus, if all the tool windows docked to a tool window bar have the split mode off, only one tool window may be shown at a time. In this case, the tool window which is visible takes all the space available along the tool window bar. So when you make a certain window visible, the previous visible window is automatically hidden.

The same behavior is observed if the split mode is on for all the windows docked to the same tool window bar.

To be able to see two windows simultaneously, the corresponding windows should belong to different groups, that is, one of the windows should have the split mode off and the other one on.

The tool window buttons for the tool windows with different settings of the split mode are grouped and shown at different corners of the corresponding tool window bar. For vertical window bars, the windows with the split mode off have the buttons at the top corner; for the horizontal bars, the buttons for such windows are at the left corner.

To turn the split mode on or off see [Ways to control the viewing modes](#) .

## Group Tabs option

If more than one view is available in a tool window, the corresponding views may be shown on separate tabs if the Group Tabs option is off. If this option is on, the views are selected from a list.

## Wide screen support

IntelliJ IDEA makes it possible for the tool windows to use the full width and height of the screen. In the Settings dialog, expand the node Appearance and Behaviour , and in the [Appearance](#) page, use the checkboxes Wide screen tool window layout and Side by side layout on the left/right to optimize placement of the tool windows.

Note also that you can turn side-by-side layout on or off by `Ctrl+MouseClicked` on splitter between the tool windows.

Refer to [Appearance](#) for details.

Speed search in the tool windows helps you find and navigate to a file or folder in the Project tool window, a member in the Structure tool window, a changelist in the Version Control tool window, an item in the TODO list, and more.

Note that speed search is performed only on expanded nodes, if a node is folded the matching items under it are not detected.

To search through a tool window, follow these steps:

1. Select the desired tool window.
2. Start typing the item name (for instance, file, class, field, etc.). As you type, the Search for field appears over the tool window toolbar showing the entered characters, and the element selection moves to the first item that matches the specified string. The matching part of the string is highlighted.

3. If several neighboring items match the pattern, use the Up and Down keys on the keyboard to navigate among them.
4. Press `Enter` when ready. As a result, the matching item is selected in the tool window. Pressing `Escape` hides the Search for field.

You can change certain tool window appearance properties by specifying the corresponding Appearance settings.

### **To change the appearance properties for tool windows**

1. In the Settings dialog, expand the Appearance&Behaviour node, and click [Appearance](#) .
2. If necessary, change the settings related to tool window appearance. These are mainly in the Transparency and the Window Options sections. For more information, see descriptions of the pages under [Appearance and Behavior](#) .

## Basics

You can arrange the most frequently used project items (files, folders, packages, instance and class members, etc.), [bookmarks](#) , and [breakpoints](#) in the lists of favorite items (favorites). In IntelliJ IDEA, there is a dedicated [tool window](#) for managing your favorites (the [Favorites tool window](#) ).

Initially, there is one (empty) favorites list which has the same name as the project.

You can create more favorites lists and manage their contents as necessary.

## Using the Project tool window to add items to favorites

1. In the [Project](#) , select the item or items you want to add to favorites .

2. Do one of the following:

- Press `Shift+Alt+F` .
- On the main menu, point to File | Add To Favorites .
- On the context menu of the selection, point to Add To Favorites .

3. To add the selected item or items to an existing favorites list, select the name of the list.

To create a new favorites list and add the selected item or items to it, select [Add To New Favorites List](#) . In the Add New Favorites List dialog, specify the name of the new list and click OK .

**Tip** Add items to favorites using drag-and-drop: drag the item of interest from the Project tool window, or an external file from Explorer or Finder , and drop it onto the desired favorites list in the Favorites tool window.

## Using the editor to add files to favorites

In the editor, you can add to favorites one file (`Shift+Alt+F` ), or all the currently opened files.

1. Right-click the editor tab of interest and select one of the following options:

- If you want to add the current file to favorites, select [Add To Favorites](#) . (For the current file, File | [Add To Favorites](#) is also available as an alternative.)
- If you want to add all the files open in the editor to favorites, select [Add All To Favorites](#) .

2. To add the item or items to an existing favorites list, select the name of the list.

To create a new favorites list and add the item or items to it, select [Add To New Favorites List](#) . In the Add New Favorites List dialog, specify the name of the new list and click OK .

## Creating a new favorites list

You have an option of creating a new favorites list when [adding items to favorites](#) or when [moving](#) a favorites list item to a different list.

You can also create a new (empty) favorites list just on its own, as a separate task:

1. Open the [Favorites tool window](#) (`Alt+2` ).

2. Do one of the following:

- Click  on the toolbar.
- Press `Alt+Insert` .

3. In the Add New Favorites List dialog, specify the name of the new list and click OK .

## Renaming a favorites list

1. Open the [Favorites tool window](#) (`Alt+2` ).

2. Do one of the following:

- Right-click the list whose name you want to change and select [Rename Favorites List](#) .
- In the toolbar of the Favorites tool window, click .

3. In the New Name for Favorites List dialog box, change the name of the list as required, and click OK .

## Moving an item to a different list

1. Open the [Favorites tool window](#) (`Alt+2` ).

2. Right-click the list item that you are going to move and select [Send To Favorites](#) .

3. To move the selected item to an existing favorites list, select the name of the destination list.

To create a new favorites list and move the item there, select [Send To New Favorites List](#) . In the Add New Favorites List dialog, specify the name of the new list and click OK .

**Tip** To move an item from one favorites list to another, use drag-and-drop.

## Removing items from favorites

To remove items from favorites, you can delete the corresponding favorites list items and/or the whole favorites lists.

1. Open the [Favorites tool window](#) (**Alt+2**).
2. Select the item or items that you want to remove from favorites. Note that you can select separate list items and the whole lists at the same time.
3. Do one of the following:
  - Click  on the toolbar.
  - Select Remove From Favorites in the context menu. (If a single favorites list is currently selected, note that there are also the following options: Delete Favorites List <list\_name> and Delete All Favorites Lists Except <list\_name> .)
  - Press **Delete** .

On this page:

- [Introduction](#)
- [Using a quick list](#)
- [Configuring a quick list](#)

## Introduction

A Quick List is a pop-up menu of IntelliJ IDEA commands, configured by the user and associated with a keyboard or mouse shortcut. You can create as many quick lists as necessary. Each command, included in a quick list, is identified by a sequential number. Numbering starts from the numerals (0 to 9), and then proceeds with the letters in alphabetical order.

## Using a quick list

### To invoke a command from a quick list

1. Invoke quick list by its keyboard shortcut.
2. Select the desired command, using its number, the mouse cursor, or navigation keys and the `Enter` key:

## Configuring a quick list

### To configure a quick list

1. Open Settings/Preferences dialog, and click [Quick Lists](#) page.
2. Click `+` to create a new quick list.
3. In the Display name field, specify the name of the quick list. Optionally, provide the quick list description.
4. Configure the quick list. Use:
  - Add to add actions to the list. Select the actions in the Add Actions to Quick List dialog that opens.
  - Add Separator to add a separator at the end of the list.
  - Move Up and Move Down to move the selected item one line up or down in the list.
  - Remove to remove the selected item from the list.
5. Apply the changes.
6. Bind the new quick list with one or more shortcuts:
  - In the [Keymaps](#) page of the Settings/Preferences dialog, expand the Quick Lists node and select the new quick list.
  - Perform the [key binding procedure](#) . Note that you can only modify a custom keymap.
7. Apply the changes and close the dialog.

On this page:

- [Introduction](#)
- [Creating a copy of a code style scheme](#)
- [Managing code style schemes](#)

## Introduction

You can define the code styles that differ from the pre-defined ones. These code style schemes are stored in XML files, in the `config/codestyles` folder under the user home directory.

You can use the created copy for modifying code styles, and for export.

If you select a code style scheme other than Project, then this code style will be saved for a project. Thus you can assign a global (IDE) code style for each project.

## Creating a copy of a code style scheme

### To create a copy of code style settings

1. In the [Code Style page](#), select the desired scheme from the drop-down list, and click  .
2. From the drop-down list, select one of the following options:
  - Copy to IDE - select this option to store the selected scheme in a global level.  
IntelliJ IDEA saves the new code style with the specified name in the `config/codestyles/<code_style_name>.xml` file under the IntelliJ IDEA home directory.
  - Copy to Project - select this option to store the selected scheme in a project level.  
The selected code style is saved in the `.idea` directory in the file `codeStyleSettings.xml` .
  - Duplicate - select this option to simply make a copy of the selected scheme and store it in the same level.
3. In the Scheme field, type the name of the new scheme and press  to save the changes.
4. Apply changes.

## Managing code style schemes

IntelliJ IDEA lets you modify existing names of code style schemes, export or import code style settings.

### To manage a code style scheme

1. In the [Code Style page](#), select the desired scheme from the drop-down list, and click  .
2. From the drop-down list, select one of the following options:
  - Rename - select this option to change the name of the selected scheme.
  - Export - select this option to export your code style settings to the desired location.
  - Import - select this option to import IntelliJ IDEA XML code style settings, JSCS config file, or Eclipse XML Profile.
3. In the Scheme field, type the name of the new scheme and press  to save the changes.
4. Apply changes.

On this page:

- [Introduction](#)
- [Creating a file type](#)
- [Registering a file type](#)

## Introduction

You can [create custom file types](#) to enable parsing these files in the editor by defining highlighting schemes for keywords, comments, numbers, etc. To enable IntelliJ IDEA decide how to treat a file, you need to [associate each file type with relevant extensions](#).

## Creating a file type

### To create a new file type

1. Open the Settings/Preferences dialog by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Then select Editor | File Types. Find more on page [Accessing Settings](#).
2. On the [File Types](#) page that opens, click **+**.
3. In the [New File Type](#) dialog box that opens, specify the name of the new type and optionally provide a description.
4. In the Syntax Highlighting section, specify the characters for line and block comments, hex prefixes, and number postfixes.
5. In the Keywords section, specify sets of keywords using the tabs from 1 to 4. To do so, select the desired tab, click **+** (`Alt+Insert`), and enter the keyword name in the Add New Keyword dialog box that opens.

**Tip** Each set of keywords has its own highlighting. You can change the highlighting color scheme for each set, on the [Color Scheme](#) page. Click the Custom tab and edit the Keyword1, Keyword2, Keyword3, and Keyword4 properties.

## Registering a file type

### To associate a file type with extensions

1. Open the [File Types](#) settings page.
2. From the Recognized File Types list, select the desired type.
3. In the Registered Patterns area, complete the list of patterns that define the file extensions to indicate that the corresponding files belong to the selected type. Do one of the following:
  - To register a new pattern, click **+** (`Alt+Insert`) and enter the desired extension pattern in the Add Wildcard dialog box that opens.
  - To update a pattern, select it in the list, click the Edit button  and make the necessary changes in the Edit Wildcard dialog box that opens.
  - To remove a pattern from the list, select it and click **-** (`Alt+Delete`).

This section describes how to configure [scopes](#) and coloring of the files belonging to these scopes:

- [Creating a new custom scope](#)
- [Configuring the list of items in a custom scope](#)
- [Associating file color with a scope](#)
- [Arranging the order of scopes](#)

## Creating a new custom scope

Project scopes are configured in the [Scopes](#) page of the [Settings/Preferences](#) dialog box.

### To create a new custom scope

1. In the [Scopes](#) settings page, click Add scope **+**.
2. Select Local Changes or Shared from the drop-down list. Shared scopes are defined for the current project and accessible for the team members via VCS, while Local scopes are intended for personal use only and are stored in your workspace.

**Tip** You can change the sharing state later using the Share scope checkbox in the bottom of the page.

3. Specify the name for the new scope.
4. Apply changes.

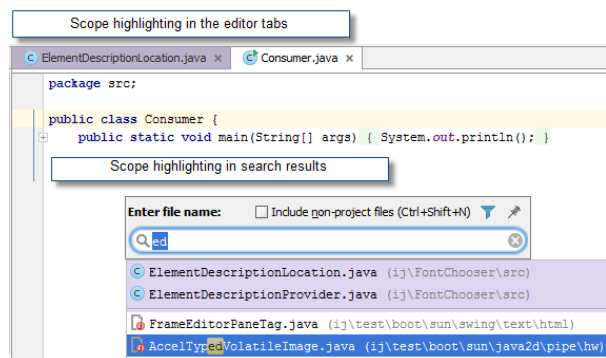

## Configuring the list of items in a custom scope

### To configure the list of items in a custom scope

1. In the [Scopes](#) settings page, select the scope that you want to configure.
2. Do one of the following:
  - Choose files and folders to be included in the scope and use buttons on the right. Based on the inclusion/exclusion, IntelliJ IDEA creates an expression and displays it in the Pattern field.
  - Specify pattern in the Pattern field manually, using the [scope language syntax](#).
3. Apply changes.

## Associating file color with a scope

Files belonging to different scopes can be highlighted in different colors throughout the IntelliJ IDEA's user interface: in [navigation lists](#), in the editor tabs, in the [Project Tool Window](#). This allows much faster and easier navigation in large projects.

### To associate file color with a scope

1. Open the [File Colors](#) settings page.
2. Decide whether you want the scope-color association to be only available to you or to be shared with the team. Depending on that, select or clear the checkbox Share colors section of the page.
3. Click Add **+**.
4. In the dialog box that opens, select a scope and pick a color for it.
5. If necessary, use the checkboxes on top of the page to define where in the user interface files belonging to the scopes are highlighted.
6. Apply changes.

## Arranging the order of scopes

If some file is included into several scopes, the order of the scopes becomes important: IntelliJ IDEA uses the color of the uppermost scope (shown in the [Scopes](#) settings page) to highlight such file. Of course, you can change the order of the

scopes, and thus the resulted highlighting.

### **To arrange the order of scopes**

1. Open the [Scopes](#) settings page.
2. Select a scope whose position in the order you want to change.
3. Click Move Up  / Move Down .
4. Apply the changes.

You can define third-party standalone applications (code generators and analyzers, pre- and post- processors, database utilities, etc.) as external tools and then run them from IntelliJ IDEA.

You can pass contextual information (like the currently selected file, or your project source path) to the external tools, view the tool output, and more.

The tools are defined on the [External Tools page](#) in the [Settings dialog](#) and appear as commands in the Tools menu and in various context menus. They can also be assigned keyboard shortcuts (see the [Configuring Keyboards and Mouse Shortcuts](#) section).

On this page:

- [Basics](#)
- [Configuring encoding for a directory or file without embedded encoding information](#)
- [Changing encoding of a file with explicit encoding](#)
- [Changing encoding of a file without explicit encoding](#)

## Basics

There are two modes of dealing with file encoding:

- **Converting** : the contents of the editor are stored in a different encoding. So doing, the contents of the underlying file change, but the contents of the editor stay unchanged.
- **Reloading** : the underlying file, opened in the editor, is shown in an encoding that differs from its original one. So doing, the contents of the editor can change, but the underlying files does not.

IntelliJ IDEA suggests the following major ways to change encoding:

- [Using the File Encodings](#) page of the Settings dialog, for directories and for the files that do not contain encoding information.
- [Using the Status bar or menu command](#) , for individual files that do not contain encoding information.
- [Using the editor](#) , for individual files that contain encoding information.

IntelliJ IDEA also supports configuring [encoding for properties files](#) .

## Configuring encoding for a directory or file without embedded encoding information

### To configure encoding for a directory or file without embedded encoding information

1. In Settings, expand the Editor node and select [File Encodings](#) .
2. The File/Directory column shows the tree view of your project. The Default Encoding column shows encoding for directories or files. Click the Default encoding column for a directory or file you want to define encoding for, and then choose the desired encoding from the drop-down list:

## Changing encoding of a file with explicit encoding

### To change encoding of a file that contains explicit encoding

1. [Open the desired file](#) in the editor.
2. Change explicit encoding information. Use error highlighting to recognize wrong encoding and press `Ctrl+Space` to have a list of available encodings displayed:

## Changing encoding of a file without explicit encoding

### To change encoding of a single file that doesn't contain explicit encoding

1. [Open the desired file](#) for editing.
2. Do one of the following:
  - On the main menu, point to File | File encoding .
  - Click file encoding on the [Status bar](#) .
3. Select the desired encoding from the pop-up window.

4. If the selected encoding will change the file contents, IntelliJ IDEA shows a dialog box, where you can choose to Reload file from disk, or Convert it to a different encoding.

You can quickly switch between various color schemes, keyboard layouts, and look-and-feels without actually invoking the corresponding page of the [Settings](#) dialog box.

1. Choose View | Quick Switch Scheme on the main menu or press `Ctrl+Back Quote`.
2. In the pop-up window that opens select the desired scheme (Colors and Fonts, Code Style, etc.).

3. In the suggestion list, click the desired option.

**Warning!** Regardless of your choice, the selected version of JDK shall be not lower than 1.8.

On this page:

- [Introduction](#)
- [Switching the IDE boot JDK](#)

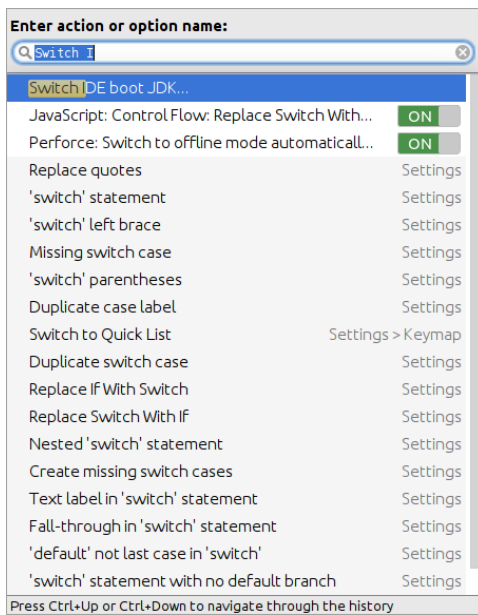

## Introduction

In case when you prefer JDK other than bundled with IntelliJ IDEA, you can choose between the latter and another kit, installed on your system.

## Switching the IDE boot JDK

### To switch the IDE boot JDK, do the following:

1. On the main menu, choose Help | Find Action or press `Ctrl+Shift+A`.
2. In the list of actions that appears, find Switch IDE boot JDK action and select it. Simplify your search by typing the first letters:

3. In the dialog that opens, select the desired JDK:

4. Click OK to apply changes.

IntelliJ IDEA lets you share your IDE settings between different instances of IntelliJ IDEA (or other IntelliJ-platform-based IDEs). This helps you recreate a comfy working environment if you are working from different computers and spare the annoyance of things looking or behaving differently from what you are used to.

You can share your settings in one of the following ways:

- By configuring a [settings repository](#) . This allows you to sync any configurable components (except for the list of enabled and disabled plugins), but requires setting up a Git repository with the settings you want to share.  
This option is useful if you want to implement the same settings among your team-members.
- By using the [IDE Settings Sync plugin](#) . It utilizes the JetBrains server, so no additional configuration is required. Synced settings are linked to your [JetBrains Account](#) , so they will not be available to other users.  
The settings you can sync include: IDE themes, keymaps, color schemes, system settings, UI settings, menus and toolbars settings, project view settings, editor settings, code completion settings, parameter name hints, live templates, code styles, and the list of enabled and disabled plugins.

## Share settings through a settings repository

**Warning!** Before you start configuring a settings repository, make sure that the Settings Repository plugin is enabled in the Settings/Preferences dialog ( `Ctrl+Alt+S` ) under Plugins .

1. Create a Git repository on any hosting service, such as [Bitbucket](#) or [GitHub](#) .
2. On the computer where the IntelliJ IDEA instance whose settings you want to share is installed, select File | Settings Repository from the main menu. Specify the URL of the repository you've created and click Overwrite Remote .
3. On each computer where you want your settings to be applied, in the Settings/Preferences dialog ( `Ctrl+Alt+S` ), expand the Tools node and choose Settings Repository . Specify the URL of the repository you've created, and click Overwrite Local .

You can click Merge if you want the repository to keep a combination of the remote settings and your local settings. If any conflicts are detected, a dialog will be displayed where you can resolve these conflicts.

If you want to overwrite the remote settings with your local settings, click Overwrite Remote .

**Tip** If you select to use [Bitbucket](#) to host your repository, the use of [App passwords](#) is recommended for authentication. You need to set the read/write permissions for your repositories.

Your local settings will be automatically synchronized with the settings stored in the repository each time you perform an Update Project or a Push operation, or when you close your project or exit IntelliJ IDEA.

On the first sync, you will be prompted to specify a username and password. It is recommended to use an [access token](#) for GitHub authentication. If, for some reason, you want to use a username and password instead of an access token, or your Git hosting provider doesn't support it, it is recommended to configure the [Git credentials helper](#) .

**Note** The [macOS Keychain](#) is supported, which means you can share your credentials between all IntelliJ Platform-based products (you will be prompted to grant access if the original IDE is different from the requestor IDE).

If you want to disable automatic settings synchronization, from the main menu select File | Settings | Tools | Settings Repository and disable the Auto Sync option. You will be able to update your settings manually by choosing VCS | Sync Settings from the main menu.

## Share more settings through additional read-only repositories

Apart from the Settings Repository , you can configure any number of additional repositories containing any types of settings you want to share, including live templates, file templates, schemes, deployment options, etc.

These repositories are referred to as read-only sources , as they cannot be overwritten or merged, just used as a source of settings as is.

To configure such repositories:

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), expand the Tools node and choose Settings Repository .
2. Click  and add the URL of the GitHub repository that contains the settings you want to share.

Synchronization with the settings from read-only sources is performed in the same way as for the Settings Repository .

## Share your settings with the Settings Sync plugin

**Warning!** Make sure that the Settings Sync plugin is enabled in the Settings/Preferences dialog ( `Ctrl+Alt+S` ) under Plugins .

1. Sign in to either of the following:
  - Your IDE: from the main menu choose Help | Register , choose to activate your license with the [JetBrains Account](#) and enter your credentials.
  - [Toolbox App](#) : click the gear icon  in the top right corner of the application, select Settings and click the Log in button. Note that by signing in to Toolbox App, you automatically sign in to all JetBrains products that you run.
2. In the bottom-right corner of the IntelliJ IDEA window, click the gear icon  and select Enable Settings Sync . Your local settings will be exported to the JetBrains repository linked to your account.
3. If you want to automatically sync the list of all enabled and disabled plugins, select the Sync plugins silently option. For

instructions on how to sync plugins manually if it is disabled, refer to [Sync plugins](#) .

4. On a different computer where you want these settings to be applied, click the gear button, and select Enable Sync . In the dialog that opens, click Get Settings from Account to import the settings from the repository.

If you want to override the repository with your local settings, click Keep and Sync Local Settings .

Your local settings will be automatically synchronized with the settings stored in the repository each time you run a different IDE instance (or activate it after more than one hour of inactivity), or when any of these settings has been modified and this change has been applied.

## Sync plugins

When you install or uninstall plugins, or change their state (enabled/disabled), you can apply these changes to all your IDE installations.

If you want to automatically sync plugins across IDE instances, select the Sync plugins silently option when you enable settings synchronization.

To sync plugins manually:

1. In the bottom-right corner of the IntelliJ IDEA window, click the gear icon  and select Sync Plugins .
2. A dialog opens showing a list of all plugins that were modified since the last sync. Click the arrow button next to each plugin and choose either to modify the plugin's state, apply the repository state to all installations, skip this change locally, or skip it across all IDE instances.
3. After you've selected which action to take for each plugin, click Apply Changes .

On this page:

- [Introduction](#)
- [Exporting settings to a JAR archive](#)
- [Importing settings from a JAR archive](#)

## Introduction

IntelliJ IDEA enables you to preserve and share your working environment. You can archive and store your preferred IDE settings, put the settings file under version control and thus make it available to your colleagues. On the other hand, you can use the settings, defined by the other team members, or your own ones intended for a different usage.

## Exporting settings to a JAR archive

1. On the main menu, choose File | Export Settings .
2. In the Export Settings dialog box that opens specify the settings to export by selecting the checkboxes next to them. By default, all settings are selected.
3. In the Export settings to text box, specify the fully qualified name of the target archive. Type the path manually or click the Browse button  and specify the target file in the [dialog that opens](#) .

## Importing settings from a JAR archive

1. On the main menu, choose File | Import Settings .
2. In the Import File Location dialog box that opens select the desired archive.
3. In the Select Components to Import dialog box that opens specify the settings to be imported, and click OK . By default, all settings are selected.

On this page:

- [Integrating browser installations with IntelliJ IDEA](#)
- [Choosing the default IntelliJ IDEA browser](#)

## Integrating browser installations with IntelliJ IDEA

To make it possible to launch a Web browser from IntelliJ IDEA, you need to integrate installations of Web browsers with IntelliJ IDEA, activate or deactivate launching Web browsers from IntelliJ IDEA and specify whether a browser will be launched by running its executable file or through the default system command .

IntelliJ IDEA is shipped with a predefined list of most popular browsers which you may like to install and use. The items are added to the list in advanced and are not based on the information on actually installed browsers. IntelliJ IDEA presumes that you install browsers according to a standard procedure. Based on this assumption, each browser in this predefined list is assigned an **alias** which stands for the path to its executable file, as IntelliJ IDEA supposes it to be. If in your actual browser installation the path to the executable file is different, you need to specify it explicitly as described below.

In addition to the predefined browsers, you can configure as many custom browser installations as you need using the controls on the toolbar. To create a list of Web browser that can be launched from IntelliJ IDEA:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Web Browsers under Tools .
2. The [Web Browsers](#) page that opens shows a **predefined list of browsers** , possibly extended with previously configured **custom browser installations** . Each browser is presented as a separate table row. The fields in each row show the name of the browser, the family to which the browser belongs, and the path to the browser's executable file or the predefined **alias** that stands for this path.
  - To activate an actually installed browser, select the Active checkbox next to its name. The browser will be added to the context menu of the Open in Browse menu item and its icon will be displayed in the Browsers pop-up toolbar. If the browser was installed according to a standard installation procedure, most likely the **alias** shown in the Path field points at the right location of the executable file. To specify the path explicitly, click `⋮` in the Path field and choose the actual location of the executable file in the dialog box that opens.
  - To configure a custom browser installation, click `+` on the toolbar. In the new row that is added to list, specify the browser name, family and the path to its executable.
  - To change the order of browsers in the list, use the `↑` and `↓` buttons. The order of browsers in the list affect the order in which they will be shown on the context menu of the Open in Browse menu item.
  - To specify a custom profile for **Firefox** or a browser of the **Chrome** family, select the browser in question, click `👉` on the toolbar. Depending on the family of the selected browser, the Firefox Settings or Chrome Settings dialog box opens.
    - For **Firefox** , specify the path to the required `profiles.ini` file and choose the profile to use from the drop-down list. Learn more at [Firefox browser profile](#) .
    - For **Chrome** , select the Use custom profile directory checkbox and specify the location of the `chrome-user-data` folder where users' profiles are stored. Learn more about **Chrome** profiles at [Multi-profiles](#) .
  - To launch a browser of the **Chrome** with additional options, click `👉` on the toolbar and type the required keys in the Command Line Options text box of the Chrome Settings dialog box that opens. Learn more about Chrome command line options by opening `chrome://flags` in **Chrome** .
  - To remove a browser from the list, select the browser and click `–` on the toolbar. Note that only custom browser can be removed.

## Choosing the default IntelliJ IDEA browser

When you want to preview your application output in the browser by choosing View | Open in Browser on the main menu or Open in Browser on the context menu of a file, you need to choose the browser to open the preview in. You can use a specific browser from the context menu or choose Default Browser . Tell IntelliJ IDEA which browser you want to be used by default. This browser is called **IntelliJ IDEA default browser** .

IntelliJ IDEA also opens the **IntelliJ IDEA default browser** to render external resources.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Web Browsers under Tools . The [Web Browsers](#) page opens.
2. From the Default Browser drop-down list, choose the browser to use by default for previewing pages.
  - To use the default operating system browser, choose System default .
  - To use the browser on top of the list, choose First listed . Change the order of browsers using the `↑` and `↓` icons on the toolbar.
  - To use another browser as default, choose Custom path and specify the location of the executable file of the required browser. Type the path manually or use the Browse button `⋮` , if necessary.
3. Specify the way to have the browsers launched.
  - To have a popup window with the enabled browsers appear in the HTML or JSP files, select the Show browser popup in the editor checkbox.
  - If the Show browser popup in the editor checkbox is cleared, previewing HTML or JSP files is available only through the View | Open in Browser command on the main menu or the Open in Browser command on the context menu of a file.

Plugins are extensions to IntelliJ IDEA core functionality. They provide the IDE integration with version control systems (VCS) and application servers, add support for various development technologies, frameworks and programming languages, and so on.

The more plugins are installed and enabled, the more features you have available. On the other hand, disabling unnecessary plugins may increase the IDE performance, especially on "less powerful" computers.

Certain plugins are independent, certain are not. Dependent plugins require other plugins to be enabled.

## Categories of plugins

In relation to IntelliJ IDEA, plugins may be attributed to one of the following categories:

- Plugins bundled with the IDE. These plugins are installed and enabled by default. You can disable unnecessary bundled plugins, but you cannot uninstall them. See [Enabling and Disabling Plugins](#) .
- Repository plugins, that is, plugins stored in [plugin repositories](#) (e.g., the JetBrains Plugin Repository). To be able to use the repository plugins, you should download and install them. See [Installing, Updating and Uninstalling Repository Plugins](#) .

## Plugin repositories

IntelliJ IDEA provides access to IntelliJ IDEA Plugin Repository at <http://plugins.jetbrains.com/idea> . You can also set up your own, [enterprise plugin repositories](#) , for example, to store plugins that you want to reserve for your company's internal use only. (A plugin repository corresponds to one or more Web servers.)

## Plugin development

IntelliJ IDEA provides an open API that enables you to extend the IntelliJ IDEA functionality: add new [intention actions](#) , code [inspections](#) and refactorings, facilities for integrating the IDE with various external systems, and more.

For plugin development, IntelliJ IDEA provides dedicated [SDK](#) , [module](#) and [run/debug configuration](#) types.

For more information, refer to:

- [Plugin Development Guidelines](#) .
- [Information for Plugin Developers](#) .

1. Open the Plugins page of IntelliJ IDEA settings ( `Ctrl+Alt+S` ).
2. On the [Plugins page](#) that opens in the right-hand part of the dialog, do one of the following:
  - To enable a plugin, select the checkbox to the right of its name.
  - To disable a plugin, clear the corresponding checkbox.
3. If the plugin of interest is not present in the list (which may be the case for a [repository plugin](#) ), [download and install](#) the plugin.
4. Restart IntelliJ IDEA for the changes to take effect.

In this section:

- [Introduction](#)
- [Downloading and installing repository plugins](#)
- [Updating repository plugins](#)
- [Uninstalling repository plugins](#)

## Introduction

To be able to use [repository plugins](#) , you have to download and install such plugins first. After that, you get the ability to update these plugins when appropriate.

When a repository plugin becomes unnecessary, you can disable or uninstall it.

## Downloading and installing repository plugins

### To download and install a repository plugin

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Plugins .
2. Click the Install JetBrains plugin or the Browse repositories button.
3. In the dialog that opens (the [Browse Repositories dialog](#) ), right-click the required plugin and select Download and Install .  
Note that when looking for the plugin of interest, you can filter the plugin list and also to perform a search.
4. Confirm your intention to download and install the selected plugin.
5. Click Close .
6. Click OK in the Settings dialog and restart IntelliJ IDEA for the changes to take effect.

Note that the plugin you have installed is automatically enabled. When necessary, you can disable it as described in [Enabling and Disabling Plugins](#) .

## Updating repository plugins

### To update a repository plugin

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Plugins .
2. Right-click any of the plugins and select Reload List of Plugins .  
The names of repository plugins that have newer versions available are shown blue.
3. Right-click the necessary plugin and select Update Plugin .
4. Click OK in the Settings dialog and restart IntelliJ IDEA for the changes to take effect.

## Uninstalling repository plugins

### To uninstall a repository plugin

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Plugins .
2. Right-click the repository plugin to be uninstalled and select Uninstall .
3. Confirm your intention to uninstall the selected plugin.
4. Click OK in the Settings dialog and restart IntelliJ IDEA for the changes to take effect.

To be able to use [plugin repositories](#) other than the JetBrains Plugin Repository (e.g., your enterprise plugin repositories), you should specify their [URLs](#) in IntelliJ IDEA.

## Adding repositories

1. In the left-hand pane of the Settings / Preferences dialog (`Ctrl+Alt+S`), click Plugins .
2. Click Browse repositories .
3. In the [Browse Repositories dialog](#) , click Manage repositories .
4. In the [Custom Plugin Repositories dialog](#) , click `+` and specify the repository URL. Click Check Now to make sure that the URL is correct.

Alternatively, you can add the repositories by editing the IntelliJ IDEA custom `.properties` , or custom `.vmoptions` file:

1. Open the file for editing: Help | Edit Custom Properties or Help | Edit Custom VM Options .
2. Depending on the file, add the following line:
  - `idea.plugin.hosts=<URL1>;<URL2>;...<URLn>` for the `.properties` file.
  - `-Didea.plugin.hosts=<URL1>;<URL2>;...<URLn>` for the `.vmoptions` file.

## Replacing JetBrains repositories with your own ones

If you want to access your corporate plugin repositories instead of the JetBrains repositories from the IntelliJ IDEA UI:

1. Open the IntelliJ IDEA custom `.properties` , or custom `.vmoptions` file for editing: Help | Edit Custom Properties or Help | Edit Custom VM Options .
2. Depending on the file, add the following line:
  - `idea.plugins.host=<yourRepositoryURL>` for the `.properties` file.
  - `-Didea.plugins.host=<yourRepositoryURL>` for the `.vmoptions` file.
3. Make sure that there is no option that points to `http://plugins.jetbrains.com` or `https://plugins.jetbrains.com` .
4. Restart IntelliJ IDEA.

As a result, the specified repository becomes your main plugin repository. You can now add repositories as described in [Adding repositories](#) .

**Note** A plugin file is an archive file: a ZIP or a JAR. You don't need to decompress it prior to installation. You should use it as is.

If you have a plugin file available on your computer, you can install it like this:

1. Open the Settings / Preferences dialog (e.g. `Ctrl+Alt+S` ).
2. In the left-hand pane, select Plugins .
3. In the right-hand part, on the Plugins page, click Install plugin from disk .
4. In the [dialog that opens](#), select the plugin archive file, and click OK .
5. In the Settings / Preferences dialog, click Apply or OK .
6. If suggested, restart IntelliJ IDEA.

In this section:

- [Introduction](#)
- [Adding a plugin to an enterprise plugin repository](#)
- [DTD for updatePlugins.xml](#)

## Introduction

To be available to IntelliJ IDEA users, all [enterprise repository plugins](#) must be listed in the file `updatePlugins.xml` along with their URLs and version numbers. This file must be available at the URL specified for the corresponding repository (see [Managing Enterprise Plugin Repositories](#)).

The plugins themselves are identified by their individual URLs and thus may be located on different Web servers.

## Adding a plugin to an enterprise plugin repository

### To add a plugin to an enterprise plugin repository

1. Upload your plugin JAR onto a Web server.
2. Add the plugin definition to `updatePlugins.xml`. If this file doesn't yet exist, create it at the location corresponding to the repository URL.

The plugin definition in `updatePlugins.xml` may look similar to this:

```
<plugins>
  ...
  <plugin id="MyPlugin" url="http://plugins.example.com:8080/myPlugin.jar" version="1.0"/>
  ...
</plugins>
```

3. To publish a new version of the same plugin, upload the corresponding plugin JAR to the repository, and change the value of the `version` attribute in the plugin definition.

## DTD for updatePlugins.xml

The file `updatePlugins.xml` must correspond to the following [Document Type Definition](#) (DTD):

```
<!DOCTYPE plugins [
  <!ELEMENT
    plugins(plugin)*>
  <!ELEMENT
    plugin (#PCDATA)>
  <!ATTLIST
    plugin id CDATA #REQUIRED url DATA #REQUIRED version CDATA #REQUIRED]>
```

IntelliJ IDEA enables you to use interactive consoles, thus making it possible to stay within the IDE, without the necessity to switch to the shell.

- [Running Console](#)
- [Configuring Output Encoding](#)
- [Configuring Color Scheme for Consoles](#)
- [Using Consoles](#)
- [Working with Embedded Local Terminal](#)

On this page:

- [Introduction](#)
- [Launching console](#)

## Introduction

The consoles built in IntelliJ IDEA completely correspond to the shell consoles.

Besides the standard functionality, these consoles feature:

- Code completion.
- Syntax check with inspections.
- Automated insertion of paired brackets, quotes and braces.
- Scrolling through the history of commands using the arrow keys.
- Quick documentation lookup `Ctrl+Q`

## Launching console

### **To launch an interactive console**

- On the main menu, choose any console-related command from the Tools menu .

IntelliJ IDEA creates files using the IDE encoding defined in the [File Encodings](#) page of the Settings dialog, which can be either system default, or the one selected from list of available encodings. Output in the consoles is also treated in this encoding.

It is possible that encoding used in the console output is different from the IDE default. To have IntelliJ IDEA properly parse text in the console, you have to do some additional editing.

### To set up encoding for the console output, depending on your operating system:

- In Windows and Linux :  
Open for editing

respectively, and add the following line at the bottom:

```
-Dconsole.encoding=<encoding name>
```

For example:

```
-Dconsole.encoding=UTF-8
```

- In macOS : Open `Info.plist` located in `/Applications/RubyMine.app/Contents` , locate the tag `<key>VMOptions</key>` , and modify it as follows:

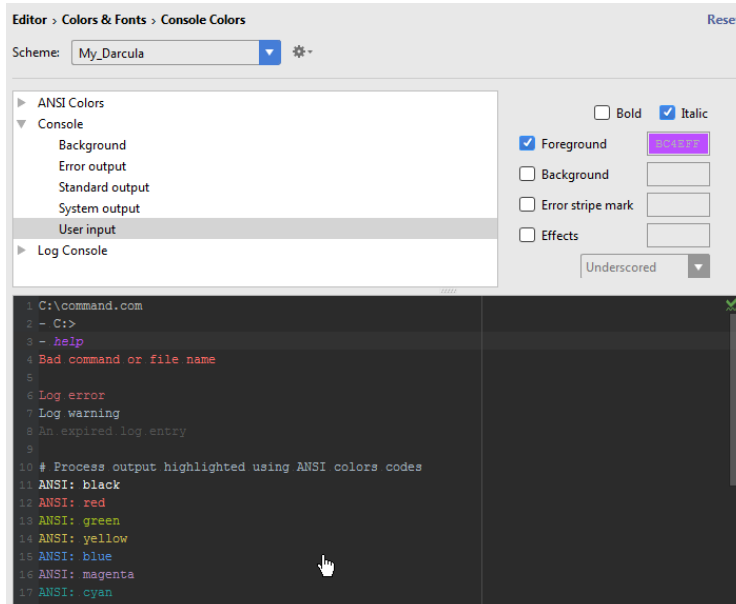

```
<key>VMOptions</key>  
<string>-Xms16m -Xmx512m -XX:MaxPermSize=120m  
-Xbootclasspath/p:../lib/boot.jar -ea  
-Dconsole.encoding=<encoding name>  
</string>
```

IntelliJ IDEA enables you to define your habitual color scheme for the various types of consoles. So doing, you can individually configure all sorts of console output and user input.

Color scheme includes numerous colors for background, user input, system output, and error output.

## To configure color and font scheme for consoles

1. Make sure you are working with an editable scheme.
2. Open the Settings/Preferences dialog, and under **Colors&Fonts** , scroll through the list of components, and select the ones related to consoles:
  - Console Colors
  - Console Font
3. In the right-hand pane, click the desired component in the list, and change color settings and font type:

## Actions available in the Interactive Console

In an interactive console, you can:

- Type commands in the lower pane of the console, and press `Enter` to execute them. Results are displayed in the upper pane.
- Use [basic code completion](#) `Ctrl+Space` .
- Use Up and Down arrow keys to scroll through the history of commands, and execute the required ones.
- Load source code from the editor into console.
- Use context menu of the upper pane to copy all output to the clipboard, compare with the current contents of the clipboard, or remove all output from the console.
- Use the toolbar buttons to control your session in the console.
- Configure color scheme of the console to meet your preferences. Refer to the section [Configuring Color Scheme for Consoles](#) for details.

On this page:

- [Overview](#)
- [Configuring embedded local terminal](#)
- [Running embedded local terminal](#)
- [Actions available in the embedded local terminal](#)
- [Example](#)

**Tip** IntelliJ IDEA implements the terminal functionality with a bundled plugin, which can be completely disabled by clearing the Terminal check box on the the Plugins page of IntelliJ IDEA settings ( [Ctrl+Alt+S](#) ).

## Overview

IntelliJ IDEA features a local terminal that makes it possible to access the command line. Depending on your platform, you can work with command prompt, Far, `powershell`, `bash`, etc. Using the terminal, you can execute any command without leaving the IDE.

## Configuring embedded local terminal

The terminal settings are configurable on several pages of the Settings/Preferences dialog.

### To configure the embedded local terminal options

1. In the Settings/Preferences dialog box, open the [Terminal](#) page, and specify the following:
  - The desired shell that will run by default, the name of a session tab
  - Name of the tab a new session will be opened in, possibility to copy to clipboard etc.
  - Ability to override the IntelliJ IDEA keymap.
2. The following settings are inherited by the embedded local terminal from the IDE settings/preferences:
  - On the [Keymap](#) page, you can configure the `Ctrl+C` and `Ctrl+V` shortcuts.
  - On the editor's [Appearance](#) page - anti-aliasing and caret blinking.

Note that the setting Use block caret is not inherited in the terminal - its caret is always block.

- Under the editor's [Color and Fonts](#) settings, you can change the following options:
  - On the Console Fonts page - line spacing, and console fonts.
  - On the Console Colors page - console colors.
  - On the General page - selection foreground and background colors.

## Running embedded local terminal

To run the console, do one of the following

- Press `Alt+F12`.
- Click the Terminal tool window button  [Terminal](#).
- Hover your mouse pointer over  in the lower left corner of the IDE, then choose Terminal from the menu, as described in the section [Tool window quick access](#).

## Actions available in the embedded local terminal

In the embedded local terminal, you can do the following:

- To create a new session:
  - Click  on the toolbar of the terminal.
  - Right-click a session tab, and then choose Create new session on the context menu.

A new session is presented in a separate tab:

- Rename a tab. Right-click a tab, and choose Rename tab on the context menu.
- Close an active session that currently has the focus. This can be done in a number of ways:
  - Click  on the terminal toolbar.
  - Right-click a session tab, and then choose Close session on the context menu.
- Use up and down arrows on your keyboard to browse through the history of entered commands.
- Toggle between the embedded local terminal and editor by pressing `Alt+F12` ( [View | Tool Windows | Terminal](#) ).

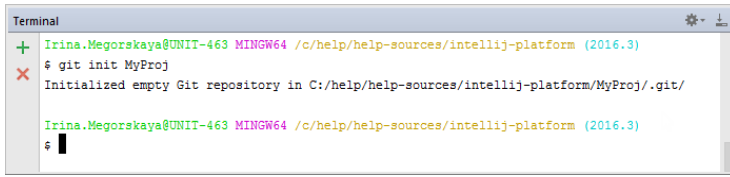

## Example

Open the [Terminal](#) page of the Settings/Preferences dialog, and configure the Shell path field as follows:

```
"[path to the git installation]\bin\sh.exe" -login -i
```

Do not forget the quotes around the command!

Now, when you open the new terminal in IntelliJ IDEA, it will recognize `git` commands:

```
Terminal
+ Irina.Megorskaya@UNIT-463 MINGW64 /c/help/help-sources/intellij-platform (2016.3)
$ git init MyProj
X Initialized empty Git repository in C:/help/help-sources/intellij-platform/MyProj/.git/

Irina.Megorskaya@UNIT-463 MINGW64 /c/help/help-sources/intellij-platform (2016.3)
$ █
```

In this part:

- [Tuning IntelliJ IDEA](#)
  - [Changing IntelliJ IDEA properties](#)
  - [Managing the \\*.vmoptions file](#)
    - [Example: Increasing the heap size](#)
  - [Managing the idea.properties file](#)
    - [Example: Changing the case of unicode literals](#)
  - [Specifying custom JDK, properties, or vmoptions files across platforms](#)
- [File 'idea.properties'](#)
- [Project and IDE Settings](#)
- [Directories Used by IntelliJ IDEA to Store Settings, Caches, Plugins and Logs](#)
- [Networking in IntelliJ IDEA](#)
- [Color-Deficiency Adjustment](#)

## Changing IntelliJ IDEA properties

IntelliJ IDEA makes it possible to change the `*.vmoptions` and the `idea.properties` files without editing them in the IntelliJ IDEA installation folder.

To create an empty `idea.properties` file or to copy the `*.vmoptions` file, choose `Help | Edit Custom Properties...` or `Help | Edit Custom VM Options...` from the main menu respectively.

## Managing the \*.vmoptions file

The location of the `*.vmoptions` file depends on your operating system:

- For **Windows**: `<IntelliJ IDEA installation folder>/bin/idea.exe.vmoptions` or `<IntelliJ IDEA installation folder>/bin/idea64.exe.vmoptions`
- For **\*NIX**: `<IntelliJ IDEA installation folder>/bin/idea.vmoptions` or `<IntelliJ IDEA installation folder>/bin/idea64.vmoptions`
- For **macOS**, you need to make a copy of the `idea.vmoptions` file in the IDE preferences folder and then edit this copy. The reason is that the app bundle is signed and you should not modify any files inside the bundle.

To avoid editing files in the IntelliJ IDEA installation folder, do one of the following:

- From the main menu, choose `Help | Edit Custom VM Options` to create a copy of the `idea.vmoptions` file in the user home directory.
- Copy the existing file from the IntelliJ IDEA installation folder somewhere and save the path to this location in the `IDEA_VM_OPTIONS` environment variable (`IDEA64_VM_OPTIONS` for 64 bit systems).
- Copy the existing `<IntelliJ IDEA installation folder>/bin/idea.exe.vmoptions` or the `<IntelliJ IDEA installation folder>/bin/idea64.exe.vmoptions` file from the IntelliJ IDEA installation folder into your user home directory.

Then edit this file in the new location.

If the `IDEA_VM_OPTIONS` (`IDEA64_VM_OPTIONS` for 64 bit systems) environment variable is defined, or the `*.vmoptions` file exists, this file is used instead of the one located in the IntelliJ IDEA installation folder.

## Example: Increasing the heap size

To increase IntelliJ IDEA heap size, you should copy the original `idea.vmoptions` file to the above-mentioned location, and then modify the `-Xmx` setting.

## Managing the IDEA.properties file

The `idea.properties` file located in the `bin` directory of the IntelliJ IDEA installation folder should not be edited. Instead of editing the original `idea.properties` file, create an `idea.properties` file in the following location, open it for editing and add the required properties:

- For **Windows**: `%USERPROFILE%\IntelliJ\IdeaXX\config` or `%USERPROFILE%\IdeaICXX\config`
- For **\*NIX**: `~/IntelliJ\IdeaXX/config` or `~/IdeaICXX/config`
- For **macOS**: `~/Library/Preferences/IntelliJ\IdeaXX/config` or `~/Library/Preferences/IdeaICXX/config`

To open the `idea.properties` file in the editor, choose `Help | Edit Custom Properties`. If the file does not exist yet, IntelliJ IDEA creates it and opens in the editor.

## Example: Changing the case of unicode literals

IntelliJ IDEA allows defining whether non-ascii characters should use literals like `'\u00AB'` or `'\00ab'`.

This behavior is controlled by the `idea.native2ascii.lowercase` system property. By default, upper-case characters are used.

If you wish to use lower-case characters, create the `idea.properties` file in the location specified above, open it for editing and add the following line:

```
idea.native2ascii.lowercase=true
```

## Specifying custom JDK, properties, or vmoptions files across platforms

A custom JDK, as well as `*.properties` and `*.vmoptions` files are specified across platforms in a unified way.

All launchers look at the following environment variables:

- `$<IDE-NAME>_JDK` ( `<IDE-NAME>_JDK_64` )
- `$<IDE-NAME>_PROPERTIES`
- `$<IDE-NAME>_VM_OPTIONS`

## Basics

The `idea.properties` file located in the `bin` directory of the IntelliJ IDEA installation folder should not be edited. Instead of editing the original `idea.properties` file, create an `idea.properties` file in the following location, open it for editing and add the required properties:

- For **Windows** : `%USERPROFILE%\IntelliJ\config` or `%USERPROFILE%\IdeaIC\config`
- For **\*NX** : `~/.IntelliJ\config` or `~/.IdeaIC\config`
- For **macOS** : `~/Library/Preferences/IntelliJ\config` or `~/Library/Preferences/IdeaIC\config`

You can create an empty file `idea.properties` and open it in the editor by choosing the Help | Edit Custom Properties command on the main menu.

## Property settings

### NameDescriptionProperty setting

Name	Description	Property setting
<b>Note</b> The Windows users should use forward slashes, i.e. <code>c:/idea/system</code> .		
<code>idea.home</code> macro	Use <code>idea.home</code> macro to specify location relative to IDE installation home. Also use <code>{xxx}</code> where <code>xxx</code> is any java property (including defined in the previous lines of this file) to refer to its value.	
Path to the IDE config folder	Uncomment this option if you want to customize path to IDE config folder.	<code>idea.config.path=\${user.home}/.IntelliJ IDEA/config</code>
Path to IDE system folder	Uncomment this option if you want to customize path to IDE system folder.	<code>idea.system.path=\${user.home}/.IntelliJ IDEA/system</code>
Path to user installed plugins	Uncomment this option if you want to customize path to user installed plugins folder.	<code>idea.plugins.path=\${user.home}/.IntelliJ IDEA/config/plugins</code>
Path to IDE logs folder	Uncomment this option if you want to customize path to IDE logs folder.	<code>idea.log.path=\${user.home}/.IntelliJ IDEA/system/log</code>
Maximum file size	Maximum file size (kilobytes) IDE should provide code assistance for. The larger file is, the slower its editor works and higher overall system memory requirements are, if code assistance is enabled. Remove this property or set to a very large number, if you need code assistance for any files to be available, regardless of their size.	<code>idea.max.intellisense.filesize=2500</code>
Console cyclic buffer	This option controls console cyclic buffer: keeps the console output size not higher than the specified buffer size (Kb). Older lines are deleted. In order to disable cycle buffer, use <code>idea.cycle.buffer.size=disabled</code>	<code>idea.cycle.buffer.size=1024</code>
Launcher	Configure if a special launcher should be used when running processes from within IDE. Using Launcher enables "soft exit" and "thread dump" features.	<code>idea.no.launcher=false</code>
Classpath	To avoid too long classpath	<code>idea.dynamic.classpath=false</code>

`ProcessCanceledException` Uncomment this property to

	<p>prevent IDE from throwing <code>ProcessCanceledException</code> when user activity detected. This option is only useful for plugin developers, while debugging PSI related activities performed in background error analysis thread. DO NOT UNCOMMENT THIS UNLESS YOU'RE DEBUGGING THE IDE ITSELF. Significant slowdowns and lockups will happen otherwise.</p>	<pre>idea.ProcessCanceledException=disabled</pre>
Pop-up window weight	<p>There are two possible values of <code>idea.popup.weight</code> property: "heavy" and "medium". If you have WM configured as "Focus follows mouse with Auto Raise" then you have to set this property to "medium". It prevents problems with the pop-up menus on some configurations.</p>	<pre>idea.popup.weight=heavy</pre>
System anti-aliasing	<p>Use default anti-aliasing in system, i.e. override value of "Settings Editor Appearance Use anti-aliased font" option. May be useful when using Windows Remote Desktop Connection for instance.</p>	<pre>idea.use.default.antialiasing.in.editor=false</pre>
Repaint	<p>Disabling this property may lead to visual glitches like blinking and fail to repaint on certain display adapter cards.</p>	<pre>sun.java2d.noddraw=true</pre>
Editor performance	<p>Removing this property may lead to editor performance degradation under Windows.</p>	<pre>sun.java2d.d3d=false</pre>
Slow scrolling	<p>Workaround for slow scrolling in JDK6.</p>	<pre>swing.bufferPerWindow=false</pre>
Editor performance under X Window	<p>Removing this property may lead to editor performance degradation under X Window.</p>	<pre>sun.java2d.pmosffscreen=false</pre>
Avoid long hangs	<p>Workaround to avoid long hangs while accessing clipboard under macOS.</p>	<pre>ide.mac.useNativeClipboard=True</pre>
Maximum load size	<p>Maximum size (kilobytes) IDEA will load for showing past file contents - in Show Diff or when calculating Digest Diff</p>	<pre>idea.max.vcs.loaded.size.kb=20480</pre>
Copy library jars	<p>IDE copies library jars to prevent their locking. If copying is not desirable, specify "true"</p>	<pre>idea.jars.nocopy=false</pre>
Start the JVM in debug mode	<p>The VM option value to be used to start the JVM in debug mode. Some JREs define it in a different way (-XXdebug in Oracle VM)</p>	<pre>idea.xdebug.key=-Xdebug</pre>
Switch into JMX 1.0 compatibility mode.	<p>Uncomment this option to be able to run IntelliJ IDEA using J2SDK 1.5+ while working with application servers (like WebLogic) running 1.4.</p>	<pre>jmx.serial.form=1.0</pre>
Fatal errors notifications	<p>Change to 'enabled' if you want to receive instant visual notifications</p>	

about fatal errors that happen to  
an IDE or plugins installed.

```
idea.fatal.error.notification=disabled
```

On this page:

- [Overview](#)
- [Project Settings](#)
- [IDE Settings](#)
- [Locations of directories](#)

## Overview

There are two types of settings that define your preferred environment:

- Project Settings , that apply to a specific project. They are marked with  in the Settings/Preferences dialog.
- IDE Settings , that are common for all projects and refer to the project-independent aspects.

## Project Settings

Project settings are stored with each specific project as a set of `xml` files under the `.idea` folder. If you specify the [default project settings](#) , these settings will be automatically used for each newly created project.

The settings that pertain to a project, are marked with the icon  in the Settings/Preferences dialog.

## IDE Settings

IDE settings are stored in the dedicated directories under IntelliJ IDEA home directory. The IntelliJ IDEA directory name is composed of the product name and version.

For IntelliJ IDEA Community edition the folder name is `.IdeaICXX` .

For example:

### Windows

- `<User home>\.IntelliJIdeaxX\config` that contains user-specific settings.
- `<User home>\.IntelliJIdeaxX\system` that stores IntelliJ IDEA data caches.

`<User home>` in WindowsXP is `C:\Documents and Settings\<User name>\` ; in Windows Vista it is `C:\Users\<User name>\`

### Linux

- `/.IntelliJIdeaxX/config` that contains user-specific settings.
- `~/IntelliJIdeaxX/system` that stores IntelliJ IDEA data caches.

### macOS

- `~/Library/Application Support/IntelliJIdeaxX` contains the catalog with plugins.
- `~/Library/Preferences/IntelliJIdeaxX` contains the rest of the configuration settings.
- `~/Library/Caches/IntelliJIdeaxX` contains data caches, logs, local history, etc. These files can be quite significant in size.
- `~/Library/Logs/IntelliJIdeaxX` contains logs.

## Locations of directories

The `config` directory has several subfolders that contain xml files with your personal settings. You can easily share your preferred keymaps, color schemes, etc. by copying these files into the corresponding folders on another IntelliJ IDEA installation. Prior to copying, make sure that IntelliJ IDEA is not running, because it can erase the newly transferred files before shutting down.

The following is the list of some of the subfolders under the `config` folder, and the settings contained therein.

Folder name	User Settings
<code>codestyles</code>	Contains <a href="#">code style schemes</a> .
<code>colors</code>	Contains <a href="#">editor colors and fonts customization schemes</a> .
<code>filetypes</code>	Contains user-defined <a href="#">file types</a> .
<code>inspection</code>	Contains <a href="#">code inspection profiles</a> .
<code>keymaps</code>	Contains IntelliJ IDEA <a href="#">keyboard shortcuts</a> customizations.
<code>options</code>	Contains various options, for example, feature usage statistics and macros.
<code>templates</code>	Contains user-defined <a href="#">live templates</a> .
<code>tools</code>	Contains configuration files for the <a href="#">user-defined external tools</a> .
<code>shelf</code>	Contains <a href="#">shelved changes</a> .

Locations of the `config` , `system` , `plugins` directories [can be modified in](#) `idea.properties` file.

IntelliJ IDEA makes it possible to change the `*.vmoptions` and the `idea.properties` files without editing them in the IntelliJ IDEA installation folder.

To create an empty `idea.properties` file or to copy the `*.vmoptions` file, choose Help | Edit Custom Properties... or Help | Edit Custom VM Options... from the main menu respectively.

To learn how to change the `idea.properties` file, read the section [File 'idea.properties'](#) .

Location of the IDE files depends on the operating system, and IntelliJ IDEA version.

On this page:

- [Windows](#)
- [Linux and the other UNIX systems](#)
- [macOS](#)

## Windows

All the files are located under this directory by default:

### Windows Vista, 7, 8, 10

```
<SYSTEM DRIVE>\Users\<USER ACCOUNT NAME>\.<PRODUCT><VERSION>
```

### Windows XP

```
<SYSTEM DRIVE>\Documents and Settings\<USER ACCOUNT NAME>\.<PRODUCT><VERSION>
```

## Example

– IntelliJ IDEA 2016.1 Ultimate Edition:

```
c:\Users\John\IntelliJIdea2016.1\
```

– IntelliJ IDEA 2016.1 Community Edition

```
c:\Users\John\IdeaIC2016.1\
```

Refer to the page [Project and IDE Settings](#) .

## Linux and the other UNIX systems

Product directory starting with dot can be found in the user home directory. The pattern is:

```
~/.<PRODUCT><VERSION>
```

~ is an alias for the home directory, for example `/home/john` .

## macOS

– Configuration

```
~/Library/Preferences/<PRODUCT><VERSION>
```

– Caches

```
~/Library/Caches/<PRODUCT><VERSION>
```

– Plugins

```
~/Library/Application Support/<PRODUCT><VERSION>
```

- Logs

```
~/Library/Logs/<PRODUCT><VERSION>
```

where <PRODUCT> is IntelliJ IDEA (IntelliJ IDEA Ultimate Edition), IdeaIC (IntelliJ IDEA Community Edition).

IntelliJ IDEA requires Internet connection for a wide variety of tasks. For example:

- Checking for IntelliJ IDEA [updates](#)
- [Code inspections](#) that can verify external resources
- Communication with the [version control](#) servers, [task servers](#)
- Anonymous usage statistics
- Resolving Maven dependencies and updating plugins
- Using the [IDEtalk plugin](#)

Besides that, IntelliJ IDEA provides IPC for commands (for example, open files), and the built-in Web server.

Some of the communication requirements are configurable:

- Checking for updates can be turned off. To disable checking for updates, open the page [Settings | Updates](#) , and clear the checkbox Check for updates in channel .
- To turn off IDEtalk plugin, open the page [Settings | Plugins](#) , and make sure that the checkbox to the left of the plugin name is cleared.
- To use only those Maven resources that are available locally, open the page [Settings| Maven](#) , and select the checkbox Work offline
- To disable code inspection that highlights dead links, open the page [Settings | Inspections](#) , and clear the checkbox to the left of the HTML inspection Non-existent web resources .
- You can control the frequency of sending usage statistics, or even completely disable this function in the page [Settings | Usage statistics](#) .

In this section:

- [Light editor schemes](#)
- [Darcula scheme](#)
- [Test runner adjustment](#)

## Light editor schemes

To people with red-green color deficiency, green, red and their hues might look the same. In the default color scheme, red is reserved for the errors and green for the strings:

```
@Nonnull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@Nonnull final Project project,
                                   @Nonnull ApplicationProfileManager applicationProfileManager,
                                   @Nonnull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

```

The simulation below shows how the same code fragment will look for a person with green color deficiency. Strings, annotations and unknown symbols are all the same color. The wavy error underline is lighter and less noticeable:

```
@Nonnull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@Nonnull final Project project,
                                   @Nonnull ApplicationProfileManager applicationProfileManager,
                                   @Nonnull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

```

The Adjust for color deficiency option changes colors so that they can be differentiated by a person with green or red color deficiency. Strings and annotations are shades of blue, and orange is reserved for the error states:

```
@Nonnull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@Nonnull final Project project,
                                   @Nonnull ApplicationProfileManager applicationProfileManager,
                                   @Nonnull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

```

Then, with the option Adjust for color deficiency turned on, and green color deficiency is selected, the simulation for the green color deficiency will look like the following:

```
@Nonnull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@Nonnull final Project project,
                                   @Nonnull ApplicationProfileManager applicationProfileManager,
                                   @Nonnull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

```

Highlight for read/write states of identifiers at caret are well distinguished for the persons without color deficiency:

```
Class callerClass = null;
for (final Object o : element.getChildren()) {
    Element listElement = (Element)o;
    if (ATTR_LIST.equals(listElement.getName())) {
        if (callerClass == null) {
            callerClass = ReflectionUtil.findCallerClass(2);
            assert callerClass != null;
        }
    }
}

```

However, these states become indistinguishable for the persons with color deficiency:

```
Class callerClass = null;
for (final Object o : element.getChildren()) {
    Element listElement = (Element)o;
    if (ATTR_LIST.equals(listElement.getName())) {
        if (callerClass == null) {
            callerClass = ReflectionUtil.findCallerClass(2);
            assert callerClass != null;
        }
    }
}

```

With the Adjust for color deficiency option, the difference between read and write states remains visible. In the example below you see the green color deficiency simulation:

```
Class callerClass = null;
for (final Object o : element.getChildren()) {
    Element listElement = (Element)o;
    if (ATTR_LIST.equals(listElement.getName())) {
        if (callerClass == null) {
            callerClass = ReflectionUtil.findCallerClass(2);
            assert callerClass != null;
        }
    }
}

```

Folded text highlight in the default scheme is easily noticeable for the persons without color deficiency:

```
String ABSTRACTION_GROUP_NAME = InspectionsBundle.message("group.names.abstraction.issues");
String ASSIGNMENT_GROUP_NAME = "Assignment issues";
String BUGS_GROUP_NAME = "Probable bugs";

```

But this is a challenge for the persons with color deficiency - it is too light to notice:

```
String ABSTRACTION_GROUP_NAME = InspectionsBundle.message("group.names.abstraction.issues");
String ASSIGNMENT_GROUP_NAME = "Assignment issues";
String BUGS_GROUP_NAME = "Probable bugs";

```

With the Adjust for color deficiency option it becomes noticeable:

```
String ABSTRACTION_GROUP_NAME = InspectionsBundle.message("group.names.abstraction.issues");
String ASSIGNMENT_GROUP_NAME = "Assignment issues";
String BUGS_GROUP_NAME = "Probable bugs";

```

## Darcula scheme

The non-adjusted Darcula text looks as follows:

```
@NonNull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@NonNull final Project project,
    @NonNull ApplicationProfileManager applicationProfileManager,
    @NonNull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

}
```

The difference between the various elements of text is not noticeable for the persons with color deficiency:

```
@NonNull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@NonNull final Project project,
    @NonNull ApplicationProfileManager applicationProfileManager,
    @NonNull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

}
```

Now turn on the option Adjust for color deficiency.

Compare the view of the editor for the persons without color deficiency:

```
@NonNull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@NonNull final Project project,
    @NonNull ApplicationProfileManager applicationProfileManager,
    @NonNull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

}
```

and that for the persons with color deficiency:

```
@NonNull private static final String PROJECT_DEFAULT_PROFILE_NAME = "Project Default";

public DefaultProjectProfileManager(@NonNull final Project project,
    @NonNull ApplicationProfileManager applicationProfileManager,
    @NonNull DependencyValidationManager holder) {

    myProject = project;
    myHolder = holder;
    myApplicationProfileManager = applicationProfileManager;
}

}
```

## Test runner adjustment

Colors of the test runner progress have also been adjusted. The usual progress bar color is indistinguishable for a person with green or red color deficiency. Compare the view of the test runner for the person without color deficiency:

with that for the persons with color deficiency:

Turn on the option Adjust for color deficiency, and compare the view of the test runner for the person without color deficiency:

with that for a person with color deficiency:

Run FrenchComplexFormatTest

FrenchComplexFormatTest 13ms

Run FrenchComplexFormatTest 31 test

Test Method	Duration	Output
testParseNegativeReal	0ms	"C:\Program Files\Java\jdk1.7.0_45\bin\java" ...
testGetImaginaryFormat	0ms	
testParseSimple	6ms	java.lang.AssertionError:
testNeqativeInfinity	0ms	Expected : (1.232323232323, 1.434343434343)

A project in IntelliJ IDEA is a directory that stores your code, resources you use for developing an application, and configuration files with your personal workspace settings. Projects can be configured — you can configure a name, an SDK, specify a language level and a compiler output.

Projects in IntelliJ IDEA are composed of one or more modules. In a project with multiple modules, each module can have its own configuration, and you can run, test and debug each module without affecting other modules.

If you're developing a framework-specific application, such as Spring, you'll need a facet. Facets come with the IDE, and include libraries, UI controls and other tools you might need to develop an application for a specific framework.

IntelliJ IDEA is integrated with build tools, such as Maven or Gradle, and provides coding assistance for editing the build file, code completion, inspections and quick-fixes, refactorings, and so on.

## Working with projects

When you create a new project, you have to select a project type, configure a JDK, and specify a project name and its location.

If you're creating a Maven or a Gradle project, you can specify the necessary settings right in the **New Project** wizard, so that when you open your project for the first time, it will be pre-configured. For example, tasks will be defined, and dependencies declared.

## Configuring the JDK when creating a project

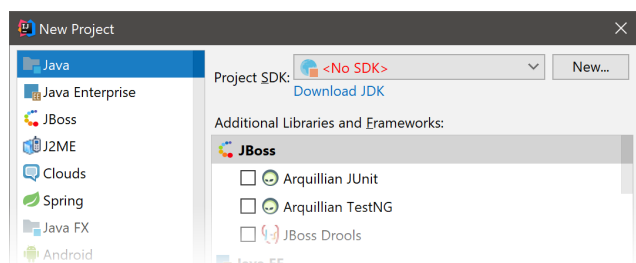

To develop applications in IntelliJ IDEA, you need the Java SDK or the JDK (Java Development Kit).

**Tip** Some frameworks require their own SDKs in addition to the JDK. For example, Android or Grails.

IntelliJ IDEA doesn't come with the JDK, so if you don't have the necessary JDK version, you should download and install it. After that, you need to let the IDE know in which folder the JDK is installed.

1. On the **New Project** wizard, click **Download JDK** below the **Project SDK** list. You will be redirected to the [Oracle official website](#).
2. Select and download the necessary JDK version.
3. Run the Java installation wizard and follow its steps until Java is installed.
4. Once Java is installed, you need to let IntelliJ IDEA know in which folder on your computer it resides. Click **New** next to the **Project SDK** list.
5. Find and select the folder in which you have installed the JDK (the JDK home directory). For example, `jdk1.8.0_144`.

On Windows, Java is usually found in `C:\Program Files\Java`. On macOS, you can find Java in `/System/Library/Java`.

You can specify another JDK

version, configure additional SDKs, and change SDK levels any time as you work with a project. For more information, see [Configuring projects](#).

## Importing a project

To import a project in IntelliJ IDEA, go to `File | New | Project from Existing Sources`.

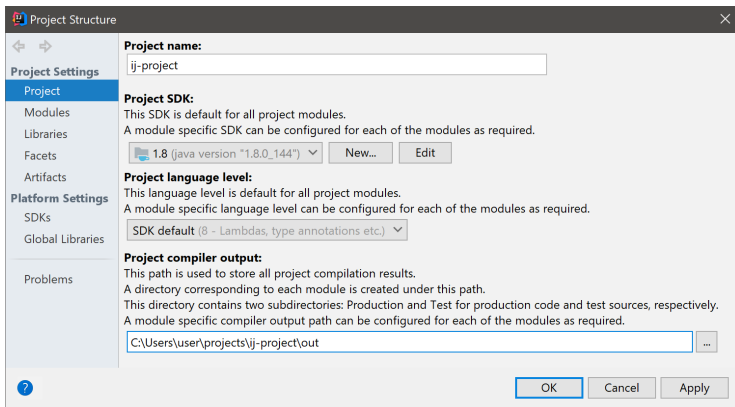

If you want to import a project that uses a build tool such as Maven or Gradle, it's recommended that you import the associated build file (`pom.xml` or `build.gradle`). In this case, IntelliJ IDEA will recognize dependencies and artifacts in the project, and will automatically restore their configuration.

**Note** For more information on how to import a project that uses a build tool, refer to [Maven](#) or [Gradle](#).

In IntelliJ IDEA, you can import a project that come from other external models. For example, **Eclipse**, **Bnd/Bndtools** and **Flash Builder**. You can also import a collection of source files to create a new project from them.

## Project settings

For projects in IntelliJ IDEA, you can configure a name, specify an SDK, set a language level and a compiler output. To change project settings, go to `File | Project Structure` or press `Ctrl+Shift+Alt+S`, and select **Project**.

Note the settings you change in this dialog will be applied only to the project you're working with at the moment. If necessary, you configure a global SDK, a language level and a compiler output. It means that these new global settings will be applied to all newly created projects. To change the global project settings, go to [File | Other Settings | Default Project Structure | Project](#).

In IntelliJ IDEA, you can also configure the IDE itself. These settings include code styles, run configurations, compiler settings, plugins, inspections, and much more. For more information, refer to [Configuring Project and IDE Settings](#).

## Project formats

In IntelliJ IDEA, there are two types of projects — the directory-based format and the file-based format.

The file-based format is a legacy format. It requires that you place personal workspace settings under version control. It means that other members of your team may have conflicts on checkout as they are likely to have different workspace configuration.

In the directory-based project (default and recommended), custom settings are stored in a separate file that you do not have to place under version control. Together with a project, IntelliJ IDEA creates a module file ( `.iml` ) that is needed to keep dependencies.

If your project uses Maven or Gradle, consider not to place the `.iml` file under version control. After you make changes in the descriptor file ( `pom.xml` in Maven, and `build.gradle` in Gradle), and the changes will be imported, IntelliJ IDEA will recreate the `.iml` file.

**Tip** If you want to change a project format, you can [reimport the project](#) with the necessary settings.

## Working with modules

In IntelliJ IDEA, a module is an essential part of any project — it is created automatically together with a project. Projects can contain multiple modules — you can add new modules, group them, unload modules you don't need at the moment.

Modules consist of a content root and a module file. A content root is a folder where you store your code. Usually, it contains subfolders for source code, unit tests, resource files, and so on. A module file (an `.iml` file) is used for keeping dependencies between files in a module and dependencies between modules within a project.

## Configuring content roots

The content in IntelliJ IDEA is a group of files that contain your source code, build scripts, unit tests and documentation. These files are usually organized in a hierarchy. The top-level folder is called a **content root folder** or a **content root**.

Modules normally have one content root. You can add more content roots. For example, this might be useful if pieces of your code are stored in different locations on your computer.

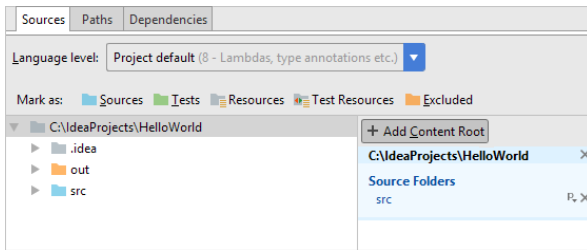

At the same time, modules can exist without content roots. In this case, you can use them as a collection of dependencies for other modules.

The content root folder in IntelliJ IDEA is marked with the  or  icon.

## Adding and removing content roots

To add a new content root:

1. Navigate to [File | Project Structure](#), or press `Ctrl+Shift+Alt+S`.
2. Select [Modules](#) under the [Project Settings](#) section.
3. Select the necessary module, and then open the [Sources](#) tab in the right-hand part of the dialog.
4. Click [Add Content Root](#).
5. Specify a folder with source files from which you want to create a new content root, and click [OK](#).

To remove a content root:

1. While on the Sources tab, select the content root that you want to remove, click **X**.
2. Confirm deletion. Note that corresponding folder won't be physically deleted.

## Folder categories

**Tip** Similarly to sources, you can specify that your resources are generated. You can also specify which folder within the output folder your resources should be copied to.

Folders within content roots can be assigned to several categories.

- **Source roots**
  - Production code that should be compiled.
- **Generated source roots** (sometimes marked as [generated])
  - These folders are not suggested as target folders when performing the **Move Class** refactoring and the **Create Class from Usage** quick fix.
- **Test source roots**
  - These folders allow you keep the code related to testing separate from the production code. Compilation results for sources and test sources, normally, are placed into different folders.
- **Generated test source roots** (sometimes marked as [generated])
  - These folders are not suggested as target folders when performing the **Move Class** refactoring and the **Create Class from Usage** quick fix.
- **Resource roots** (available only in Java modules)
  - Resource files used in your application (images, configuration XML and properties files, etc.). During the build process, resource files are copied to the output folder as is.
- **Load path roots** (available only when the Ruby plugin is enabled)
  - The load path is the path where the `require` and `load` statements look for files.
- **Test resource roots** (available only in Java modules)
  - These folders are for resource files associated with your test sources.
- **Excluded roots**
  - Files in excluded folders are ignored by code completion, navigation and inspection. That is why, when you exclude a folder that you don't need at the moment, you can increase the IDE performance.

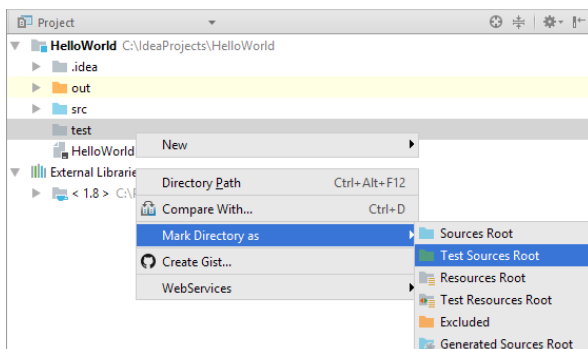

Normally, compilation output folders are marked as excluded.

Apart from excluding the entire folders, you can also [exclude specific files](#).

## Configuring folder categories

To assign a folder to a specific category:

1. Right-click the necessary folder in the directory tree of the Project tool window.
2. Select Mark Directory as from the shortcut menu.
3. Select the necessary category.

This way, you can assign categories to sub-folders as well.

To restore previous category of the folder, right-click this folder again, select Mark Directory as, and then select Unmark as <folder category>. For excluded folders, select Cancel Exclusion.

You can also configure folder categories in Project Structure | Modules | Sources.

## Excluding files

If you don't need specific files, but you don't want to completely remove them, you can temporarily exclude these files from the project. Excluded files are ignored by code completion, navigation and inspections.

**Tip** Java files and binaries cannot be excluded.

To exclude file, you need to mark it as a plain text text file. You can always return excluded files to their original state.

1. Right-click the necessary file in the directory tree of the Project tool window.
2. Select Mark as Plain Text from the menu.

Plain text files are marked with the  icon in the directory tree.

To revert the changes, right-click the file and select Mark as <file type> from the menu.

## Excluding files and folders by name patterns

In some cases, excluding files or folders one by one is not convenient. For example, if your source code files and files that are generated automatically (by a compiler, for instance) are placed in the same directories, and you want to exclude the generated files only. In this case, you can configure one or several name patterns for a specific content root.

If a folder name or a file name located inside the selected content root matches one of the patterns, it will be marked as excluded. Objects outside the selected content root won't be affected.

**Tip** All files within excluded folders will be excluded as well.

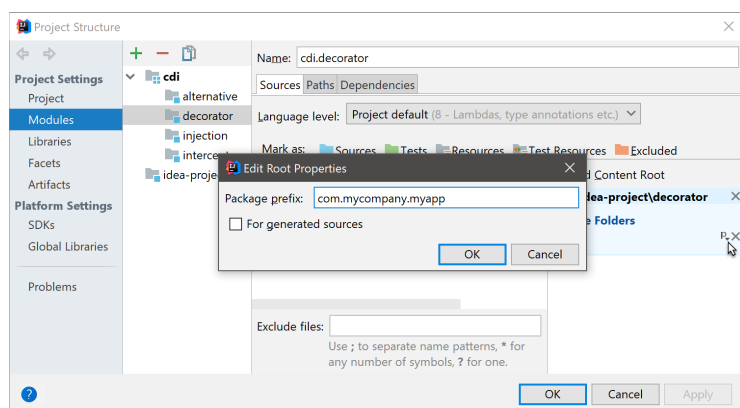

1. Navigate to File | Project Structure , or press `Ctrl+Shift+Alt+S` .
2. Click Modules under the Project Settings section, and then select a module. If there're several content roots in the module, select the one that you want to exclude files or folders from.
3. In the Exclude files field located at the bottom of the dialog, enter a pattern. For example, enter `*.aj` to exclude AspectJ files.

You can configure multiple patterns and separate them with the `;` (semicolon) symbol.

## Assigning a package prefix to Java sources

In Java, you can assign a package prefix to a folder instead of configuring a folder structure manually. A package prefix can be assigned to source folders, generated source folders, test source folders and generated test source folders.

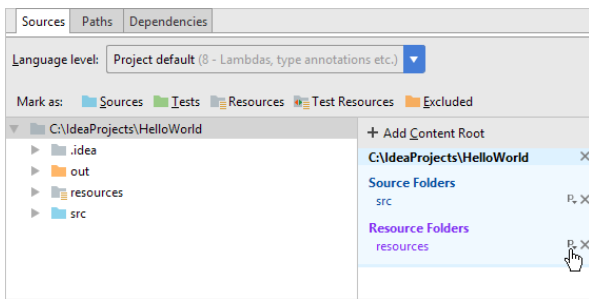

1. Press `Ctrl+Shift+Alt+S` to open the Project Structure dialog, and then select Modules .
2. Select the necessary module, and open the Sources tab.
3. In the right-hand pane, click  next to Source Folders or Test Source Folders .
4. Specify the package prefix and click OK .

## Changing the output path for resources

When you're building a project, the resources are copied into the compilation output folder by default. You can specify a different directory within the output folder to place resources.

1. Press `Ctrl+Shift+Alt+S` to open the Project Structure dialog.
2. Select Modules and then select the necessary module.
3. In the right-hand part of the dialog, select the Sources tab.
4. In the right-hand pane, under Resource Folders or Test Resource Folders , click  to the right of the necessary folder (folder path).
5. Specify the path relative to the output folder root, and click OK .

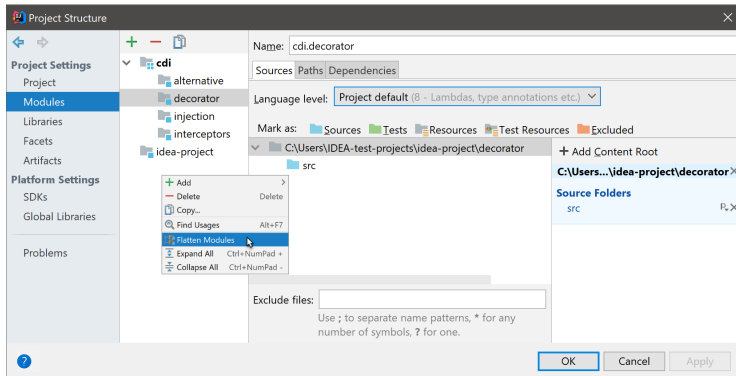

## Grouping modules

IntelliJ IDEA allows you to logically group modules. If you have a large project with multiple modules, grouping will make it easier to navigate through your project.

To sort out modules, you should give them fully qualified names. Support for qualified names is enabled by default in IntelliJ IDEA of version 2017.3 and higher, so no further configuration is required. For example, if you want to group all CDI modules, you can add the `cdi.` prefix to their names.

You can use the **Flatten Modules** shortcut menu option to view modules on the same level.

Note that if you've configured manual module groups in a project in IntelliJ IDEA version 2017.2 or lower, you will be able to continue working with them in version 2017.3, but qualified names won't be available.

To enable qualified names, select all modules in the **Project** tool window, open the shortcut menu and select **Move Module to Group | Outside Any Group**. After that all manually defined modules groups will be disabled, and you will be able to use qualified names to group modules.

## Working with module dependencies

Modules can depend on SDKs, JAR files (libraries) or other modules within a project. When you compile or run your code, the list of module dependencies is used to form the classpath for the compiler or the JVM.

To add a new dependency:

1. Navigate to **File | Project Structure** or press `Ctrl+Shift+Alt+S`.
2. Select **Modules | Dependencies**.
3. Click **+** or press `Alt+Insert`, and then select a dependency type:
  - **JARs or directories**.
  - **Library**. You can select an existing library or create a new one and then add it to the list of dependencies.
  - **Module Dependency**.

To remove a dependency, select it and then click **-** or press `Alt+Delete`.

Before removing a dependency you can make sure that it is not used in other modules in the project. To do so, select the necessary dependency and press `Alt+F7`. You can also use the **Find Usages** option of the shortcut menu.

## Specifying dependency scope

Specifying dependency scope allows you control at which step of the build the dependency should be used.

To configure dependency scope:

1. Navigate to **File | Project Structure** or press `Ctrl+Shift+Alt+S`.
2. Select **Modules | Dependencies**.
3. Select the necessary scope from the list in the **Scope** column:
  - **Compile** — the default scope. Compile dependencies are needed to build, test, and run a project.
  - **Test** — test dependencies are needed to compile and run unit tests.
  - **Runtime** — runtime dependencies are a part of the classpath to test and run a project.
  - **Provided** — the dependency is used for building and testing a project.

IntelliJ IDEA processes dependencies for test sources differently from other build tools (e.g. Gradle and Maven). If your

module (say, module A) depends on another module (module B), IntelliJ IDEA assumes that the test sources in A depend not only on the sources in B but also on its own test sources. Consequently, the test sources of B are also included in the corresponding classpaths.

## Sorting dependencies

The order of dependencies is important as IntelliJ IDEA will process them in the same order as they are specified in the list.

During compilation, the order of dependencies defines the order in which the compiler (javac) looks for the classes to resolve the corresponding references. At runtime, this list defines the order in which the JVM searches for the classes.

You can sort the dependencies by their names and scopes. You can also use the  and  buttons to move the items up and down in the list.

## Analyzing dependencies

If you want to check whether a dependency still exists in your project, and find its exact usages, you can run dependency analysis:

1. Navigate to File | Project Structure or press  .
2. Select Modules | Dependencies .
3. Right-click the necessary dependency and select **Analyze This Dependency** .

IntelliJ IDEA will show you collected dependency usages in the **Dependency Viewer** tool window. You can analyze several dependencies one by one without closing the dialog. The result of each analysis will be open in a separate tab of the tool window. After you analyze all necessary dependencies, you can close the **Project Structure** dialog and view results of each dependency analysis.

If IntelliJ IDEA finds no dependency usages in the project, you will be prompted to remove this dependency.

## Adding support for frameworks and technologies

For developing framework-specific applications, IntelliJ IDEA features facets.

A facet is a set of tools that are specific for a particular framework or a technology. Facets can include libraries, coding assistance features, artifact configurations, UI controls that are essential for the framework you are working with, and much more. The exact set of features depends on each facet.

## Adding a facet to a module

IntelliJ IDEA can identify a file or a directory that is typical for a certain framework, and add a the necessary facet for you. Once a framework is detected and added, IntelliJ IDEA will inform you about missing configuration and will suggest necessary actions. For example, to configure facet settings.

If a facet is not detected automatically, you can add it manually:

 You can add more than one facet to one module.

1. Navigate to File | Project Structure , or press  , and click Facets .
2. Click  (or press  ) and select a framework from the list.
3. Select a module to which you want to add a facet and configure the facet, if required.

You can also add a facet as you create a new project or a new module.

## Excluding frameworks from auto-detection

By default, auto-detection is enabled for all the supported frameworks. You can disable framework auto-detection completely, or exclude individual frameworks from auto-detection.

1. Open the **Project Structure** dialog, select **Facets** , and then select **Detection** .
2. Click  (or press  ), then select the necessary option. For example, you can disable auto-detection of all frameworks in one directory only.
3. Deselect the **Enable framework detection** checkbox to disable auto-detection of all frameworks in the entire project.

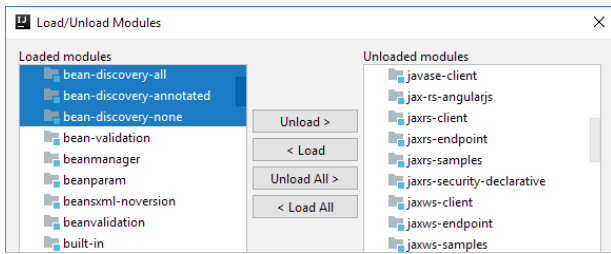

## Unloading modules

To make the IDE work faster, you can temporary set aside or unload modules that you don't need at the moment. IntelliJ IDEA ignores the unloaded modules when you search through or refactor your code, or compile your project.

When you unload modules, you do it locally — the information about unloaded modules is not shared through version control.

To unload or load modules:

1. In the Project tool window, right-click a module, and select Load/Unload Modules .
2. Use the buttons in the middle section of the dialog to manage modules. You can also double-click a module in the dialog to load or unload it.

## Troubleshooting

If modules in your project depend on each other, you may face errors when you unload one or more of them.

For example, if Module 1 depends on Module 2, and you unload Module 2, IntelliJ IDEA won't be able to resolve references to classes in Module 2. Moreover, compilation of Module 1 will probably fail.

To avoid such errors, the IDE analyzes dependencies when you load or unload modules. When you load modules, IntelliJ IDEA will suggest to load all dependencies as well. When you unload modules, the IDE will find all dependent modules and

If you unload Module 1, you may not see any errors in code in Module 2, and you will also be able to compile Module 2. However, you may accidentally break compilation of dependant code in Module 1 by making changes in code in Module 2. Since Module 1 is unloaded, you won't be able to see any errors until you load it back and compile.

If you invoke Find Usages or refactoring on a class, field, method, etc. contained in Module 2, the result may be incomplete because the contents of Module 1 are not taken into account. IntelliJ IDEA will inform you about that.

Moreover, the IDE will compile unloaded modules every time you commit changes, and will check, that the changes don't affect unloaded modules. See more information in [Configuring projects](#).

## Automatically loading and unloading new modules

If your teammates add new modules to the project, you will download them to your computer on the project update. After that, the IDE will analyze dependencies between all modules in the updated project.

If you have unloaded modules, IntelliJ IDEA will load or unload new modules according to the results of the dependency analysis.

If new modules depend on the existing unloaded modules, the new modules will be marked as unloaded. IntelliJ IDEA will ignore them because otherwise you may face errors when you try to compile them.

If existing loaded modules have direct dependencies on new modules, the new modules will be marked as loaded.

If existing loaded modules have no dependencies on the newly added modules, the new modules will be marked as unloaded. You can manually mark them as loaded as soon as you need them.

## Committing changes with unloaded modules

If you have unloaded modules, and you make changes in files that your unloaded modules depend on, compilation of these modules may fail after you load them back.

To avoid compilation failures of unloaded modules, make sure that the `Compile affected unloaded modules` option is selected in the `Commit Changes` dialog.

Before committing changed files, IntelliJ IDEA will compile unloaded modules to make sure that the changes don't affect these modules. The IDE will inform you about the detected errors, and will suggest resolving them before the commit.

## Working with SDKs

A Software Development Kit, or an SDK, is a collection of tools that you need to develop an application for a specific software framework. For example, for Android applications, you will need the Android SDK.

**Note** To develop applications in IntelliJ IDEA, you need the Java SDK (JDK).

SDKs contain binaries, source code for the binaries, and documentation for the source code. For Java, SDKs also contain annotations.

### Note

- [Java SE Development Kits \(JDKs\)](#)
- [Java Micro Edition \(ME\) SDKs](#)
- [Android SDKs](#)
- [Flex and AIR SDKs](#)
- [Python SDKs](#)
- [Ruby SDKs](#)
- [Google App Engine SDK](#)
- IntelliJ Platform Plugin SDKs (for developing IntelliJ IDEA plugins)

## SDK levels

SDKs can be configured at all three levels:

**Global** — used by multiple projects. Generally, SDKs are global; after you define an SDK for the first IntelliJ IDEA project, it will be suggested as a default SDK for all project that you will create afterwards.

**Project** — used by all modules within a project. For example, this might be useful if you want to compile a project with a specific SDK version.

**Module** — used by a specific module.

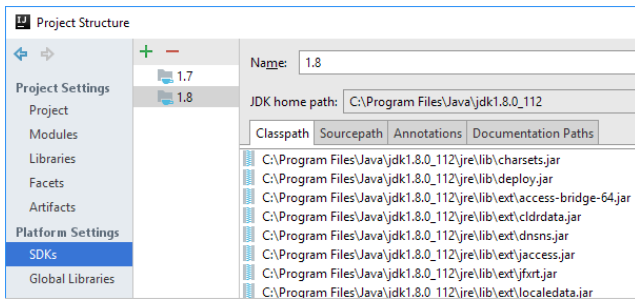

## Defining SDKs

To define an SDK means to let IntelliJ IDEA know in which folder on your computer the necessary SDK version is installed. This folder is called SDK home directory.

## Managing global SDKs

To manage the list of global SDKs available for your projects:

1. Navigate to `File | Project Structure`.
2. Select SDKs under the `Platform Settings` section.
3. To add a new SDK or a new SDK version, click `+` (or press `Alt+Enter`), select an SDK type and specify its installation directory.
4. To remove an SDK, select it in the list and click `-` (or press `Alt+Delete`).

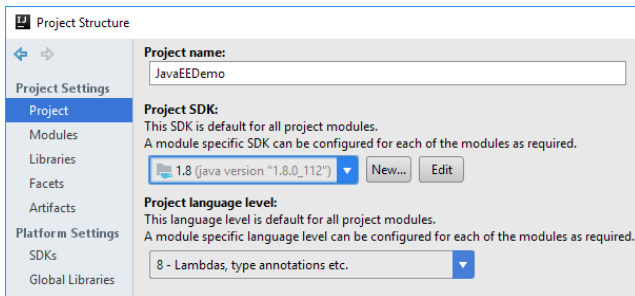

## Changing project SDK

To change the project SDK:

1. Navigate to File | Project Structure .
2. Select Project under the Project Settings section.
3. From the Project SDK list, select another SDK or SDK version.

If the necessary SDK is not defined in IntelliJ IDEA yet, click New and specify its installation folder.

Note that after you change the project SDK, all modules within this project will inherit this new SDK.

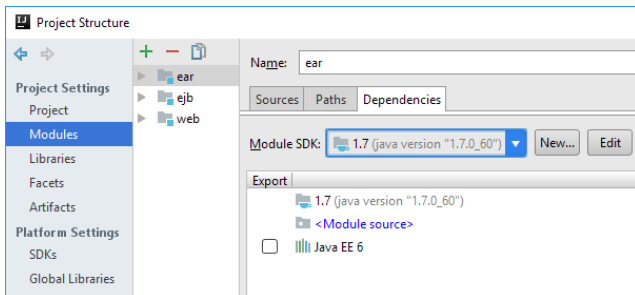

## Changing module SDK

To change the module SDK:

1. Navigate to File | Project Structure .
2. Select Modules under the Project Settings section.
3. Select the necessary module, and click Dependencies .
4. From the Module SDK list, select another SDK or SDK version you want to use.

If the necessary SDK is not defined in IntelliJ IDEA yet, click New and specify its installation folder.

## What is a library?

A library is a collection of compiled code that you use as is. A Java library, for example, can include class files, archives and directories with class files as well as directories with Java native libraries ( `.dll` , `.so` or `.jnlib` ).

Libraries may optionally include the source code for the library classes as well as corresponding API documentation. Including the source files and documentation is optional. It adds the ability to use inline documentation extracted from the source code ( View | Quick Documentation or `Ctrl+Q` ), and also to view the API documentation right from the IDE ( View | External Documentation or `Shift+F1` ).

Libraries let you reuse the code developed by others instead of implementing corresponding functionality yourself.

## Library levels

You can define the libraries at the global (IDE), project, and module levels. The level of a library defines the scope of its potential or actual use:

- Global libraries can be used in any of your [projects](#) . That is, they can be added to [dependencies](#) of any [module](#) in any project.
- Project libraries can be used in any of the modules within the corresponding project. However, they are not available outside of the project in which they are defined.
- Module libraries exist only as dependencies of the corresponding module.

Note that a global or project library is actually unused unless added to dependencies of a module.

IntelliJ IDEA lets you move the libraries to a higher level (e.g. from project to global), create library copies at a lower level (e.g. you can create a copy of a global library at the project level), etc.

## Application server libraries

Application server libraries let you use the classes available in corresponding server distributions.

When you add a definition of an application server (see e.g. [Defining Application Servers in IntelliJ IDEA](#) ), an associated application server library is created.

In terms of the [library levels](#) , the application server libraries are global libraries. They can be added to [dependencies](#) of any [module](#) in any of your projects.

## Excluded library items

You can make library items "excluded". IntelliJ IDEA will ignore such items when you write your code. As a result, the classes from excluded packages won't be present in code completion suggestion lists, references to such classes will be shown in the editor as unresolved, etc. However, when you compile or run your code, a library is still used as a whole, irrespective of whether there are excluded items in that library or not.

You can exclude folders, archives (e.g. JARs) and folders within the archives.

When your code references only a small portion of a big library, making the "unnecessary" items excluded may considerably increase the IDE performance.

## Where do I manage my libraries?

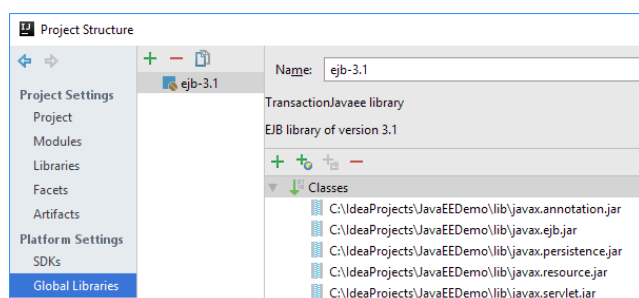

Most of the tasks related to working with [libraries](#) are performed in the Project Structure dialog ( File | Project Structure ).

The exceptions are the [application server libraries](#) and JavaScript libraries. Those are managed in the Settings / Preferences dialog:

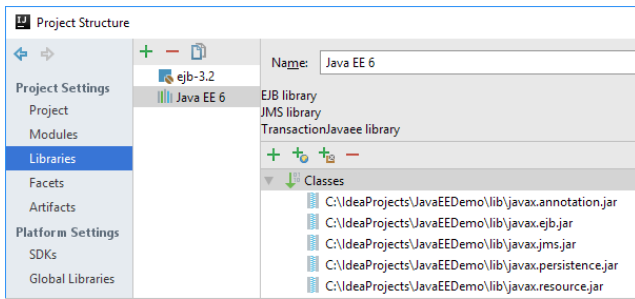

- The application server libraries: `Ctrl+Alt+S` | Build, Execution, Deployment | Application Servers . For more info, see the [Application Servers page description](#) .
- The JavaScript libraries: `Ctrl+Alt+S` | Languages and Frameworks | JavaScript | Libraries . For more info, see [Configuring JavaScript Libraries](#) .

In the Project Structure dialog, depending on the [library level](#) :

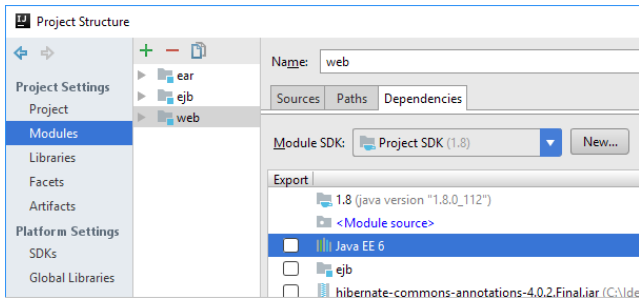

Global (IDE). To see you global libraries, select Global Libraries .

Project. To see your project libraries, select Libraries .

Module. To see the libraries included in the dependencies of a module, select Modules, select the module of interest, and then select Dependencies.

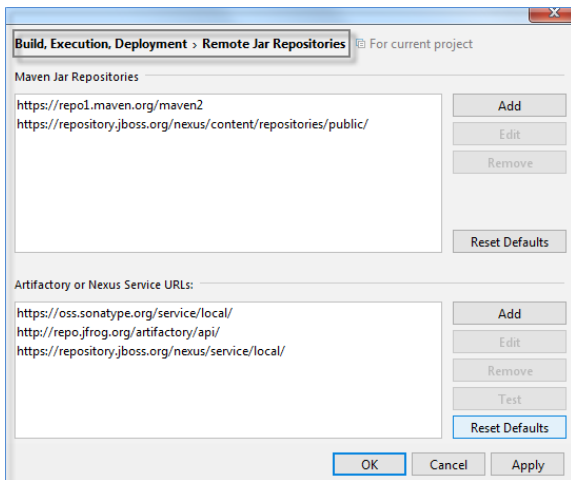

What's not an SDK or module in the list of dependencies, is a library.

The libraries here are not necessarily all module libraries. There may be global and project libraries as well.

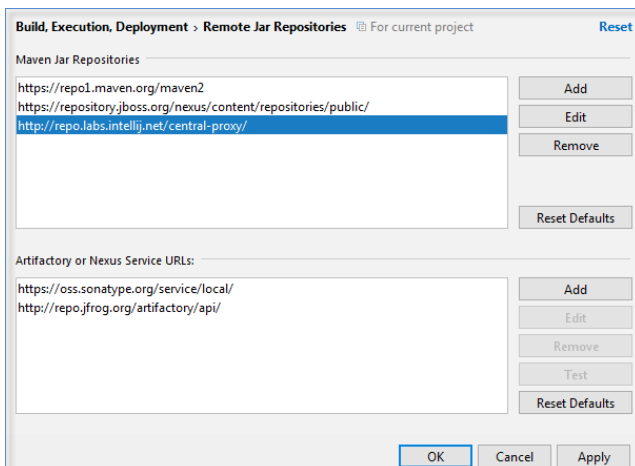

If you want to know the library level, select the library of interest and click . The library level will be reflected in the name of the dialog that will open, e.g. Configure Module Library.

## About downloading libraries from Maven

When you are adding a library ( | From Maven), IntelliJ IDEA downloads a library from Maven or Nexus public repositories. The repositories are configured on the Settings | Build, Execution, Deployment | Remote Jar Repositories page.

You don't have to have the Maven plugin enabled to download your library from [Maven repository](https://repo1.maven.org/maven2). Moreover, you can configure a custom remote repository from which IntelliJ IDEA downloads a library.

It might be helpful if, for example, your company uses some artifact repository manager for the company's remote repository that needs to be accessed. You can add URLs for the services and a repository to access the authorized versions of the

libraries. In this case there is no need to save the libraries for all the projects in VCS since you can always access the specified repository and a version of the library that is stored there.

In all other cases, you compose a library by specifying the files and folders already available on your computer.

## Creating a library

Depending on the level you are currently on:

**Global or project.** Above the list of libraries, click **+** and select the library type (e.g. Java ). Select the files and folders you want to include in your library. Select the modules to whose dependencies you want to add the library.

**Module.** Next to the list of dependencies, click **+**. Now, you can select one of the following routes, both leading to about the same result:

- JARs or directories. In the dialog that opens, select the files and folders to be included in your library. As a result, an unnamed module library is created and added to the dependencies of the module.
- Library. In the dialog that opens, click **New Library** and select the library type (e.g. Java ). Then select the files and folders to be included in the library. In the **Configure Library** dialog, specify the library name and level. To add the new library to the dependencies of the module, click **Add Selected** .

## Creating a library in the Project tool window

If the .jar files that you want to use as a library are within your project **content roots** , you can start creating your library in the Project tool window ( **View | Tool Windows | Project** ).

1. Select the .jar file or files to be included in the library, or a directory that contains the .jar files of interest.
2. Select **Add as Library** from the context menu.
3. In the dialog that opens, specify the library name, level and the module in which this library will be used.

## Adding a global or project library to module dependencies

Depending on the level you are currently on:

**Global or project.** Right-click the library of interest and select **Add to Modules** . Select the modules to whose dependencies you want to add the library.

**Module.** Next to the list of dependencies, click **+** and select **Library** . In the dialog that opens, select one or more libraries and click **Add Selected** .

## Moving a library onto a higher level

You can move a module library to the project or global level. Also, you can move a project library onto the global level.

1. Right-click the library and select **Move to Project Libraries** or **Move to Global Libraries** .
2. In the dialog that opens, specify if and where you want to move the library contents.

## When would I want to move a library onto a higher level?

Say, there's a module library which you want in another module. In that case, you'd:

1. Move the library onto the project level.
2. [Add the library to the dependencies of the corresponding module.](#)

## Creating a copy of a library at a lower level

You can create a copy of a global library at the project level: right-click the library and select **Copy to Project Libraries** . Then, in the dialog that opens, specify if you also want a copy of the library files and where that copy should be created.

For a global or project library included in the dependencies of a module, to start creating a copy at the module level, right-click the corresponding library and select **Copy to Module Libraries** .

## When would I want a copy of a library at a lower level?

Say, there's a project library that is used in a number of modules. And you want more classes in that library but only in one of the modules. In that case, you'd:

1. Create a copy of the library in the dependencies of the corresponding module. (As a result, a new module library is created.)
2. [Add the classes to your new module library.](#)

## Finding usages of a project or global library

You can find out in which modules a project or global library is used: right-click the library and select **Find Usages** ( **Alt+F7** ).

## Adding classes, sources and documentation to a library

Depending on the level you are currently on:

**Global or project.** In the right-hand part of the dialog, where the library name and contents are shown, click **+** ( **Alt+Insert** ), and then select the files and folders that contain the classes, sources and documentation you want to add.

**Module.** Select the library of interest and click . In the dialog that opens, click  ( `Alt+Insert` ). Then select the files and folders that contain the classes, sources and documentation you want to add.

## Making online documentation accessible in IntelliJ IDEA

If online documentation is available for the library that you are using, you can make that documentation accessible when coding. To do that, you should specify the documentation URL. (At a later time, to view the online documentation, use View | External Documentation or `Shift+F1`.)

Depending on the level you are currently on:

**Global or project.** In the right-hand part of the dialog, where the library name and contents are shown, click  and then specify the documentation URL.

**Module.** Select the library of interest and click . In the dialog that opens, click  and then specify the documentation URL.

## Making library items excluded. Cancelling the excluded status

To make library items **excluded**, depending on the level you are currently on:

**Global or project.** In the right-hand part of the dialog, where the library name and contents are shown, click . In the dialog that opens, select the items you want to make excluded. (You can exclude folders, archives (e.g. JARs) and folders within the archives.)

As a result, the items with the excluded status appear. They are shown as .

**Module.** Select the library of interest and click . In the dialog that opens, click  and then select the items you want to make excluded.

To cancel the excluded status of the library items:

**On the global or project level:** select the items whose excluded status you want to cancel () , and then click  ( `Delete` ).

**On the module level:** select the library of interest and click . In the dialog that opens, select the items whose excluded status you want to cancel () , and then click  ( `Delete` ).

## Switching from dependencies to library configuration

To see the library configuration (settings and contents) for a library included in module dependencies, right-click the library and select Navigate ( `F4` ).

IntelliJ IDEA lets you create, edit and modify your source code, save and revert changes.

## Navigate between editor and other tool windows

### Description/Action

Press this shortcut to quickly switch schemes, keymaps, or view modes.

Ctrl+Back Quote

In the Switch menu, select your option and press **Enter** . Use the same shortcut to undo your changes.

You can also find and adjust the color scheme settings in File | Settings/Preferences | Editor | Color Scheme and the keymap settings in File | Settings/Preference | Keymap .

To maximize editor pane, press this shortcut.

Ctrl+Shift+F12

To switch the focus from other windows to an active editor.

Escape

To return to an editor from the command-line terminal, press this shortcut. However, note that in this case IntelliJ IDEA closes the terminal window.

Alt+F12

To keep the terminal window open when you want to switch back to an active editor, press **Ctrl+Tab** .

Press this shortcut to hide all windows. In this case only the editor you currently work in is open.

Ctrl+Shift+F12

Press this shortcut to return to a default layout. In this case IntelliJ IDEA hides the Project tool window. However, you can select Window | Store Current Layout as Default from the main menu to save the current layout you are working in as default and use the same shortcut to restore it.

Shift+F12

To jump to last active window you have used, press this shortcut.

F12

## Navigate inside the editor

**Tip** To find any action in the editor, press **Ctrl+Shift+A** .

## Line numbers

### Description/Action / Access

By default, IntelliJ IDEA shows line numbers in the editor. If you do not want to see line numbers, select File | Settings/Preferences | Appearance and from the options on the right, select this option. You can also assign a shortcut to the Show line numbers action.

Show line numbers

To navigate to a specific line or a column in the editor, press this shortcut. In the dialog that opens, specify the line or column number and click OK .

Ctrl+G

## Cursor position and edit location

### Description/Action / Access

To find **current cursor location** in the editor, press this shortcut. It might be helpful if you have a large project and do not want to scroll through the file.

Ctrl+M

To see on what **element the cursor is currently positioned** , press this shortcut.

Alt+Q

To find a **previous cursor position** , press this shortcut.

Ctrl+Alt+Left

To navigate to the **last edited location** , press this shortcut.

Ctrl+Shift+Backspace

To show the list of **recently edited files** , press this shortcut.

Ctrl+Shift+E

To see **recent files** , press this shortcut.

Ctrl+E

## Lens mode

The lens mode in the editor is available on a mouse hover by default. To disable this option, right-click the code analysis marker located on the right side of the editor and from the context menu clear the Show code lens on the scrollbar hover checkbox.

Alternatively, you can perform the following steps:

1. Press **Ctrl+Alt+S** to open the Settings/Preferences dialog.
2. From the options on the left, select Editor | General | Appearance .
3. From the options on the right, clear the Show code lens on the scrollbar hover checkbox.

## Breadcrumbs

Breadcrumbs let you navigate through the source code, by showing the names of classes, variables, functions, methods and tags in the file with which you are currently working in the editor. By default, breadcrumbs are enabled and displayed at the bottom of the editor.

- To change the location of breadcrumbs, right-click a breadcrumb, from the context menu select Breadcrumbs and the location preference.
- To edit breadcrumbs settings, press **Ctrl+Alt+S** and on the page that opens, select Editor | General | Breadcrumbs . On the Breadcrumbs page, adjust the settings and click OK .

**Note** Clear the Show breadcrumbs option to hide the appearance of breadcrumbs in the editor.

## Manage editor tabs

IntelliJ IDEA lets you manage the open tabs in the editor. You can close, hide, and detach them. Every time you open a file for editing, the tab with its name is added next to the active editor tab.

**Tip** You can select Window | Editor Tabs to see what additional actions you can perform with the editor tabs.

**Tip** To configure settings for editor tabs, use the Editor Tabs page located in Editor | General .

**Tip** You can use a context menu on a tab, to select the appropriate action or to see its shortcut.

#### DescriptionAction / Access

To close all of the opened tabs, select this option on the main menu.	Window   Editor Tabs   Close All
To close all inactive tabs leaving only the active one, press this shortcut and the icon on the active tab.	<b>Alt</b> and click
To close only the active tab , press this shortcut.	<b>Ctrl+F4</b>
To move between tabs , press these shortcuts.	<b>Alt+Right</b> / <b>Alt+Left</b>
To detach a tab , drag the tab you need outside of the main window (drag the tab back to attach it) or press this shortcut.	<b>Shift+F4</b>
To switch focus between tabs , press this shortcut.	<b>Ctrl+Tab</b>
To place editor tabs in a different part of the editor or remove the tabs, from the main menu, select this path and the appropriate placement option.	Window   Editor Tabs   Editor Placement
To sort editor tabs , select this option from the main menu.	Window   Editor Tabs   Sort Tabs by File Name
To split the editor window , right-click the desired editor tab, and from the context menu select how you want to split the editor window (vertically or horizontally). In this case IntelliJ IDEA makes a copy of the file and places it according to your selection. If you want to move the file without copying it first, select the Move Right or Move Down option.	Split Vertically / Split Horizontally

## Tabs limits

IntelliJ IDEA limits number of tabs that you can open in the editor simultaneously (the default tab limit is 10).

To prevent closing editor tabs automatically after the number of editor tabs reaches its limit

1. Press **Ctrl+Alt+S** .
2. From the options on the left, select Editor | General | Editor Tabs .
3. From the options on the right, in the Tab closing policy section, adjust the settings according to your preferences and click OK .

**Note** If the tab limit equals to 1, the tabs in the editor will be disabled. If you want the editor to never close the tabs, type some unreachable number.

You can hide editor tabs if there is no more space:

1. Press **Ctrl+Alt+S** .
2. From the options on the left, select Editor | General | Editor Tabs .
3. From the options on the right, select the Hide tabs if there is no space option. Extra tabs will be placed in the drop-down list located in the upper right part of the editor.

## Edit code

**Tip** The selection extends or shrinks according to capitalization, if the Use "CamelHumps" words checkbox is selected on the Smart Keys page ( File | Settings | Editor | General | Smart Keys ).

If you want to make selection according to capitalization, using double-click, make sure that the Honor CamelHumps words... checkbox is selected on the General page ( File | Settings | Editor | General ).

## Select, move, copy code

#### DescriptionAction

Press this shortcut to extend the selection of your code. For plain text and comments, the selection starts within the whole word then moves to the next word, sentence, etc. For lines of code, the selection starts with argument, extends to a group of arguments then all arguments inside method call.	<b>Ctrl+W</b>
To shrink the code selection , press this shortcut.	<b>Ctrl+Shift+W</b>
Press this shortcut to make the initial selection of your code, press the same key again to find the matching occurrence in the file. Alternatively, to make a multiselection of your code, press <b>Shift+Alt</b> and double-click the left mouse button.	<b>Alt+J</b>
To find all the occurrences in the file, press this shortcut .	<b>Ctrl+Shift+Alt+J</b>
Press these shortcuts to copy / paste a reference of a line or symbol placing a caret on the line or symbol in	<b>Ctrl+Shift+Alt+C</b>

question.

/ **Ctrl+V**

To **paste from history**, press this shortcut. In the dialog that opens, select your entry and click Paste.

**Ctrl+Shift+V**

You can configure the depth of the clipboard stack in the Limits section located in File | Settings/Preferences | Editor | General. When the specified number is exceeded, the oldest entry is removed from the list.

To **undo or redo** your changes, press these shortcuts.

**Ctrl+Z** /

**Ctrl+Shift+Z**

Place the caret immediately after the block closing brace/bracket or before the block opening brace/bracket. **Highlight braces**

**Tip** By default, when you paste anything in the editor, IntelliJ IDEA performs 'smart' paste, for example, pasting multiple lines in comments will automatically add comment markers ( // ) to the lines you are pasting. If you need to paste just plain text, press **Ctrl+Shift+Alt+V**.

## Select, move, copy lines and code blocks

### DescriptionAction / Access

Choose this action to use **multiple cursor**.

**Shift+Alt** and click the left mouse button at the location of the caret.

Alternatively, press **Ctrl** (for Windows or UNIX) / **Alt** (for macOS) twice, and then without releasing it, press up or down arrow keys.

The new carets are added to the specified locations, according to the setting specified in the Virtual Space section located in File | Settings/Preferences | Editor | General.

If you want to delete all existing carets, press **Escape** or press **Shift+Alt** and click the left mouse button on the caret you want to delete.

Choose this action to extend the caret up or down.

**Alt** and drag your mouse vertically.

**Note** If the Allow placement of caret after end of line option in File | Settings/Preferences | Editor | General is selected, you will not be able to clone the caret.

To **add a next line**, press this shortcut. IntelliJ IDEA moves the cursor to the next line.

**Shift+Enter**

To **add a line before the current one**, press this shortcut.

**Ctrl+Alt+Enter**

To **duplicate a line**, press this shortcut.

**Ctrl+D**

To **remove a line**, press this shortcut.

**Ctrl+Y**

To **move a line up or down**, press these shortcuts.

**Shift+Alt+Up** /

**Shift+Alt+Down**

To **move a code element** to the left or to the right, press these shortcuts. Place the caret at the desired code element, or select the elements to be moved and press the appropriate shortcut.

**Ctrl+Shift+Alt+Left** /

**Ctrl+Shift+Alt+Right**

For example, for Java you can use these actions for method invocation or method declaration arguments, enum constants, array initializer expressions. For XML or HTML, use these actions for tag attributes.

To **join lines**, press this shortcut. Place the cursor on the line to which you want to join the other lines and press the shortcut. Keep pressing the shortcut until all the needed elements are joined. You can successfully join string literals, a field or variable declaration, and statement. Note that IntelliJ IDEA checks the syntax and eliminates unwanted spaces and redundant characters.

**Ctrl+Shift+J**

To **split string literals** into two parts, press this shortcut in the string. IntelliJ IDEA splits the string and provides the correct syntax. You can also use the Break string on '\n' intention to split the string literals.

**Enter**

To **toggle between upper and lower case**, press this shortcut.

**Ctrl+Shift+U**

Note that when you apply the toggle case action to the *Came/Case* name format, IntelliJ IDEA converts the name to lower case.

To **comment or uncomment blocks** of code, select your code block and press this shortcut.

**Ctrl+Shift+Slash**

For a line of code, press **Ctrl+Slash**.

**Note** To configure settings for commenting behavior in Java, use options in the Comment Code section, on the Code Generation tab located in File | Settings/Preferences | Editor | Code Style | Java.

To move or copy code fragments using **drag-and-drop** actions in the editor, make sure the this option is selected. This option is located in File | Settings/Preferences | Editor | General and selected by default. If you want to move the item, select the desired fragment of your code and drag the fragment to the target location.

**Enable Drag'n'Drop functionality in editor**

If you want to copy your code selection, keep the **Ctrl** key pressed, drag the selection to the target location.

## Move, remove statements

### DescriptionAction / Access

To **move statement**, select the one you want and press one of these shortcuts. Note that if moving of statement is not allowed in the current context, the commands will be disabled. Also, note that IntelliJ IDEA moves the selected statement performing a syntax check.

**Ctrl+Shift+Up** /

**Ctrl+Shift+Down**

To **unwrap or remove statement**, place the caret on the expression you want to extract or unwrap and

**Ctrl+Shift+Delete**

press this shortcut.

IntelliJ IDEA shows a pop-up window with all the actions that are available in the current context. Statements to be extracted are displayed on the blue background, statements to be removed are displayed on the grey background.

You can select the desired action and press `Enter`.

## Reformat and rearrange code

IntelliJ IDEA lets you reformat your code according to the requirements you've specified in the Code Style settings.

To access the settings, select `File | Settings/Preferences | Editor | Code Style`. You can also rearrange code based on the arrangement rules specified on the Arrangement tab.

### Description / Access

To reformat code in the current file, in the editor, select part of the code you want to reformat / rearrange and use these options respectively.

`Ctrl+Alt+L` / Code  
| Rearrange Code

**Note** If you don't select part of the code, IntelliJ IDEA will reformat the whole file.

To invoke the Reformat File dialog for details, press this shortcut.

`Ctrl+Shift+Alt+L`

To reformat a module or directory, right-click the module or the directory in question and from the context menu, select Reformat Code or press this shortcut.

`Ctrl+Alt+L`

If you need to exclude part of code from reformatting, select this option located in `File | Settings/Preferences | Editor | Code Style`. Then in the editor, at the beginning of a region that you want to exclude, create a line comment (`Ctrl+Slash`) and type `//@formatter:off`, at the end of the region, again create a line comment and type `//@formatter:on`.

Enable formatter  
markers in comments

To quickly reformat line indents based on the specified settings on the Tabs and Indents tab located in `File | Settings/Preferences | Editor | Code Style`, on the language page, press this shortcut.

`Ctrl+Alt+I`

**Note** In some cases, the option Detect and use existing file indents for editing located in the Indent Detection section in `File | Settings/Preferences | Editor | Code Style` can override your settings. In this case IntelliJ IDEA will display the appropriate notification message.

## Use quick pop-ups

### Description / Access

To view quick definition of a symbol (tag, class, method/function, field, etc.), press this shortcut. IntelliJ IDEA displays the information in a pop-up. If you need, click the  icon to open the pop-up in the Documentation tool window.

`Ctrl+Shift+I`

To view quick documentation on a code element, press this shortcut.

`Ctrl+Q`

IntelliJ IDEA displays a pop-up with the appropriate information. You can press `Ctrl+Q` twice or click the  icon to open the pop-up in the Documentation tool window.

If you need to change the font size of the text displayed in the pop-up window, click the  icon and in the window that opens, change the font size according to your preferences.

You can also view an external documentation while in the quick documentation pop-up. Click  or press `Shift+F1`.

**Note** External documentation becomes available when you properly configure it in the [module structure](#). For example, in the module paths, you can add a path to a JavaDoc file, or a link to documentation; or specify a documentation URL for a library.

If you invoke the quick documentation pop-up when you look for a class (`Ctrl+N`), you can look up the documentation on any class displayed in the list. To switch focus to the pop-up, press the same shortcut.

to view the context information (the action shows the current method or class declaration when it is not visible), press this shortcut.

`Alt+Q`

To view an error description, press this shortcut. This action shows an error or warning description at the caret.

`Ctrl+F1`

`Ctrl+Q`

To see all usages for code element, press this shortcut on the element in question.

`Ctrl+Alt+F7`

To enable/disable import pop-up messages, select or clear this option in the Formatting section located in `Settings/Preferences | Editor | General`.

Show notification after  
optimize imports  
action

## Spellchecking

For spellchecking you can use Typo inspection that highlights the code based on the pre-defined dictionaries.

You can also configure the spellchecker's custom dictionary (a file with the `dic` extension) in the Custom Dictionaries Folder section located on the Dictionaries tab, in `File | Settings/Preferences | Editor | Spelling`.

– To check the spelling of the highlighted word, press `Alt+Enter` to show the available intention actions and choose the appropriate one.

– To configure pre-defined and custom dictionaries, press `Ctrl+Alt+S`, select `Editor | Spelling` and specify the appropriate options.

– To configure Typo inspection settings:

1. Press `Ctrl+Alt+S` and select Editor | Inspections .
2. In the list of inspection types, expand the Spelling node, click Typo and configure spellchecking options.

## Configure file encodings

– You can choose file encoding on the status bar located at the bottom of the screen.

In this case, IntelliJ IDEA opens a dialog where you can decide what you want to do with your file. You can click either Reload or Convert .

(In case of *Reload* , you load the file in the editor from a disk and the encoding changes are applied to editor only. In case of *Convert* , the file on a disk is overwritten with the encoding of your choice.)

– To configure settings for file encodings, press `Ctrl+Alt+S` , select Editor | File Encodings .

**Tip** You can change file encoding explicitly in the editor for `.xml` files by pressing `Alt+Enter` on the `encoding` element and selecting the encoding you need.

## Editor settings

IntelliJ IDEA lets you use settings for configuring different editor options to customize the editor.

### DescriptionAction / Access

To access **settings** , press this shortcut.

`Ctrl+Alt+S`

To navigate inside the Settings dialog, use search field for your queries.

Search field

To configure the settings for the **code formatting** , such as *tabs and indents* , *spaces* , *wrapping and braces* , hard and soft margins, etc., use the Code Style page and the appropriate language.

Editor | Code Style

To configure main settings for **fonts, size, and font ligatures** , use the Font page.

Editor | Font / Editor | Color Scheme | Color Scheme Font / Editor | Color Scheme | Console Font

If you need to override main settings, you can configure the settings on the Color Scheme Fonts page. After you configure your settings, click Apply . The link with the notification will appear on the Font page.

You can also override the color scheme font settings using the Console Font page.

To change font size in the editor, on the General page, select the Change font size (Zoom) with Ctrl+Mouse Wheel option. In the editor, press `Ctrl` , hold it and using the wheel on your mouse, adjust the font.

Editor | General (mouse section)

To configure **color scheme** settings for different languages and frameworks, open the Color Scheme node and select the one you need. You can also use the General option from the list to configure color schemes settings for general items such as code, editor, errors and warnings, popups and hints, search results, etc.

Editor | Color Scheme

To configure **code completion** options, use Code Completion page. You can configure case sensitive completion, configure how to sort your code, configure auto-display options, etc.

Editor | General | Code Completion

To configure **caret placement** options, such as Allow placement of caret after end of line , use the General page. When you select this option, the caret on the next line is placed in the same position as the end of previous line. If this option is cleared the caret on the next line is placed at the end of the actual line.

Editor | General

**Note** If the Allow placement of caret after end of line option is selected, the **up/down extension of a caret** will not work.

You can also select the Allow placement of caret inside tabs option which might be helpful when you scroll your file and want the cursor to remain in the same position.

To configure **editor appearance** options, for example, showing line numbers, or showing hard wrap guide, use the Appearance page.

Editor | General | Appearance

To manage the appearance of **long code lines** , use the Soft Wraps section on the General page.

Editor | General

To configure the certain **behavior** for different **basic editor actions** , use the Smart Keys page.

Editor | General | Smart keys

In this part:

- File and Code Templates
  - [Overview](#)
  - [Per-project vs default scheme](#)
  - [Predefined, internal, and custom templates](#)
  - [When are file and code templates used?](#)
  - [Are the choices of templates context-sensitive?](#)
- [File Template Variables](#)
- [#parse Directive](#)
- [Creating and Editing File Templates](#)

## Overview

File templates are specifications of the contents to be generated when creating a new file. They let you create the source files that already contain some initial code.

You can view, edit and create the templates on the [File and Code Templates page](#) of the Settings/ Preferences dialog.

File and code templates are written in the [Velocity Template Language](#) (VTL).

So they may include:

- Fixed text (markup, code, comments, etc.). In a file based on a template, the fixed text is used literally, as-is.
- [File template variables](#) . When creating a file, the variables are replaced with their values.
- [#parse directives](#) to include other templates defined in the Includes tab on the File and Code Templates page of the Settings/Preferences dialog box.
- Other VTL constructs.

Here is a typical template example. (This template is used for creating a Java class.)

```
#if (${PACKAGE_NAME} != "")package ${PACKAGE_NAME};#end
#parse("File Header.java")
public class ${NAME} {
}
```

In this template:

- `${PACKAGE_NAME}` and `${NAME}` are template variables.
- The `#parse` directive is used to include the other template `File Header.java` .
- The first line contains an `#if` VTL directive.

Applying this template leads to generating a file whose contents look similar to this:

```
package demo;

/**
 * Created by IntelliJ IDEA.
 * User: John.Smith
 * Date: 6/1/11
 * Time: 12:54 PM
 * To change this template use File | Settings | File and Code Templates.
 */
public class Demo {
}
```

## Per-project vs default scheme

IntelliJ IDEA suggests using file and code templates on the **project** or **default (global)** level.

If you need a sharable set of file and code templates, then these templates should be per-project; otherwise the templates are global and pertain to the entire workspace.

The file and code templates are stored in the following locations:

- The default (global) templates are stored in the IntelliJ IDEA home directory, in the folder `config | fileTemplates` .
- The per-project file and code templates are stored in the `.idea | fileTemplates` folder. These templates can be shared among the team members.

Refer to the section [Project and IDE Settings](#) to learn where the settings are stored, and to the [File and Code Templates](#) for the description of the Schema field.

## Predefined, internal, and custom templates

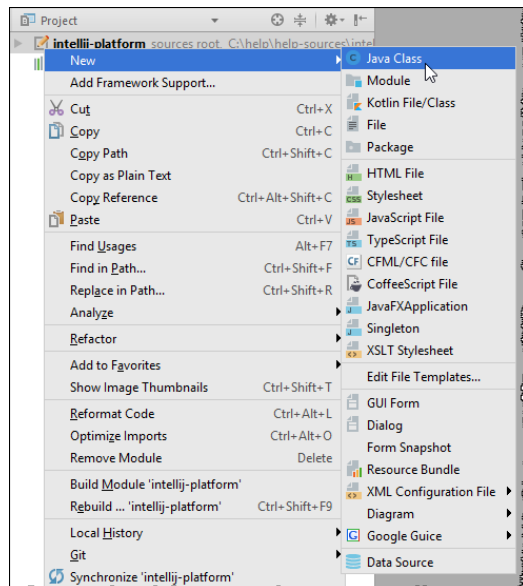

IntelliJ IDEA comes with a set of predefined file and code templates. You can use these templates as-is or modify them as necessary. You can as well create your own templates (custom templates).

Internal file and code templates are a subset of the predefined templates. These templates differ from all the other templates in that they cannot be deleted.

On the [File and Code Templates page](#) of the Settings/Preferences dialog, the names of internal templates are shown in bold. The names of the custom templates and the predefined templates that you have modified are shown in blue.

### When are file and code templates used?

Whenever you create a new file, you can choose to create an empty file (e.g. File | New | File ) or use a file template. In the latter case, the initial contents of the new file will be generated according to the template you have selected. (Basically, all the options in the New menu except File , Package and Directory correspond to using a template.)

### Are the choices of templates context-sensitive?

Generally, the set of the templates you can choose from when creating a new file depends on your [module](#) nature and configuration as well as the properties of your current location in the Project tool window. For example, you are not offered to use a template for an ActionScript class or interface, or an MXML component if your module is not a Flash module. Similarly, you cannot choose to create a Java class, interface, etc. outside of Java source or test directories ([roots](#) ).

However, there are many templates that are available in any context.

## Basics

A [file template](#) can contain template variables. When a template is applied, the variables are replaced with their values.

A file template variable is a string that starts with a dollar sign which is followed by the variable name. The variable name may be enclosed in curly braces. For example: `MyVariable` or `{MyVariable}` .

## Predefined template variables

IntelliJ IDEA comes with a set of predefined template variables.

The available predefined file template variables are:

- `{PACKAGE_NAME}` - the name of the target package where the new class or interface will be created.
- `{PROJECT_NAME}` - the name of the current project.
- `{FILE_NAME}` - the name of the PHP file that will be created.
- `{NAME}` - the name of the new file which you specify in the New File dialog box during the file creation.
- `{USER}` - the login name of the current user.
- `{DATE}` - the current system date.
- `{YEAR}` - the current year.
- `{MONTH}` - the current month.
- `{DAY}` - the current day of the month.
- `{TIME}` - the current system time.
- `{HOUR}` - the current hour.
- `{MINUTE}` - the current minute.
- `{PRODUCT_NAME}` - the name of the IDE in which the file will be created.
- `{MONTH_NAME_SHORT}` - the first 3 letters of the month name. Example: Jan, Feb, etc.
- `{MONTH_NAME_FULL}` - full name of a month. Example: January, February, etc.

IntelliJ IDEA provides a set of additional variables for [PHP include templates](#) . Include templates are used to define reusable pieces of code (namely, file headers and [PHPDoc comments](#) ) to be inserted in file templates via the [#parse directive](#) .

The following variables are available in [PHP include templates](#) :

- `{NAME}` - the name of the class, field, or function (method) for which the PHPDoc comment will be generated.
- `{NAMESPACE}` - the fully qualified name (without a leading slash) of the class or field namespace.
- `{CLASS_NAME}` - the name of the class where the field to generate the PHPDoc comment for is defined.
- `{STATIC}` - gets the value `static` if the function (method) or field to generate the comment for is `static` . Otherwise evaluates to an `empty string` .
- `{TYPE_HINT}` - a prompt for the `return` value of the function (method) to generate the comment for. If the return type cannot be detected through the static analysis of the function (method), evaluates to `void` .
- `{PARAM_DOC}` - a documentation comment for parameters. Evaluates to a set of lines `@param type name` . If the function to generate comments for does not contain any parameters, the variable evaluates to empty content.
- `{THROWS_DOC}` - a documentation comment for exceptions. Evaluates to a set of lines `@throws type` . If the function to generate comments for does not throw any exceptions, the variable evaluates to empty content.
- `{DS}` - a dollar character ( `$` ). The variable evaluates to a plain dollar character ( `$` ) and is used when you need to escape this symbol so it is not treated as a prefix of a variable.
- `{CARET}` - indicated the position of the caret after generating and adding the comment.

This `{CARET}` variable is applied only when a PHPDoc comment is generated and inserted during file creation. When a PHPDoc comment is created through Code | Generate | PHPDoc block , multiple selection of functions or methods is available so documentation comments can be created to several classes, functions, methods, or fields. As a result, IntelliJ IDEA cannot "choose" the block to apply the `{CARET}` variable in, therefore in this case the `{CARET}` variable is ignored.

- `{DATE}` - the current system date.
- `{YEAR}` - the current year.
- `{MONTH}` - the current month.
- `{DAY}` - the current day of the month.

## Custom template variables

In addition to the predefined template variables, it is possible to specify custom variables. If necessary, you can define the values of custom variables right in a template using the `#set` VTL directive.

For example, if you want to use your full name instead of your login name defined through the pre-defined variable `{USER}` , write the following construct:

```
#set( $MyName = "John Smith" )
```

If the value of a variable is not defined in the template, IntelliJ IDEA will ask you to specify it when the template is applied.

You can prevent treating dollar characters ( `$` ) in template variables as prefixes. If you need a dollar character ( `$` ) inserted as is, use the `{DS}` file template variable instead. When the template is applied, this variable evaluates to a plain dollar character ( `$` ).

Using the `#parse` directive, you can include other templates in [file templates](#) . This is useful for inserting reusable contents (e.g. standard headers, copyright statements, etc.) into multiple file templates.

The syntax for the `#parse` directive is:

```
#parse("<template_name.extension>")
```

For example: `#parse("File Header.java")` .

The templates that can be referenced like this in other templates, are shown on the Includes tab of the [File and Code Templates](#) settings page.

## Creating a file template from scratch

1. Open [Settings/Preferences dialog](#) and under the Editor node, select [File and Code Templates page](#) .
2. Switch to the Files tab.
3. Click  on the toolbar and specify the template name, file extension, and the body of the template, which can contain:
  1. Plain text.
  2. [#parse](#) directives to work with [includes](#) .
  3. Predefined variables to be expanded into corresponding values in the format `${<variable_name>}` .

The available predefined file template variables are:

- `${PACKAGE_NAME}` - the name of the target package where the new class or interface will be created.
- `${PROJECT_NAME}` - the name of the current project.
- `${FILE_NAME}` - the name of the PHP file that will be created.
- `${NAME}` - the name of the new file which you specify in the New File dialog box during the file creation.
- `${USER}` - the login name of the current user.
- `${DATE}` - the current system date.
- `${YEAR}` - the current year.
- `${MONTH}` - the current month.
- `${DAY}` - the current day of the month.
- `${TIME}` - the current system time.
- `${HOUR}` - the current hour.
- `${MINUTE}` - the current minute.
- `${PRODUCT_NAME}` - the name of the IDE in which the file will be created.
- `${MONTH_NAME_SHORT}` - the first 3 letters of the month name. Example: Jan, Feb, etc.
- `${MONTH_NAME_FULL}` - full name of a month. Example: January, February, etc.

IntelliJ IDEA provides a set of additional variables for [PHP include templates](#) . Include templates are used to define reusable pieces of code (namely, file headers and [PHPDoc comments](#) ) to be inserted in file templates via the [#parse directive](#) .

The following variables are available in [PHP include templates](#) :

- `${NAME}` - the name of the class, field, or function (method) for which the PHPDoc comment will be generated.
- `${NAMESPACE}` - the fully qualified name (without a leading slash) of the class or field namespace.
- `${CLASS_NAME}` - the name of the class where the field to generate the PHPDoc comment for is defined.
- `${STATIC}` - gets the value `static` if the function (method) or field to generate the comment for is `static` . Otherwise evaluates to an `empty string` .
- `${TYPE_HINT}` - a prompt for the `return` value of the function (method) to generate the comment for. If the return type cannot be detected through the static analysis of the function (method), evaluates to `void` .
- `${PARAM_DOC}` - a documentation comment for parameters. Evaluates to a set of lines `@param type name` . If the function to generate comments for does not contain any parameters, the variable evaluates to empty content.
- `${THROWS_DOC}` - a documentation comment for exceptions. Evaluates to a set of lines `@throws type` . If the function to generate comments for does not throw any exceptions, the variable evaluates to empty content.
- `${DS}` - a dollar character ( `$` ). The variable evaluates to a plain dollar character ( `$` ) and is used when you need to escape this symbol so it is not treated as a prefix of a variable.
- `${CARET}` - indicated the position of the caret after generating and adding the comment.  
This `${CARET}` variable is applied only when a PHPDoc comment is generated and inserted during file creation. When a PHPDoc comment is created through Code | Generate | PHPDoc block , multiple selection of functions or methods is available so documentation comments can be created to several classes, functions, methods, or fields. As a result, IntelliJ IDEA cannot "choose" the block to apply the `${CARET}` variable in, therefore in this case the `${CARET}` variable is ignored.
- `${DATE}` - the current system date.
- `${YEAR}` - the current year.
- `${MONTH}` - the current month.
- `${DAY}` - the current day of the month.

4. Custom variables. Their names can be defined right in the template through the `#set` directive or will be defined during the file creation.
4. To have the dollar character ( `$` ) in a variable rendered "as is", use the `${DS}` variable instead. This variable evaluates to a plain dollar character ( `$` ).
5. Apply the changes and close the dialog box.

## Creating a file template from an existing one

1. Open the [File Templates](#) settings page and switch to the Files tab.
2. Click  on the toolbar and change the template name, extension, and source code as required.
3. Apply the changes and close the dialog box.

## Creating a file template from a file

1. Open the desired file in the editor.

2. On the main menu, choose Tools | Save File as Template .
3. In the [File and Code Templates](#) dialog box that opens specify the new template name and edit the source code, if necessary.
4. Apply the changes and close the dialog box.

## Creating and referencing include templates

Include templates are used to define reusable pieces of code to be inserted in file templates through the `#parse` directives.

### To create and reference an include template

1. In the [File and Code Templates](#) settings page, switch to the Includes tab.
2. Click  on the toolbar and specify the template name, extension, and the source code. Do one of the following:
  - Use the [predefined file template variables](#) .
  - Create custom template variables and define their values right in the include template using the `#set` VTL directive.

For example, to insert your full name in the file header instead of your login name defined through the `${USER}` variable, write the following construct:

```
#set( $MyName = "John Smith" )
```

If the values of a certain template variable are not known at the point of applying a template, IntelliJ IDEA will ask you to specify them.

You can prevent treating dollar characters ( `$` ) in template variables as prefixes. If you need a dollar character ( `$` ) inserted as is, use the `#{DS}` file template variable instead. When the template is applied, this variable evaluates to a plain dollar character ( `$` ).

3. To use the include template, switch to the Templates tab, select the desired template and click Edit .
4. To include a template, insert the `#parse` directive in the source code.

## Basics

IntelliJ IDEA editor is a powerful tool for creating and modifying source code. As any other IDE editor, it supports basic features like [bookmarks](#) , [breakpoints](#) , [syntax highlighting](#) , [code completion](#) , [zooming](#) , [folding code blocks](#) , etc. There are, however, plenty of advanced features like [macros](#) , [highlighted TODO items](#) , [code analysis](#) , [intention actions](#) , [intelligent and fast navigation](#) , and a lot more.

To configure your editing environment, use the [Editor](#) settings page and its child pages. There is also a [Quick Switch Scheme](#) command that lets you change color schemes, themes, keymaps, etc. with a couple of keystrokes.

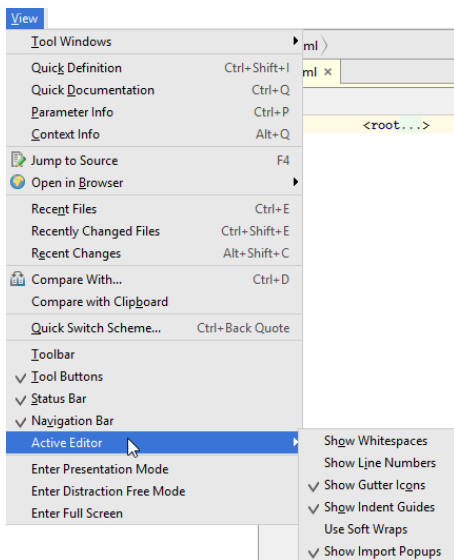

The editor is tab-based. All operations with the editor tabs are available from the context menu of a tab , or from Window | Editor tabs node of the main menu .

## Active editor

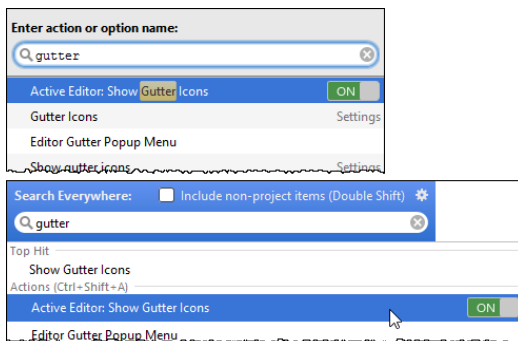

**Tip** You always return the focus to the active editor from any tool window by pressing the [Escape](#) key.

When you [open a file for editing](#) , it opens in its own tab. The editor you are currently working in, is the active editor .

You can change behavior of the active editor using the commands under View | Active Editor node of the main menu:

Alternatively, you can invoke the commands related to the active editor, from [Find Action](#) or [Search Everywhere](#) :

## Editor's areas

### 1. Editor area

Use this area to type and edit your source code. The editor suggests numerous coding assistance facilities. Refer to the sections under this node for details.

### 2. Gutter area

The left gutter provides additional information about your code and displays the various icons that identify the code structure, bookmarks, breakpoints, scope indicators, change markers and the code folding lines that let you hide arbitrary code blocks.

You can change the behavior of the left gutter.

For example, it's possible to make the left gutter thinner by hiding the gutter icons. This is done either for the [active editor](#)

, or for all the [newly created editors](#) .

To change the behavior of the left gutters, use either the [Appearance](#) page of the editor settings, or the Editor Gutter Popup Menu :

By default, this command is not mapped to any keyboard shortcut. You can create your own shortcut as described in the section [Configuring Keyboard Shortcuts](#) .

### 3. Smart completion pop-up

This is one of the key editing assistance features that suggests method names, functions, tags and other keywords you are typing.

### 4. Document tabs

Enable quick navigation across the multiple documents you are working on. Clicking a tab brings its contents to front and makes it available for editing in the active editor.

To navigate between the tabs, use the keyboard shortcuts `Alt+Right` or `Alt+Left` .

Clicking a tab while the `Ctrl` / `⌘` key is pressed, allows navigating to any part of the file path, through opening it in an external browser.

Context menu of a tab provides all commands applicable to a file opened in the editor, for example:

- [Close one or more tabs](#).
- [Pin active tab](#).
- [Split and unsplit tabs](#).
- [Manage groups of tabs](#).
- [Navigate between tabs](#).
- [Add to Favorites](#).
- Move to a changelist.
- [Run](#) , or [debug](#)
- Perform [local history](#) and [version control](#) commands.
- Perform commands of [your own tools](#) .

By default, the tabs appear on top of the editor, but you can change their location as described in the section [Changing Placement of the Editor Tab Headers](#) .

### 5. Validation side bar / marker bar

This is the bar to the right from the editing area, showing the green, red or yellow box on its top depending on whether your code is okay, or contains errors or warnings. This bar also displays active red, yellow, white, green and blue navigation stripes that let you jump exactly to the erroneous code, changed lines, search results, or TODO items.

This section describes how to perform the most common editing tasks:

- [Selecting Text in the Editor](#)
- [Cutting, Copying and Pasting](#)
- [Copy and Paste Between IntelliJ IDEA and Explorer/Finder](#)
- [Commenting and Uncommenting Blocks of Code](#)
- [Undoing and Redoing Changes](#)
- [Opening and Reopening Files in the Editor](#)
- [Closing Files in the Editor](#)
- ['Lens' Mode](#)
- [Multicursor](#)
- [Adding Editors to Favorites](#)
- [Saving and Reverting Changes](#)
- [Zooming in the Editor](#)

In this section:

- [Basics](#)
- [Selecting all text in the active editor tab](#)
- [Selecting with navigation keys](#)
- [Alternative ways to select code](#)
- [Extending selection](#)
- [Shrinking selection](#)
- [Multiselection](#)
- [Toggling between line and column selection modes](#)
- [Sticky selection](#)
- [Tips and tricks](#)

## Basics

The basic way to select a piece of text is to extend the selection with the mouse cursor. IntelliJ IDEA, as a keyboard-centric IDE, suggests to use navigation keys to make selections.

You can opt to select pieces of text, or select rectangular fragments in the column mode, extend and shrink the selection, use multiselection, and sticky selection.

### Selecting all text in the active editor tab

To select the entire text in the current editor tab, do one of the following:

- On the main menu, choose Edit | Select All .
- Press `Ctrl+A` .

### Selecting with navigation keys

To select text from the current caret position to the beginning/end of the current word:

- `Ctrl+Shift+Left` , `Ctrl+Shift+Right` .

To select text from the caret position to the beginning/end of the current line:

- Double-click `Ctrl` and press `Home` / `End`

To select text from the current caret position to the top/bottom of the screen:

- `Ctrl+Shift+Page Up` , `Ctrl+Shift+Page Down` .

### Alternative ways to select code

To make selection of a column of text, do one of the following:

- Keeping the `Alt` key pressed, drag your mouse pointer to select the desired area.
- Keeping the middle mouse button pressed, drag your mouse pointer to select the desired area.
- Press `Shift+Alt` and the middle mouse button. This is specially helpful, if you want to avoid dragging.

### Extending selection

To extend selection from the word at caret to the piece of code the caret is contained in, do one of the following:

- On the main menu, choose Edit | Extend Selection
- Press `Ctrl+W` to select the word where the caret is currently located.
- Press `Ctrl+W` successively to extend selection to the next containing node (for example, an expression, a paired tag, an entire conditional block, a method body, a class, a group of vararg arguments, etc.)

While extending selection, keep in mind that:

- Pressing `Ctrl+W` successively in plain text or comments extends the selection first to the current sentence, then to the current paragraph.
- Pressing `Ctrl+W` successively in a method call that contains vararg arguments, first selects a vararg argument the caret rests at, then the whole group of vararg arguments, and then all arguments in the method call.

### Shrinking selection

To shrink selection in the reverse order (from the outermost container to the word where the caret currently resides), do one of the following:

- On the main menu, choose Edit | Shrink Selection
- Press `Ctrl+Shift+W` .

**Tip** The selection extends or shrinks according to capitalization, if the Use "CamelHumps" words checkbox is selected on the [Smart Keys](#) page of the editor settings.

If you want to make selection according to capitalization, using double-click, make sure that the checkbox Honor CamelHumps words... is selected on the [General](#) page of the editor settings.

### Multiselection

IntelliJ IDEA supports selecting multiple text fragments. So doing, one can select multiple words, lines or rectangles.

## To select multiple words, follow these steps

1. Do one of the following:

- Press `Shift+Alt` and double-click the left mouse button.

```
<procedure title="To select multiple words" alternative-title="Using a
  <step...>
</procedure>
<anchor name="column selection"/>
<procedure title="To toggle between the line and the column selection
<anchor name="altdrag"/>
<procedure title="To make selection in the Column Selection Mode"
```

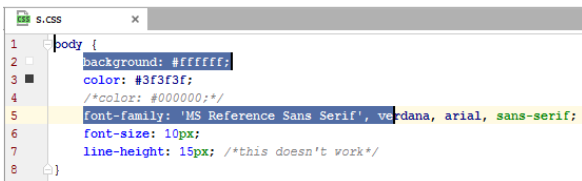

- Press `Alt+J`, or select some text fragment. Then press `Alt+J` again, to find the matching piece of text.

2. After selection is complete, you can start editing all the fragments as if they were one.

## To select multiple fragments of text, follow these steps

1. Press `Shift+Alt`

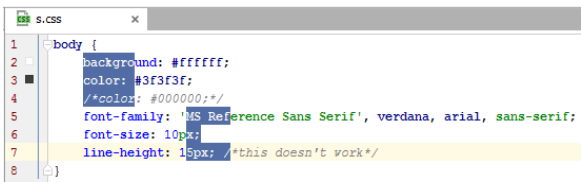

2. Drag the mouse pointer

## To select multiple rectangular fragments of text, follow these steps

1. Press `Ctrl+Shift+Alt` (Windows or UNIX) `Shift+Alt+Cmd` (macOS)

2. Drag the mouse pointer

Refer to the section [Multicursor](#) for additional information.

## Toggling between line and column selection modes

To toggle between the line and the column selection modes, do one of the following:

- On the main menu, choose Edit | Column Selection Mode .
- On the context menu of the editor, choose Column Selection Mode .
- Press `Shift+Alt+Insert` .

## Sticky selection

To toggle sticky selection, press `Ctrl+Shift+A`, in the pop-up frame type sticky, and choose Toggle Sticky Selection from the suggestion list:

**TIP** In the Emacs keymap, use keyboard shortcut `N/A` .

## Tips and tricks

- When sticky selection is on, you can turn it off by invoking copy or cut, or by toggling it again.
- To create a large rectangular selection, create a normal selection first, with the given starting and ending points, and then press `Shift+Alt+Insert` to toggle to the column selection mode.

On this page:

- [Basics](#)
- [Copying a selected fragment of text](#)
- [Copying the path to a file](#)
- [Copying the reference to a line or a symbol](#)
- [Cutting a selected fragment of text](#)
- [Pasting the last entry from the clipboard](#)
- [Pasting the last entry from the clipboard as plain text](#)
- [Pasting the last entry from the clipboard](#)
- [Pasting a specific entry from the clipboard](#)

## Basics

IntelliJ IDEA provides a number of handy Clipboard operations. You can copy, cut, and paste selected text, a path to a file, or a reference to a symbol or a line of code.

Because IntelliJ IDEA uses the system Clipboard, you can copy and paste between applications. So doing, when pasting Clipboard entries, IntelliJ IDEA removes any formatting from the text and any special symbols from the `String` values.

The Paste command smartly understands what is being inserted. If you paste a reference to a symbol, it is analyzed for possible imports, references, etc. So doing, IntelliJ IDEA provides the necessary brackets and places the caret at the appropriate insertion point. The Paste Simple command helps paste any Clipboard entry as a plain text, without any analysis.

IntelliJ IDEA enables Clipboard stacking, which means that you can store multiple Clipboard entries and access them with a single shortcut. The number of entries that can be kept in the Clipboard stack is customizable on the [Editor](#) page of the Settings/Preferences dialog.

## Copying a selected fragment of text

Do one of the following:

- On the main menu, choose Edit | Copy .
- Press `Ctrl+C` .
- Click the Copy button  on the toolbar.

Note that the `Ctrl+D` keyboard shortcut clones a line at the caret or a selected arbitrary fragment of text.

## Copying the path to a file

When you copy the path to a file, the absolute path to a file is copied to the clipboard.

To copy the path to a file, do one of the following:

- Open the desired file in the editor, then choose Edit | Copy Path on the main menu or press `Ctrl+Shift+C` .
- Select the desired file in the [Project](#) tool window and choose Copy Path on the context menu of the selection.

## Copying the reference to a line or a symbol

1. Open the desired file in the editor.
2. Place the caret at a certain line of code.
3. Do one of the following:
  - On the main menu, choose Edit | Copy Reference .
  - On the context menu of the line at caret, choose Copy Reference .
  - Press `Ctrl+Shift+Alt+C` .

IntelliJ IDEA creates a string in the format that depends on a symbol at caret. For example:

```
/MetersToInchesConverter.java:14 for a Java class (format <fully qualified path>:<line number> )
```

```
java.io.PrintStream#println(java.lang.String) for a Java method (format <full class name>.  
<method_signature> )
```

## Cutting a selected fragment of text

1. [Select](#) the desired fragment in the editor.
2. Do one of the following:
  - On the main menu, choose Edit | Cut .
  - Press `Ctrl+X` .
  - Click the Cut button  on the toolbar.

## Pasting the last entry from the clipboard

1. Place the caret in the location where you want to paste content.
2. Do one of the following:
  - On the main menu, choose Edit | Paste .

– Press `Ctrl+V` .

– Click the Paste button  on the toolbar.

If you perform paste in a Java file, the further behavior depends on the settings in the [Auto Import](#) page of the Editor options. If the Ask option has been selected, select the necessary imports from the list of missing imports. In all other cases, the last clipboard entry is pasted silently.

## Pasting the last entry from the clipboard as plain text

Do one of the following:

– On the main menu, choose Edit | Paste Simple .

– Press `Ctrl+Shift+Alt+V` .

## Pasting the last entry from the clipboard

Depending on the chosen [paste mode](#) , do one of the following:

– To apply the **Paste Simple** mode, place the caret in the location where you want to paste the content and choose Edit | Paste Simple on the main menu or press `Ctrl+Shift+Alt+V` .

– To apply the **Paste** mode, place the caret in the location where you want to paste the content and choose Edit | Paste on the main menu, or press `Ctrl+V` , or click the Paste button  on the toolbar.

## Pasting a specific entry from the clipboard

1. On the main menu, choose Edit | Paste from History or press `Ctrl+Shift+V` .

2. In the Choose Content to Paste dialog box select the desired entry from the list of recent Clipboard entries.

3. Click Paste to paste the content using the **Paste mode** or hover your mouse over this button to display the available [paste mode](#) options. Depending on the chosen paste mode, do one of the following:

– Paste : select this option to apply the **Paste** mode.

– Paste Simple : select this option to apply the **Paste Simple** mode.

The depth of the Clipboard stack is configured in the Limits section on the [Editor](#) page of the [Settings/Preferences](#) dialog box. When the specified number is exceeded, the oldest entry is removed from the list.

IntelliJ IDEA enables tight interaction with the native file managers (Explorer on Windows, or Finder on Mac), and allows you to exchange files and directories via the system clipboard, using numerous techniques:

- Cut, copy and paste files and directories from the Project tool window of IntelliJ IDEA to a directory in the file manager, and vice versa, using menu commands and keyboard shortcuts:

Keyboard shortcut	Function	Use this shortcut to...
Ctrl+C	Copy	Copy selected text to the Clipboard.
Ctrl+X	Cut	Cut to the Clipboard.
Ctrl+V	Paste	Paste from the Clipboard.

- Move (drag) or copy (Ctrl+drag) a file or directory from the file manager to a directory in the Project tool window.
- Move (drag) or copy (Ctrl+drag) a file from the Project tool window to a directory in the file manager.
- Open any file for editing, by dragging it from a file manager to the editor.

## Basics

You can comment or uncomment the current line or selected block of source code.

Commenting feature extends to all supported file types. For the custom file types, you can define line and block comments characters, as described in the section [Creating and Registering File Types](#).

## Configuring commenting behavior

It is possible to force IntelliJ IDEA to place Java comments strictly at the left margin. To do that, in the Settings dialog, open [Code Style | Java](#), and click [Code Generation tab](#).

In the section Comment Code select the required checkboxes:

If the checkboxes are cleared, the comments characters are placed at the current caret position.

## Commenting and uncommenting lines of code

Do one of the following:

- On the main menu, choose [Code | Comment with Line Comment](#).

- Press [Ctrl+Slash](#).

```
// {  
//     user = em.merge(user);  
//     facesMessages.add("Password updated");  
//     changed = true;  
// }
```

## Commenting and uncommenting blocks of code

To add or remove a block comment, do one of the following:

- On the main menu, choose [Code | Comment with Block Comment](#).

- Press [Ctrl+Shift+Slash](#).

```
/* {  
    user = em.merge(user);  
    facesMessages.add("Password updated");  
    changed = true;  
}*/
```

On this page:

- [Basics](#)
- [How it works?](#)
- [Undoing and redoing changes](#)

## Basics

The Undo command discards the last changes to the file in the editor. The Redo command discards the results of the last Undo command.

You can undo or redo your changes as many times as required. However, when you exit IntelliJ IDEA, the undo history is lost.

IntelliJ IDEA smartly defines the logical steps that can be undone and redone. The following events signal about the end of a logical step:

- Pressing `Enter` .
- Repositioning the mouse cursor.
- Using navigation keyboard shortcuts.
- Cutting or pasting.
- Pressing `Tab` .

IntelliJ IDEA expands the undo and redo mechanism to complex operations, such as reformatting or refactoring source code, creating or deleting files. When you undo or redo a complex operation, IntelliJ IDEA requests for your confirmation.

## How it works?

IntelliJ IDEA moves the caret before each step of undo/redo, and then performs the **Undo/Redo** actions.

## Undoing and redoing changes

### To undo an action, do one of the following

- On the main menu, choose Edit | Undo .
- Press `Ctrl+Z` .

### To redo an action, do one of the following

- On the main menu, choose Edit | Redo .
- Press `Ctrl+Shift+Z` .

On this page:

- [Opening files for editing](#)
- [Opening external files](#)
- [Reopening files](#)
- [Opening files in a separate window](#)

## Opening files for editing

### To open a file for editing

1. Do one of the following:

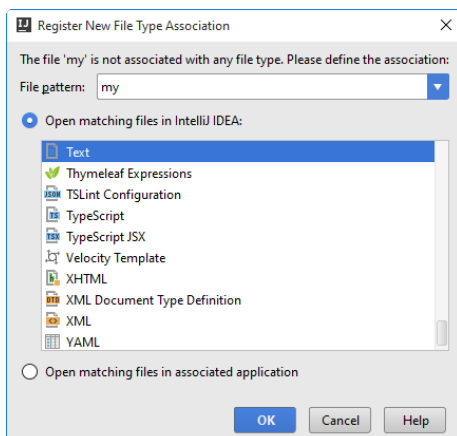

- Double-click the desired file in one of the [Tool Windows](#).
- Select the desired file in one of the [Tool Windows](#) and press `F4`.
- Select the desired file in one of the [Tool Windows](#) and choose Jump to Source on the context menu.
- Use the [Navigate](#) command for a Class, File, or Symbol.
- Click the desired directory in the [Navigation bar](#), and select file from the drop-down list:

2. If the file type is registered, the file opens silently in IntelliJ IDEA's editor.

If the file type is registered under the category Files opened in associated applications, it will be opened in its associated application, rather than in the IntelliJ IDEA editor. By default, IntelliJ IDEA suggests a number of such file types, for example `.doc`, `.chm`, or `.pdf`.

If the file type is unknown, IntelliJ IDEA suggests to choose whether you want to register a new file type, or open such file in its associated application. Specify your choice in the [Register New File Type Association](#) dialog box:

You can register the required file types on the [File Types](#) page of the Settings/Preferences dialog.

The maximum size of files parsed by IntelliJ IDEA is controlled by the `idea.max.intellisense.filesize` setting in `idea.properties` file.

The `idea.properties` file located in the `bin` directory of the IntelliJ IDEA installation folder should not be edited. Instead of editing the original `idea.properties` file, create an `idea.properties` file in the following location, open it for editing and add the required properties:

- For **Windows**: `%USERPROFILE%\IntelliJ\config` or `%USERPROFILE%\IdeaIC\config`
- For **\*NIX**: `~/IntelliJ\config` or `~/IdeaIC\config`
- For **macOS**: `~/Library/Preferences/IntelliJ\config` or `~/Library/Preferences/IdeaIC\config`

Note that the larger the file is, the slower its editor works and the higher overall system memory requirements are.

## Opening external files

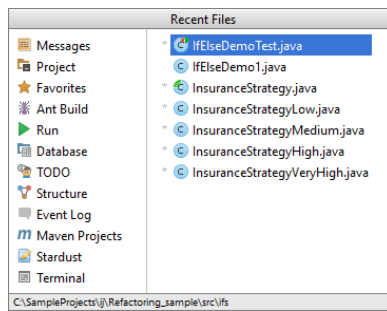

Do one of the following:

- Choose File | Open on the main menu and select the desired file in the dialog box that opens.
- **Drag** the required file from the Explorer (Windows), File Browser (Linux), or Finder and **drop** it to the editor. The file opens for editing in a new tab.

## Reopening files

### To reopen a file

- To open a recently opened file, choose View | Recent Files on the main menu or press `Ctrl+E`. Then select the desired file from the Recent Files pop-up window, that opens.

- To open a recently updated file, on the main menu, choose View | Recently Changed Files or press `Ctrl+Shift+E`. Then select the desired file from the Recently Edited Files pop-up window, that opens.

**Tip** Use Recent files limit text box in the [Editor](#) settings page to define the maximum number of recent files.

## Opening files in a separate window

### To open a file in a separate IntelliJ IDEA window

Do one of the following:

- Drag and drop an editor tab outside of the current IntelliJ IDEA window.
- Press `Shift+F4` for a file selected in the Project tool window.
- `Shift+mouse double click` on a file name in the Project tool window.

IntelliJ IDEA suggests several ways to close editor tabs.

## To close a file in the editor, do one of the following

- On the main menu point to Window | Editor Tabs , choose one of the appropriate closing commands.

Close

Closes the file in the active tab.

Close All

Closes all editor tabs.

Close Others

Closes all tabs except the current one. The alternative way to close all other tabs lays with clicking the **x** button, while holding the **Alt** key pressed:

Close Unmodified

Closes all files that were not changed. This command is only available, when version control integration is enabled in project.

Close All But Pinned

Closes all files that were not pinned. This command appears, if there are pinned editor tabs.

- Right-click any editor tab, and choose same commands on the context menu.

- Point with your mouse cursor to a tab and click the middle mouse button.

- Point with your mouse cursor to a tab and click **x** .

- Press **Ctrl+F4** .

**Tip** When you close modified files, IntelliJ IDEA preserves all changes in the current editing session. After reopening such files, the results of editing are restored.

Hover the mouse pointer over a warning, error stripe or just some section on the scroll bar outside of the scroll box. IntelliJ IDEA shows the source code fragment annotated with the warning/error messages.

This helps viewing the context a marker applies to, and the source code outside of the editor visible area.

Must-read This topic describes the usage of lens.

This behavior is enabled by default.

## To toggle the lens mode

1. Do one of the following:
  - Open the [Appearance](#) page of the Settings dialog.
  - Right-click the code analysis marker on top of the current editor.
2. Select or clear the checkbox Show code lens on scrollbar hover .

On this page:

- [Basics](#)
- [Adding, deleting, and cloning carets](#)
- [Copying and pasting](#)

## Basics

IntelliJ IDEA supports multiple carets. The majority of the editor actions, such as keyboard navigation, text insertion and deletion, etc., apply to each caret. Live templates and autocompletion are supported as well.

It is possible to add or delete carets; at least one caret always exists in an editor tab.

The most recently added caret is considered primary. Highlighting of an editor line at caret applies to the primary caret only.

Placement and behavior of the carets depend on:

- Enabled or disabled [column selection mode](#).
- Enabled or disabled [placement of caret after the end of line](#).

Refer to the section [Selecting Text in the Editor](#) for additional information.

## Adding, deleting, and cloning carets

### To add carets, do one of the following

- Press `Shift+Alt` and click the left mouse button at the location of the caret.
- Press `Ctrl` (Windows or UNIX)/`Alt` (macOS) twice, and then without releasing it, press up or down arrow keys.

The new carets are added to the specified locations, according to setting of the Allow placement of caret after end of line checkbox:

### To delete carets, do one of the following

- Press `Esc` to delete all the existing carets, except the primary one.
- Press `Shift+Alt` and click the left mouse button on a caret to be deleted.

### To clone an existing caret upward or downward, do one of the following:

- Press `Ctrl+Shift+A`, type `Clone caret`, and choose the desired action from the suggestion list:

Note that by default these actions are not bound to the keyboard shortcuts. You can do it yourself, as described in the section [Configuring keyboard shortcuts](#).

The primary caret is propagated upwards or downwards:

## Copying and pasting

When a text with multiple cursors is copied (`Ctrl+C`) or cut (`Ctrl+X`), selections for each caret are placed to the clipboard. On paste (`Ctrl+V`), text from the clipboard is split into lines.

You can group most needed items into Favorite lists and get quick access to them through the [Favorites](#) tool window.

## To add one or more items to Favorites

1. Do one of the following:
  - Open the desired files in the Editor.
  - Select one or more items in the [Project](#) tool window.
2. Right-click the editor tab or the selection in the Project tool window, and choose Add to Favorites on the context menu.

3. On the submenu, specify the Favorites list to add the selected items to. Do one of the following:
  - To add the items to an existing list, select the desired list in the submenu.
  - To create a new list, choose Add to New Favorites List . In the Add New Favorites List dialog box that opens enter the desired group name or accept default settings.

- [Introduction](#)
- [When does IntelliJ IDEA auto save changed files?](#)
- [Tuning the autosave behavior](#)
- [Using the Save All command](#)
- [Marking files with unsaved changes in the editor](#)
- [Saving a file under a different name](#)
- [Reverting changes](#)

## Introduction

When working with IntelliJ IDEA, you don't need to worry about saving changed files: all changes are auto saved.

Unwanted changes can be undone at any stage of your development workflow. Any file or directory can be reverted to any of the previous states.

## When does IntelliJ IDEA auto save changed files?

Autosave is initiated by:

- Compiling a project, a module or a class
- Starting a run/debug configuration
- Performing a version control operation such as pull, commit, push, etc.
- Closing a file in the editor
- Closing a project
- Quitting the IDE

In fact, there is a lot more autosave triggers, and only the most important ones are mentioned above.

## Tuning the autosave behavior

The following options are available for tuning the autosave behavior ( File | Settings | Appearance and Behavior | System Settings / ( IntelliJ IDEA | Preferences | Appearance and Behavior | System Settings ):

- Save files on frame deactivation (i.e. on switching from IntelliJ IDEA to a different application).
- Save files automatically if application is idle for N seconds.

Note that those are optional autosave triggers, and you cannot turn off autosave completely.

## Using the Save All command

If necessary, you can initiate saving all changed files yourself. There is the Save All command for that:

- File | Save All

- 

## Marking files with unsaved changes in the editor

Changed but yet unsaved files can be marked. For this purpose, there is the Mark modified tabs with asterisk option ( File | Settings | Editor | General | Editor Tabs / IntelliJ IDEA | Preferences | Editor | General | Editor Tabs ).

When this option is on, the files with unsaved changes have an asterisk  on their editor tabs.

 Saving\_and\_Reverting\_Changes.xml ×

## Saving a file under a different name

There is no File | Save As command in IntelliJ IDEA. To save a file under a different name or in a different directory, use Refactor | Copy or .

## Reverting changes

You can undo changes by using Edit | Undo or . To revert files to their previous states, use [Local History](#) and corresponding [version control functionality](#).

IntelliJ IDEA makes it possible to change font size (zoom) in the active editor, and reset font size to the default value. These operations apply to the active editor only. In the other editor tabs, font size is not affected.

### To enable changing font size in the editor

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Editor | General .
2. Make sure that the setting Change font size (Zoom) with Ctrl+MouseWheel is enabled.

### To change font size using the mouse wheel

1. Place the caret in the editor.
2. While keeping the `Ctrl` / `⌘` key pressed, rotate the mouse wheel. As you rotate the mouse wheel forward, font size grows larger; as you rotate the mouse wheel backwards, font size decreases.  
The macOS users can use the trackpad "Pinch-to-Zoom" gesture to change the size of the font and the whole editing area.

### To change the font size using the keyboard

1. Press `Ctrl+Shift+A` .
2. In the popup frame, start typing Increase font size or Decrease font size , and press `Enter` as soon as the corresponding command gets the focus.
3. The font will grow larger or smaller.

### To reset the font size

1. Press `Ctrl+Shift+A` .
2. In the popup frame, start typing Reset font size and press `Enter` as soon as the corresponding command gets the focus.
3. The default font size will be restored.

**Tip** There are no default keyboard shortcuts associated with the actions Increase font size , Decrease font size , and Reset font size actions. However, you can [assign your own shortcuts to these actions](#) .

This part describes more sophisticated editing techniques provided by IntelliJ IDEA:

- [Reformatting Source Code](#)
- [Changing Indentation](#)
- [Folding Code Elements](#)
- [Viewing Current Caret Location](#)
- [Toggling Writable Status](#)
- [Toggling Case](#)
- [Highlighting Braces](#)
- [Spellchecking](#)
- [Scratches](#)
- [Adding, Deleting and Moving Code Elements](#)
- [Joining Lines and Literals](#)
- [Splitting Lines With String Literals](#)
- [Splitting String Literals on Newline Symbols](#)
- [Editing CSV and Other Delimiter-Separated Files as Tables](#)
- [Using Drag-and-Drop in the Editor](#)
- [Using Macros in the Editor](#)

On this page:

- [Basics](#)
- [Reformatting the code of a module or directory](#)
- [Reformatting the code of the current file](#)
- [Skipping a region when reformatting source code](#)
- [Example of using formatting markers](#)

## Basics

IntelliJ IDEA lets you reformat source code to meet the requirements of your code style. IntelliJ IDEA will lay out spacing, indents, keywords etc. Reformatting can apply to the selected text, entire file, or entire project.

It is also possible to apply reformatting to the parts of the source code only, using the [formatting markers](#).

## Reformatting the code of a module or directory

To reformat code for a module or directory, follow these steps:

1. In the Project tool window, select the module or directory you want to apply your reformatting to.
2. Choose Code | Reformat Code on the main menu or press `Ctrl+Alt+L`.  
Alternatively, in the [Project Tool Window](#), right-click the directory and from the context menu, select Reformat Code.
3. In the Reformat Code dialog box, specify the necessary options and filters for your reformatting and click Run.

## Reformatting the code of the current file

To reformat code for the current file, follow these steps:

1. In the editor of the currently opened file, press `Ctrl+Shift+Alt+L`.  
Note that if you select Code | Reformat Code from the main menu or press `Ctrl+Alt+L`, IntelliJ IDEA will try to reformat the source code automatically without opening the [Reformat File](#) dialog.
2. In the [Reformat File](#) dialog, specify options for the reformatting and click Run.

## Skipping a region when reformatting source code

To enable formatter markers, make sure to select the checkbox Enable formatter markers in comments in the [Code Style](#) page of the Settings/Preferences dialog, and type the markers in the Formatter off/on fields.

To skip a certain region on reformatting, follow these steps:

1. At the beginning of the region, create a line comment (`Ctrl+Slash`), and then manually type the marker specified in the Formatter off field of [Code Style](#) page.
2. At the end of the region, create a line comment (`Ctrl+Slash`), and then manually type the marker specified in the Formatter on field of [Code Style](#) page.
3. Perform code reformatting, as described above.

Alternatively, create a [live template](#) to surround a block of code with formatter off/on markers, see [Creating and Editing Live Templates](#).

## Example of using formatting markers

The original source code

The code after reformatting

```
/**@formatter:off
 * "scripts": {
 *   "post-install-cmd": [
 *     "php artisan optimize"
 *   ],
 *   "post-update-cmd": [
 *     "php artisan clear-compiled",
 *     "php artisan optimize"
 *   ],
 *   "post-create-project-cmd": [
 *     "php artisan key:generate"
 *   ]
 * },
 */
/**@formatter:on
```

When the formatting markers are disabled, the original formatting is broken:

```
/**@formatter:off
 * "scripts": {
 *   "post-install-cmd": [
 *     "php artisan optimize"
 *   ],
 *   "post-update-cmd": [
 *     "php artisan clear-compiled",
 *     "php artisan optimize"
 *   ],
 *   "post-create-project-cmd": [
 *     "php artisan key:generate"
 *   ]
 * },
 */
/**@formatter:on
```

When the formatting markers are enabled, the original formatting is preserved:

```
/**@formatter:off
 * "scripts": {
 *   "post-install-cmd": [
 *     "php artisan optimize"
 *   ],
 *   "post-update-cmd": [
 *     "php artisan clear-compiled",
 *     "php artisan optimize"
 *   ],
 *   "post-create-project-cmd": [
 *     "php artisan key:generate"
 *   ]
 * },
 */
/**@formatter:on
```

IntelliJ IDEA makes it possible to:

- [Indent or unindent](#) text. This action applies to a selection, or to a line at caret.
- [Fix wrong indentation](#) according to the code style.
- Choose [tabs or spaces](#) for indentation. This action applies to a selection, or the whole current file in the active editor.

### **To change indentation of a text fragment, do one of the following**

- On the main menu, choose Edit | Indent Selection / Edit | Unindent Selection .
- Press `Tab` / `Shift+Tab` .

### **To fix indentation**

Sometimes it is necessary to change indentation of a line at caret.

1. Place the caret at a line with wrong indentation.

2. Press `Ctrl+Alt+I` .

### **To toggle between tabs and spaces**

- On the main menu, choose Edit | Convert Indents , and then choose To Spaces or To Tabs respectively.

## Basics

You can collapse (fold) code fragments reducing them to a single visible line. In this way, you can hide the details that, at the moment, seem unimportant. If and when necessary, the folded code fragments can be expanded (unfolded).

Folded code fragments, normally, are shown as shaded ellipses (...).

## Code folding means

You can collapse and expand code fragments by using:

- Code folding toggles (⌵, ⌴ or ⌶). These toggles are shown in the editor to the left of the corresponding folding regions. If a region is unfolded, ⌵ indicates the beginning of the region while ⌴ is located at its end. For folded regions, the toggle is shown as ⌶.
- If you hold the **Alt** key and click ⌵, ⌴ or ⌶, the region is collapsed or expanded recursively, i.e. along with all its subordinate regions.
- Commands of the Folding menu and associated keyboard shortcuts. The Folding menu can be accessed from the main menu bar (Code | Folding), or as a context menu in the editor. The shortcuts are shown right in the menu. See [Commands of the Folding menu and associated shortcuts](#).
- Folded fragments themselves: click ... to expand the corresponding fragment. See also, [Viewing folded code fragments](#).

## Folding predefined and custom regions

You can fold and unfold:

- Code blocks, i.e. code fragments surrounded by a matched pair of curly braces `{ }`.  
To collapse a code block, place the cursor within that block and then select Code | Folding | Fold Code Block or press **Ctrl+Shift+Period**.
- As a result, a custom folding region is formed, and the folding toggles for it appear. After that, the region can be collapsed and expanded as any other folding region.  
To remove a custom folding region, use the Fold Selection / Remove Region command for that region (**Ctrl+Period**).
- Predefined regions that correspond to such elements as import declarations, method bodies, anonymous and inner classes, documentation comments, etc. The predefined regions, roughly, correspond to the ones listed under Collapse by default on the Editor | General | Code Folding page in the Settings/Preferences dialog.  
For the predefined regions, the folding toggles are available right away, without the need to perform any additional actions.
- Any selected code fragment. A custom folding region for a selection is created and removed by means of the Fold Selection / Remove Region command (**Ctrl+Period**).
- Regions surrounded by corresponding commented folding markers (e.g. `//<editor-fold desc="Description">...//</editor-fold`). See [Using code folding comments](#).

**Note** Code folding works for the keywords `if` / `while` / `else` / `for` / `try` / `except` / `finally` / `with` in case of at least two statements.

## Commands of the Folding menu and associated shortcuts

The Folding menu can be accessed from the main menu bar (Code | Folding), or as a context menu in the editor.

### CommandShortcutDescription

Command	Shortcut	Description
Expand	<b>Ctrl+NumPad Plus</b>	Expand the current collapsed fragment
Collapse	<b>Ctrl+NumPad -</b>	Collapse the current folding region
Expand Recursively	<b>Ctrl+Alt+NumPad Plus</b>	Expand the current folded fragment and all the subordinate collapsed folding regions within that fragment
Collapse Recursively	<b>Ctrl+Alt+NumPad -</b>	Collapse the current folding region and all the subordinate folding regions within it
Expand All	<b>Ctrl+Shift+NumPad Plus</b>	Expand all collapsed fragments within the selection, or, if nothing is selected, expand all the collapsed fragments in the current file
Collapse All	<b>Ctrl+Shift+NumPad -</b>	Collapse all folding regions within the selection, or, if nothing is selected, collapse all the folding regions in the current file
Expand to level   1, 2, 3, 4 or 5	<b>Ctrl+NumPad *, 1</b> <b>Ctrl+NumPad *, 2</b> <b>Ctrl+NumPad *, 3</b>	Expand the current fragment and all the nested fragments up to the specified level

Ctrl+NumPad \*, 4

Expand all to level | 1, 2, 3, 4 or 5

Ctrl+NumPad \*, 5

Ctrl+Shift+NumPad \*, 1 Expand all the collapsed fragments in the file up to the specified nesting level

Ctrl+Shift+NumPad \*, 2

Ctrl+Shift+NumPad \*, 3

Ctrl+Shift+NumPad \*, 4

Ctrl+Shift+NumPad \*, 5

Expand doc comments	Expand all documentation comments in the current file
Collapse doc comments	Collapse all documentation comments in the current file
Fold Selection / Remove region	Ctrl+Period Collapse the selected fragment and create a custom folding region for it to make it "foldable" / Expand the current fragment and remove the corresponding custom folding region to make the fragment "unfoldable"
Fold Code Block	Ctrl+Shift+Period Collapse the code fragment between the matched pair of curly braces {} and create a custom folding region for that fragment to make it "foldable"

## Specifying code folding preferences

You can specify:

- Whether the code folding toggles should be shown.
- Which folding regions should be collapsed by default.

The corresponding settings are in the Settings dialog ( Ctrl+Alt+S ) on the Editor | General | Code Folding page.

For more information, see [Code Folding page](#) .

## Viewing folded code fragments

To see the contents of a folded fragment, point to the ellipsis ... that indicates that fragment.

## Viewing the beginning of a folding region

To see the beginning of a folding region - if it's not currently visible - point to the folding toggle at the end of that region.

## Using code folding comments

- [Supported folding comments](#)
- [Surrounding a fragment with folding comments](#)
- [Navigating to folding regions](#)

## Supported folding comments

You can create custom folding regions by surrounding code fragments with the commented lines. So doing, the comments can be either NetBeans style, or Visual Studio style.

### NetBeans style

```
//<editor-fold desc="Description">  
...  
//</editor-fold>
```

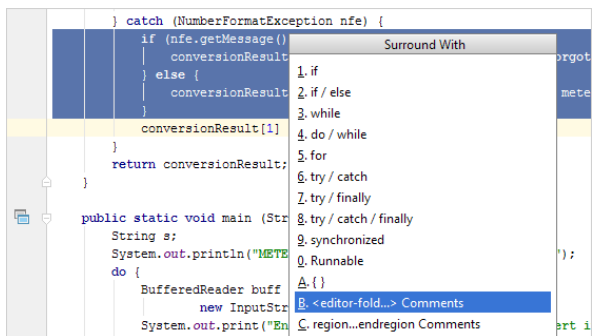

### Visual Studio style

```
//region Description  
...  
//endregion
```

Once you have chosen the style for a file, don't use the other style in that file.

## Surrounding a fragment with folding comments

1. Select the code fragment of interest.
2. Select Code | Surround With or press `Ctrl+Alt+T`.
3. Select the folding comments to be used.

4. Specify the fragment description.

Now if you collapse the fragment, the description you have specified is shown in place of the code.

## Navigating to folding regions

You can navigate to custom folding regions that were formed by surrounding code fragments with the corresponding commented folding markers:

1. Select Navigate | Custom Folding or press `Ctrl+Alt+Period`.
2. Select the target folding region. (The regions in the list are identified by their descriptions.)

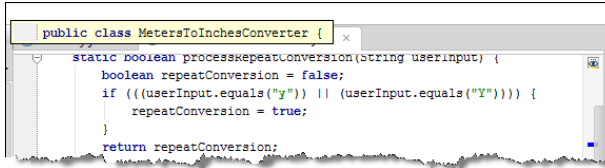

If in course of editing, searching, or navigating through a file, the cursor position runs out of the visible editor area, above the upper editor edge, you don't need to scroll through the file to obtain instant information about the current caret location.

### To view the current caret position, do one of the following

- On the main menu, choose View | Context Info
- Press `Alt+Q`.

The pop-up frame appears on top of the editor, showing the name of the class or method where the caret currently resides:

The screenshot shows a code editor window with a pop-up window overlaid on top. The pop-up window displays the name of the class or method where the caret currently resides. The code in the editor is as follows:

```
public class MetersToInchesConverter {  
    static boolean processRepeatConversion(String userInput) {  
        boolean repeatConversion = false;  
        if (((userInput.equals("y")) || (userInput.equals("Y")))) {  
            repeatConversion = true;  
        }  
        return repeatConversion;  
    }  
}
```

If a file is read-only, it is marked with the closed lock icon  in the [Status bar](#) , in its editor tab, or in the Project tool window. If a file is writable, then it is marked with the open lock icon  in the Status bar. This section describes how to change read-only attribute of a file.

**Tip** If a read-only status is set by a version control system, it's suggested that you use IntelliJ IDEA version control integration features. For more information, see [Version control with IntelliJ IDEA](#).

## To toggle read-only attribute of a file

1. Open file in the editor, or select it in the [Project Tool Window](#) .
2. Do one of the following:
  - On the main menu, choose File | Make File Read-Only , or File | Make File Writable .
  - Click the lock icon in the [Status bar](#) .

On this page:

- [Toggling between upper and lower cases](#)
- [Tips and tricks](#)

## Toggling between upper and lower cases

### To toggle between upper case and lower case

1. Select text fragment, or just place the caret at the line you want to change case in.
2. On the main menu, choose Edit | Toggle Case , or press `Ctrl+Shift+U` .

### Tips and tricks

Did you know that

- Applying Toggle Case to CamelCase name format converts the name format to lower case?
- The lowercase names are converted to the uppercase format?
- Applying Toggle Case to the uppercase name format converts the name format to lower case?

This editor feature significantly improves readability of the code, and simplifies search for unclosed blocks or tags.

## To highlight block borders

- Place the caret immediately after the block closing brace/bracket or before block opening brace/bracket.

If the editor can find the block border, its braces, brackets or tags are highlighted with blue and a blue outline appears in the gutter area.

If the opening brace, bracket or tag is currently out of sight, you don't need to scroll to the beginning of the block. The editor shows a pop-up window on top that displays the beginning of the block.

```
22 static Connection getConnection(int aInt1, HashMap mPool, String name){
23     aInt1 = 2;
24     return (Connection) mPool.get(name);
25 }
```

If the editor cannot find the pair brace, bracket or tag, the unmatched one is highlighted with pink when the caret is placed next to it, and is underlined with a red curly line.

```
43 }
44
45 }
```

On this page:

- [Basics](#)
- [Checking the spelling of a word](#)
- [Configuring the dictionaries to use](#)
- [Configuring spellchecking options](#)
- [Changing the language](#)

## Basics

IntelliJ IDEA helps you make sure that all your source code, including textual strings, comments, and literals, and commit messages, is spelt correctly. For this purpose, IntelliJ IDEA suggests a dedicated **Typo** inspection, which is supported by the corresponding bundled plugin and is enabled by default.

Correctness of spelling is checked against pre-defined dictionaries (as of now, `jetbrains.dic` and `english.dic`), and any number of user-defined custom dictionaries.

A **user dictionary** is a textual file with the `dic` extension, containing the words you want to be accepted by the **Typo** inspection as correct. The words in such dictionaries are delimited with the newline.

Besides that, you can define your own list of words that will be skipped by the inspection. You can add words to this list "on-the-fly", or intentionally while setting up your spellchecker options.

With the **Typo** inspection enabled, IntelliJ IDEA detects and highlights words not included in dictionaries and user's words list. It up to the user to provide correct spelling, accept word as is, or disable inspection.

If a word is accepted, it will be added to the user's words list, and skipped by the spellchecker in future. If inspection is disabled, all typos will be ignored.

In the textual strings and comments, spelling of a word at caret can be changed to a correct one. In the contexts that enable **Rename** refactoring, the inspection suggests to rename all occurrences of a symbol.

## Checking the spelling of a word

1. Place the caret on a word highlighted by the **Typo** inspection.
2. Press `Alt+Enter` to show the available intention actions.
3. Choose one of the following actions:
  - Change to : select the desired spelling of a textual string or comment from the suggestion list.
  - Save to dictionary : add word to the user's list and skip it in future.

## Configuring the dictionaries to use

1. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Spelling under Editor .
2. Define the set of dictionaries to be used for spellchecking.
  1. Switch to the Dictionaries tab.
  2. The Dictionaries area in the bottom of the page shows a list of the dictionaries that can be used in spellchecking. The list contains the dictionaries that come bundled with IntelliJ IDEA by default and user-defined dictionaries detected in the folders from the Custom Dictionaries Folder area above.
    - To have a default dictionary applied in the current project, select the check box next to it.
    - To exclude a default dictionary from spellchecking within the scope of the current project, clear the check box next to it.
  3. In the Custom Dictionaries Folder area, configure your custom dictionaries to use. This area displays a list of directories that contain user-defined dictionary files (text files with the `dic` extension, containing words separated with a newline).
    - To add a new folder to the list, click `+` and choose the required folder in the **Select Path Dialog** dialog that opens . The full path to the folder is added to the Custom Dictionaries Folder list, and all the `*.dic` files found in this folder are added to the Dictionaries list.
    - To remove a folder from the list, select it and click `-` .
3. Besides configuring a custom dictionary, you can create your own **Word List** with the words that you want to be skipped during spell checking without being included in a custom dictionary.
  1. Switch to the Accepted Words tab.
  2. Create a **Word List** :
    - Click the `+` icon to open the Add New Word dialog box and specify a new entry there. **CamelCase** or **snake\_case** are not supported. If you try to add a word that is already included in one of the spelling dictionaries, IntelliJ IDEA displays an error message **The word <just typed word> is already in the dictionary** .
    - To remove an item from the list, select it and click `-` .

## Configuring spellchecking options

1. Open the **Settings / Preferences Dialog** by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Inspections under Editor .
2. On the **Inspections** page, that opens showing a list of inspection types, expand the Spelling node and click Typo in the

central pane.

3. In the right-hand pane, configure the **Typo** inspection:

- In the Options area, define the type of contents to be inspected by selecting or clearing the Process Code , Process Literals , and Process Comments checkboxes.
- In the Severity area, choose the [inspection severity level](#) and the **scope** to apply this level in.

## Changing the language

The spellchecking feature doesn't allow you to change the language per se, but allows you to add your own dictionaries to a directory. This is how it's done.

### **To add a dictionary, follow these steps:**

1. Create a directory in your file system, and in it a text file with the `.dic` extension.
2. Under the node Editor of the Settings/Preferences dialog, click [Spelling](#) .
3. In the Dictionaries tab, click [+](#) in the section Custom Dictionaries Folder .
4. In the [Select Path](#) dialog that opens, point to the directory you've created.

Thus IntelliJ IDEA will not report a typo for a word in the language you've created a dictionary for.

On this page:

- [Basics](#)
- [Creating scratch files](#)
- [Creating scratch buffers](#)
- [Observing the available scratches](#)
- [Closing scratches](#)
- [Deleting scratches](#)
- [Changing the language of a scratch](#)
- [Renaming, copying and moving scratches](#)
- [Important notes about scratches](#)

## Basics

IntelliJ IDEA provides a temporary editor. You can create a text or a piece of code for search or exploration purposes. IntelliJ IDEA suggests two types of temporary files:

### Scratch files

The scratch files are fully functional, runnable, debuggable, etc. They require a language to be specified and have an extension. The scratch files are created via `Ctrl+Shift+Alt+Insert`.

### Scratch buffers

The scratch buffers are only intended for pure editing, and as such they do not require specifying a language and do not have an extension. The scratch buffers belong to `.txt` type by default.

This action has no dedicated shortcut, but you can configure one as described in the section [Configuring Keyboard Shortcuts](#) `Configuring Keyboard Shortcuts-->`.

Buffer files are reused after creating 5 files. So doing, after reuse, the content and language are reset.

## Creating scratch files

To create a scratch file

1. Do one of the following:

- On the main menu, choose `File | New | Scratch File`.
- Press `Ctrl+Shift+Alt+Insert`.
- Right-click anywhere in the [Project Tool Window](#) and choose `New | New Scratch File` from the context menu.
- Press `Ctrl+Shift+A`, start typing `scratch file..`, and choose the corresponding action.

2. Select the language of the future scratch from the list that IntelliJ IDEA suggests. IntelliJ IDEA creates a temporary editor tab with the name `scratch.<extension>`. In the future, the default names will be `scratch_<number>.<extension>`.

3. Type the desired code.

## Creating scratch buffers

To create a scratch buffer, follow these steps:

1. Press `Ctrl+Shift+A` or [search everywhere](#).
2. Start typing the command name `New Scratch Buffer`:

IntelliJ IDEA creates a temporary editor tab with the name `buffer1`. In the future, the default names will be `buffer<number>`.

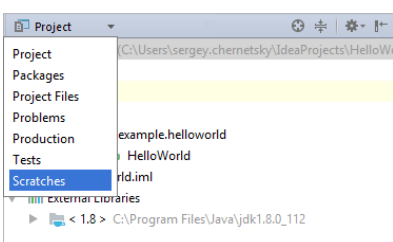

3. Type the desired code.

Note that though this action has no keyboard shortcut, you can still configure one as described in the section [Configuring Keyboard Shortcuts](#). You can also switch from scratch files to scratch buffers by reassigning the shortcut to avoid garbage buildup.

## Observing the available scratches

To observe the available scratch files and buffers, do one of the following:

- Choose `Scratches` view in the [Project Tool Window](#).

- Press `Alt+F1` and choose `Scratches` ([Navigating Between IDE Components](#)).

## Closing scratches

To close a scratch file or buffer, just click  $\times$  on the editor tab. Refer to the section [Closing Files in the Editor](#) for details.

## Deleting scratches

To delete a scratch file or buffer, follow these steps:

1. Switch to the Scratches view of the [Project Tool Window](#).
2. Under the `Scratches` pseudo-folder, right-click the scratch to be deleted, and choose Delete on the context menu.
3. Confirm deletion.

## Changing the language of a scratch

If you want to change the scratch's language when a scratch is already created, you can do so with the aid of the editor's context menu. This is how it's done:

1. Switch to the Scratches view of the [Project Tool Window](#), and open for editing the scratch file or buffer you want to change language for.
2. Right-click the editor background, and choose Change Language (<current language>) on the context menu.
3. Select the desired language.

Note the following:

- Four latest items appear on top of the list before a separator.
- You can narrow down the list by typing the language name.
- You can assign a shortcut to this action as described in the section [Configuring keyboard shortcuts](#).
- Change Language action keeps extension in sync, if it exists.

## Renaming, copying and moving scratches

IntelliJ IDEA makes it possible to perform [rename refactoring](#) of the scratches. To rename a scratch, follow these steps:

1. In the [Project Tool Window](#), switch to the Scratches view and select the scratch to be renamed.
2. Press `Shift+F6`.

You can also perform renaming in the other ways:

- In [NavBar](#): Jump to NavBar (`Alt+Home`) -> Rename (`Shift+F6`).
- In the [Project tool window | Scratches view](#): Select In | Project | Scratches (`Alt+F1`) -> Rename (`Shift+F6`).
- Right from the editor: Refactor | Rename File.

Copy and Move file actions are available the same way. Refer to the sections [Copy](#) and [Move Refactorings](#) for details.

Note that when copying a scratch, IntelliJ IDEA includes the respective extension that corresponds to the file type. This is how it's done:

1. In the [Project Tool Window](#), switch to the Scratches view and select the scratch to be copied.
2. Press `F5`. IntelliJ IDEA shows the following dialog box:

This dialog box shows the scratch name with the corresponding extension. Note that when you copy a [scratch buffer](#), the extension is `..txt`:

## Important notes about scratches

Note the following:

- The scratch code in scripting languages is executable: you can [run](#) and [debug](#) it.
- [Local history](#) for scratches is supported.
- It is possible to perform [clipboard operations](#) with scratches.
- The scratches are stored, depending on your operating system,
  - Under IntelliJ IDEA home, in the directory `config/scratches` (on Windows/\*NIX)
  - `~ Library->Preferences-><IntelliJ IDEA>XX->scratches` (on macOS)
- You can [undo or redo changes](#) in scratches.

On this page:

- [Adding lines](#)
- [Duplicating lines](#)
- [Deleting lines](#)
- [Moving lines](#)
- [Moving statements](#)
- [Moving code element left or right](#)

## Adding lines

### To add a line

- Press `Shift+Enter` to add a new line after the one where the caret is currently located and move the caret to the beginning of this new line.

For instance, you have typed some text:

```
94 public static void main(String[] args) {
95     System.out.println("Hello, world!");
96 }
```

- Press `Shift+Enter` to start the next line immediately:

```
94 public static void main(String[] args) {
95     System.out.println("Hello, world!");
96     |
97 }
```

- To add a line before the current one, press `Ctrl+Alt+Enter`.

**Tip** Make sure that keyboard shortcuts are not in conflict. You can do that in the [Keymap](#) page of the [Settings/Preferences dialog](#).

## Duplicating lines

### To duplicate a line or fragment

1. Place the caret at the line to be duplicated, or [select](#) the desired fragment of text.
2. Press `Ctrl+D`.

## Deleting lines

### To remove a line

- Press `Ctrl+Y` to delete the line at caret.

## Moving lines

### To move a line

1. Place the caret at the line to be moved.
2. Do one of the following:
  - On the main menu, choose Code | Move Line Up or Code | Move Line Down.
  - Press `Shift+Alt+Up` or `Shift+Alt+Down`.

IntelliJ IDEA moves the selected line one line up or down, performing the syntax check. For example:

```
public static void main(String[] args) {
    System.out.println("HW!!!");
}
```

After moving line at caret:

```
System.out.println("HW!!!");
public static void main(String[] args) {
}
```

## Moving statements

### To move a statement up or down

1. [Select](#) a statement to be moved, or just place the caret at the first or last lines of a multi-line statement. Note that if moving a statement is not allowed in the current context, the commands will be disabled.
2. Do one of the following:
  - On the main menu, choose Code | Move Statement Up/Move Statement Down.

– Press `Ctrl+Shift+Up` or `Ctrl+Shift+Down` .

If you apply the same commands to a line at caret, or a to a selection, it will be moved one line up or down.

IntelliJ IDEA moves the selected statement above the previous one, or directly underneath the next one, performing the syntax check. For example, place the caret at the method declaration:

```
public static void main(String[] args) {
    System.out.println("HW!!!");
}
public int foo(int a,int b){
    return a + b;
}
```

After moving the statement:

```
public int foo(int a,int b){
    return a + b;
}
public static void main(String[] args) {
    System.out.println("HW!!!");
}
```

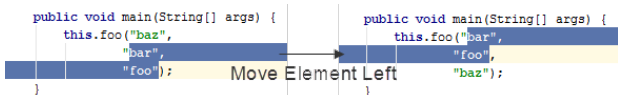

## Moving code element left or right

### To move code element to the left or to the right

1. Place the caret at the desired code element, or select the elements to be moved.
2. Do one of the following:
  - On the main menu, choose the commands Code | Move Element Left or Code | Move Element Right
  - Press `Ctrl+Shift+Alt+Left` or `Ctrl+Shift+Alt+Right`

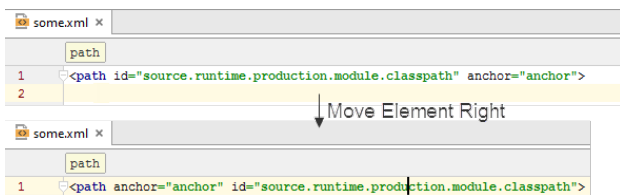

Examples of code elements for which this functionality is currently implemented:

– **Java** : method invocation arguments, method declaration arguments, enum constants, array initializer expressions.

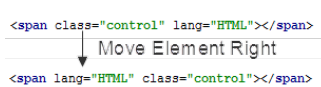

```
public void main(String[] args) {
    this.foo("bar",
            "foo");
}
public void main(String[] args) {
    this.foo("bar",
            "baz");
}
```

– **XML** : tag attributes.

```
some.xml x
path
1 <path id="source.runtime.production.module.classpath" anchor="anchor">
2
Move Element Right
some.xml x
path
1 <path anchor="anchor" id="source.runtime.production.module.classpath">
```

– **HTML** : tag attributes.

```
<span class="control" lang="HTML"></span>
Move Element Right
<span lang="HTML" class="control"></span>
```

## Basics

IntelliJ IDEA makes it possible to concatenate two unselected or several selected lines into one, removing the extra spaces, and providing the proper syntax. This operation smartly analyzes the lines being joined and treats them accordingly. For example, you can join lines of code, lines of comments, field declaration and initialization.

### Joining lines

1. Place the caret on the line, to which the other lines should be added.

```
141     foo(a,  
142         b,  
143         c,  
144         str);
```

2. Sequentially press `Ctrl+Shift+J` keyboard shortcut, until all fragments are joined in a single line.

```
141     foo(a, b, c,  
142         str);  
  
141     foo(a, b, c, |str);
```

**Tip** You can select the lines and press `Ctrl+Shift+J` to obtain the same result.

### Joining string literals

1. Select the lines with string literals that should be joined.

```
153     String theBest = new String("IntelliJ IDEA is " +  
154         "the most intelligent " +  
155         "IDE around");
```

2. Press `Ctrl+Shift+J` keyboard shortcut. All redundant characters (spaces, quotes, and plus signs) are gone.

```
153     String theBest = new String("IntelliJ IDEA is the most intelligent IDE around");
```

## Examples

Joining a field or variable declaration and assignment:

```
140     int myInt;  
141     myInt = 1;
```

Pressing `Ctrl+Shift+J` produces the following result, with the unwanted spaces and variable name in the second line removed:

```
140     int myInt | = 1;
```

Consider the following pair of statements:

```
46     int intVar_1 = START_RATE;  
47     intVar_1 -= END_RATE;
```

Press `Ctrl+Shift+J` to join these lines into a correct single-line statement.

```
46     int intVar_1 = START_RATE - END_RATE;
```

This feature is designed to correctly split string literals, providing the necessary quotation marks and plus signs.

To split a string literal into two parts:

1. Set the caret in the string literal to be split.

```
31 |  
32 | System.out.println("Hello,|world!");  
33 |
```

2. Press  .

```
32 | System.out.println("Hello," +  
33 |     "world!");
```

You can split a string literal on newline symbols ( `\n` ) by using the Break string on '\n' [intention action](#) . That is, a string literal in a code fragment like this:

```
String s = "Hello,\nWorld!";
```

can be easily transformed into corresponding concatenation:

```
String s = "Hello,\n" +  
    "World!";
```

To do that:

1. Place the cursor within the literal of interest.
2. Click the yellow light bulb icon  or press `Alt+Enter` , and select Break string on '\n' .

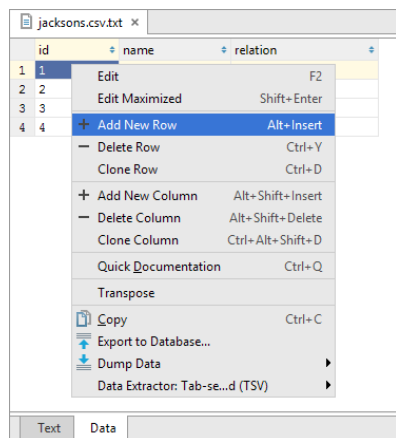

This feature is only supported in the Ultimate edition.

For text files containing [delimiter-separated values](#) (e.g. CSV, TSV), IntelliJ IDEA provides a table editor, which you can open in a dialog or right in the editor (See [Opening the table editor](#) .)

Most of the functions in the table editor are accessed as context menu commands. Many of the commands have dedicated [keyboard shortcuts](#) .

Note that the context menus for the header row and the rest of the table are different.

## Prerequisites

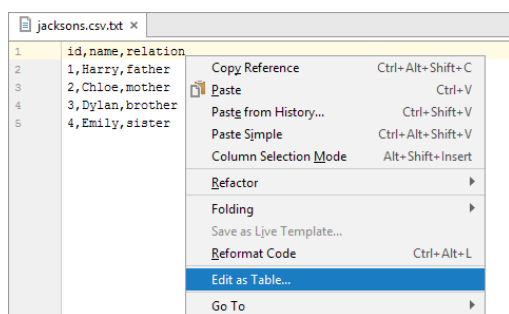

For the table editor and associated features to be available:

- You should be using the Ultimate Edition of IntelliJ IDEA. (The corresponding functionality is not available in the Community Edition.)
- The Database Tools and SQL [plugin](#) must be enabled. (This plugin is bundled with the IDE and enabled by default.)
- The file name extension must be associated with the text file type. See e.g. [File Types](#) .

## Opening the table editor

You can open the table editor for a whole file or for its fragment.

1. Open the file of interest in the editor.
2. If you want to open the table editor for a fragment, select that fragment.
3. Select Edit as Table from the context menu.

4. In the [dialog that opens](#) , specify conversion setting and click OK .

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  name  . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  name  1 . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  name  1 .

Finally, when you click the cell for the third time, the initial state is resorted. That is, sorting by the corresponding column is

canceled:  .

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

To show a hidden column:

1. Do one of the following:

- Right-click any of the cells in the header row and select Column List .
- Press **Ctrl+F12** .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	/ name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

2. Select (highlight) the column name of interest and press **Space** .
3. Press **Enter** or **Escape** to close the list.

## Transposing the table

The transposed table view is available. In this view, the rows and columns are interchanged.

To turn this view on or off, click on the toolbar and select Transpose . Alternatively, use the Transpose context menu command.

## Enabling coding assistance for a column

You can assign a column one of the supported languages (e.g. SQL, HTML or XML): right-click the corresponding header cell, select Edit As and select the language. As a result, you get coding assistance for the selected language in all the cells of the corresponding column.

You can also assign a language to an [individual cell](#) .

## Modifying cell contents

1. To start editing a value, do one of the following:

- Double-click the corresponding table cell.
- Right-click the cell and select Edit or Edit Maximized from the context menu.
- Select the cell and press **F2** or **Shift+Enter** . In the latter case, the cell will be maximized.
- Select the cell and start typing. Note that in this case the initial cell contents are deleted right away and is replaced with the typed value.

2. When in the editing mode, you can:

- Modify the value right in the cell. To start a new line, use **Ctrl+Enter** . To enter the value, press **Enter** . To restore an initial value and quit the editing mode, press **Escape** .

Oxygen	O	Highly reactive nonmetallic element
Fluorine	F	Lightest halogen Extremely reactive Highly toxic pale yellow diatom
Neon	Ne	Colorless, odorless, inert monatomic g...

- Use value completion. Press **Ctrl+Space** to open the suggestion list. The list contains the values from the current column that match your input.
- Maximize the cell if you need more room for editing. To do that, press **Ctrl+Shift+Alt+M** , or right-click the cell and select Maximize .

When working in a maximized cell, use **Enter** to start a new line and **Ctrl+Enter** to enter the value. To restore an initial value and quit the editing mode, press **Escape** .

Highly reactive nonmetallic element
Lightest halogen
Extremely reactive
Highly toxic pale yellow diatomic gas

- Insert the contents of a text file into the cell. To do that, right-click the cell and select Load File . Then select the necessary file in the dialog that opens.
- Edit a value in the cell as a fragment in one of the supported languages (e.g. SQL, HTML or XML). To do that, right-click the cell, select Edit As and select the language. As a result, you get coding assistance for the language you have selected.

Highly reactive nonmetallic element
<ul>
<li>Lightest halogen</li>
<li>Extremely reactive</li>
<li>Highly toxic pale yellow diatomic gas</li>
</ul>
locator http://www.w3.org/1999/html
simple http://www.w3.org/1999/xhtml

## Adding and deleting rows and columns

Use the following context menu commands and shortcuts:

- Add New Row ( [Alt+Insert](#) ).
- Delete Row ( [Ctrl+Y](#) ). To delete more than one row at once, first, select the corresponding rows or cells in the corresponding rows.
- Clone Row ( [Ctrl+D](#) ). This command creates a copy of the current row.
- Add New Column ( [Shift+Alt+Insert](#) ).
- Delete Column ( [Shift+Alt+Delete](#) ). To delete more than one column at once, first, select the cells in the corresponding columns.
- Clone Column ( [Ctrl+Shift+Alt+D](#) ). This command creates a copy of the current column.

## Copying data to the clipboard or saving them in a file

1. Use one of the following context menu commands:

- Copy ( [Ctrl+C](#) ). This command copies the data for the selected cells to the clipboard.
- Dump Data | To Clipboard. This command copies the data for the whole table to the clipboard.
- Dump Data | To File. This command saves the data for the whole table in a file. Before actually saving the data, the dialog is shown which lets you select the output format and see how your data will look in a file.

2. If you are saving the data in a file, specify the file name and location.

See also, [Specifying data output format and options](#) .

## Specifying data output format and options

To specify the output format and options for the Copy and Dump Data commands (see [Copying data to the clipboard or saving them in a file](#) ), right-click the table and point to Data Extractor: <current\_format> .

In the menu that opens, the output formats are in the upper part: SQL Inserts , SQL Updates , etc. (The options that look like file names are also the output formats or, to be more exact, the scripts that implement corresponding data converters.)

The output option are:

- Allow Transposition. This option affects only delimiter-separated values formats (TSV, CSV). If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. [Ctrl+C](#) ), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.
- Skip Generated Columns (SQL). This is the option for SQL INSERTs and UPDATEs. When on, auto-increment fields are not included.
- Add Table Definition (SQL). This is also the option for SQL INSERTs and UPDATEs. When on, the table definition (CREATE TABLE) is added.

Additionally:

- Configure CSV Formats. This command opens the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. This command lets you switch to the directory where the scripts that convert table data into various output formats are stored.

## Exporting the data to a database

You can export the data to a database (your database must be defined as a [data source](#) ):

1. Select Export to Database from the context menu.
2. Select the target schema (a new table will be created) or table (the data will be added to the selected table).
3. In the [dialog that opens](#) , specify the data mapping info and the settings for the target table.

IntelliJ IDEA allows copying and moving code fragments within the active editor tab, by means of drag-and-drop.

## To move or copy code fragment

1. Make sure that using drag-and-drop is enabled in the [Editor](#) page of the IDE Settings.
2. [Select](#) the desired fragment in the editor.
3. Move or copy selection:
  - Move: Drag the selected fragment to the target location.
  - Copy: Keeping the `Ctrl` key pressed, drag selection to the target location.

Macros provide a convenient way to automate repetitive procedures you do frequently while writing code. You can record, edit and playback macros, assign them a shortcut, and share them. Generally speaking, macros are designed for rather simple operations, and as such have the following limitations:

- Macros can be used for editor-related actions within a file.
- You cannot record such actions as button clicks, navigating to pop-up dialog boxes, and accessing tool windows or menus.

If a macro is intended for temporary use only, it is unnamed; permanent macros have unique names.

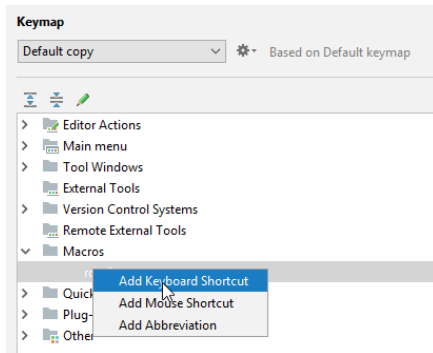

In this section:

- [Binding Macros With Keyboard Shortcuts](#)
- [Editing Macros](#)
- [Playing Back Macros](#)
- [Recording Macros](#)

## To bind a macro with a keyboard shortcut

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Keymap .
2. [Create a new keymap](#) or select a keymap from the list of keymaps.
3. Expand the Macros node and select the macro for which a keyboard shortcut should be created.
4. Right-click the macro and choose Add Keyboard Shortcut in the context menu:

5. In the [Enter Keyboard Shortcut](#) dialog, press the keys to be used as a shortcut. The keystrokes are immediately reflected in the First Stroke field. Optionally, select the Second stroke checkbox and specify the second stroke. As you press the keys, the Preview field displays the keystrokes you pressed, and the Conflicts field displays warnings, if the keystrokes are already in use.
6. Click OK using the mouse pointer to create a shortcut and bind it with the macro.
7. Apply changes.

**Tip** It is important that you use the mouse pointer, because any keystroke is interpreted as a shortcut.

After recording, you can remove or rename any or all of the macros from the list of available macros. The actions list of each macro is also editable - you can remove unnecessary actions.

## To edit macros

1. On the main menu, choose Edit | Macros | Edit macros .
2. In left-hand pane of the Edit Macros dialog, select the macro to be edited or deleted:

3. To delete a macro, click — . To change the macro name, click ✎ , and specify the new name in the Rename Macro dialog.
4. To change the list of actions for a macro, select an action in the action list, and click — .

You can play back the recorded macros using the Edit | Macros menu commands, or [custom shortcuts](#) .

### **To play back a temporary macro**

– On the main menu, choose Edit | Macros | Play Back Last Macro .

### **To play back a named macro**

– On the main menu, choose Edit | Macros | <Macro name> .

### **To play back a macro with a keyboard shortcut**

1. Select a keymap with the [macro bindings](#) on the [Keymap](#) settings page.
2. Press keyboard shortcut that corresponds to the desired macro.

## To record a macro

1. On the main menu, choose Edit | Macros | Start Macro Recording . From that moment on, all your recordable actions are recorded.
2. When you are done with the procedure, choose Edit | Macros | Stop Macro Recording .
3. In the Enter Macro Name dialog, specify the name of the new macro, and click OK . If the macro is intended for temporary use only, you can leave the name blank.

Every time you open a file for editing, a dedicated tab is added to the editor window, next to the active editor tab.

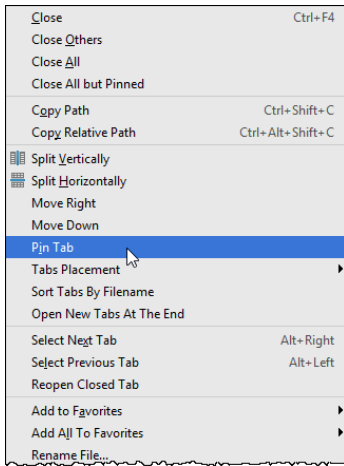

IntelliJ IDEA can limit the number of tabs opened in the editor simultaneously. When the number of tabs reaches its limit, the editor closes the tabs according to the tab closing policy, that is defined in the [Editor Tabs](#) settings page. By default, the tab limit is 10, but you can change it if necessary.

All commands, related to managing editor tabs, are available from:

– Window | Editor Tabs menu.

– Context menu of a tab.

On this page:

- [Changing the number of editor tabs](#)
- [Disabling editor tabs](#)
- [Tips and tricks](#)

## Changing the number of editor tabs

### To change the maximum allowed number of tabs

1. Open the Editor settings. To do that, click  on the main toolbar, then click the Editor node in the [Setting/Preferences](#) dialog box that opens.
2. In the [Editor Tabs](#) page of the Editor settings ( Settings/Preferences - Editor - General - Editor Tabs ), type the desired maximum allowed number of the editor tabs to be opened at a time in the Tab limit field.

## Disabling editor tabs

### To disable editor tabs

- In the [Editor Tabs](#) page of the Editor settings, select None from the Tab placement drop-down list.

## Tips and tricks

- If the tab limit equals to 1, the tabs will be disabled. If you want the editor to never close the tabs, type some unreachable number.
- With the disabled tabs, use the View | Recent files (  ) command to quickly switch between files.

## Navigating between editor tabs

### To navigate from the current tab to the next or previous tab

- Right-click the current editor tab and choose Select Next/Previous Tab on the context menu.
- Press `Alt+Right` or `Alt+Left` . So doing, the focus moves to the editor tab located next to the right or to the left from the active editor tab.
- Press `Ctrl+Tab` to use the [Switcher](#) .

This approach allows jumping from one tab to another as your editing session requires. While you move between the editor tabs, IntelliJ IDEA remembers the caret position within each opened file.

## Navigating through the previously visited tabs

### To go back and forth through the history of visited tabs

- On the main toolbar, click  .
- On the main menu, choose `Navigate | Back / Forward` .
- Press `Ctrl+Alt+Left` or `Ctrl+Alt+Right` .

This approach enables you to move back and forth through the history of your navigation, same way as it is done in a Web browser. As you move from file to file during your editing session, IntelliJ IDEA keeps track of the visited locations and enables you to go back, using the `Navigate | Back / Forward` commands.

**Note** On a macOS computer, you can also use the three-finger right-to-left and left-to-right swipe gestures.

## Viewing all opened editor tabs and choosing the active editor

### To view all editor tabs and select the active editor

If all opened tabs are shown in a single row, some of the tabs may become invisible. IntelliJ IDEA helps display the list of the opened editor tabs that did not fit in the editor window and have become invisible whereupon you can choose the tab to activate.

1. Do one of the following:
  - On the main menu, choose `Window | Editor Tabs | Show Hidden Tabs`
  - Click 

The list of all the tabs that are opened but invisible appears. So doing the names of the tabs, which are currently visible, are displayed on the light background; the names of the tabs outside of the main window are shown on the darker background.

2. Click the name of the desired editor tab:

The selected editor tab becomes active and gets the focus.

The command `Show All Tabs` and the icon  are only available when:

- The `Show tabs in single row` checkbox is selected in the [Editor tabs](#) page of the Editor settings.
- Some of the opened tabs are not visible because they do not fit in the editor window.

## Basics

IntelliJ IDEA can limit the number of tabs opened in the editor simultaneously. When the number of tabs reaches its limit, the editor closes the tabs according to the tab closing policy, that is defined in the [Editor Tabs](#) settings page. By default, the tab limit is 10, but you can change it if necessary.

To prevent a tab from being closed automatically, you can pin this tab. Besides, when you close the editor tabs, you have an option to preserve pinned tabs opened and close only the unpinned tabs.

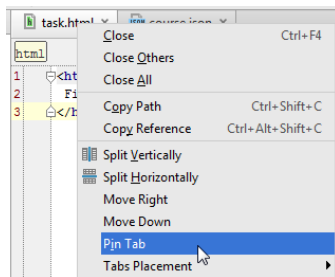

When a tab is pinned, there is a special marker on it.

**Tip** The pinned status of a tab is helpful when you open a file for reference, rather than for editing.

## Pinning an editor tab

1. Switch to the desired editor tab.
2. Right-click the editor tab, and choose Pin Tab on the context menu:

## Unpinning a tab

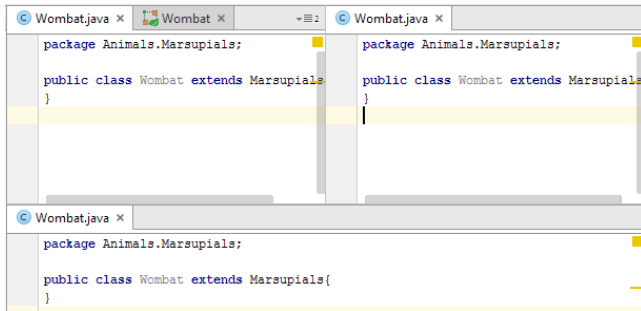

1. Switch to the desired editor tab.
2. Right-click the editor tab, and choose Unpin Tab on the context menu.

## Basics

Splitting the editor window divides it into independent panes. You can split the editor window into as many panes as required, each one containing multiple tabs.

Each pane can be allocated vertically or horizontally. Thus, splitting helps create different editor layouts, organize tabs into groups, and [edit multiple files simultaneously](#) . For example, you can scroll through a part of a file, having at the same time the possibility to view the lines in its other part.

## Splitting editor tab

### To split an editor tab creating a file copy

1. Switch to the desired tab.
2. Right-click the tab header and choose Split Vertically or Split Horizontally on the context menu.

### To split an editor tab without copying a file

1. Switch to the desired tab.
2. Right-click the tab header and choose Move Right or Move Down on the context menu.

## Changing splitter orientation

### To change splitter orientation

1. Switch to the desired tab.
2. Right-click the tab header and choose Change Splitter Orientation on the context menu.

## Removing a splitter

### To remove splitter

1. Switch to the desired tab.
2. Right-click the tab header and choose one of the following commands on the context menu:
  - To remove splitting in the active tab, choose Unsplit .
  - To remove splitting in all the open editor tabs, choose Unsplit All .

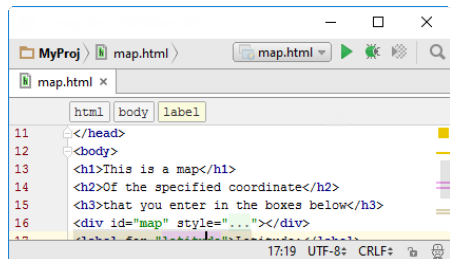

IntelliJ IDEA makes it possible to detach editor tabs, and move them to separate frames.

### To detach an editor tab, do one of the following

- Drag this tab outside of the main window. A preview thumbnail appears:

- Press **Shift+F4**.

The content of the editor tab opens in a separate frame.

### To attach an editor tab

- drag it from its frame and drop to the main IntelliJ IDEA frame until tab name appears:

**Tip** The detached editor tabs can be [split](#) or [unsplit](#).

- You can move editor tabs between split panes.

You can arrange tabs into groups to facilitate working with multiple files at a time. IntelliJ IDEA allows you to have an unlimited number of tab groups, thus enabling you to view several files or several places within the same file.

### **To create a new group of tabs**

- Just [split](#) the desired editor tab.

### **To move a tab from one group to another**

1. Switch to the desired tab.
2. Right-click the desired editor tab and choose Move Tab to Opposite Tab Group on the context menu.

By default, the tab headers appear on top of the editor, but you can change their location as required, and have the headers at the bottom, left, or right sides of the editor. Note that the tab header placement is a global setting that applies to all projects.

**To change location of the editor tab headers, do one of the following**

- In the [Editor Tabs](#) settings page, select editor tab headers position from the Placement drop-down list.
- Right-click an editor tab, point to the menu item Tabs Placement , and then select the desired placement in the sub-menu.

## Overview

The alphabetical sorting of the editor tabs is available regardless of the tabs position. However, alphabetical order for top and bottom placement becomes available, when the Show tabs in single row check command is selected on the Window | Editor Tabs | Tabs Placement menu.

## Enabling alphabetical sorting

To enable alphabetical sorting:

1. On the main menu, choose Window menu.
2. Point to Editor Tabs | Tabs Placement .
3. Select the check command Show Tabs in Single Row .

## Sorting editor tabs alphabetically

To sort editor tabs alphabetically:

1. Right-click an editor tab.
2. Select the check command Sort Tabs by Filename .

If this check command is selected, the tabs headers are presented in alphabetical order. Otherwise, the editor tab headers appear in the opening order of the corresponding files.

Working on a large project, you often need to create the lists of tasks, and keep your team mates informed about the issues that require their attention. Such issues can include the questions that should be answered, certain changes that should be done later, areas of optimization and improvement etc.

IntelliJ IDEA suggests to use special TODO comments in the source code. Such comments can be used in all supported file types, and should match a certain TODO pattern . IntelliJ IDEA comes with one pre-defined pattern, but you can define as many TODO patterns as required. When a matching occurrence is encountered, it is interpreted as a TODO item. IntelliJ IDEA highlights such comments in accordance with the [Color Scheme](#) settings.

## To create TODO items

1. Open the desired file in the editor and position the caret at the place where a TODO item should be created.
2. [Create a comment](#) . For example, you can use the `Ctrl+Slash` keyboard shortcut.
3. In the comment, type the string that matches one of your TODO patterns. By default, any string that starts with `TODO` (regardless of the case) is interpreted as a TODO item and is highlighted accordingly.
4. View the list of TODO items in the TODO tool window.

On this page:

- [Basics](#)
- [Defining TODO patterns](#)
- [Defining filters](#)

## Basics

TODO items in the source code are defined by a certain pattern.

Whenever a pattern is changed, or a new pattern is added, IntelliJ IDEA scans the whole project and rebuilds the index of TODO items. Results display in the [TODO tool window](#), as described in the section [Viewing TODO Items](#).

By default, IntelliJ IDEA provides two patterns:

- `\btodo\b.*`
- `\bfixme\b.*`

A generic pattern looks like `todo.*`

You might want to view the TODO comments of certain a type, and hide the others. For this purpose, IntelliJ IDEA suggests to use filters. This way you can show those items that match certain patterns only.

## Defining TODO patterns

### To define a TODO pattern, follow these general steps

1. Open the [TODO page](#) of the Settings dialog.
2. In the Patterns section, click the Add button  to create a new pattern, or the Edit button  to update an existing one. The [Add/Edit Pattern dialog](#) opens.
3. In the Pattern field, enter the regular expression that describes the desired pattern.
4. In the Icon list, select the desired icon that will mark the matching TODO items in the [TODO tool window](#).
5. Specify the color and font properties, which IntelliJ IDEA will use to highlight the matching comments in the source code.
6. Select the Case sensitive checkbox, if you want the pattern to be case-sensitive.

## Defining filters

### To define a filter that will be used to show specific types of TODO items, follow these general steps

1. Open the [TODO page](#) of the Settings dialog.
2. In the Filters section, click the Add button  to create a new filter, or the Edit button  to update an existing one.
3. In the [Add/Edit Filter](#) dialog, specify the filter name, and select the patterns to be included in the filter.

## To view TODO items in project, follow these general steps

1. Open TODO tool window, as described in the procedure [Showing a tool window](#) .

The tool window displays the encountered TODO items in several tabs:

- All over the project ( Project tab)
- In the file currently active in the editor( Current File tab)
- In one of the already defined scopes ( Scope Based tab), which is quite useful for large projects.
- In the current changelist, if version control support is enabled.

2. Click the desired tab (view), and explore the list of encountered TODO items. For example, with the Scope Based view selected, one has to choose scope from the drop-down list.

3. Narrow down the list of search results by choosing scope, and applying filters.

In this part:

- Live Templates
  - [Overview](#)
  - [Important notes](#)
- [Simple, Parameterized and Surround Live Templates](#)
- [Live Template Abbreviation](#)
- [Live Template Variables](#)
- [Groups of Live Templates](#)
- [Creating and Editing Live Templates](#)
- [Creating and Editing Template Variables](#)
- [Sharing Live Templates](#)

## Overview

**Live templates** let you insert frequently-used or custom code constructs into your source code file quickly, efficiently, and accurately.

Live templates are stored in the following location:

- **Windows**: `<your_user_home_directory>\.IntelliJ IDEA<version_number>\config\templates`
- **Linux**: `~IntelliJ IDEA<version>/config/templates`
- **macOS**: `~/Library/Preferences/IntelliJ IDEA<version>/templates`

## Important notes

- To create or edit the **Live templates**, use the [Live Templates](#) page of the Settings/Preferences dialog.
- Having [created a custom live template](#), you can export all the **live templates** together with the other settings, and import them. Refer to the section [Exporting and Importing Settings](#) for details.

## Simple live templates

**Simple templates** contain some fixed code that expands into plain text. When invoked and expanded in the editor, the code specified in the template is automatically inserted into your source code, replacing the abbreviation.

## Parameterized live templates

**Parameterized templates** contain plain text and **variables** that enable user input.

**Tip** If you need a dollar sign (\$) in the template text, escape it by duplicating this character (\$\$).

After a template is expanded, variables appear in the editor as input fields whose values can be either filled in by the user or calculated by IntelliJ IDEA automatically.

When a parameterized live template is invoked and expanded in the Editor, IntelliJ IDEA can suggest some predefined values at the input positions of the variables. For example, if a parameterized template contains code for an iteration, then, on expanding the template, IntelliJ IDEA will suggest:

- A name for the index variable (`i`, `j`, etc.).
- A list of all suitable variables in the current scope (e.g. Arrays) as an expression for the iterated container.
- A name for the assigned variable that holds the current container element.
- Type of the elements in the iterated container.

## Surround live templates

**Surround templates** work only with blocks of selected text. Such templates place code before and after the selected block.

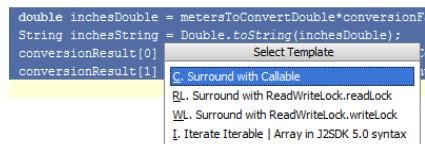

## Examples

**Insert parameterized live template** (`Ctrl+J`):

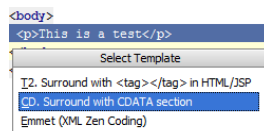

```
for (int i = 0; i < .; i++) {  
}
```

Refer also to the page [Iterating over an Array. Example of Applying Parameterized Live Templates](#).

**Surround with live template** (`Ctrl+Alt+J`):

```
double inchesDouble = metersToConvertDouble*conversionF;  
String inchesString = Double.toString(inchesDouble);  
conversionResult[0]  
conversionResult[1]
```

```
<body>  
<p>This is a test</p>
```

Refer also to the page [Wrapping a Tag. Example of Applying Surround Live Templates](#).

Each live template is identified by a template abbreviation .

The template abbreviations work like shortcuts and are expanded into fragments of source code, depending on the surrounding context . So doing, IntelliJ IDEA can format the generated code fragments according to the code style settings.

An abbreviation may contain alphanumeric characters, dots, and hyphens, and must be unique within its [group](#) . However, you can use the same abbreviation for different templates provided that they are in different groups.

Whole code constructs can be created using the template abbreviations. To do that, type the template abbreviation, and press expansion key (for example, `Tab` ). Refer to the section [Creating Code Constructs by Live Templates](#) for details.

## What are template variables

Template variables in live templates enable user input. After a template is expanded, variables appear in the editor as **input fields**.

## Declaring template variables

Variables within templates are declared in the following format:

```
<code>$<variable_name>$</code>
```

## Creating and editing template variables

Variables are defined by expressions, and can accept some default values.

This expression may contain constructs of the following basic types:

- String constants in double quotes.
- The name of another variable defined in a live template.
- Predefined functions with possible arguments.

Template variables are editable in the [Edit Template Variables Dialog](#), which contains a complete list of available functions.

See the [list of predefined functions](#) below on this page.

## Predefined template variables

IntelliJ IDEA supports two predefined live template variables: `$END$` and `$SELECTION$`.

You cannot edit the predefined live template variables `$END$` and `$SELECTION$`.

- `$END$` indicates the position of the cursor after the template is expanded. For example, the template `return $END$;` will be expanded into

```
<code>return ;</code>
```

with the cursor positioned **right before** the semicolon.

- `$SELECTION$` is used in surround templates and stands for the code fragment to be wrapped. After the template is expanded, the selected text is wrapped as specified in the template.

For example, if you select `EXAMPLE` in your code and invoke the `"$SELECTION$"` template via the assigned abbreviation or by pressing `Ctrl+Alt+T` and selecting the desired template from the list, IntelliJ IDEA will wrap the selection in double quotes as follows:

```
<code>"EXAMPLE"</code>
```

## Predefined functions to use in live template variables

### ItemDescription

<code>annotated("annotation qname")</code>	Creates a symbol of type with an annotation that resides at the specified location. For an example, see Live Templates in the iterations group.
<code>arrayVariable()</code>	Suggests all array variables applicable in the current scope. For an example, see Live Templates in the iterations group.
<code>anonymousSuper()</code>	Suggests a supertype for a Kotlin object expression.
<code>camelCase(String)</code>	Returns the string passed as a parameter, converted to camel case. For example, <code>my-text-file / my_text_file / my_text_file</code> will be converted to <code>myTextFile</code> .
<code>capitalize(String)</code>	Capitalizes the first letter of the name passed as a parameter.
<code>capitalizeAndUnderscore(sCamelCaseName)</code>	Capitalizes the all letters of a CamelCase name passed as a parameter, and inserts an underscore between the parts. For example, if the string passed as a parameter is <code>FooBar</code> , then the function returns <code>FOO_BAR</code> .
<code>castToLeftSideType()</code>	Casts the right-side expression to the left-side expression type. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>className(sClassName)</code>	Returns the name of the current class (the class where the template is expanded).
<code>classNameComplete()</code>	This expression substitutes for the <a href="#">class name completion</a> at the variable position.

<code>clipboard()</code>	Returns the contents of the system clipboard.
<code>snakeCase(String)</code>	Returns CamelCase string out of snake_case string. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>complete()</code>	This expression substitutes for the code completion invocation at the variable position.
<code>completeSmart()</code>	This expression substitutes for the smart type completion invocation at the variable position.
<code>&lt;componentTypeOf (&lt;array variable or array type&gt;)</code>	Returns component type of an array. For example, see the <a href="#">Live Templates</a> in the iterations group in the other group.
<code>currentPackage()</code>	Returns the current package name.
<code>date(sDate)</code>	Returns the current system date in the specified format. By default, the current date is returned in the default system format. However, if you specify date format in double quotes, the date will be presented in this format:
	
<code>decapitalize(sName)</code>	Replaces the first letter of the name passed as a parameter with the corresponding lowercase letter.
<code>descendantClassEnum(&lt;String&gt;)</code>	Shows the children of the class entered as a string parameter.
<code>enum(sCompletionString1,sCompletionString2,...)</code>	List of comma-delimited strings suggested for completion at the template invocation.
<code>escapeString(sEscapeString)</code>	Escapes the specified string.
<code>expectedType()</code>	Returns the type which is expected as a result of the whole template. Makes sense if the template is expanded in the right part of an assignment, after return, etc.
<code>fileName(sFileName)</code>	Returns file name with extension.
<code>fileNameWithoutExtension()</code>	Returns file name without extension.
<code>firstWord(sFirstWord)</code>	Returns the first word of the string passed as a parameter.
<code>groovyScript("groovy code")</code>	Returns Groovy script with the specified code.  You can use <code>groovyScript</code> macro with multiple arguments. The first argument is a script text that is executed or a path to the file that contains a script. The next arguments are bound to <code>_1</code> , <code>_2</code> , <code>_3</code> , ... <code>_n</code> variables that are available inside your script.  Also, <code>_editor</code> variable is available inside the script. This variable is bound to the current editor.
<code>guessElementType (&lt;container&gt;)</code>	Makes a guess on the type of elements stored in a <code>java.util.Collection</code> . To make a guess, IntelliJ IDEA tries to find the places where the elements were added to or extracted from the container.
<code>iterableComponentType(&lt;ArrayOrIterable&gt;)</code>	Returns the type of an iterable component, such as an array or a collection.
<code>iterableVariable()</code>	Returns the name of a variable that can be iterated.
<code>lineNumber()</code>	Returns the current line number.
<code>lowercaseAndDash(String)</code>	Returns lower case separated by dashes, of the string passed as a parameter. For example, the string <code>MyExampleName</code> is converted to <code>my-example-name</code> .
<code>methodName()</code>	Returns the name of the embracing method (where the template is expanded).
<code>methodParameters()</code>	Returns the list of parameters of the embracing method (where the template is expanded).
<code>methodReturnType()</code>	Returns the type of the value returned by the current method (the method within which the template is expanded).
<code>qualifiedClassName()</code>	Returns the fully qualified name of the current class (the class where the template is expanded).  <b>Tip</b> Clear the Shorten FQ names check box.
<code>rightSideType()</code>	Declares the left-side variable with a type of the right-side expression. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>snakeCase(sCamelCaseText)</code>	Returns snake_case string out of CamelCase string passed as a parameter.
<code>spaceSeparated(String)</code>	Returns string separated with spaces out of CamelCase string passed as a parameter. For example, if the string passed as a parameter is <code>fooBar</code> , then the function returns <code>foo bar</code> .
<code>subtypes(sType)</code>	Returns the subtypes of the type passed as a parameter.

<code>suggestIndexName()</code>	Suggests the name of an index variable. Returns <code>i</code> if there is no such variable in scope, otherwise returns <code>j</code> if there is no such variable in scope, etc.
<code>suggestVariableName()</code>	<p>Suggests the name for a variable based on the variable type and its initializer expression, according to your code style settings that refer to the variable naming rules.</p> <p>For example, if it is a variable that holds an element within iteration, IntelliJ IDEA makes a guess on the most reasonable names, also taking into account the name of the container being iterated.</p>
<code>suggestFirstVariableName(sFirstVariableName)</code>	Doesn't suggest <code>true</code> , <code>false</code> , <code>this</code> , <code>super</code> .
<code>time(sSystemTime)</code>	Returns the current system time.
<code>typeOfVariable(VAR)</code>	Returns the type of the variable passed as a parameter.
<code>underscoresToCamelCase(sCamelCaseText)</code>	Returns the string passed as a parameter with CamelHump letters substituting for underscores. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>underscoresToSpaces(sParameterWithSpaces)</code>	Returns the string passed as a parameter with spaces substituting for underscores.
<code>user()</code>	Returns the name of the current user.
<code>variableOfType(&lt;type&gt;)</code>	Suggests all variables that may be assigned to the type passed as a parameter, for example <code>variableOfType("java.util.Vector")</code> . If you pass an empty string ("") as a parameter, suggests all variables regardless of their types.
<code>JsArrayVariable</code>	Returns JavaScript array name.
<code>jsClassName()</code>	Returns the name of the current JavaScript class.
<code>jsComponentType</code>	Returns the JavaScript component type.
<code>jsMethodName()</code>	Returns the name of the current JavaScript method.
<code>jsQualifiedClassName</code>	Returns the complete name of the current JavaScript class.
<code>jsSuggestIndexName</code>	Returns a suggested name for an index.
<code>jsSuggestVariableName</code>	Returns a suggested name for a variable.

## Overview

**Live Templates** are managed on the [Live Templates](#) page of the [Settings / Preferences Dialog](#) . For your convenience, templates are arranged in **groups** , most often in accordance with the **context** they are sensitive to.

IntelliJ IDEA comes with a set of **predefined** groups of templates. In addition to them, you can define your own **custom** groups and templates. It is strongly recommended that you avoid storing custom templates in predefined IntelliJ IDEA groups. For this purpose, use the **user** group, or a new group.

IntelliJ IDEA stores definitions of custom live template groups and templates added to predefined template groups in automatically generated configuration files `<group_name>.xml` .

- For a custom group, the file contains definitions of all the templates the group includes.
- For a customized predefined group, the file contains definitions of the added templates only.

Depending on the operating system you are using, the `<group_name>.xml` files are stored at the following locations:

- **Windows** : `<your_user_home_directory>\.IntelliJ IDEA<version_number>\config\templates`
- **Linux** : `~IntelliJ IDEA<version>/config/templates`
- **macOS** : `~/Library/Preferences/IntelliJ IDEA<version>/templates`

## Managing groups of live templates

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Live Templates under Editor . The [Live Templates](#) page that opens shows all the groups of live templates that are currently configured in IntelliJ IDEA.
2. Do one of the following:
  - To create a new custom group, click `+` on the toolbar and choose Template Group on the context menu. Then specify the name for the group in the Create New Group dialog box that opens.
  - To remove a group, select it in the list and click `-` on the toolbar.
  - To add a template to a group, select the group, click `+` , and choose Live Template on the context menu. In the [Template editing area](#) , specify the settings for the new template as described in [Creating and Editing Live Templates](#) .

## Introduction

IntelliJ IDEA comes with a set of the predefined [Live Templates](#) . You can use them as is, or modify them to suit your needs. If you want to create a new live template, you can do it from scratch, on the base of the copy of an existing template, or from a fragment of source code.

If a template has been changed, it is always possible to restore its default settings.

## Modifying existing templates

### To modify an existing template

1. In the Settings/Prefereces dialog, open the [Live Templates](#) page.
2. Expand the desired template group, and select the template you want to change.
3. In the [Template Text](#) area, change the [template abbreviation](#) as required.
4. In the Template Text field, edit the template body which may contain plain text and variables in the format `<variable name>$` .

When editing the live template variables, mind the following helpful hints:

- If you need a dollar sign ( \$ ) in the template text, escape it by duplicating this character ( \$\$ ) .
- To change the variables in a template, click the Edit Variables button and [configure the variables](#) .

The Edit Variables button is enabled only if the template body contains at least one user-defined variable, that is, a variable different from `$END$` or `$SELECTION$` .

### Side note about predefined template variables

IntelliJ IDEA supports two predefined live template variables : `$END$` and `$SELECTION$` .

You cannot edit the predefined live template variables `$END$` and `$SELECTION$` .

- `$END$` indicates the position of the cursor after the template is expanded. For example, the template `return $END$;` will be expanded into

```
return ;
```

with the cursor positioned **right before** the semicolon.

- `$SELECTION$` is used in surround templates and stands for the code fragment to be wrapped. After the template is expanded, the selected text is wrapped as specified in the template. For example, if you select `EXAMPLE` in your code and invoke the `"$SELECTION$"` template via the assigned abbreviation or by pressing `Ctrl+Alt+T` and selecting the desired template from the list, IntelliJ IDEA will wrap the selection in double quotes as follows:

```
"EXAMPLE"
```

5. In the Options section, specify how the template will be expanded and reformatted.
6. In the Available in section, specify the languages and places of code where the editor should be sensitive to the template abbreviation.
7. Click OK when ready.

## Creating a new live template from scratch

### To create a new template from scratch

1. In the Settings dialog, open the [Live Templates](#) page, and expand the template group where you want to create a new template.
2. Click **+** . A new template item is added to the group and the focus moves to the [Template Text](#) area.
3. Specify the new template abbreviation, type the template body, define the variables and the template group, configure the options, as described in the [template modification](#) procedure.
4. Click OK when ready.

## Creating a new live template from a text fragment

### To create a live template from a text fragment

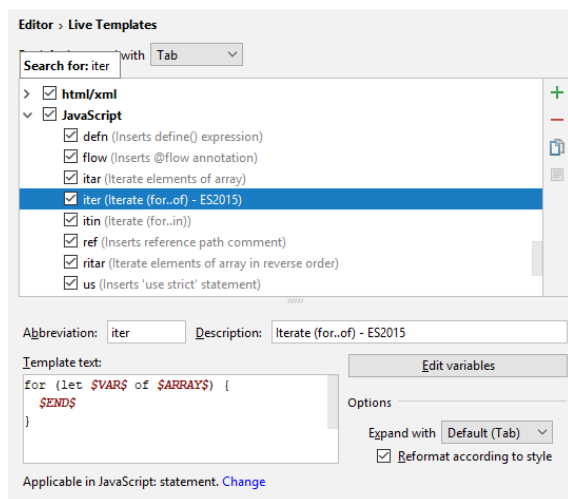

1. In the editor, select the text fragment to create a live template from.
2. On the main menu, choose Tools | Save as Live Template . The [Live Templates](#) page opens, with the [Template Text](#) area in focus.
3. In the Abbreviation field, type abbreviation to identify your new live template.
4. Specify the new template abbreviation, type the template body, define the variables and the template group, configure the options, as described in the [template modification](#) procedure.
5. Click OK when ready.

## Searching through the list of live templates

### To search through the list of live templates

- In the [Live Templates](#) page, start typing any string, which you expect to exist in the template abbreviation, body, or description.

IntelliJ IDEA shows all matching templates:

## Restoring defaults

### To restore default settings of a template

Note that a modified template is color-coded - it is shown blue.

1. In the [Live Templates](#) page, right-click a modified template to reveal its context menu.
2. Choose Restore defaults on the context menu of the modified template.

## Basics

After a [template](#) is expanded, its variables are presented in the editor as input fields. The values of these fields can be either filled in by the user or calculated by IntelliJ IDEA.

To have it done automatically, for each variable you need to specify the following:

- Expression to be calculated in association with the variable.
- Default value to be entered in the input field if the calculation fails.

The order in which IntelliJ IDEA will process input fields after the template expansion, is determined by the order of variables in the list.

## Configuring variables used in a template

### To configure variables used in a template

1. [Open the template settings](#), and in the [Template Text](#) area click the Edit Variables button.  
The Edit Variables button is enabled only if the template body contains at least one user-defined variable, that is, a variable different from `$END$` or `$SELECTION$`.
- The [Edit Template Variables](#) dialog box opens, where you can define how the variables will be processed when the template is used.
2. In the Name text box, specify the variable name to be used in the template body.
3. In the Expression drop-down list, specify the expression to be calculated by IntelliJ IDEA when the template is expanded. Do one of the following:
  - Type a string constant in double quotes.
  - Type a predefined function with possible arguments or select one from the drop-down list.  
An argument of a function can be either a line constant or another predefined function. See the [list of predefined functions](#) below on this page.
4. To enable IntelliJ IDEA to proceed with the next input field, if an input field associated with the current variable is already defined, select the Skip if defined checkbox.
5. To arrange variables in the order you want IntelliJ IDEA to switch between associated input fields, use the Move Up and Move Down buttons.

## Predefined functions to use in live template variables

### ItemDescription

<code>annotated("annotation qname")</code>	Creates a symbol of type with an annotation that resides at the specified location. For an example, see <a href="#">Live Templates in the iterations group</a> .
<code>arrayVariable()</code>	Suggests all array variables applicable in the current scope. For an example, see <a href="#">Live Templates in the iterations group</a> .
<code>anonymousSuper()</code>	Suggests a supertype for a Kotlin object expression.
<code>camelCase(String)</code>	Returns the string passed as a parameter, converted to camel case. For example, <code>my-text-file / my text file / my_text_file</code> will be converted to <code>myTextFile</code> .
<code>capitalize(String)</code>	Capitalizes the first letter of the name passed as a parameter.
<code>capitalizeAndUnderscore(sCamelCaseName)</code>	Capitalizes the all letters of a CamelCase name passed as a parameter, and inserts an underscore between the parts. For example, if the string passed as a parameter is <code>FOOBAR</code> , then the function returns <code>FOO_BAR</code> .
<code>castToLeftSideType()</code>	Casts the right-side expression to the left-side expression type. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>className(sClassName)</code>	Returns the name of the current class (the class where the template is expanded).
<code>classNameComplete()</code>	This expression substitutes for the <a href="#">class name completion</a> at the variable position.
<code>clipboard()</code>	Returns the contents of the system clipboard.
<code>snakeCase(String)</code>	Returns CamelCase string out of snake_case string. For example, if the string passed as a parameter is <code>foo_bar</code> , then the function returns <code>fooBar</code> .
<code>complete()</code>	This expression substitutes for the code completion invocation at the variable position.
<code>completeSmart()</code>	This expression substitutes for the smart type completion invocation at the variable position.
<code>componentTypeOf (&lt;array variable or array type&gt;)</code>	Returns component type of an array. For example, see the <a href="#">Live Templates in the iterations group in the other group</a> .
<code>currentPackage()</code>	Returns the current package name.
<code>date(sDate)</code>	Returns the current system date in the specified format. By default, the current date is returned in the default system format. However, if

you specify date format in double quotes, the date will be presented in this format:

<code>decapitalize(sName)</code>	Replaces the first letter of the name passed as a parameter with the corresponding lowercase letter.
<code>descendantClassEnum(&lt;String&gt;)</code>	Shows the children of the class entered as a string parameter.
<code>enum(sCompletionString1,sCompletionString2,...)</code>	List of comma-delimited strings suggested for completion at the template invocation.
<code>escapeString(sEscapeString)</code>	Escapes the specified string.
<code>expectedType()</code>	Returns the type which is expected as a result of the whole template. Makes sense if the template is expanded in the right part of an assignment, after return, etc.
<code>fileName(sFileName)</code>	Returns file name with extension.
<code>fileNameWithoutExtension()</code>	Returns file name without extension.
<code>firstWord(sFirstWord)</code>	Returns the first word of the string passed as a parameter.
<code>groovyScript("groovy code")</code>	Returns Groovy script with the specified code.  You can use <code>groovyScript</code> macro with multiple arguments. The first argument is a script text that is executed or a path to the file that contains a script. The next arguments are bound to <code>_1, _2, _3, ..._n</code> variables that are available inside your script.  Also, <code>_editor</code> variable is available inside the script. This variable is bound to the current editor.
<code>guessElementType (&lt;container&gt;)</code>	Makes a guess on the type of elements stored in a <code>java.util.Collection</code> . To make a guess, IntelliJ IDEA tries to find the places where the elements were added to or extracted from the container.
<code>iterableComponentType(&lt;ArrayOrIterable&gt;)</code>	Returns the type of an iterable component, such as an array or a collection.
<code>iterableVariable()</code>	Returns the name of a variable that can be iterated.
<code>lineNumber()</code>	Returns the current line number.
<code>lowercaseAndDash(String)</code>	Returns lower case separated by dashes, of the string passed as a parameter. For example, the string <code>MyExampleName</code> is converted to <code>my-example-name</code> .
<code>methodName()</code>	Returns the name of the embracing method (where the template is expanded).
<code>methodParameters()</code>	Returns the list of parameters of the embracing method (where the template is expanded).
<code>methodReturnType()</code>	Returns the type of the value returned by the current method (the method within which the template is expanded).
<code>qualifiedClassName()</code>	Returns the fully qualified name of the current class (the class where the template is expanded).  <b>Tip</b> Clear the Shorten FQ names check box.
<code>rightSideType()</code>	Declares the left-side variable with a type of the right-side expression. It is used in the iterations group to have a single template for generating both raw-type and Generics Collections.
<code>snakeCase(sCamelCaseText)</code>	Returns snake_case string out of CamelCase string passed as a parameter.
<code>spaceSeparated(String)</code>	Returns string separated with spaces out of CamelCase string passed as a parameter. For example, if the string passed as a parameter is <code>fooBar</code> , then the function returns <code>foo bar</code> .
<code>subtypes(sType)</code>	Returns the subtypes of the type passed as a parameter.
<code>suggestIndexName()</code>	Suggests the name of an index variable. Returns <code>i</code> if there is no such variable in scope, otherwise returns <code>j</code> if there is no such variable in scope, etc.
<code>suggestVariableName()</code>	Suggests the name for a variable based on the variable type and its initializer expression, according to your code style settings that refer to the variable naming rules.  For example, if it is a variable that holds an element within iteration, IntelliJ IDEA makes a guess on the most reasonable names, also taking into account the name of the container being iterated.
<code>suggestFirstVariableName(sFirstVariableName)</code>	Doesn't suggest <code>true</code> , <code>false</code> , <code>this</code> , <code>super</code> .
<code>time(sSystemTime)</code>	Returns the current system time.
<code>typeOfVariable(VAR)</code>	Returns the type of the variable passed as a parameter.
<code>underscoresToCamelCase(sCamelCaseText)</code>	Returns the string passed as a parameter with CamelHump letters substituting for underscores. For example, if the string passed as a parameter is <code>foo_bar</code> ,

	then the function returns <code>fooBar</code> .
<code>underscoresToSpaces(sParameterWithSpaces)</code>	Returns the string passed as a parameter with spaces substituting for underscores.
<code>user()</code>	Returns the name of the current user.
<code>variableOfType(&lt;type&gt;)</code>	Suggests all variables that may be assigned to the type passed as a parameter, for example <code>variableOfType("java.util.Vector")</code> . If you pass an empty string ("") as a parameter, suggests all variables regardless of their types.
<code>JsArrayVariable</code>	Returns JavaScript array name.
<code>jsClassName()</code>	Returns the name of the current JavaScript class.
<code>jsComponentType</code>	Returns the JavaScript component type.
<code>jsMethodName()</code>	Returns the name of the current JavaScript method.
<code>jsQualifiedClassName</code>	Returns the complete name of the current JavaScript class.
<code>jsSuggestIndexName</code>	Returns a suggested name for an index.
<code>jsSuggestVariableName</code>	Returns a suggested name for a variable.

## Configuration files with definitions of custom live templates

IntelliJ IDEA stores definitions of custom live template groups and templates added to predefined template groups in automatically generated configuration files `<group_name>.xml` .

- For a custom group, the file contains definitions of all the templates the group includes.
- For a customized predefined group, the file contains definitions of the added templates only.

Depending on the operating system you are using, the `<group_name>.xml` files are stored at the following locations:

- **Windows** : `<your_user_home_directory>\.IntelliJ IDEA<version_number>\config\templates`
- **Linux** : `~IntelliJ IDEA<version>/config/templates`
- **macOS** : `~/Library/Preferences/IntelliJ IDEA<version>/templates`

## Sharing live templates manually through configuration files

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Live Templates under Editor .
2. Create the required custom template groups and update the relevant predefined groups as necessary and click OK .  
Based on these changes, IntelliJ IDEA generates the `<group_name>.xml` files, see [Location of Custom Live Templates Definitions](#) above.
3. Locate the generated `<group_name>.xml` files and do one of the following:
  - To share the templates among your teammates, send the relevant files to them with the instruction to save the files in the `templates` folder.
  - To use the templates in another IntelliJ IDEA installation on your computer, copy the relevant files to the `templates` folder under the relevant `IntelliJ IDEA<version>` folder.

## Sharing live templates through export/import

IntelliJ IDEA allows you to easily share live templates among your team members, numerous IntelliJ IDEA installations, and even different IDE by using the standard **Export/Import** functionality. You can share custom template groups and updates to predefined groups.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Live Templates under Editor .
2. Create the required custom template groups and update the relevant predefined groups as necessary and click OK .  
Based on these changes, IntelliJ IDEA generates the `<group_name>.xml` files, see [Location of Custom Live Templates Definitions](#) above.
3. On the main menu, choose File | export Settings .
4. In the Export Settings dialog box that opens, select the Live Template checkbox and specify the name of the `.jar` file where the exported settings will be stored. When you click OK , IntelliJ IDEA generates a file with the specified name based on the `.xml` configuration files stored in the `templates` folder.
5. Do one of the following:
  - To share the templates among your teammates, pass the generated `.jar` file to them with the following instructions:
    1. Save the received `.jar` file on your computer.
    2. Choose File | Import Settings on the main menu and and specify the location of the received `.jar` file.
    3. In the Select Components to Import dialog box that opens, select the Live Templates checkbox and click OK .

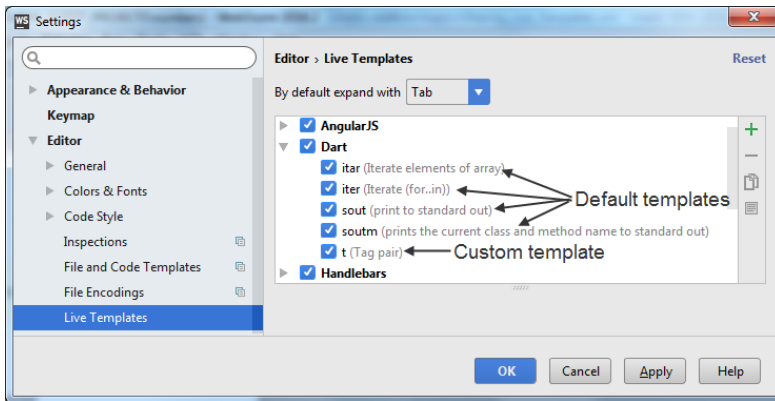

IntelliJ IDEA restarts whereupon the imported templates are displayed on the Live Templates page.

- To use the templates in another IntelliJ IDEA installation or in another IDE on your computer, open the required installation, choose File | Import Settings on the main menu, and specify the location of the generated `.jar` file.

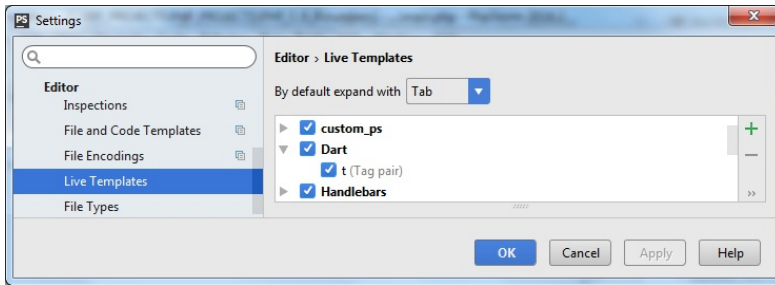

## Example of sharing templates among different IDE

Be careful when sharing templates among different IDE. If you import custom templates (updates) from a group which is predefined in the source IDE but is not predefined in the target IDE, such group will be created but will contain only the custom templates. The example below shows what happens if we add a template to a predefined group in **WebStorm** and then reuse it in **PhpStorm** .

In **WebStorm** , the **Dart** template group is predefined. If we add the `t (tag pair)` template to it, this update will be saved in the `Dart.xml` file:

In **PhpStorm**, there is no predefined template group **Dart**. So when we export the live templates from **WebStorm** and then import them into **PhpStorm**, a **Dart** group is created but it contains only one template `t (tag pair)`, which we added to the group in **WebStorm** before export:

## Sharing live templates among template groups

You can copy and move templates from one group to another.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing `File | Settings for Windows` and `Linux` or `IntelliJ IDEA | Preferences for macOS`, and click `Live Templates` under `Editor`.
2. Do one of the following:
  - To copy a template to another group:
    1. Select the template in interest. Use `Ctrl` and `Shift` keys for multiple selection.
    2. Choose `Copy` on the context menu of the selection.
    3. Select the group to copy the template to and choose `Paste` on the context menu of the selection.
  - To move a template to another group, select the required template, choose `Move` on the context menu of the selection and choose the group to move the template to.

This section describes how to quickly and accurately populate your source code with the complicated code constructs.

- [Unwrapping and Removing Statements](#)
- [Completing Punctuation](#)

On this page:

- [Introduction](#)
- [Inserting a live template](#)
- [Using live templates for smart completion of parameters in function calls](#)

## Introduction

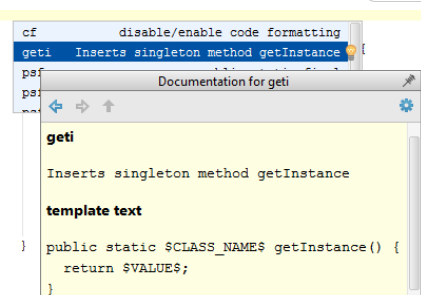

This page describes how to generate source code using [live templates](#).

Using Live Templates enables you to create such code constructs as the [main\(\) method](#), [iteration over an array](#), , typical variable declarations, output statements, Emmet, etc.

To explore the list of available live templates, in the Settings/Preferences dialog, open the [Live Templates](#) page.

## Inserting a live template

1. Place the caret at the desired position, where the new construct should be added.
2. Do one of the following:
  - On the main menu, choose Code | Insert Live Template .
  - Press `Ctrl+J` .
  - Type some initial letters of the [template abbreviation](#) to get the matching abbreviations in the suggestion list. Note that the suggestion list may contain same abbreviations for different templates.
3. From the [suggestion list](#), select the desired template. While the suggestion list is displayed, it is possible to view Quick Documentation for the items at caret, by pressing `Ctrl+Q` .

4. Press the template invocation key (this may be `Space`, `Tab` or `Enter`, depending on the template definition). The new code construct is inserted in the specified position.
5. If the selected template is [parametrized and requires user input](#), the editor enters the template editing mode and displays the first input field highlighted with the red frame. Type your value in this frame and press `Enter` or `Tab` to complete input and pass to the next input field. After completing the last input field, the caret moves to the end of the construct, and the editor returns to the regular mode of operation.

It is also possible to type a template abbreviation, and then press `Ctrl+J` .

## Using live templates for smart completion of parameters in function calls

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In the PHP context, you can use an "automatic" live template that provides completion lists for the parameters passed into functions, methods, or class constructors.

- To activate this functionality:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click Smart Keys under General .
  2. On the [Smart Keys](#) page that opens, select the Enable smart function parameters completion checkbox in the PHP area.
- To invoke the magic live template, type the `params` keyword as the first parameter in the call of the function, method, or class:

```
$result = foo(params).  
params (smart function parameters completion) [Tab]  
pg_parameter_status([connection : null|resource ... string
```

IntelliJ IDEA displays a live template where the parameters are automatically completed with the variable names defined in the function declaration. To move to the next parameter, press `Enter` or `Tab`. To move to the previous parameter, press `Shift+Tab`.

The completion list contains variables from a local scope in the next order: with the same type, with a similar name, defined nearby. You can always switch to the usual completion mode by pressing `Ctrl+Space` or just typing anything which is not in the list. Variables with similar names are inserted automatically.

This section describes how to wrap fragments of code according to [surround templates](#) .

## To surround a block of code with a live template

1. In the editor, select the piece of code to be surrounded.
2. Do one of the following:
  - On the main menu, choose Code | Surround With Live Template... .
  - Press `Ctrl+Alt+J` .
3. Select the desired template from the suggestion list.

This section contains examples demonstrating how to populate your source code with the complicated code constructs using [live templates](#) .

In this part:

- [Generating main\(\) method. Example of Applying a Simple Live Template](#)
- [Iterating over an Array. Example of Applying Parameterized Live Templates](#)
- [Wrapping a Tag. Example of Applying Surround Live Templates](#)

As an example of applying a simple live template, let us create a main() method.

## To create main() method

1. [Open](#) the desired class for editing.

2. Type the abbreviation of the main() method template:

```
psvm|
```

3. Press the template invocation key. By default, it is `Tab`. The abbreviation expands to the `main()` method:

```
public static void main(String args[]) {  
|  
}
```

As an example of applying a parameterized template, let us create a construct that iterates over an array.

## To iterate over an array

1. Open the desired class for editing.

2. Type the `itar` abbreviation:

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
itar
```

3. Press the template invocation key. The abbreviation expands into a code construct, with the suggested values for the template's variables already inserted:

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
for (int i = 0; i < arrayOfChars.length; i++) {
    char aChar = arrayOfChars[i];
}
```

4. The Editor is now in its special template editing mode. The cue is the red border around the index variable, which is the first input position in this template.

IntelliJ IDEA automatically suggests `i` as the value for the index variable. If you want to change the suggested name, type a new one. All references to the variable within the expanded template will be automatically changed as you type the new name.

In figure below, `i` is changed to `idx` :

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
for (int idx = 0; idx < arrayOfChars.length; idx++) {
    char aChar = arrayOfChars[idx];
}
```

5. Press `Tab` or `Enter` to move to the next input position defined by the template:

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
for (int idx = 0; idx < arrayOfChars.length; idx++) {
    char aChar = arr(arrayOfChars, char[])
    arrayOfInts int[]
}
```

As you can see on the image above, IntelliJ IDEA automatically detects all array elements in the scope, and suggests selecting the correct one. If there is only one array element in the scope, IntelliJ IDEA inserts its name automatically without displaying a pop-up list.

6. IntelliJ IDEA detects whether the type of the array elements changes. It automatically updates the type of the variable that holds the current array element, and suggests a list of reasonable names for it:

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
for (int idx = 0; idx < arrayOfInts.length; idx++) {
    int anInt = arrayOfInts[idx];
    anInt
    arrayOfInt
    i
    ofInt
}
```

7. Press `Tab` or `Enter` to apply the selected/specified variant. This will move you to the next input position which in our case is the END position of the template:

```
int[] arrayOfInts = new int[] {7,9,3,17,11,23,37};
char[] arrayOfChars = new char[] {'a', 'b', 'c'};
for (int idx = 0; idx < arrayOfInts.length; idx++) {
    int anInt = arrayOfInts[idx];
    |
}
```

As an example of applying a surround template, let's wrap a piece of XML code with tags.

## To surround a code fragment

1. [Open](#) the desired file for editing.
2. Select a code fragment.

```
<company>
  <name>Peter</name>
  <name>John</name>
  <name>Sarah</name>
</company>
```

3. Press invocation shortcut `Ctrl+Alt+J`. IntelliJ IDEA suggests the following surround templates:

```
<company>
  <name>Peter</name>
  <name>John</name>
  <name>Sarah</name>
</company>
Select Template
T Surround with <tag></tag>
```

4. Select the tag template from the suggestion list. The code fragment is surrounded with empty tags:

```
<company>
  < >
  <name>Peter</name>
  <name>John</name>
  <name>Sarah</name>
  </ >
</company>
```

5. The caret rests within the opening one. On typing the tag name in the opening tag, the name is automatically reproduced in the closing tag:

```
<company>
  <staff>
  <name>Peter</name>
  <name>John</name>
  <name>Sarah</name>
  </staff>
</company>
```

On this page:

- [Introduction](#)
- [Generating a constructor](#)
- [Example](#)

## Introduction

Constructor generator makes it possible to create constructors with arguments. The value of these arguments are assigned to the field variables.

The generated constructors are inserted at the points defined in the [Order of Members](#) section of the Code Style settings. By default, the code generator places constructors after the fields.

## Generating a constructor

### To generate a constructor

1. On the main menu, choose Code | Generate . Alternatively, right-click the editor and choose Generate on the context menu, or use `Alt+Insert` keyboard shortcut.
2. In the pop-up list that is displayed in the editor, select Constructor option.
3. If the class in question contains fields, IntelliJ IDEA suggests to select the fields to be initialized by constructor. In the Choose Fields to Initialize by Constructor dialog, select the desired fields.

**Tip** Use `Ctrl` and `Shift` keys for multiple selection.

4. Click OK .

## Example

```
public class MyClass {
    int aInteger;
    double bDouble;

    public MyClass(int myAIntegerParam, double myBDoubleParam) {
        aInteger = myAIntegerParam;
        bDouble = myBDoubleParam;
    }
}
```

On this page:

- [Introduction](#)
- [Creating delegation methods](#)
- [Example](#)

## Introduction

You can create methods that delegate behavior to the fields or methods of your class. This approach makes it possible to give access to the information of a field or method without direct exposing this field or method.

## Creating delegation methods

### To create a delegation method

1. Do one of the following:
  - On the main menu, choose Code | Generate .
  - Right-click the editor and choose Generate on the context menu
  - Press `Alt+Insert` .
2. In the pop-up list that is displayed in the editor, select Delegate Methods . Select Target To Generate Delegates For dialog appears, displaying the list of objects to be delegated to.
3. Select the target field or method, and click OK . The Select Method To Generate Delegation For dialog appears, displaying the list of methods to delegate.
4. Select the desired methods. For multiple selection, use `Ctrl` and `Shift` keys. Click OK .

## Example

`Currency` class has a field `calendar` of the type `Calendar` . To gain access to certain functionality of the `Calendar` class from the `Currency` class, we need to create a new method that will delegate the request to `calendar` .

```
Calendar calendar;  
public int get(int i) {  
    return calendar.get(i);  
}
```

On this page:

- [Basics](#)
- [Generating equals\(\) and hashCode\(\) methods](#)
- [Example](#)

## Basics

```
public boolean equals(Object obj)
```

This method returns `true` , if an object passed to it as an argument is equal to the object on which this method is invoked.

```
public int hashCode()
```

This method returns the integer hash code value for the object on which this method is invoked.

## Generating equals() and hashCode() methods

**Tip** If `equals()` and `hashCode()` methods already exist in a class, you will be prompted to delete them before proceeding.

To generate `equals()` and `hashCode()` methods, follow these steps:

1. Do one of the following:

- On the main menu, choose Code | Generate .
- Right-click the editor and choose Generate on the context menu.
- Press `Alt+Insert` .

2. From the pop-up list that opens in the editor, select `equals()` and `hashCode()` option to open the [Generate equals\(\) and hashCode\(\) wizard](#) .

3. Follow the steps of the wizard:

- On the first page of the wizard, select or clear the checkboxes to accept subclasses, and use getters during code generation. You can also select a [velocity template](#) from the Template drop-down list to generate the code or create a custom template.
- On the second page of the wizard, select the fields that should be used to determine equality, and click Next .
- On the third page, select the fields to generate hash code.  
Note that only the fields that were included in the `equals()` method, can participate in creating hash code. All these fields are selected by default, but you can unselect them, if necessary.

Click Next .

- On the fourth page of the wizard, select the fields that contain non-null values. This optional li help the generated code avoid check for null and thus improves performance. Click Finish .

## Example

```
public boolean equals(Object o) {
    if (this == o) return true;
    if (o == null
        || getClass() != o.getClass()) return false;
    FixedRateCurrencyExchangeService that = (FixedRateCurrencyExchangeService) o;
    if (Double.compare(that.rate, rate) != 0) return false;
    return true;
}

public int hashCode() {
    long temp = rate != +0.0d ? Double.doubleToLongBits(rate) : 0L;
    return int (temp ^ (temp >>> 32));
}
```

On this page:

- [Introduction](#)
- [Generating accessor and mutator methods](#)
  - [Example 1](#)
  - [Example 2](#)
- [Note for PHP](#)

## Introduction

You can generate accessor and mutator methods (getters and setters) for the fields of in your classes. IntelliJ IDEA generates getters and setters with only one argument, as required by the JavaBeans API.

The getter and setter method names are generated by IntelliJ IDEA according your [code generation naming preferences](#) .

## Generating accessor and mutator methods

1. Do one of the following:
  - On the main menu, choose Code | Generate .
  - Right-click the editor and choose Generate on the context menu.
  - Press `Alt+Insert` .
2. In the pop-up list that is displayed in the editor, select one of the following options:
  - Getter: Accessor methods for getting the current values of the fields that will be selected in the Choose Fields to Generate Getters and Setters dialog box.
  - Setter: Mutator methods for setting specified values to the fields.
  - Getter and Setter: Both methods.
3. In the Choose Fields to Generate Getters and Setters dialog box, select the fields to generate getters or setters for. You can add a custom setter or getter by clicking  and accessing [Getter/Setter Templates](#) dialog. If getters and setters for a field already exist, this field is not included in the list.
4. Click OK when ready.

## Example 1

Consider the following code:

```
public class MyClass {
    int aInteger;
}
```

In the Naming section of the [Code Generation](#) page, parameter prefix is set to `my` , and parameter suffix to `Param` .

After generating the getter and setter the following code will be produced:

```
public class MyClass {
    int aInteger;
    public int getAInteger() {
        return aInteger;
    }
    public void setAInteger (int myAIntegerParam) {
        aInteger = myAIntegerParam;
    }
}
```

## Example 2

However, if `a` is specified as a field prefix in the [Code Generation](#) page, then it will not take part in the generation of the method and parameter names:

```
public class MyClass {
    int aInteger;
    public int getInteger() {
        return Integer;
    }
    public void setInteger (int myIntegerParam) {
        aInteger = myIntegerParam;
    }
}
```

## Note for PHP

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In the **PHP** context, getters and setters are generated using the **PHP getter/setter** file template. By default, as specified in these templates, setters are generated with the `set` prefix and getters with the `set` or `get` prefix according to the inferred field type `boolean` or `con-boolean`. The prefix is the value of the `#{GET_OR_IS}` variable in the default getter template. The default template is configured in the Code tab on the [File and Code Templates](#) page of the [Settings / Preferences Dialog](#).

On this page:

- [Introduction](#)
- [Generating toString\(\) method](#)
  - [Inspections](#)
  - [Logging](#)
- [Examples](#)
  - [Basic code](#)
  - [Getter is enabled](#)
  - [Excluding fields and methods](#)
  - [JavaDoc](#)

## Introduction

The action Generate toString() enables creating or updating `toString()` method.

The beans usually needs to dump their field values for debug purposes, and it's rather tedious to write the dump code for it. The Generate toString() action generates the `toString()` method, dumping all the fields in a simple manner.

## Generating toString() method

### To generate toString() method

1. Open the desired class for editing and do one of the following:
  - On the main menu, choose Code | Generate .
  - Right-click the editor and choose Generate on the context menu
  - Press `Alt+Insert` .
2. From the pop-up list that shows up, select toString() option. Generate toString() wizard displays the list of fields in the class.
3. In the wizard, specify the following:
  - Select the fields to be used to generate a `toString()` method.  
By default, all the available fields are selected. Clicking the button Select None results in adding a `toString()` method consisting of method declaration and return statement only.
  - Select the desired way of generating a `toString()` method from the Templates drop-down list.
  - Select the checkbox Insert @Override if necessary.  
Refer to the section [Generate toString\(\) Dialog](#) for details.
  - If you are not happy with the settings, click the Settings button. This results in showing the toString() Generation Settings dialog box, where one can tune the function's behavior. Refer to the section [Generate toString\(\) Settings Dialog](#) for details.

When ready, click OK .

**Tip** If `toString()` method already exists in a class, you will be prompted to delete this method before proceeding, depending on the value of When method already exists setting ([Generate toString\(\) Settings Dialog](#)).

## Inspections

There are two related [code inspections](#) under the node toString() issues :

- Class does not override 'toString()' method
- Field not used in 'toString()' method

The inspection Class does not override toString() method can be used to identify any classes where you might have forgotten to add a `toString()` method.

This inspection uses the [exclude settings](#) to ignore classes with the fields not supposed to be dumped. An additional settings is to exclude certain classes by using a regular expression matching their classname. As default, this is used to exclude any Exception classes.

The inspection Field not used in 'toString()' method : This inspection can be used to identify out-of-synchronization situations, where you have an existing `toString()` method that dumps the fields. However, some fields have been added to the class later, and these new fields are not dumped in the `toString()` method.

[Change the severity of this inspection](#) by enabling it to show errors as warnings. This will highlight any unused fields on-the-fly in the editor; the right gutter will indicate the location of the errors using a yellow marker.

## Logging

Log4j is used for logging. To enable logging, open for editing the file `log.xml` used by IntelliJ IDEA. This file resides in the `bin` folder of IntelliJ IDEA installation. Add the following lines to this file:

```
<category name="org.jetbrains.generate.toString">
  <priority value="DEBUG"/>
  <appender-ref ref="FILE"/>
</category>
```

## Examples

### Basic code

Consider the following code:

```
public class MyServerConfigBean {
    private String name;
    private String url;
    private int port;
    private String[] validIPs;
    ...
}
```

Place the caret somewhere within the class, press `Alt+Insert`, and choose `toString()` from the pop-up list. The following method is now added to the bean:

```
public String toString() {
    return "MyServerConfigBean{" +
        "name='" + name + '\'' +
        ", url='" + url + '\'' +
        ", port=" + port +
        ", validIps=" + Arrays.toString(validIps) +
        '\'';
}
```

### Getter is enabled

Consider the following code:

```
public class MyServerConfigBean {
    private String name;
    private String url;
    private int port;
    private String[] validIPs;
    ...
    public String getServerAddress() {
        return url + ":" + port;
    }
    ...
}
```

Place the caret somewhere within the class, press `Alt+Insert`, and choose `toString()` from the pop-up list. After invoking the action `Generate toString()`, the result is:

```
public String toString() {
    return "MyServerConfigBean{" +
        "name='" + name + '\'' +
        ", url='" + url + '\'' +
        ", port=" + port +
        ", serverAddress='" + getServerAddress() + "'" +
        ", validIps=" + Arrays.toString(validIps) +
        '\'';
}
```

### Excluding fields and methods

Refer to the [Exclude section](#) of the Settings dialog.

Usually you don't want to add constant fields as the debug information in your `toString()` method. So you select the checkbox `Exclude constant fields`, and prevent constant fields in the output.

Besides that, it is possible to filter by the field's name, to exclude, say, an internal debug field. So, type `^debug` in the text field `Exclude fields by name (reg exp)`, to prevent debug fields.

The example below shows the results with excluded fields. The original code is:

```

public class MyServerConfigBean {
    private final static String USERNAME = "scott";
    private final static String PASSWORD = "tiger";
    private String name;
    private String url;
    private int port;
    private String[] validIPs;
    ...
    public String getServerAddress() {
        return url + ":" + port;
    }
    private boolean debug = true;
}
...
}

```

After generating a `toString()` method, the code looks like the following:

```

public String toString() {
    return "MyServerConfigBean{" +
        "name='" + name + '\'' +
        ", url='" + url + '\'' +
        ", port=" + port +
        ", validIps=" + Arrays.toString(validIps) +
        '\'' +
    }
}

```

As you see, the constant fields (USERNAME, PASSWORD) are not used in the generated code. The regular expression excludes the debug field. The excluded fields do not appear in the [Generate toString\(\) Dialog](#).

To exclude a method, select the checkbox Exclude methods by name (reg exp) field. For example, if you type `^getCausedBy.*` in the text field Exclude methods by name (reg exp), you will thus prevent outputting methods whose names start with `getCausedBy`.

## JavaDoc

It is possible to add JavaDoc comments to the generated `toString()` method. This is done by inserting the JavaDoc comments in a [Velocity template](#). See the following template example:

```

/**
 * Insert your JavaDoc comments here
 *
 * @return a string representation of the object.
 */
return "${classname}";

```

## Introduction

If a class is declared as implementing a certain interface or extending a class with abstract methods, it has to implement the methods of such interface or class. IntelliJ IDEA creates stubs of the implemented methods, with the default return values for the primitive types, and null values for the objects.

## Implementing methods

To implement method of an interface or abstract class, follow these steps:

1. Do one of the following:

- On the main menu, choose Code | Implement methods... .
- Press `Ctrl+I`
- Right-click the editor, choose Generate on the context menu, or press `Alt+Insert`, and choose Implement methods... .

The Select methods to implement dialog appears, displaying the list of classes and interfaces with the methods that can be implemented.

2. Select one or more methods to implement. For multiple selection, use `Ctrl` and `Shift` keys.
3. If necessary, select the checkbox Copy JavaDoc to insert JavaDoc comments from the implemented interface of abstract methods (if any).
4. Click OK .

## Changing method body

File template responsible for implementing a method ( Implemented method body ) accepts predefined template variables from "File Header" File | Settings/IntelliJ IDEA | Preferences - Editor - File and Code Templates - Code - File Header e.g. `${USER}`, `${DATE}`, etc.

For example, consider the following file template:

```
#if ( $RETURN_TYPE != "void" )return $DEFAULT_RETURN_VALUE;#end
// TODO ($USER, $DATE):To change the body of an implemented method, use File | Settings - Editor - File
```

Provided that an implemented interface contains two methods, this template expands into the following code:

```
@Override
public void hunt() {
// TODO (wombat, 9/21/12): To change the body of an implemented method, use File | Settings - Editor -
}
@Override
public String sniff() {
return null; // TODO (wombat, 9/21/12): To change body of implemented methods use File | Settings - Edi
}
```

On this page:

- [Overview](#)
- [Overriding methods](#)
- [Changing method body](#)

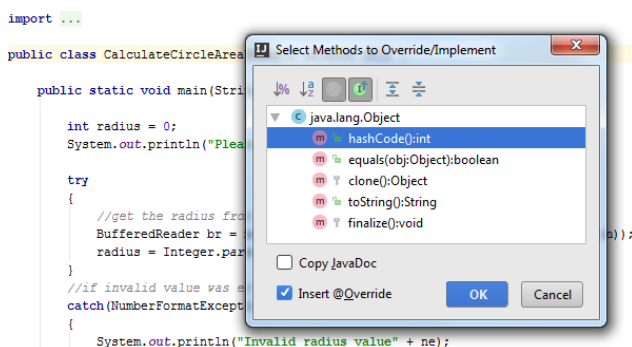

## Overview

You can override any method of a parent class, using the code generation facility. IntelliJ IDEA creates a stub that contains a call to the method of the superclass, leaving the developer with the task of providing some meaningful source code.

## Overriding methods

To override methods, follow these steps:

1. With the class in question having the focus, invoke the Override method command in one of the following ways:
  - Press `Ctrl+O`.
  - On the main menu, choose Code | Override method.
  - Right-click the editor, choose Generate on the context menu, or press `Alt+Insert`, and choose Override methods.
2. Select methods that can be overridden from the Select methods to override dialog box. The list of methods does not include the methods that are already overridden, or cannot be accessed from the current subclass.

3. Select one or more methods to override.
4. If necessary, select the following options:
  - Insert @Override to add the @Override annotation.
  - Copy JavaDoc to insert JavaDoc comments from the overridden methods (if any).
5. Having generated the overriding method, create the required source code. Note the  icon that marks the overriding method in the left gutter. Use this icon to view the name of the base class, and [navigate to the overridden method](#).

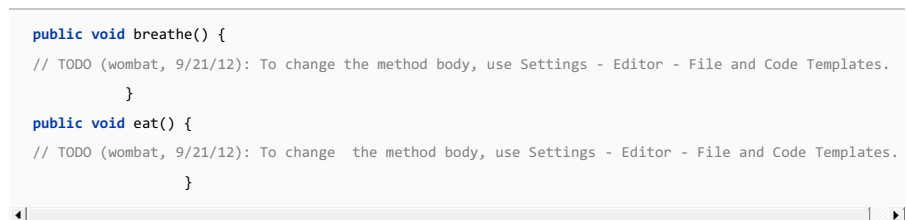

## Changing method body

File template responsible for overriding a method ( Overridden method body ) accepts predefined template variables from "File Header" ( File | Settings - Editor - File and Code Templates - Code - File Header ), e.g. `${USER}` , `${DATE}` , etc.

For example, consider the following file template:

Provided that an overridden class contains two methods, this template expands into the following code:

On this page:

- [Defining arrangement rules](#)
- [Rearranging code](#)
- [Example](#)

## Defining arrangement rules

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Code Style under Editor .
2. Under the Code Style node, select the appropriate language.
3. On the Arrangement tab of the language settings, specify [rules](#) for your code rearrangement and click OK .

## Rearranging code

You can rearrange your code according to your [arrangement rules preferences](#) .

1. In the editor select a part of the code that you want to rearrange.
2. On the main menu, choose Code | Rearrange Code .

Alternatively, in the project tool window, right-click the file where you want to perform the code rearranging, select Code | Reformat Code .

3. In the dialog that opens, select Rearrange entries checkbox and click OK .

## Example

Consider the following code that lets you test an arrangement rule that puts fields before methods:

### BeforeAfter

```
class Test {
public void test(){
}
private int i;
}
class Test2 {
public void test(){
}
private int i;
private int j;
}
```

```
class Test {
private int i;
public void test() {
}
}
class Test2 {
private int i;
private int j;
public void test() {
}
}
```

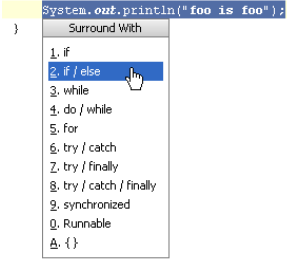

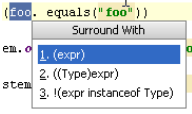

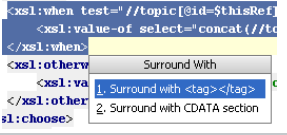

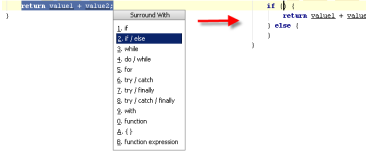

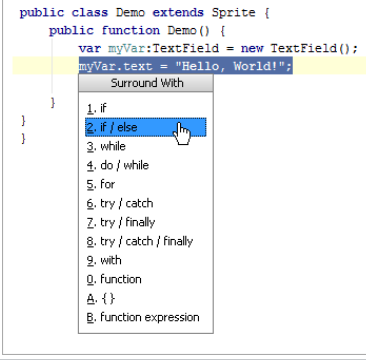

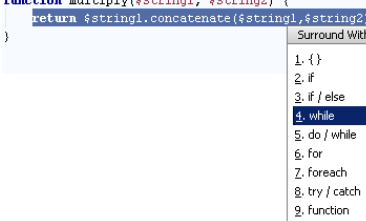

On this page:

- [Applicable contexts](#)
- [Surrounding blocks of code](#)

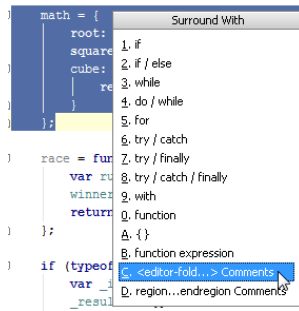

## Applicable contexts

The Surround with feature ( Code | Surround with or `Ctrl+Alt+T` ) lets you put expressions or statements within blocks or language constructs. This feature in IntelliJ IDEA applies to:

### Context Surround with

Context	Example
Java statements	<pre>- if - if/else - while - do/while - for - try/catch - try/finally - try/catch/finally - synchronized - Runnable - {}</pre> 
Java expressions	<pre>- (expr) - ((Type)expr) - !(expr instanceof Type)</pre> 
XML/HTML /JSP/JSPX tags	<pre>- Tag - CDATA section - &lt;% ... %&gt; - Emmet</pre> 
JavaScript statements	<pre>- (expr) - !(expr) - if - if / else - while - do / while - for - try / catch - try / finally - try / catch / finally - with - function - { } - function expression</pre> 
ActionScript statements	<pre>- if - if / else - while - do / while - for - try / catch - try / finally - try / catch / finally - with - function - { } - function expression</pre> 
PHP statements	<pre>- if - if / else - while - do / while - for - foreach - try / catch - function</pre> 

Custom folding region comments Any fragment of code, where Surround With is applicable

## Surrounding blocks of code

### To surround a block of code

1. Select the desired code fragment.
2. Do one of the following:
  - On the main menu, choose Code | Surround With
  - Press `Ctrl+Alt+T` .

A pop-up window displays the list of enclosing statements according to the context.

3. Select the desired surround statement from the list. To do that, use the mouse cursor, up and down arrow keys, or a shortcut key displayed next to each element of the list.

IntelliJ IDEA enables you to quickly unwrap or extract expressions from the enclosing statements. This action is available for:

- Java: `for`, `foreach`, `if...elseif...else`, `try...catch...finally`, `while...do`, `do...while`, and lone braces.

- Groovy

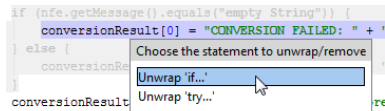

- JavaScript: `if...else`, `for`, `while`, and `do...while` control structures.

- XML, HTML, and JSP.

- PHP: `if`, `else`, `while`, `do...while`, `for`, and `try...catch` control structures

## To unwrap or remove a statement

1. Place the caret on the expression you want to extract or unwrap.
2. Choose Code | Unwrap/Remove on the main menu or press `Ctrl+Shift+Delete`. IntelliJ IDEA shows a pop-up window with all the actions that are available in the current context. Statements to be extracted are displayed on the blue background, statements to be removed are displayed on the grey background.

3. Click the desired action or select it using the up and down arrow keys and press `Enter`.

On this page:

- [Introduction](#)
- [Configuring paired elements behavior](#)

## Introduction

In the [Editor](#), you can configure the editor's behavior related to the paired braces. When the option `Insert pair }` is enabled, the closing brace is automatically added with indent on pressing `Enter`. Indentation level is defined in the [Code Style settings](#).

## Configuring paired elements behavior

### To configure insertion of paired elements

1. Press `Ctrl+Alt+S` or choose `File | Settings` (for Windows and Linux) or `IntelliJ IDEA | Preferences` (for macOS) on the main menu, and then go to `Editor | General | Smart Keys`.
2. Configure automatic insertion of paired elements by selecting the following checkboxes:
  - `Insert pair bracket`
  - `Insert pair quote`
  - `Auto-close tag on typing '</'`
  - `Insert pair %> in JSP`
3. To have the closing braces inserted upon pressing `Enter`, select the `Insert pair }` checkbox.
4. Apply changes and click `OK`.

This section covers various techniques of context-aware code completion that allow you to speed up the coding process.

## Basic code completion. Completing names and keywords

Basic code completion helps you complete names of classes, methods, fields, and keywords within the visibility scope.

When you invoke code completion, IntelliJ IDEA analyses the context and suggests the choices that are reachable from the current caret position.

Code completion covers supported and custom file types. However, IntelliJ IDEA does not recognize the structure of custom file types and suggests completion options regardless of whether a specific type is appropriate in the current context.

If basic code completion is applied to part of a field, parameter, or a variable declaration, IntelliJ IDEA suggests a list of possible names depending on the item type.

Invoking Basic code completion for the second time shows the names of classes available through module dependencies.

When invoked once more (for the third time in a row), the suggestion list expands to the whole project, regardless of dependencies. This action completes the names of classes and interfaces searching through the entire project. If the desired class is not yet imported, it will be imported automatically.

**Note** Live templates also appear in the basic completion suggestions list.

To use basic code completion:

1. Start typing a name.
2. Press `Ctrl+Space` or choose Code | Completion | Basic from the main menu.

```
} catch (NumberFormatException nfe) {
    if (nfe.getMessage().equals("empty String")) {
        nfe
        conversionFactor
    }
}
```

Press Ctrl+Shift+Space to show only variants that are suitable by type

3. If necessary, press `Ctrl+Space` for the second time (this action produces the same effect as pressing `Ctrl+Alt+Space`).

This shows all classes available through module dependencies. The second completion also shows static fields and methods.

```
} catch (NumberFormatException nfe) {
    if (nfe.getMessage().equals("empty String")) {
        nfe
        new
        null
        notify()
        notifyAll()
    }
}
return Query.not(QueryExp queryExp) (javax.management) QueryExp
Bindings.not(ObservableBooleanValue op) (javaxf.. BooleanBinding
Expression.not(...) (com.sun.javafx.fxml.expre.. UnaryExpression
Collections.nCopies(int n, T o) (java.util) List<T>
Collections.newSetFromMap(Map<E, Boolean> map) (java.ut.. Set<E>
To import a method statically, press Alt+Enter >>
```

When invoked for the third time, basic code completion expands the suggestion list to all classes throughout the project, regardless of the dependencies.

**Tip** You can configure IntelliJ IDEA to automatically invoke the suggestions list, without having to call basic completion explicitly. To do this, in the main menu select File | Settings (or press `Ctrl+Alt+S`), on the left choose Editor | General | Code Completion, and select the Autopopup code completion option.

You can also select the Insert selected variant by typing dot, space, ect. option to use some keys to accept completion. These keys depend on the language, your context, etc.

For Java, such keys include `Space`, `Tab`, `[` and `]`, `(` and `)`, and some more.

Note that while this setting helps you save time, turning it on may result in items being inserted accidentally.

## Smart code completion. Completing code based on type information

Smart code completion filters the suggestions list and shows only the types applicable to the current context.

Smart code completion is useful in situations when it is possible to determine the appropriate type:

- In the right part of assignment statements
- In variable initializers
- In `return` statements
- In the list of arguments of a method call
- After the `new` keyword in an object declaration
- In chained expressions

To use smart code completion:

1. Start typing. Press `Ctrl+Shift+Space` or choose Code | Completion | SmartType from the main menu.

SmartType code completion automatically highlights the selection in the suggestions list that is most suitable for the current context.

For example, consider smart type code completion after the `new` keyword in Java:

For chained expressions, suggestions are sorted by how frequently they are used in the project. When any of the suggested method calls takes an argument that is not yet available in the context, after you select it the IDE defines a local variable of the required type.

- If necessary, press `Ctrl+Shift+Space` once again. This lets you complete:
  - Collections, lists and arrays. IntelliJ IDEA searches for symbols with the same component type and suggests converting them.
  - Static method calls or constant references. IntelliJ IDEA scans for static methods and fields, and suggests the ones suitable in the current context.

**Note** This is only available for Java and requires the project to be built with the IntelliJ IDEA compiler (not the Gradle compiler).

## Completing statements

Complete statements enables you to create syntactically correct code constructs. This command inserts necessary syntax elements (parentheses, braces, semicolons etc.) and gets you in position where you can start typing the next statement.

To automatically complete a statement, start typing it. The punctuation required in the current context is added and the caret moves to the next editing position.

- Completing a method declaration : start typing a method declaration and press `Ctrl+Shift+Enter` after the opening parenthesis:

```
public void readLineItem(LineItem lineItem) {
```

This will create an entire construct of a method, the caret resting inside the method body:

```
public void readLineItem(LineItem lineItem) {
    |
```

- Completing code constructs : start typing a code construct and press `Ctrl+Shift+Enter` :

```
public void readLineItem(LineItem lineItem) {
    if (
    }
    |
```

IntelliJ IDEA automatically completes the construct, and the caret is placed at the next editing position:

```
public void readLineItem(LineItem lineItem) {
    if ( ) {
    }
    |
```

- Automatic encapsulation : IntelliJ IDEA automatically encapsulates a method call when you directly type a new method call next to it.

For example, type

```
| "test"
```

and then type the method call. When `println` gets the focus in the suggestion list, select it with

`Ctrl+Shift+Enter` :

```
System.out.println("test");
System.out.println()
System.out.print(boolean b)
System.out.print(char c)
System.out.print(char[] s)
```

The resulting code will look like the following:

```
System.out.println("test");
```

## Completing tag names

IntelliJ IDEA automatically completes tags and attributes names and values in the following file types:

- HTML/XHTML
- XML/XSL
- JSP/JSPX

Automatic tag name completion is based on the [DTD or Schema](#) the file is associated with.

If there is no schema association, IntelliJ IDEA will use the file content (tag and attribute names and their values) to complete your input.

In XML/XSL and JSP/JSPX files, completion for taglibs and namespaces is available.

## Completing tag names

1. Press `<` and start typing the tag name. IntelliJ IDEA displays the list of tag names appropriate in the current context.  
Use the `ArrowUp` and `ArrowDown` buttons to scroll through the list.
2. Press `Enter` to accept a selection from the list.  
IntelliJ IDEA automatically inserts the mandatory attributes according to the schema.

## Inserting a taglib declaration

1. Start typing a tag and press `Ctrl+Alt+Space`.
2. Select a tag from the list. The `uri` of the taglib it belongs to is displayed in brackets.

3. Select the desired taglib and press `Enter`. IntelliJ IDEA adds the declaration of the selected taglib:

```
<%@ taglib prefix="h" uri="http://java.sun.com/jsp/html" %>
<h:inputText|
```

## Importing a taglib declaration

1. Start typing a taglib prefix and press `Alt+Insert`.
2. Select a taglib from the list and press `Enter`.

IntelliJ IDEA imports the selected taglib and adds the import statement automatically.

## Hippie completion. Expanding words based on context

Hippie completion is a completion engine that analyses your text in the visible scope and draws its completion proposals from the current context. It helps you complete a word with a keyword, class name, method or variable.

To expand a string at caret to an existing word, do the following:

1. Type the initial string and do one of the following:
  - Press `Alt+Slash` or choose Code | Completion | Cyclic Expand Word to search for matching words before the caret
  - Press `Shift+Alt+Slash` or choose Code | Completion | Cyclic Expand Word (Backward) to search for matching words after the caret and in other open files.

The first suggested value appears, and the prototype is highlighted in the source code:

```
static String[] convertMetersToInches (String metersToConvertString) {
    String[] conversionResult = new String[2];
    double conversionFactor = 39.37;
    try {
        double metersToConvertDouble = Double.parseDouble(metersToConvertString);
        double
```

2. Press `Enter` to accept the suggestion, or hold the `Alt` key and keep pressing `Slash` until the desired word is found.

## Postfix code completion

Postfix code completion helps you reduce backward caret jumps as you write code. It allows you to transform an already typed expression to a different one based on a postfix you type after a dot, the type of expression, and its context.

For example, the `.if` postfix applied to an expression wraps it with an `if` statement.

### Before After

To enable/disable the postfix completion feature or separate templates, in the [Settings / Preferences Dialog](#) dialog, go to Editor | General | Postfix completion. You can also choose which key you want to use to expand postfix templates: `Tab`, `Space`, or `Enter`.

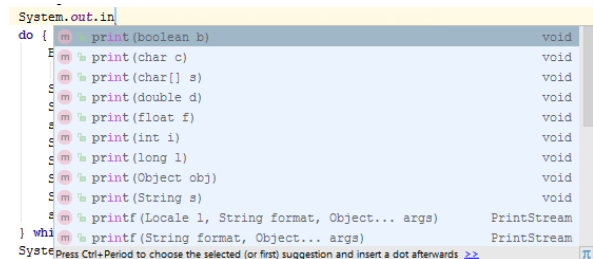

Postfix completion suggestions are shown as part of the basic completion suggestions list. To see a full list of postfix completions applicable in the current context, press `Ctrl+J`.

## Completion tips and tricks

### Narrow down the suggestions list

You can narrow down the suggestions list by typing any part of a word (even characters from somewhere in the middle), or invoking code completion after a dot separator. IntelliJ IDEA will show suggestions that include the characters you've entered in any positions.

This makes the use of wildcards unnecessary:

In case of CamelCase or snake\_case names, type the initial letters only. IntelliJ IDEA automatically recognizes and matches the initial letters.

### Accept a suggestion

You can accept a suggestion from the list in one of the following ways:

- Press `Enter` or double-click the desired choice to insert completion to the left from the caret.
- Press `Tab` to replace the characters to the right from the caret.
- Use `Ctrl+Shift+Enter` to make the current code construct syntactically correct (balance parentheses, add missing braces and semicolons, etc.)

### Negate an expression

You can negate an expression in Java by pressing `!` after you have selected it from the suggestions list:

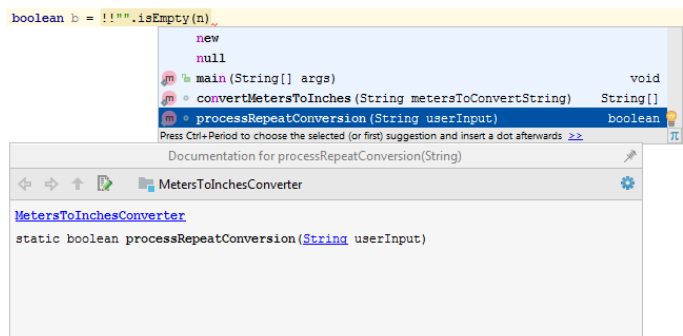

Negating an expression works this way if you have the Insert selected variant by typing dot, space, etc. option enabled in the [Code Completion settings page](#), or invoke code completion explicitly, or change a selection in the suggestions list explicitly.

### View reference information

- You can use the [Quick Definition View](#) by pressing `Ctrl+Shift+I` when you select an entry in the suggestions list:

- You can use the [Quick Information View](#) by pressing `Ctrl+Q` when you select an entry in the suggestions list:

## Sort entries in the suggestions list

You can sort the suggestions list alphabetically or by relevance. To toggle between these modes, click **A** or **z** respectively in the lower-right corner of the list.

**Note** The sorting icons only appear if the list is long and are not displayed for lists containing just a few entries.

IntelliJ IDEA will remember your choice. You can change the default behavior in the [Code Completion settings page](#).

## View code hierarchy

You can view code hierarchy when you've selected an entry from the suggestions list:

- Press **Ctrl+H** to view type hierarchy.
- Press **Ctrl+Alt+H** to view call hierarchy.
- Press **Ctrl+Shift+H** to view method hierarchy.

In this part:

- [Creating Imports](#)
- [Excluding Classes from Auto-Import](#)
- [Optimizing Imports](#)

In this section:

- [Introduction](#)
- [Importing packages on the fly](#)
- [Completing a short class name and importing a PHP namespace on-the-fly](#)
- [Importing a PHP namespace using a quick fix](#)
- [Importing TypeScript symbols](#)
- [Importing an XML namespace](#)

## Introduction

When you reference a class that has not been imported, IntelliJ IDEA helps you locate this file and add it to the list of imports. You can import a single class or an entire package, depending on your settings.

The import statement is added to the imports section, but the cursor does not move from the current position, and your current editing session does not suspend. This feature is known as the Import Assistant .

**Tip** To configure the way auto-import works, [open the IntelliJ IDEA settings](#) , and then go to the page [Auto Import](#) .

The same possibility applies to the XML , JSP, and JSPX files. When you [type a tag with an unbound namespace](#) , import assistant suggests to create a namespace and offers a list of appropriate choices.

When you reference a PHP class that is defined outside the current file, IntelliJ IDEA locates the class definition, whereupon you can do one of the following:

- Have IntelliJ IDEA automatically complete the fully qualified class name, including the namespace the class is defined in. This will result in littering your code.
- Have IntelliJ IDEA automatically complete the short class name and import the namespace the class is defined in.
- Import the namespace manually using a quick fix.

In the PHP context, a namespace is imported by inserting a `use` statement.

## Importing packages on the fly

To import packages on-the-fly, follow these steps:

1. Start typing a name in the editor. If the name references a class that has not been imported, the following prompt appears:

If the pop-up annoys you, change this behavior for the current file. Just click Hector  in the [Status bar](#) , and clear the check box `Import Pop-up` :

The unresolved references will be underlined, and you will have to [invoke intention action](#) `Add import` explicitly.

2. Press `Alt+Enter` . If there are multiple choices, select the desired import from the list.

**Tip** IntelliJ IDEA provides a quick fix that automatically installs the package you're trying to import; if, after the keyword `import` , you type a name of a package that is not currently available on your machine, a quick fix suggests to either ignore the unresolved reference, or download and install the missing package:

**Tip** If the option `Add unambiguous imports on the fly` is checked, IntelliJ IDEA does not inform you about the needed import, if there is only one choice, and adds the only possible import automatically.

## Completing a short class name and importing a PHP namespace on-the-fly

To compile a short class name and import a PHP namespace, follow these steps:

1. To enable on-the-fly namespace import, [open the IntelliJ IDEA settings](#) , and then click `Auto Import` under the `Editor` node. In the `Editor: Auto Import` page that opens, configure automatic namespace import in the `PHP` section.
  - To have IntelliJ IDEA automatically import PHP namespaces, add `use` statements, and complete short class names on the fly when you are typing in a class or file that belongs to a certain namespace, select the `Enable auto-import in`

namespace scope check box. This check box is selected by default.

- To have automatic namespace import applied when you are typing in a file that does not belong to any specific namespace, select the Enable auto-import in file scope check box.

2. Open the desired file for editing and start typing the short name of a class.
3. From the suggested variants for completion, select the relevant class name:

IntelliJ IDEA completes the short class name and inserts a `use` statement with the namespace where the selected class is defined:

## Importing a PHP namespace using a quick fix

To import a PHP class using a quick fix, follow these steps:

1. Open the desired file for editing and reference a PHP class. If the referenced class is not bound, the following prompt appears:

2. Press `Alt+Enter`. IntelliJ IDEA suggests to import the namespace where it has detected the declaration of the class:

3. Press `Enter`. IntelliJ IDEA inserts a namespace declaration statement (`use` statement):

## Importing TypeScript symbols

In the **TypeScript** context, IntelliJ IDEA can generate `import` statements for modules, classes, and any other symbol that can be exported and called as a type. Open the desired file in the editor and do one of the following:

- Start typing the short name of a symbol. From the suggested variants for completion, select the relevant symbol name:

- Position the cursor at the unresolved symbol, which is displayed in red, and press `Alt+Enter`:

On the context menu, select `Add import statement` and press `Enter`.

- Configure IntelliJ IDEA to show a pop-up every time you hover the mouse pointer over an unresolved reference which required import:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`. Expand the `Editor` node, and then click `Auto Import` under `General`.
2. On the [Auto Import](#) page that opens, select the `Show import pop-up` check box in the `TypeScript` area.

Every time you hover the mouse pointer over an unresolved symbol, IntelliJ IDEA will display the following pop-up message:

Press `Alt+Enter` to have an import statement generated and inserted automatically.

In either case, IntelliJ IDEA inserts an `import` statement:

```
import One = MyModule.One;
var test: One;
```

You can configure the quotes style for generated `import` statements on the [Code Style. TypeScript](#) page, tab Punctuation (File | Settings | Editor | Code style | TypeScript | Punctuation for Windows and Linux or IntelliJ IDEA | Preferences | Editor | Code style | TypeScript | Punctuation for macOS).

## Importing an XML namespace

To import an XML namespace, follow these steps:

1. Open the desired file for editing, and start typing a tag. If a namespace is not bound, the following prompt appears:

2. Press `Alt+Enter`. If there are multiple choices, select the desired namespace from the list.

Depending on the file type, IntelliJ IDEA creates a namespace declaration, or a taglib:

On this page:

- [Introduction](#)
- [Configuring imports](#)
- [Excluding classes from imports](#)

## Introduction

The list of imports suggested by IntelliJ IDEA can be sometimes far too wide, and can include the classes you don't actually need. For example, some of the class names in your project can match the names of internal SDK or unrelated library classes.

IntelliJ IDEA lets you configure the classes to be excluded from import assistance and code completion, thus helping avoid unintentional use of the wrong classes. Besides that, IntelliJ IDEA provides an intention action that allows you to exclude unnecessary classes on-the-fly.

These settings apply to code completion as well. The classes and packages specified as the ones to be ignored by the code completion feature, will not be added to the suggestion list.

## Configuring imports

### To configure classes to be excluded from import

1. [Open the Settings/Preferences dialog box](#) , and under the Editor / General node, click Auto-Import .
2. On the [Auto-Import](#) page, click **+** ( `Alt+Insert` ).
3. In the dialog box that opens, type the name of the class or a whole package to be excluded, and click OK . Use **+** ( `Alt+Insert` ) and **-** ( `Alt+Delete` ) to manage the list of classes and packages that IntelliJ IDEA shouldn't place to the suggestion list.
4. Apply changes and close Settings/Preferences dialog.

## Excluding classes from imports

### To exclude classes from imports in the fly

1. Start typing a name in the editor, and use intention action as described in the section [Creating Imports](#) :

`java.io.OutputStream? (multiple choices...) Alt+Enter`  
`OutputStream,`

2. In the Class to Import suggestion list, select the class you want to be ignored, and click the right arrow to reveal the nested list of intention actions. IntelliJ IDEA suggests you to exclude specific class or the whole containing package:

3. Click the desired class or package to be excluded.

In this section:

- [Introduction](#)
- [Optimizing imports in project](#)
- [Optimizing imports in the current file](#)

## Introduction

Sooner or later, some of the imported classes or packages become redundant to the code.

Typically, you have to stop what you are doing, scroll to the head of the file, find the unused imports, and remove them. It is rather easy to forget to remove imports when you remove usages.

IntelliJ IDEA provides the Optimize Imports feature, which enables you, whenever it is convenient, to remove unused imports from your current file, or from all files in the current directory at once. This helps you avoid unused, excessive and duplicating imports in your project.

One can remove unused import statements in the entire project or in the current file only.

## Optimizing imports in project

To optimize imports in the entire project, follow these steps:

1. Place the caret at the Project tool window and do one of the following:
  - On the main menu, choose Code | Optimize Imports .
  - On the context menus of the Project tool window, choose Optimize Imports .
  - Press `Ctrl+Alt+O` .

The [Optimize Imports](#) dialog box opens.

2. If your project is under version control, the option Only VCS changed files is enabled. Select or clear this option as required.
3. Click Run .

## Optimizing imports in the current file

One way of dealing with unused import is to use the quick-fix that appears when you set the caret at the highlighted unused import . However, you can optimize imports in a larger scope as described below.

To optimize imports in the currently opened file, do one of the following:

- On the main menu, choose Code | Optimize Imports .
- Press `Ctrl+Alt+O` .
- Place the caret at the import statements, click , and choose Remove unused import .
- Open the [Reformat File Dialog](#) (`Ctrl+Shift+Alt+L`) and select the Optimize imports checkbox.

## Code analysis basics

IntelliJ IDEA features robust, fast, and flexible static code analysis. It detects the language and runtime errors, suggests corrections and improvements before you even compile .

IntelliJ IDEA performs code analysis by applying inspections to your code. Numerous code inspections exist for Java and for the other supported languages.

The inspections detect not only compiling errors, but also different code inefficiencies. Whenever you have some unreachable code, unused code, non-localized string, unresolved method, memory leaks or even spelling problems – you'll find it very quickly.

IntelliJ IDEA's code analysis is flexibly configurable. You can [enable/disable](#) each code inspection and [change its severity](#) , create [profiles](#) with custom sets of inspections, apply inspections differently [in different scopes](#) , [suppress](#) inspections in specific pieces of code, and more.

The analysis can be performed in several ways:

- By default, IntelliJ IDEA analyses all open files and highlights all detected code issues right in the editor. On the right side of the editor you can see the analysis status of the whole file (the icon in the top-right corner).  
When an error is detected, this icon is  ; in case of a warning, it is  ; if everything is correct, the icon is  .
- Alternatively, you can run code analysis in a [bulk mode](#) for the specified scope, which can be as large as the whole project.
- If necessary, you can [apply a single code inspection](#) in a specific scope.

For the majority of the detected code issues, IntelliJ IDEA provides [quick fix suggestions](#) . You can quickly review errors in a file by navigating from one highlighted line to another by pressing [F2](#) [Shift+F2](#) .

For more information and procedural descriptions, see [Configuring Inspection Severities](#) .

## Inspection profiles

When you inspect your code, you can tell IntelliJ IDEA which types of problems you would like to search for and get reports about. Such configurations can be preserved as inspection profiles .

An inspection profile defines the types of problems to be sought for, i.e. which code inspections are [enabled/disabled](#) and the [severity](#) of these inspections. Profiles are configurable in the [Inspections](#) settings page.

To set the current inspection profile (the one that is used for the on-the-fly code analysis in the editor), simply select it in the [Inspections](#) settings page and apply changes. When you [perform code analysis](#) or [execute a single inspection](#) , you can specify which profile to use for each run.

Inspection profiles can be applicable for the entire IDE or for a specific project:

- Project profiles are shared and accessible for the team members via VCS. They are stored in the project directory:  
`<project>/idea/inspectionProfiles` .
- IDE profiles are intended for personal use only and are stored locally in XML files under the `USER_HOME/.<IntelliJ IDEA version>/config/inspection` directory.

IntelliJ IDEA comes with the following pre-defined inspection profiles:

- Default : This local (IDE level) profile is intended for personal use, applies to all projects, and is stored locally in the `Default.xml` file under the `USER_HOME/.<IntelliJ IDEA version>/config/inspection` directory.
- Project Default : when a new project is created, the Project Default profile is copied from the [settings of a template project](#) . This profile is shared and applies to the current project.

After a project is created, any modifications to the project default profile will pass unnoticed to any other projects.

When the settings of the Project Default profile are modified in the [Template Project settings](#) , the changed profile will apply to all newly created projects, but the existing projects will not be affected as they already have a copy of this profile.

Project Default profile is stored in the `Project_Default.xml` file located in the `<project>/idea/inspectionProfiles` directory.

One can have as many inspection profiles as required. There are two ways of creating new profiles: you can [add a new profile](#) as a copy of the Project Default profile or [copy](#) the currently selected profile. The newly created profiles are stored in XML files, located depending on the [type of the base profile](#) .

The `<profile_name>.xml` files representing inspection profiles appear whenever some changes to the profiles are done and applied. The files only store differences against the default profile.

In case of the [file-based project format](#) , the shared profiles are stored in the project file `<project name>.ipr` .

Refer to the section [Customizing Profiles](#) for details.

## Synchronizing profiles between computers

If an inspection profile is made project-specific, it is synchronized with your project automatically. Each user, who opens this project after checking it out, will have the same inspection profile enabled.

If an IDE Default inspection profile is used, it can be synchronized between multiple machines via the **Settings Repository plugin**, bundled with IntelliJ IDEA. So doing, the file is stored in `USER_HOME/.<IntelliJ IDEA version>/config/inspection/<profile_name>.xml`.

Note that the Global profile may have a different name. Copy your current project profile to the Global Level (click the button Manage and choose Copy as Global) and call it as you like.

Then, on the main menu, choose File | Other Settings | Default Settings and select this global profile as the default one for all the new projects. Now all the newly-created projects will use this global profile by default and this global profile will be synchronized between the various machines via the **Settings Repository plugin**.

## Inspection severity

Inspection severity indicates how seriously the code issues detected by the inspection impact the project and determines how the detected issues should be highlighted in the editor. By default, each inspection has one of the following severity levels:

- Server problem 
- Typo 
- Info 
- Weak Warning 
- Warning 
- Error 

You can increase or decrease the severity level of each inspection. That is, you can force IntelliJ IDEA to display some warnings as errors or weak warnings. In a similar way, what is initially considered a weak warning can be displayed as a warning or error, or just as info.

You can also configure the color and font style used to highlight each severity level. Besides, you can create custom severity levels and set them for specific inspections.

If necessary, you can set different severity levels for the same inspection [in different scopes](#).

All modifications to inspections mentioned above are saved in the [inspection profile](#) currently selected in the [inspection settings](#) and apply when this profile is used.

## Inspection scope

By default, all enabled code inspections apply to all project files. If necessary, you can configure each code inspection ([enable/disable](#), [change its severity level](#) and options) individually for different [scopes](#). Such configurations, like any other inspection settings, are saved and applied as part of a specific [profile](#).

There may be complicated cases when an inspection has different configurations associated with different scopes. When such inspection is executed in a file belonging to some or all of these scopes, the settings of the highest priority scope-specific configuration are applied. The priorities are defined by the relative position of the inspection's scope-specific configuration in [inspection settings](#): the uppermost configuration has the highest priority. The Everywhere else configuration always has the lowest priority.

For more information and procedural descriptions, see [Configuring Inspection for Different Scopes](#).

## Examples of code inspections

In the [Inspections](#) page, all inspections are grouped into categories. The most common tasks covered by code analysis are:

- Finding probable bugs.
- Locating dead code.
- Detecting performance issues.
- Improving code structure and maintainability.
- Conforming to coding guidelines and standards.
- Conforming to specifications.

## Finding probable bugs

IntelliJ IDEA analyzes the code you are typing and is capable of finding probable bugs as non compilation errors right on-the-fly. Below are the examples of such situations.

For example, potential NPE can be thrown at runtime:

### Before After

```
Method invocation 'fromCurrency.equals("USD")' may produce 'java.lang.NullPointerException'.  
double answer = 0;  
if (fromCurrency.equals("USD") && toCurrency.equals("CNY")) {  
    Assert 'fromCurrency != null'
```

```
double answer = 0;  
assert fromCurrency != null;  
if (fromCurrency.equals("USD") && toCurrency.equals("CNY")) {
```

So, this is exactly what we get from the intention action.

Here the first if condition may lead to a `NullPointerException` exception being thrown in the second if, as not all situations are covered. At this point adding an assertion in order to avoid a `NullPointerException` being thrown during the application runtime would be a good idea.

## Locating dead code

IntelliJ IDEA highlights in the editor pieces of so-called *dead* code. This is the code that is never executed during the application runtime. Perhaps, you don't even need this part of code in your project. Depending on situation, such code may be treated as a bug or as a redundancy. Anyway it decreases the application performance and complicates the maintenance process. Here is an example.

So-called *constant conditions* - conditions that are never met or are always *true*, for example. In this case the responsible code is not reachable and actually is a *dead* code.

```
attribute = parseAttribute(isempty, asp, php);

if (attribute == null) {
    ...
    return;
}
value = parseValue(attribute, false, isempty, delim);

if (attribute != null) {
    ... Condition 'attribute != null' is always 'true'.
}
else {
    av = new AttVal( null, null, null, null,
        0, attribute, value );
    Report.attrError(this, this.token, value,
        Report.BAD_ATTRIBUTE_VALUE);
}
```

IntelliJ IDEA highlights the if condition as it's always true. So the part of code surrounded with else is actually a dead code because it is never executed.

## Highlighting unused declarations

IntelliJ IDEA is also able to instantly highlight Java classes, methods and fields which are unused across the entire project via Unused declarations inspection. All sorts of Java EE `@Inject` annotations, test code entry points and other implicit dependencies configured in the Unused declarations inspection are deeply respected.

## Unresolved JavaScript function or method

This inspection detects references to undefined JavaScript functions or methods.

## Examples of PHP Code Inspections

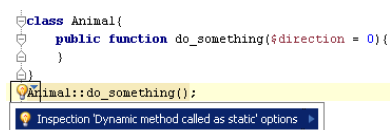

### Unresolved Include

This inspection detects attempts to include not actually existing files and suggests two quick fixes: to create a file with the specified name or use a PHPDOC annotation.

### Dynamic method is called as static

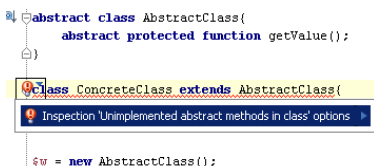

This inspection checks whether a call to a static function is actually applied to a static function.

The function `do_something()` is called as static while actually it is dynamic.

### Unimplemented abstract method in class

This inspection checks whether classes inherited from abstract superclasses are either explicitly declared as abstract or the functions inherited from the superclass are implemented.

The class `ConcreteClass` is inherited from an abstract class `AbstractClass` and has not been explicitly declared as abstract. At the same time, the function `getValue()`, which is inherited from `AbstractClass`, has not been implemented.

### Parameter type

PHP variables do not have types, therefore basically parameter types are not specified in definitions of functions.

However, if the type of a parameter is defined explicitly, the function should be called with parameters of the appropriate type.

```

class Animal{
    public function do_something($direction = 0){
    }
}
$obj = new Animal();
$obj->do_something("run");

```

The function `do_something` has the parameter of the type `integer` but is called with a `string`.

– Undefined class constant

This inspection detects references to constants that are not actually defined in the specified class.

```

class Animal{
    public function do_something($direction = 0){
    }
}
const NotExistingConst = Animal::NotExistingConst;

```

The constant `NotExistingConst` is referenced to as a constant of the class `Animal`, while actually it is not defined in this class.

– Undefined constant inspection

This inspection detects references to constants that are not actually defined anywhere within the inspection scope.

```

const NotExistingConst = UndefinedConst;

```

The referenced constant `UndefinedConst` is not defined anywhere within the inspection scope.

– Undefined class

This inspection detects references to classes that are not actually defined anywhere within the inspection scope.

```

const NotExistingConst = new NotExistingClass();

```

The referenced class `NotExistingClass` is not defined.

– Undefined field

This inspection detects references to fields of a class that are not actually defined in this class.

```

class Animal{
    public function do_something($direction = 0){
    }
}
$obj = new Animal();
$var = $obj->field;

```

The `$obj` variable is an instance of the class `Animal`. The declaration of the `$var` contains a reference to the `field` field of the class `Animal`, which is not defined on this class.

To suppress reporting **Undefined method** errors in such cases, [re-configure the inspection severity](#). To do that, open the **Inspections** page of the Settings dialog box, click the inspection name in the list and select the Downgrade severity if `__magic methods` are present in class checkbox in the Options area. After that undefined properties in such cases will be indicated one step lower than specified for inspections in general, by default, **Info** instead of **Warning**.

To suppress irrelevant reporting of **Undefined field** errors, clear the Notify about access to a field via magic method and Notify about PHP dynamic field declaration checkboxes. When the checkboxes are selected, IntelliJ IDEA reports errors even if the class contains the `__get()` and `__set()` magic methods.

– Call of undefined function

This inspection detects references to functions that are not defined anywhere within the inspection scope.

```

class Animal{
    public function do_something($direction = 0){
    }
}
$obj = new Animal();
$var = undefined_function($obj);

```

The called function `undefined_function()` is not defined anywhere within the inspection scope.

– Undefined variable

This inspection detects references to variables that are not declared and initialized anywhere within the inspection scope. PHP does not require that each variable should be declared and initialized. PHP can initialize such variable on the fly and assign it the zero value. However, this inspection allows you to detect discrepancies of this kind.

The **Undefined variable** inspection can be configured through the checkboxes on the Inspections page of the Settings dialog:

- Enable inspection in global space: select this checkbox to run the inspection against variables outside functions/methods, classes, and namespaces, that is, in the [global space](#).

```

<?php
/** Created by PhpStorm. ... */
$y = $c;

```

- Report that variable might have not been defined: select this checkbox to have a warning displayed even if the definition of a variable is not definitely missing. Such situation may take place when a variable is used in several paths and some of them may never be reached, for example, in `if()` statements:

```
function test($x) {  
    if ($x==0) {  
        $d=5;  
    }  
    return $d;  
}
```

Variable 'd' might have not been defined [more...](#) (Ctrl+F1)

- Ignore 'include' and 'require' statements Suppose the inspection scope contains an `include` or `require` statement. If this checkbox is cleared, IntelliJ IDEA treats such variable as defined in the classes referenced through these statements and no error is reported. If this checkbox is selected, an **Undefined variable** error is reported.

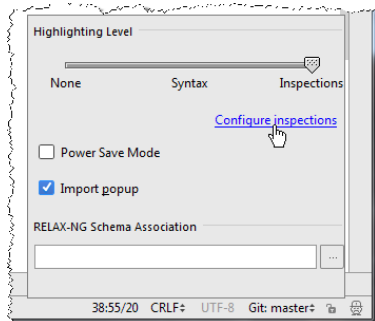

Inspections and [inspection profiles](#) are editable in the [Inspections](#) settings page. IntelliJ IDEA provides several ways to gain access to inspection settings.

## To access inspections and profiles settings, do one of the following

- Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Inspections under Editor .
- On the main toolbar, click , then expand the Editor node, and click [Inspections](#) .
- Click the current profile icon in the Status bar

and then click the Configure inspection link.

- In the editor, open the suggestion list, click the right arrow, and choose Edit inspection profile settings on the

- In the [Inspection Results Tool Window](#) , click Edit Settings  on the toolbar or use the corresponding context menu command.

## Introduction

IntelliJ IDEA lets you configure settings for your code validation analysis and save them as inspection profiles. You can customize the existing inspection profiles (including default profiles), and create new ones. You can also share, import and export inspection profiles.

IntelliJ IDEA distinguishes between IDE and project profiles.

### Stored in IDE

These profiles are saved in an application config directory (for example, `~/.IntelliJ IDEA XXXX/config/inspection` on Linux) and are available for any project.

### Stored in Project

These profiles are saved in a particular project's `.idea` directory (for example, `$PROJECT_DIR/.idea/inspectionProfiles` on Linux).

## Customizing profiles

1. In the [inspection settings](#), select the profile to be changed.

Note that the default profiles are also editable.

2. Customize the desired inspections: [enable or disable](#), [change their severity](#) and the other options, which can be different for the various inspections.  
Note that the selectors of severity and scopes, and the options section (if any) are only available for the enabled inspections.
3. To apply an inspection to a restricted set of files, [associate it with the corresponding scopes](#).  
By default, all inspections apply to all the sources of the current project.
4. Apply changes.

## Managing profiles

1. In the [inspection settings](#), select the profile you want to manage.
2. Click  and from the drop-down list, select one of the following options:
  - Copy to IDE or Copy to Project - to copy the selected profile to either IDE level or the project level.
  - Duplicate - to make a copy of the selected profile. You can change the name of the profile in the Profile field.
  - Rename - to rename the selected profile.
  - Delete - to delete the selected profile.
  - Restore Defaults - to change the selected profile back to its default settings.
  - Add Description or Edit Description - to add a new or edit an existing description for the selected profile.
  - Export - to export the selected profile in a form of XML file. You can select where to export your profile.
  - Import Profile - to import the desired profile (XML file). You can select where to import your profile.
3. Apply changes.

On this page:

- [Basics](#)
- [Defining the order of scopes](#)

## Basics

By default, all enabled code inspections apply to all project files. If necessary, you can configure each code inspection ([enable/disable](#) , [change its severity level](#) and options) individually for different [scopes](#) . Such configurations, like any other inspection settings, are saved and applied as part of a specific [profile](#) .

There may be complicated cases when an inspection has different configurations associated with different scopes. When such inspection is executed in a file belonging to some or all of these scopes, the settings of the highest priority scope-specific configuration are applied. The priorities are defined by the relative position of the inspection's scope-specific configuration in [inspection settings](#) : the uppermost configuration has the highest priority. The Everywhere else configuration always has the lowest priority.

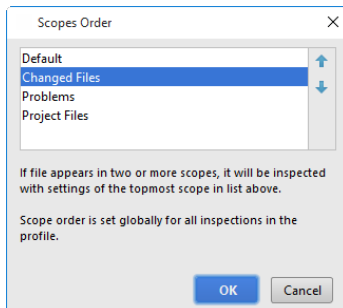

## Defining the order of scopes

### To define the order of scopes, follow these steps

1. In the [Inspections](#) page of the Settings/Preferences dialog, click the button In All Scopes :

2. Choose Edit Scopes Order... from the scopes drop-down list.
3. In the Scopes Order dialog box that opens, select the desired scope, and click the up and down arrows  :

## Basics

Inspection severity indicates how seriously the code issues detected by the inspection impact the project and determines how the detected issues should be highlighted in the editor. By default, each inspection has one of the following severity levels:

- Server problem 
- Typo 
- Info 
- Weak Warning 
- Warning 
- Error 

You can increase or decrease the severity level of each inspection. That is, you can force IntelliJ IDEA to display some warnings as errors or weak warnings. In a similar way, what is initially considered a weak warning can be displayed as a warning or error, or just as info.

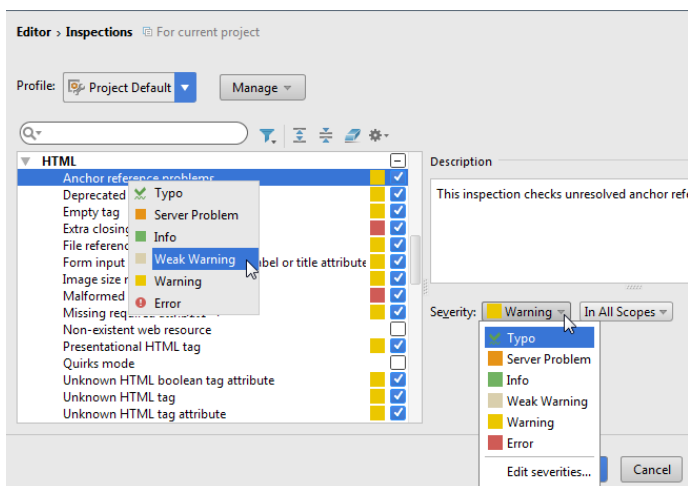

You can also configure the color and font style used to highlight each severity level. Besides, you can create custom severity levels and set them for specific inspections.

If necessary, you can set different severity levels for the same inspection [in different scopes](#).

All modifications to inspections mentioned above are saved in the [inspection profile](#) currently selected in the [inspection settings](#) and apply when this profile is used.

## Changing severity of an inspection

1. In the [inspection settings](#), select the desired [profile](#). The inspections associated with the profile are displayed in the tree view.
2. Select the desired inspection. If this inspection is disabled, select the checkbox next to it.
3. Select the desired severity from the context menu of the inspection or from the Severity selector on the right:

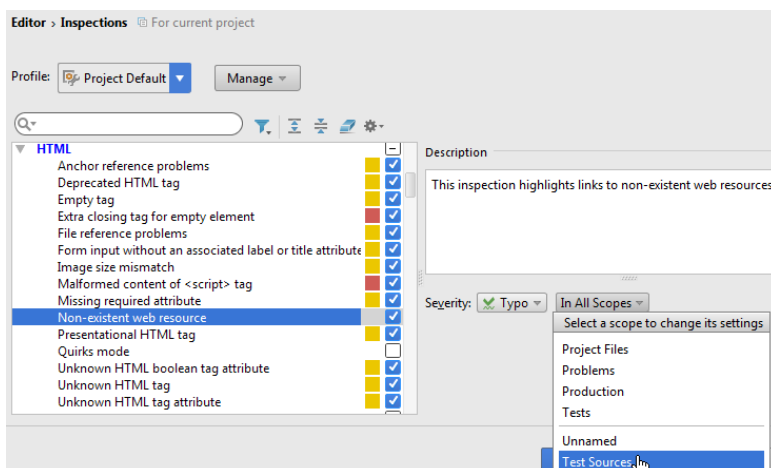

Note that inspections, whose state is changed relative to the default values, and all their grouping nodes are highlighted with blue.

4. Apply the changes. The modified inspection will now have the new severity level when this [profile](#) is used.

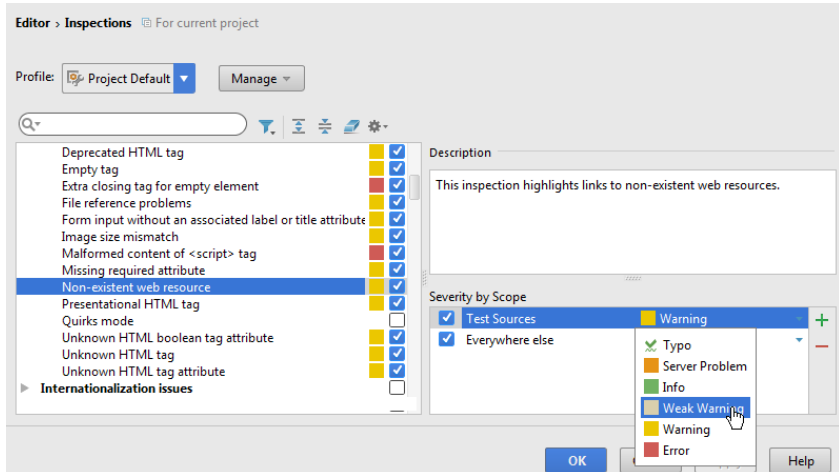

## Changing severity of an inspection for different scopes

1. Choose the desired profile and inspection.
2. Click the drop-down list [In All Scopes](#), and select the scope you want to change inspection severity in:

IntelliJ IDEA shows severities for two scopes: for the selected one and Everywhere else

3. Click severity drop-down list for the selected scope and choose the appropriate severity level from the drop-down list:

### Changing the highlighting style for a specific severity level

1. Do one of the following:

- In the [Settings/Preferences](#) dialog, select Editor | Colors & Fonts -> General , and then select the style corresponding to the desired severity level.
- In the [inspection settings](#) , select the desired inspection and choose Edit severities from the Severity selector. Next, in the Severities Editor dialog box that opens, select the desired severity level and click Editor | Colors & Fonts .

Either way you will see the styles associated with this severity in the [Color Scheme](#) settings page.

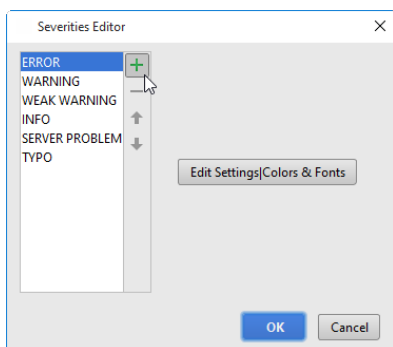

2. Configure the color and font styles as necessary and apply changes. The detected issues with the corresponding severity will now be highlighted in the editor with the modified style when the current [profile](#) is used.

### Defining a custom severity level

1. In the [inspection settings](#) , select the desired inspection and choose Edit severities from the Severity selector.

2. In the Severities Editor dialog box that opens, click **+** :

3. Type the name for the new severity in the New Highlight Severity dialog box.

The custom severity is added to the list of severities.

4. Specify color and font settings for the new severity using the controls to the right of the list of severities.

5. Use the Up **↑** and Down **↓** buttons to change the priority of the new severity.

6. Apply the changes. The new severity level will now be available for all inspections within the current [profile](#) . You can assign it to specific inspections and get the corresponding code issues highlighted with the specified style in the editor.

If necessary, you can remove the custom severity level later by selecting it in the Severities Editor dialog box and clicking **-** .

You cannot change priorities of the pre-defined severity levels, or remove them.

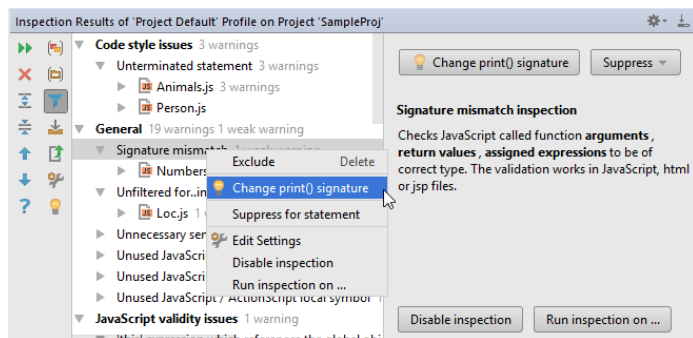

Although code analysis is performed on-the-fly in all open files, you may want to run it for the whole project or a custom scope and examine the results in a friendly view.

**Note** Inspecting code in a large scope, for example, the whole project, can be time consuming. For large projects, it is recommended to [create](#) a number of smaller [scopes](#) and run analysis in each of them separately.

- If you do not want to have some code issues in the analysis report, you can [disable some inspections](#).

## To run a code inspection

1. Open the desired file in the editor. Alternatively select files or directories in the [Project Tool Window](#). For multiple selection, click the items holding down the [Ctrl](#) / [⌘](#) key. The initial inspection scope will be confined to the opened file or the selection.
2. On the main menu, choose Analyze | Inspect Code. The [Specify Inspection Scope](#) dialog box opens.
3. In the Inspection scope area, specify which files should be inspected.
  - To have the source code of the entire project inspected, select the Whole Project option.
  - If you are using [version control integration](#), you can choose to only inspect uncommitted files.
  - To run an inspection for the currently opened file, or the file(s)/folder(s) selected in the Project view, select the File/Module <name> option.
  - To apply inspect code in a specific [scope](#), select the Custom scope option, then choose the desired scope from the drop-down list or click the Browse button  and configure a new scope in the [Scopes](#) dialog box.
4. To have test source files inspected too, select the Include test sources check box.
5. Specify the [inspection profile](#) to apply. Do one of the following:
  - Select one of the existing profiles from the Inspection Profile drop-down list.
  - Click the Browse button  and [configure a new profile](#) in the [Inspections](#) dialog box.
6. Click OK to run code analysis.
7. [Examine results](#) in the [Inspection Results Tool Window](#).

It is also possible to run inspections offline, without starting the IDE. Follow the procedure described in the section [Working with IntelliJ IDEA Features from Command Line](#).

Rather than running all enabled inspections, IntelliJ IDEA makes it possible to exactly specify the desired inspection by its name and run it to inspect the code in the specific scope.

## To run a code inspection by name

1. Open the desired file in the editor. Alternatively select files or directories in the [Project Tool Window](#) . For multiple selection, click the items holding down the `Ctrl` / `⌘` key. The initial inspection scope will be confined to the opened file or the selection.
2. On the main menu, choose `Analyze | Run Inspection by Name` , or press `Ctrl+Shift+Alt+I` .
3. In the pop-up frame that opens, start typing the inspection name. As you type, the suggestion list shrinks to show the matching inspection only.

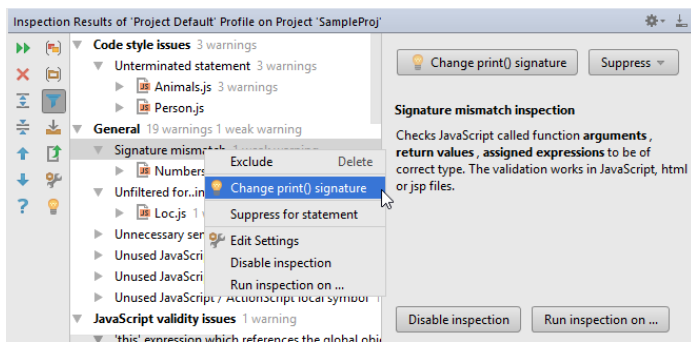

**Tip** Use CamelHumps to match camel case words and white spaces to match initial letters of the words.

The [Specify Inspection Scope](#) dialog box opens.

4. In the Inspection scope area, specify which files should be inspected.
  - To have the source code of the entire project inspected, select the Whole Project option.
  - If you are using [version control integration](#) , you can choose to only inspect uncommitted files.
  - To run an inspection for the currently opened file, or the file(s)/folder(s) selected in the Project view, select the File/Module <name> option.
  - To apply inspect code in a specific [scope](#) , select the Custom scope option, then choose the desired scope from the drop-down list or click the Browse button `⋮` and configure a new scope in the [Scopes](#) dialog box.
5. To have test source files inspected too, select the Include test sources check box.
6. To apply inspection only in files matching the specific mask, select the File Masks(s) and specify the file mask. Use comma to separate multiple file masks.
7. Click OK to run the inspection.
8. [Examine results](#) in the [Inspection Results Tool Window](#) .

After you [perform code analysis](#) or [execute a single inspection](#), you can examine the results in the [Inspection Results Tool Window](#).

Each run of the code analysis or a single inspection is displayed in a new tab in the tool window. The left part of the tab displays detected code issues grouped by inspection groups, inspections and files. If necessary, you can change the default grouping. When you select a specific issue, its report appears in the right part.

In the Inspection Results tool window you can:

- [Resolve issues using quick-fixes](#) where available.
- [Jump to the source of the problem](#) to resolve it manually.
- [Export inspection results](#) to an XML or HTML file.
- [Disable inspections](#) to skip all corresponding issues next time you ran code analysis.
- [Suppress inspections](#) for specific code issues.
- [Access inspection settings](#) to configure inspections.

## Introduction

When you run an inspection against your code, the [Inspection Results Tool Window](#) is displayed showing the results of code analysis. You can then [examine the issues](#) that have been detected and [apply the suggested quickfixes](#) .

However, you may want to streamline this process by automatically applying the quickfixes from your inspection profile to the selected scope, without having to examine the results and implement each separate fix individually.

## Applying quickfixes automatically

### To apply quickfixes automatically

1. From the main menu, select [Analyze | Code Cleanup](#) .
2. In the [Specify Code Cleanup Scope](#) dialog that opens, select the scope to which you want the inspection profile to be applied.
3. Select the inspection profile from the drop-down list, or click the  button to configure a new profile in the [Inspections](#) dialog that opens. You can also click the  button to check which fixes will be applied.
4. Click OK to launch the inspection.

IntelliJ IDEA will perform code analysis and will automatically apply quickfixes from the selected inspection profile to all issues that are detected.

Alternatively, you can place the caret at an error in the source code that corresponds to a quickfix, click the red bulb (quick-fix suggested) icon  that appears on the left, and select Code Cleanup from the drop-down menu. Code cleanup will be performed for the current file with the current inspection profile.

## Applying quickfixes on commit to VCS

### To apply quickfixes when committing changes to a VCS

1. From the main menu, select [VCS | Commit Changes](#) .
2. In the [Commit Changes](#) dialog that opens, select the files that you want to commit, and select the Cleanup code option in the Before Submit area.

Code cleanup will be performed for all selected files before they are committed to your version control system (the current project inspection profile will be applied).

## Introduction

By default, IntelliJ IDEA analyses the code in all open files and highlights the detected code issues. You can fix most of the issues immediately by [applying quick-fixes](#).

If you [perform code analysis](#) or [execute a single inspection](#) in a larger scope of source files, IntelliJ IDEA displays the detected code issues in the [Inspection Results Tool Window](#). When you select a specific issue in this window, its report is shown in the right part of the window.

If there are available fixes to the issue, IntelliJ IDEA notifies it in the following ways:

- The Apply a Quickfix  button becomes available on the toolbar of the Inspection Results tool window.
- The available fixes are shown in the optional Problem resolution field of the report.
- The available fixes are shown in the context menu of the issue.

If there are no available fixes, the only option is to fix the issue manually.

Please note the following:

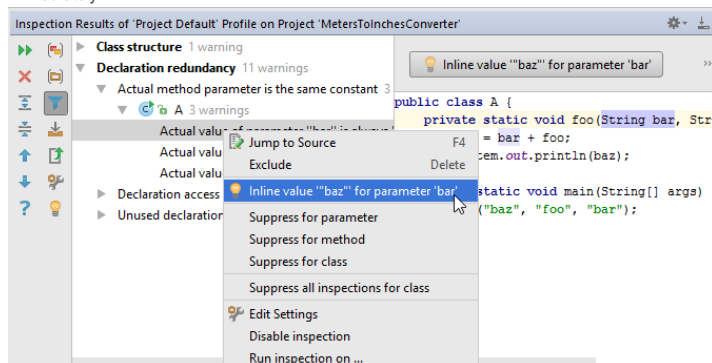

- To display the source code of an issue in the editor, when it is selected in the [Inspection Results Tool Window](#), toggle the Autoscroll to Source  button.
- If you find that some of the reported issues are minor or not helpful to you, you can ignore them either by [disabling](#) the corresponding inspection or by [suppressing](#) it in a specific piece of code.

## Fixing problems

### To fix a problem reported by code inspection

In the [Inspection Results Tool Window](#), select the code issue you are interested in and do one of the following:

- If IntelliJ IDEA suggests any fixes to the issue as described above, you can use one of them to fix the problem immediately.

- If no resolutions are suggested, use the Jump to source command in the context menu and fix the problem manually.

## Introduction

For some reasons, you may want to partly disable a specific inspection, i.e. ignore some code issues while continuing to detect the other issues with this inspection.

For example, IntelliJ IDEA considers some code to be "dead", and you can see that it is true. The inspection is helpful and you do not want to [disable](#) it. However, you may want to use this code later and do not want it to be highlighted in the editor or appear in the issue reports.

To do so, IntelliJ IDEA allows you to **suppress** certain inspections for a specific statement, function/method, tag or file. You can do it either [in the editor](#), using the suggestion list or [in the Inspection Results tool window](#) when analysing inspection results.

Let's summarize the difference between suppressing and [disabling](#) code inspections:

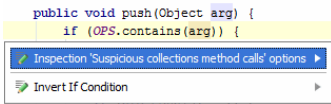

When **suppressing** an inspection, IntelliJ IDEA inserts a special comment that tells the code analysis engine to ignore the issues found by this inspection in the specific piece of code.

When **disabling** an inspection, you just turn it off so the code analysis engine just ignores the code issues found by this inspection.

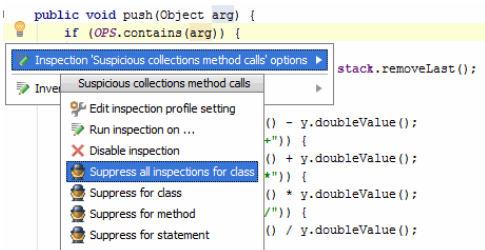

Some code inspections (e.g. those detecting errors) cannot be suppressed.

## Suppressing inspections in the editor

1. Set the cursor to the highlighted code issue in the editor.
2. Press `Alt+Enter`, or click the light bulb icon  to expand the suggestion list.

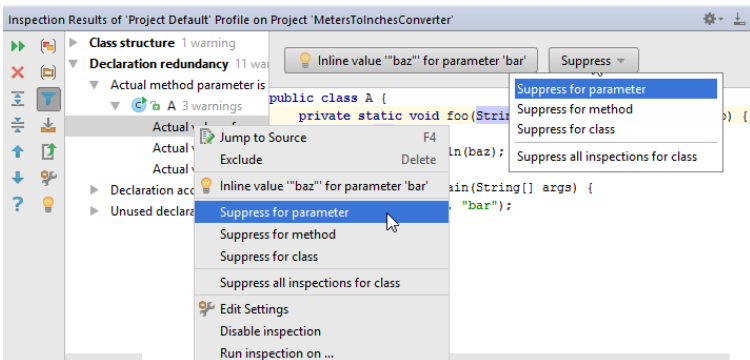

3. Depending on the issue, you will see either quick-fixes related to the inspection or the Inspection "<inspection name>" options item.
4. Use the up/down arrow keys to select this item and then press the right arrow key or just click the right arrow  next to this item.  
Pressing the left arrow key, or `Escape` hides the suggestion list.
5. In the inspection options list, select the desired suppress action:

The inspection will be suppressed with special comments in the corresponding piece of code.

## Suppressing inspections from the Inspection Results tool window

1. After [running code analysis](#), select a code issue, for which you want to suppress the inspection, in the [Inspection Results Tool Window](#).
2. Click the button **Suppress** and choose the scope of suspension, or just right-click the selected inspection.
3. Choose the desired suppress action. For example:

The inspection will be suppressed with special comments in the corresponding piece of code.

**Note** The set of suppress actions depends on the language to which inspection applies. For example, for Cucumber, one can suppress inspections for a whole feature, for a scenario, or for a particular step:

Feature: Buying beer cans  
Scenario: Go to a store  
Given I have enough money  
And I see many beers cans  
When I choose sort of beer  
Create All Steps Definition  
Create Step Definition  
Conv  
Undefined step  
Edit inspection profile setting  
Disable inspection  
Suppress for feature  
Suppress for scenario/background  
Suppress for step

## Introduction

If you think that some inspections report about the problems that you are not interested in, you can disable such inspections. Note that when you disable an inspection, it is disabled in the current [inspection profile](#) ; in all other profiles, it remains enabled.

There are several ways to disable/enable inspections:

- [Using the Inspections page in the Settings/Preferences dialog](#) - this is the main interface for managing inspections; here you can see at once, which inspections are enabled or disabled in all inspection profiles.
- [Using the intention actions](#) - this is the way to disable a highlighted code issues right in the editor.
- [In the Inspection Results tool window](#) - this is a quick way to disable uninteresting issues when [analyzing inspection results](#) . Note that here you can only disable inspections.

**Note** Note the difference between disabling and [suppressing](#) code inspections:

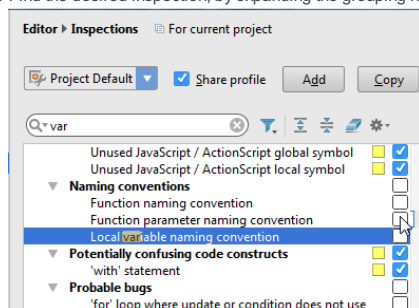

When [suppressing](#) an inspection, IntelliJ IDEA inserts a special comment that tells the code analysis engine to ignore the issues found by this inspection in the specific piece of code.

When [disabling](#) an inspection, you just turn it off so the code analysis engine just ignores the code issues found by this inspection.

## Disabling or enabling inspections

### To disable or enable an inspection in the Settings/Preferences dialog

1. Find the desired inspection, by expanding the grouping nodes or using the search field.

2. Use the checkbox next to the inspection to disable or enable it.
3. Apply the changes and close the dialog box.

### To disable an inspection for highlighted issue in the editor

- When you disable inspections this way, they are disabled for the current [inspection profile](#) .

- To re-enable inspections disabled this way, use the [main procedure](#) described above.

1. Set the caret at a highlighted issue.
2. Click the bulb icon or press `Alt+Enter` to reveal the inspection alert and suggestion list.
3. Select the inspection to be disabled, then click right arrow button or just press the right arrow key.
4. On the submenu, click `Disable <inspection name>` .

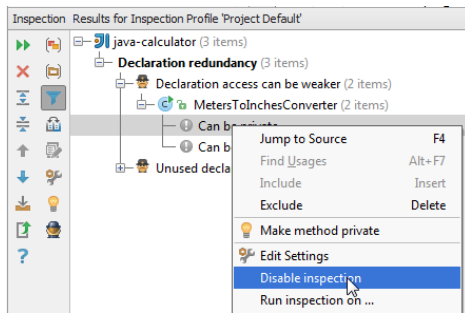

### To disable inspections from the Inspection results report

- When you disable inspections this way, they are disabled for the [inspection profile](#) that was used for [running inspections](#) . You can see it in the header of the Inspection Results window's tab.

- To re-enable inspections disabled this way, use the [main procedure](#) described above.

1. In the [Inspection Results Tool Window](#) , right-click the inspection you want to disable.
2. On the context menu, choose `Disable inspection` .

3. Press the filter button  to hide the disabled inspection alerts.

After you [perform code analysis](#) or [execute a single inspection](#) , you can save the inspection results for further examination or for sharing with colleagues. IntelliJ IDEA enables you to export inspection results to the HTML or XML format.

## To export inspection results

1. On the toolbar of the [Inspection Results Tool Window](#) , click the Export button  .
2. From the Export To context menu, select the target format. The available options are HTML and XML .
3. In the [dialog that opens](#) , specify the target directory to store the inspection results in.

## Basics

In addition to running code inspections from the main menu, or from the context menus of the [Project Tool Window](#), you can also launch the inspector from the command line, without actually running IntelliJ IDEA.

This way you can perform regular code inspections as a part of your development process, which is especially important for large projects. Inspection results are stored in the XML format.

## Launching a code inspection from the command line

### To launch a code inspection from the command line

- Specify the following command line arguments:
  - Path to the launcher : specify the **full path** to one of the following launchers (which reside under the `bin` directory of your IntelliJ IDEA installation):
    - For **Windows** : `inspect.bat`
    - For **UNIX** and **macOS** : `inspect.sh`
  - Project file path is the **full path** to the directory that contains the project to be inspected.
  - Inspection profile path is the **full path** to the profile, against which the project should be inspected. The inspection profiles are stored under `USER_HOME\.IntelliJ IDEAXX\config\inspection`
  - Output path is the **full path** to an existing directory where the report will be stored.
  - Options . You can specify:
    - The directory to be inspected `-d <full path to the subdirectory>`
    - The verbosity level of output `-vX`, where X is 0 for quiet, 1 for noisy and 2 for extra noisy.

**Warning!** Please note that you have to specify full paths. Relative paths are not accepted!

**Tip** If SDK is not defined, the inspection will fail. The SDK descriptions should be stored in `config\options\jdk.table.xml`. Learn how to configure SDK [here](#).

## Examples

### Windows

```
"C:\Program Files (x86)\JetBrains\IntelliJ IDEA home\bin\inspect.bat" E:\SampleProjects\MetersToInches
```

Note that your paths should be adjusted to your particular local system.

### macOS

```
/Applications/IntelliJ IDEA.app/Contents/bin/inspect.sh ~/IntelliJ IDEAProjects/MyTestProject ~/Library/
```

## Viewing the results of an offline inspection

If you have performed an offline inspection and exported the inspection results to a directory in the XML format you can always download and view these results.

### To view the results of an offline inspection, follow these steps

1. Open the project against which the inspection was performed.
2. On the main menu, choose Analyze | View Offline Inspection Results .
3. In the Select Path dialog box that opens, navigate to the directory that contains inspection results in XML format.
4. Click OK . Inspection results display in the Offline View tab in the [Inspection Results Tool Window](#) .

**Tip** Alternatively, you can open the relevant XML file in IntelliJ IDEA or in any other text processor without opening the inspected project.

## Introduction

If you have exported inspection results to a directory in XML format, or [performed offline inspection](#) outside IntelliJ IDEA, as a part of the automated build process, you can always download and view the results.

## Prerequisite

The relevant project should be opened in the IDE, and should contain the classes that have been inspected. Otherwise, you have to review inspection results, opening the reports as XML files in the editor.

## Viewing offline inspection results

### To view inspection results offline

1. On the main menu, choose Analyze | View Offline Inspection Results .
2. In the Select Path dialog, navigate to the directory that contains inspection results in XML format.
3. Click OK . Inspection results display in the Offline View tab in the [Inspection Results Tool Window](#) .

Use the [Status bar](#) to quickly re-configure highlighting for the file which is currently opened in the editor. With Hector , you can choose to highlight syntax problems, inspection issues, or turn off highlighting.

### To change the highlighting level for the current file

1. Open the Highlighting level pop-up window by doing one of the following:
  - On the main menu, choose Analyze | Configure Current File Analysis .
  - Press `Ctrl+Shift+Alt+H` .
  - Click the Hector icon  on the Status bar.
  - Right-click the code inspection indicator on top of the scroll bar.
2. Move the slider to one of the three available positions that define the highlighting level:
  - None : turn off problems highlighting in the editor.
  - Syntax : highlight syntax problems only.
  - Inspections : (default) highlight syntax problems and inspection issues.

IntelliJ IDEA allows you to create custom inspections based on [search templates](#) . The inspection list provides a Structural Search Inspection , which is a powerful tool for creating search templates. Based on this inspection, you can create any number of search templates to inspect your source code and any number of replace templates to be used as means to resolve detected problems.

**Tip** Using the Structural Search Inspection is the only way to create custom inspections through the IntelliJ IDEA interface. Alternatively, you can develop an [external plugin](#) to implement a custom inspection.

## To create a custom inspection

1. [Open the Inspections dialog box](#) .
2. Select the desired profile from the drop-down list. The inspections associated with the selected profile are displayed in the tree view.
3. In the list of inspections, expand the General node and select the checkbox next to the Structural Search Inspection item. This enables the controls in the Options area, where you can configure a custom inspection.
4. Click the Add Search Template button. In the [Structural Search](#) dialog box that opens specify the [search options](#) .
5. Click the Add Replace Template button. In the [Structural Replace](#) dialog box that opens specify the replace options.
6. Complete the list of inspection templates:
  - To edit a template, select it in the Selected Templates list, click the Edit button, and edit the template in the Edit Template dialog box that opens.
  - To remove a template, select it in the list and click the Remove button.
7. Specify the [inspection severity](#) using the Severity drop-down list.
8. [Associate the inspection with a scope](#).  
If an inspection is not associated with a scope, it applies to all the sources of the current project.

In this section:

- Intention Actions
  - [Introduction](#)
  - [Intention action icons](#)
  - [Intention action types](#)
- [Applying Intention Actions](#)
- [Configuring Intention Actions](#)
- [Disabling Intention Actions](#)

## Introduction

IntelliJ IDEA helps you handle the situations when you use classes that haven't been imported, or methods that haven't been written etc., which can result in errors. When a possible problem is suspected, IntelliJ IDEA suggests a solution, and in certain cases can implement this solution (properly assign variables, create missing references and more). Besides syntax problems, IntelliJ IDEA recognizes code constructs that can be optimized or improved, and suggests appropriate intention actions, denoted with the special icons.

## Intention action icons

### ItemIconDescription

Intention actions suggested	 A yellow bulb indicates that IntelliJ IDEA just proposes to alter your code. It covers a range of situations from warning correction to suggestions for code improvement (like micro-refactorings).
Specific intention action	 This sign appears in the suggestion list before each specific intention action. If an intention action alert is disabled, the sign turns to  . Disabled intention action is still available and can be enabled again.
Quickfix suggested	 A red bulb with an exclamation mark indicates that IntelliJ IDEA suggests a way to fix an error. It is related to Create from usage intentions and Quick fixes.
Disabled	 Alert is disabled, but the intention action is still available and can be enabled again.

## Intention action types

Find descriptions of specific intention actions on the [Intentions page](#) of the editor settings/preferences, where they are grouped according to the areas of their usage. Generally, intention actions can be divided into several categories, for example:

### Create from usage

This type of intention action creates new code items: classes, methods, etc. They are smart enough to analyze your code and provide actions suitable for a particular case. The main concept behind this type is that you can begin using new things without declaring them first. You are not taken away from your current task for mundane minutiae like creating declarations, new files, etc. which IntelliJ IDEA handles while you keep focused.

For example, Create Constant Field is suggested if the reference is uppercase, or Create class appears when a name is typed after the `new` keyword, or when an identifier starts with a capitalized letter, etc.

### Quick fixes

This type of intention action responds to common coding mistakes: using an improper access modifier, or an expression of the wrong type, or missing resources, etc. IntelliJ IDEA catches these kinds of problems as you type, and provides a quick way to fix them using Intentions Actions with appropriate suggestions for the error.

### Micro-refactorings

These intention actions appear for code that is syntactically correct, but can be structurally improved by such things as:

- Converting code constructs.
- Splitting declarations and assignments.
- Splitting or merging statements and tags, etc.

### Edit <Injected Language> Fragment

For string literals that represent [language injections](#), the Edit <Injected Language> Fragment intention action is available. You can use this intention action to open the corresponding code fragment in a separate editor.

```
numbers.js x
if (name == "") {
  heading = ""
  Flip if-else >
  Inject Language/Reference >
  Remove braces from if statement >
  Replace double-quoted string with single-quoted string >
  Run Query in Console >
  Edit <SQL keywords> Fragment >
  Un-inject Language/Reference >
```

IntelliJ IDEA displays an intention action alert, and it is your task to define which action (if any) should be performed.

### To apply an intention action

1. Click the light bulb icon, or use the `Alt+Enter` keyboard shortcut to bring up the suggestion list.
2. Click the desired option, or use the arrow keys to select the option and press `Enter`.

## Introduction

IntelliJ IDEA makes it possible to configure intention action settings either in the [Intentions](#) page of the Settings/Preferences dialog, or "on-the-fly".

By default, all available intention actions that ship with IntelliJ IDEA, are enabled. By changing the Intention settings, you can disable the actions that are not required for your current working environment.

## Configuring intention settings using the Settings/Preferences dialog

### To configure intention settings using the Settings/Preferences dialog

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Intentions under Editor .
2. In the [Intentions](#) page, clear the checkboxes of the intention actions or action categories that you do not currently need.  
Selecting or clearing a category affects all intention actions in this category.
3. Apply changes and close the dialog.

## Configuring intentions on-the-fly

### To configure intention settings on-the-fly

1. In the editor, press `Alt+Enter` to reveal the inspection alert and suggestion list.
2. Select the action to be disabled, then click right arrow button or just press the right arrow key.
3. On the submenu, choose Disable <intention action name> .

If an intention action is enabled, the alert shows automatically, when the caret rests on the problem-causing piece of code. You can disable alert for any type of intention actions, and show it by explicit invocation only.

Disabled intention actions are marked with the grey light bulb icon . Though disabled, such actions are still available and can be applied to the source code.

You can suppress intention actions related to inspections "on-the-fly", as described in the section [Suppressing Inspections](#) .

## To disable an intention action alert

1. Click `Alt+Enter` , or click the light bulb icon to show the suggestion list.
2. Select the action to be disabled and click the right arrow button.
3. On the submenu, click Disable <intention action name> :

For the disabled intention action, the menu item changes to Enable <intention action name> .

In this section you will find the basics of IntelliJ IDEA's annotations, and the related procedures:

- [Enabling Annotations](#) .
- [@Nullable and @NotNull](#) annotations, which are used, when IntelliJ IDEA supposes that a certain element can become `Null` .
- [@NonNls](#) annotation, which is used to ignore the hardcoded string literals.
- [@Contract](#) annotations, which is a powerful and flexible tool for making the APIs safer.
- [Annotating Source Code Directly](#) , which describes how to add annotations to your source code.
- [Inferring Nullity](#) , which describes how to analyze the source code for the possible `@Nullable` and `@NotNull` annotations.

Besides that, you can also find the following information:

- [External Annotations](#) that are stored outside the source code.
- [Using External Annotations](#)

Bundled IntelliJLang plugin provides three new annotations you may find useful:

- `@Language` : responsible for the Language injection feature.
- `@Pattern` : is used to validate Strings against a certain regular expression pattern
- `@Subst` : is used to substitute non-compile time constant expressions with a fixed value.

On this page:

- [Introduction](#)
- [Enabling annotations in the project](#)
- [Enabling annotations in Gradle or Maven projects](#)
- [Enabling annotations using editor](#)

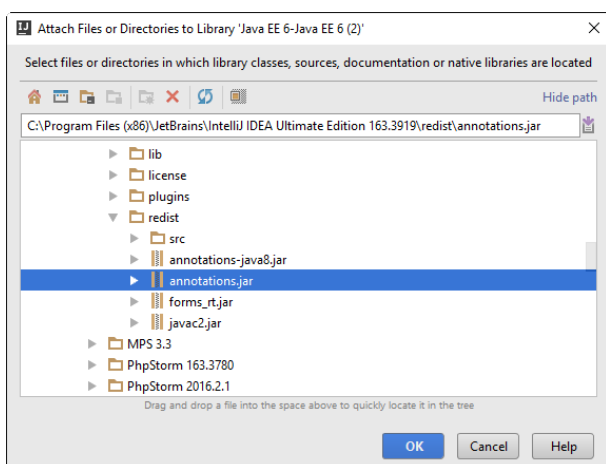

## Introduction

IntelliJ IDEA lets you enable annotations in projects locally, through Maven repository for projects imported from Gradle or Maven model and through the editor.

## Enabling annotations in the project

To enable annotations, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the Project Structure dialog box, click Libraries .
3. Click **+**. **Select Library Files** dialog box opens.
4. Under <IntelliJ IDEA home> directory, select `redist/annotation.jar` / `redist/annotation-java8.jar` , and click OK

5. If your project contains more than one module, choose the desired module to be modified, and click OK :

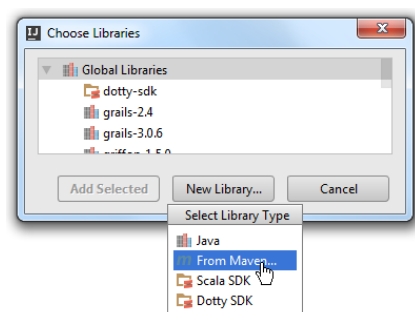

6. The new library is added to the classpath:

## Enabling annotations in Gradle or Maven projects

To enable annotations in Gradle or Maven projects, follow these steps:

1. Click **+** to open the project structure dialog.
2. In the Project Structure dialog box, on the Modules page, click the Dependencies tab.
3. On the Dependencies tab, click **+** and from the list that opens, select Library .
4. In the Choose Library dialog, click New Library and from the Select Library Type list, select From Maven .

5. In the Download Library From Maven Repository dialog, enter `org.jetbrains:annotations:15.0` that contains annotations for Java 8 or `org.jetbrains:annotations-java5:15.0` that contains annotations compatible with Java 5 and click OK .

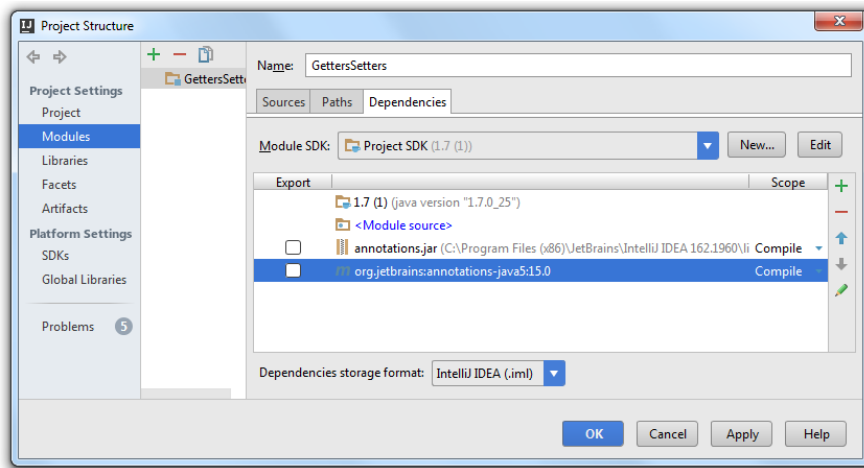

6. In the Choose Libraries dialog box, click Add Selected .

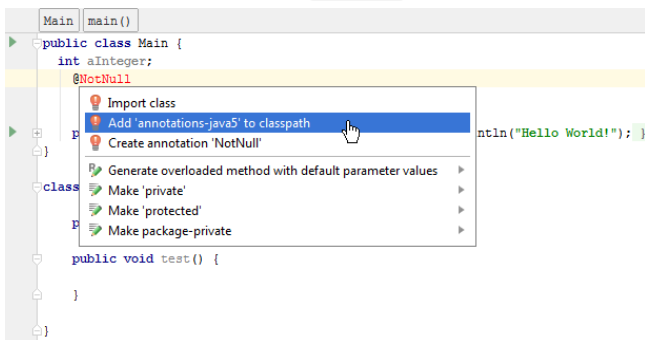

The new library is added to the list of dependencies and to the classpath.

## Enabling annotations using editor

To enable annotations in the editor:

– In the editor, write `@NotNull` and press `Alt+Enter` :

The selected JAR file is added:

```

4
5  import org.jetbrains.annotations.NotNull;
6
7
8
9  public class Main {
10     @NotNull
11
12     public static void main(String[] args) { System.out.println("Hello World!"); }
13
14 }

```

Note that if a project is imported from the Maven model, IntelliJ IDEA will add the dependency to the `pom.xml` .

On this page:

- [Overview](#)
- [@Nullable](#)
- [@NotNull](#)
- [Formal Semantics](#)

## Overview

This section describes [@Nullable](#) and [@NotNull](#) annotations introduced in IntelliJ IDEA for catching NullPointerException's (NPE's) through the Constant Conditions & Exceptions and [@Nullable](#) problem inspections.

These annotations are designed to help you watch contracts throughout method hierarchies to avoid emergence of NPE's. Moreover, IntelliJ IDEA provides another benefit for them: the Code Inspection mechanism informs you on such contracts' discrepancies in places where annotated methods are called and provides automated solutions in some cases.

Two annotations - [@Nullable](#) and [@NotNull](#) - handle method invocations and field dereferences outside methods.

## @Nullable

The [@Nullable](#) Annotation reminds you about the necessity to introduce an NPE check when:

- Calling methods that can return null.
- Dereferencing variables (fields, local variables, parameters) that can be null.

## @NotNull

The [@NotNull](#) Annotation is, actually, an explicit contract declaring the following:

- A method should not return null.
- A variable (like fields, local variables, and parameters) cannot hold null value.

IntelliJ IDEA warns you if these contracts are violated.

**Tip** For more information and code examples, refer to online [how-to](#).

## Formal Semantics

An element annotated with [@Nullable](#) claims null value is perfectly valid to return (for methods), pass to (for parameters) and hold (for local variables and fields).

An element annotated with [@NotNull](#) claims null value is forbidden to return (for methods), pass to (for parameters) and hold (for local variables and fields).

There is a covariance-contravariance relationship between [@Nullable](#) and [@NotNull](#) when overriding/implementing methods with annotated declaration or parameters.

- Overriding/implementing methods with an annotated declaration:
  - The [@NotNull](#) annotation of the parent method requires the [@NotNull](#) annotation for the child class method.
  - Methods with the [@Nullable](#) annotation in the parent method can have either [@Nullable](#) or [@NotNull](#) annotations in the child class method.
- Overriding/implementing methods with annotated parameters:
  - The [@Nullable](#) annotation of the parameter in the parent method requires the [@Nullable](#) annotation for the child class method parameter.
  - Methods with the [@NotNull](#) annotation of the parameter in the parent method can have either [@Nullable](#) or [@NotNull](#) annotations (or none of them) for the child class method parameter.

This section describes formal semantics and usage examples for `@NonNls` annotation introduced in IntelliJ IDEA. This annotation indicates that the annotated code element is not a string requiring internationalization and it does not contain such strings.

## Formal Semantics

When an element is annotated with `@NonNls`, internationalization mechanisms will skip it or strings inside it.

annotated method parameter

A string constant passed as a parameter in the method call is skipped. Also, if the property setter method parameter is annotated, such property values are not highlighted in the GUI Designer forms.

annotated field/variable

String literals in field/variable initializer are skipped.

method is called on an annotated field/parameter/variable

String literals passed as parameters to the method are skipped.

annotated field/parameter/variable passed as a parameter to the `equals()` method invoked on a string literal

The string literal is skipped.

annotated field/parameter/variable at the left part of the assignment expression

All string literals in the right part of the expression are skipped.

annotated method

All string literals returned by the method are skipped.

annotated class

All string literals in the class and all its subclasses are skipped.

annotated package

All string literals in the package and all its subpackages are skipped.

On this page:

- [Overview](#)
- [Syntax of the @Contract annotation](#)
- [Attributes of the @Contract annotation](#)
- [Example](#)
- [Useful hints](#)

## Overview

The `@Contract` annotation brings more safety to your code by defining dependencies between method arguments and return values. This information provides smarter control flow analysis for the source code and helps avoid probable errors.

The `@Contract` annotation is a powerful and flexible tool that helps make your APIs safer. Furthermore, it's possible to use it not only for annotating your own code but also for other existing libraries.

Once the annotations are configured for the project libraries, IntelliJ IDEA stores information about the annotations in simple XML files, to share with the team via version control.

To enable the annotations in a project, add `<IntelliJ IDEA Home>/lib/annotations.jar` to the classpath via [Project Structure](#) dialog.

The usage of `@Contract` annotations can be clarified by the following examples:

- `@Contract("_", null -> null")` - method returns `null` if its second argument is `null` .
- `@Contract("_", null -> null; _, !null -> !null")` - method returns `null` if its second argument is `null` , and not-null otherwise.
- `@Contract("true -> fail")` - a typical `assertFalse()` method which throws an exception if `true` is passed to it.

To learn more about `@Contract` annotations, refer to [this page](#) .

## Syntax of the @Contract annotation

The `@Contract` annotation value has the following syntax:

- `contract ::= (clause ';'*) clause`
- `clause ::= args '->' effect`
- `args ::= ((arg ','*) arg )?`
- `arg ::= value-constraint`
- `value-constraint ::= '_' | 'null' | '!null' | 'false' | 'true'`
- `effect ::= value-constraint | 'fail'`

The constraints here are:

- `_` - any value
- `null` - null value
- `!null` - a value statically proved to be not-null
- `true` - true boolean value
- `false` - false boolean value
- `fail` - the method throws an exception, if the arguments satisfy argument constraints

## Attributes of the @Contract annotation

The `@Contract` annotation has two attributes: `value` and `pure` .

The `value` attribute contains the contract clauses describing causal relations between call arguments and the returned value.

The `pure` attribute is intended for the methods that do not change the state of their objects, but just return a new value. This attribute may be used as a hint to the "Result of method call ignored" inspection to indicate that the method's return value should be used when called. It is either `false` (by default), or `true` .

## Example

Consider the following code:

```

private static void printSorted(){
    List<Integer> sorted = Quicksort.sort(null);
    if (sorted != null){
        System.out.println("Sorted array" + sorted);
    }
}

public static <T extends Comparable<T>> List<T> sort(List<T> list){
    if(list != null){
        List<T> copy = new ArrayList<T>(list);
        sort(copy);
        return copy;
    }
    else {
        return null;
    }
}
}

```

IntelliJ IDEA doesn't complain, because it doesn't know that a null input yields a null output.

Let's decorate the `sort()` method with `@Contract` annotation, specifying that null inputs yield null outputs.

```

@Contract("null -> null")
public static <T extends Comparable<T>> List<T> sort(List<T> list)
{
    if (list != null){
        List<T> copy = new ArrayList<T>(list);
        sort(copy);
        return copy;
    }
    else {
        return null;
    }
}

```

IntelliJ IDEA immediately recognizes that `if` statement is extraneous, and reports about the condition that is always false:

```

private static void printSorted() {
    List<Integer> sorted = Quicksort.sort(null);
    if (sorted != null){
        System.out.println("Sorted array" + sorted);
    }
}

```

Condition 'sorted != null' is always 'false' [more...](#) (Ctrl+F1)

## Useful hints

IntelliJ IDEA suggests the two intention actions for the methods of the library classes:

- Add method contract / Edit method contract :

```

DataStructureIterator iterator = this.new EvenIterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next());
}
System.out.println("Even iterator");

```

Intention actions for `while (iterator.hasNext())`:

- Remove braces from 'while' statement
- Add method contract to 'hasNext'
- Annotate method 'hasNext' as @Deprecated

```

// Print out values of even indices of the array
DataStructureIterator iterator = this.new EvenIterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next());
}
System.out.println("Even iterator");

```

Intention actions for `while (iterator.hasNext())`:

- Remove braces from 'while' statement
- Annotate method 'hasNext' as @Deprecated
- Deannotate org.jetbrains.annotations.Contract
- Edit method contract of 'hasNext'

```

interface DataStructureIterator extends java.util.Iterator<Integer>

```

- Both intentions have the possibility to set `pure = true` :

- [Overview](#)

- [Example](#)

## Overview

Annotation `@ParametersAreNonnullByDefault` gives the developer an option to define that for a given class or package all the elements (methods, parameters, fields and variables) have `@NotNull` semantic, unless they are explicitly annotated with the `@Nullable` annotation.

This is done by adding annotation `@javax.annotation.ParametersAreNonnullByDefault` to the entire package, class, or method.

To use `@javax.annotation.ParametersAreNonnullByDefault` annotation, make sure that `jsr305 jars` are added to the module libraries.

## Example

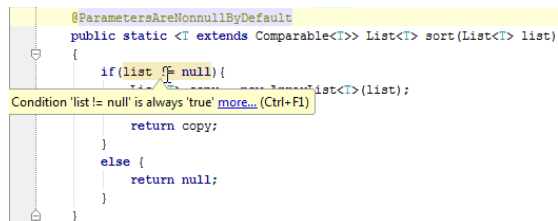

Consider the following code:

```
public static <T extends Comparable<T>> List<T> sort(List<T> list)
{
    if(list != null){
        List<T> copy = new ArrayList<T>(list);
        sort(copy);
        return copy;
    }
    else {
        return null;
    }
}
```

IntelliJ IDEA doesn't complain.

Let's decorate the `sort()` method with `@ParametersAreNonnullByDefault` annotation, which means that all the symbols of this method behave as if they were `@NotNull`.

IntelliJ IDEA immediately recognizes that `if` statement is extraneous, and reports about the condition that is always true:

```
@ParametersAreNonnullByDefault
public static <T extends Comparable<T>> List<T> sort(List<T> list)
{
    if(list != null){
        List<T> copy = new ArrayList<T>(list);
        sort(copy);
        return copy;
    }
    else {
        return null;
    }
}
```

Condition 'list != null' is always 'true' [more...](#) (Ctrl+F1)

However, if you decorate the parameter of the method `sort()` as nullable, you will see no inspection messages:

```
@ParametersAreNonnullByDefault
public static <T extends Comparable<T>> List<T> sort(@Nullable List<T> list)
{
    if(list != null){
        List<T> copy = new ArrayList<T>(list);
        sort(copy);
        return copy;
    }
    else {
        return null;
    }
}
```

Your source code can contain various annotations. For example, `@Nullable` and `@NotNull` annotations are used, when IntelliJ IDEA suggests that a certain element can become `Null`. The `@Nonnull` annotation is used to ignore the hardcoded string literals.

## To use annotations

1. Make sure that `annotations.jar` that can be found in the `lib` folder under the IntelliJ IDEA installation, is added to the module dependencies.

For `@javax.annotation.ParametersAreNonnullByDefault` annotations, `javax` should be added to the module libraries.

**Tip** You can also use annotations from JSR-305 and FindBugs. In this case, make sure they are added to the classpath.

You can configure `@Nullable`, `@NotNull` and `@Contract` annotations in the [Inspections](#) page of the Settings dialog ( Constant conditions and exceptions - Configure annotations ).

2. Introduce the desired annotation before the package/class/field/variable/method/method parameter declaration.

On this page:

- [Annotating automatically nullable and non-null elements](#)
- [Example](#)

## Annotating automatically nullable and non-null elements

IntelliJ IDEA makes it possible to analyse the source code for the elements that can become null, and annotate them, provided that annotations are available in the project sources.

### To automatically annotate nullable and non-null elements

1. Make sure that `annotations.jar` is added to your project. If it is not the case, IntelliJ IDEA will suggest to configure the annotations first. This can be done either manually ( `File | Settings | Project Settings - Inspections - Probable bugs - Constant conditions and exceptions` ), or automatically.
2. On the main menu, choose `Analyze | Infer Nullity` .
3. In the `Specify Infer Nullity Scope` dialog box, do the following:
  - Select the scope where you want to infer nullity: the entire project, the current file, etc.
  - If you want to perform nullity analysis for the test sources as well, and annotate local variables, select the corresponding checkboxes.

Click `OK` . IntelliJ IDEA adds import statement for annotations if required, and annotates parameters and variables.

### Example

Consider the following code:

```
public Color myMethod(){
    Color color = null;
    return color;
}
```

Infer nullity for this code, with the checkbox `Annotate local variables` selected. IntelliJ IDEA annotates the method and local variable with the `Nullable` annotation:

```
@Nullable
public Color myMethod(){
    @Nullable Color color = null;
    return color;
}
```

However, if in the initial code the variable is initialized with some value, rather than null, the method and the local variable will be annotated with the `NotNull` annotation:

```
@NotNull
public Color myMethod(){
    @NotNull Color color = new Color(255);
    return color;
}
```

Consider a situation, when one needs to annotate symbols with `@Nullable/@NotNull` or `@NonNls` , but to avoid annotations in the source code. This may be the case when a team works on a project, using different IDEs, for example, IntelliJ IDEA and Eclipse; or when working with library classes.

This section provides brief description of external annotations. To learn how to enable, configure and create external annotations, refer to the section [Using External Annotation](#) .

IntelliJ IDEA suggests using external annotations that are stored outside of the source code. Information about annotated symbols is stored in XML files, rather than in the source code. Each entry maps a method parameter or return value to the desired annotation class.

Such file has the name `annotations.xml` and resides in the path that depends on the origin of the specific annotation. If an annotation pertains to the SDK, configured for your project, the path is to be defined in the SDK settings. If an annotation pertains to a module, the path should be defined in the module settings.

On this page:

- [Introduction](#)
- [Enabling external annotations](#)
- [Defining the path to external annotations on the SDK level](#)
- [Defining the path to external annotations for a module](#)
- [Annotating a symbol with an external annotation](#)

## Introduction

If you want IntelliJ IDEA to use [external annotations](#), you have to enable this facility, and specify the directories, where the external annotations will be stored.

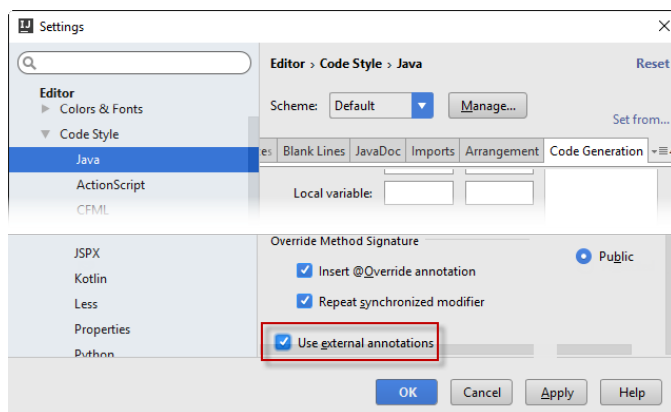

This section describes how to:

- [Enable external annotations](#).
- Configure paths to the external annotations on the [SDK](#) or [module](#) level.
- [Apply](#) external annotations.

## Enabling external annotations

### To enable external annotations

1. In the Code Generation section of the [Java](#) code style page, select the checkbox Use external annotations.

2. Apply changes and close the dialog box.

## Defining the path to external annotations on the SDK level

### To define the path to external annotations on the SDK level

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the Platform Settings section, click SDK.
3. In the SDK page, select Annotations tab.
4. Click Add button and specify the desired path in the Select Path dialog. You can create as many annotation paths as you like.
5. Apply changes and close the dialog box.

## Defining the path to external annotations for a module

### To define the path to external annotations for a module

1. On the context menu of a project, choose Module Settings. Project Structure dialog is displayed on the [Modules page](#).
2. Select Paths tab.
3. In the External Annotations section, click Add and specify the desired path in the [Select Path dialog](#). You can create as many annotation paths as required.
4. Apply changes and close the dialog box.

## Annotating a symbol with an external annotation

### To annotate a symbol with an external annotation

Follow these general steps:

1. If code inspection alerts you about the necessity to annotate a symbol, press `Alt+Enter` to show the list of intention actions, and select the appropriate Annotate command, for example:

2. In the dialog box that opens, click the Add externally button.

**Note** This dialog appears if external annotations are `enabled`. Otherwise, annotations are added to the source code by default.

In this part you will find:

- [General refactoring procedure](#)
- [Procedures and examples of the available refactorings](#)

## To perform refactoring, follow these general steps

1. Select (or hover caret on) a symbol or code fragment to refactor. The set of available refactorings depends on your selection. You can select symbols in the following IntelliJ IDEA components:
  - Project view
  - Structure tool window
  - Editor
  - UML Class diagram
2. Do one of the following:
  - On the main Refactor menu or on the context menu of the selection, choose the desired refactoring or press the corresponding keyboard shortcut (if any).
  - On the main menu, choose Refactor | Refactor This , or press `Ctrl+Shift+Alt+T` , and then select the desired refactoring from the pop-up window.
3. In the dialog box that opens, specify the refactoring options.
4. To apply the changes immediately, depending on the refactoring type, click Refactor or OK .
5. For certain refactorings, there is an option of previewing the changes prior to actually performing the refactoring. In such cases the Preview button is available in the corresponding dialog. To preview the potential changes and make the necessary adjustments, click Preview . IntelliJ IDEA displays the changes that are going to be made on a dedicated tab of the [Find tool window](#) .

One of the possible actions at this step is to exclude certain entries from the refactoring. To do so, select the desired entry in the list and press `Delete` .

If conflicts are expected after the refactoring, IntelliJ IDEA displays a dialog with a brief description of the encountered problems. If this is the case, do one of the following:

- Ignore the conflicts by clicking the Continue button. As a result, the refactoring will be performed, however, this may lead to erroneous results.
  - Preview the conflicts by clicking the Show in View button. IntelliJ IDEA shows all conflicting entries on the Conflicts tab in the [Find tool window](#) , enabling you to navigate to the problematic lines of code and to make the necessary fixes.
  - Cancel the refactoring and return to the editor.
6. When you are satisfied with the proposed results, click Do Refactor to apply the changes.

IntelliJ IDEA provides the following common refactorings:

- [Change Class Signature](#)
- [Change Signature](#)
- [Convert Anonymous to Inner](#)
- [Convert to Instance Method](#)
- [Copy](#)
- [Encapsulate Fields](#)
- [Extract Refactorings](#)
- [Generify Refactoring](#)
- [Inline](#)
- [Invert Boolean](#)
- [Make Class Static](#)
- [Make Method Static](#)
- [Migrate](#)
- [Move Refactorings](#)
- [Pull Members Up](#)
- [Push Members Down](#)
- [Remove Middleman](#)
- [Rename Refactorings](#)
- [Replace Constructor with Builder](#)
- [Replace Constructor with Factory Method](#)
- [Replace Inheritance with Delegation](#)
- [Find and Replace Code Duplicates](#)
- [Replace Temp With Query](#)
- [Safe Delete](#)
- [Type Migration](#)

- Use Interface Where Possible
- Wrap Return Value

The following language-specific refactorings are available:

- Change Class Signature
- Change Signature
- Convert Anonymous to Inner
- Convert to Instance Method
- Copy
- Encapsulate Fields
- Extract Refactorings
- Generify Refactoring
- Inline
- Invert Boolean
- Make Class Static
- Make Method Static
- Migrate
- Move Refactorings
- Pull Members Up
- Push Members Down
- Remove Middleman
- Rename Refactorings
- Replace Constructor with Builder
- Replace Constructor with Factory Method
- Replace Inheritance with Delegation
- Find and Replace Code Duplicates
- Replace Temp With Query
- Safe Delete
- Type Migration
- Use Interface Where Possible
- Wrap Return Value

The Change Class Signature refactoring lets you turn a class into a generic and manipulate its type parameters. The refactoring automatically corrects all calls, implementations and overridings of the class.

- [Example](#)
- [Use cases](#)
- [Changing a class signature](#)

## Example

### Before After

<pre>// This is the class whose signature will be changed:  public class MyClass {     // some code here }  public class MyOtherClass {      // Here are the references to MyClass:      MyClass myClass;     void myMethod(MyClass myClass) {         // some code here     }     // some code here }  // Now we are going to add two formal type parameters // to MyClass.</pre>	<pre>// Two formal type parameters have been added:  public class MyClass&lt;Param1, Param2&gt; {     // some code here }  public class MyOtherClass {      // The references to MyClass have changed accordingly:      MyClass&lt;String, Integer&gt; myClass;     void myMethod(MyClass&lt;String, Integer&gt; myClass) {         // some code here     }     // some code here }  // When performing the refactoring, String and Integer // were specified as the default values for Param1 and // Param2 respectively.</pre>
--	--

## Use cases

- The type parameters can have bounds extending other constructs including other type parameters from another class. For instance, the code like `public class ClassA<T, E>` can be easily transformed to `public class ClassA<T, E extends T>`. However, if the parameter order was initially `public class ClassA<E, T>`, the Change Class Signature refactoring may be useful for changing the parameter order in the class signature as well as in all its usages.
- IntelliJ IDEA can successfully deal with rather complicated cases and can alter parameters and corresponding usages if one parameter depends on another.

## Changing a class signature

### To change a class signature, follow these steps

1. In the editor, place the cursor within the name of the class whose signature you want to change.
2. Do one of the following:
  - Press `Ctrl+F6`.
  - Choose Refactor | Change Signature in the main menu.
  - Select Refactor | Change Signature from the context menu.
3. In the [Change Class Signature dialog](#), use the available controls to manage the formal type parameters:
  - To add a new parameter, click `+` or press `Alt+Insert`. Specify the parameter name and default type in the Name and the Default Value fields respectively.
  - To remove a parameter, select the parameter and click `-` (`Alt+Delete`).
  - To move a parameter up or down in the list, select the parameter and then use `↑` (`Alt+Up`) or `↓` (`Alt+Down`).
4. To perform the refactoring right away, click Refactor.  
To see the expected changes and make the necessary adjustments prior to actually performing the refactoring, click Preview.

## Basics

The Change Signature refactoring combines several different modifications that can be applied to a method signature. You can use this refactoring for the following purposes:

- To change the method name.
- To change the method return type.
- To add new parameters and remove the existing ones.
- To assign default values to the parameters.
- To reorder parameters.
- To change parameter names and types.
- To propagate new parameters through the method call hierarchy.

When changing a method signature, IntelliJ IDEA searches for all usages of the method and updates all the calls, implementations, and override replacements of the method that can be safely modified to reflect the change.

**Note** The Change Method Signature refactoring is supported for Java, PHP, JavaScript, and ActionScript.  
- You can access this refactoring from a [UML Class diagram](#).  
- The Change Method Signature refactoring is applicable to a constructor. In this case, however, the name and the return type cannot be changed.

## Examples

### Before/After

```
// The function paint() is declared in
// the IShape interface.

public interface IShape {
    function paint(g: Graphics): void;
}

// This function is then called within the
// paint() function of the Canvas class.

public class Canvas {
    private var shapes: Vector.<IShape>;

    public function paint(g: Graphics): void {
        for each (var shape: IShape in shapes) {
            shape.paint(g);
        }
    }
}

// Now we are going to show an example of the
// Change Signature refactoring for the function
// paint() of the IShape interface.
```

```
// In this refactoring example we have changed the name of the existing parameter
// and introduced two new parameters. Note that the first of the new parameters is
// a required parameter while the second is optional because the default value
// for it is specified in the function definition.

public interface IShape {
    function paint(graphics:Graphics, wireframe:Boolean, offset:Point = null):void;
}

// When performing this refactoring, the new parameters were propagated to
// the paint() function of the Canvas class. As a result, the signature of
// Canvas.paint() has changed. Also note how IShape.paint() within
// Canvas.paint() is called now.

public class Canvas {
    private var shapes: Vector.<IShape>;

    public function paint(g:Graphics, wireframe:Boolean): void {
        for each (var shape: IShape in shapes) {
            shape.paint(g, wireframe);
        }
    }
}

// Other results for this refactoring are possible.
// For more information, see the discussion that follows.
```

**Warning!** The following is only valid when Python Plugin is installed and enabled!

<pre># This function will be renamed: def fibonacci( n ): a, b = 0, 1 while b &lt; n: print( b ) a, b = b, a+b  n = int(input("n = "))</pre>		<pre># Function with the new name: def fibonacci_numbers( n ): a, b = 0, 1 while b &lt; n: print( b ) a, b = b, a+b  n = int(input("n = "))</pre>
<pre># New parameters will be added: def fibonacci( n ): a, b = 0, 1 while b &lt; n: print( b ) a, b = b, a+b  n = int(input("n = ")) fibonacci( n )</pre>	<pre># Function with the new parameters. # Do not forget to specify the default values of the parameters, which will be used in the function call. def fibonacci( n,a,b ): a, b = 0, 1 # this should be done manually! while b &lt; n: print( b ) a, b = b, a+b  n = int(input("n = ")) fibonacci( n,0,1 )</pre>	

## Initializer, default value, and propagation of new parameters

For each new parameter added to a method, you can specify:

- A value (or an expression) to be used for initializing the parameter (the Initializer field in IntelliJ IDEA).
- A default value (or an expression) (the Default value field).

You can also propagate the parameters you have introduced to the methods that call the function whose signature you are changing.

The refactoring result depends on whether you specify the default value and whether you use propagation.

Propagation. New parameters can be propagated to any method that calls the method whose signature you are changing. In such case, generally, the signatures of the calling methods change accordingly.

These changes, however, also depend on the combination of the initializer and the default value set for the new parameters.

Initializer. The value specified in the Initializer field is added to the function definition as the default parameter value. This makes the corresponding parameter an optional parameter. (See the discussion of required and optional parameters in [Flex/ActionScript documentation](#).)

If the default value for the new parameter is not specified (in the Default value field), irrespective of whether or not the propagation is used, the method calls and the signatures of the calling methods don't change.

If both, the initializer and the default value are specified, the refactoring result depends on whether or not the propagation is used:

- If the propagation is not used, the initializer value don't affect the function calls and the signatures of the calling functions.
- If the propagation is used, the initializer value is added to the definition of the calling function as the default value for the corresponding parameter (in the same way as in the function whose signature you are changing).

Default value. Generally, this is the value to be added to the method calls.

If the new parameter is not propagated to a calling method, the calls within such method will also use this value.

If propagation is used, this value won't affect the method calls within the calling methods.

## More refactoring examples

To see how different refactoring settings discussed above affect the refactoring result, let us consider the following examples.

All the examples are a simplified version of the refactoring [shown earlier](#). In all cases, a new parameter `wireframe` of the type `Boolean` is added to the function `paint()` defined in the `IShape` interface.

In different examples, different combinations of the initializer and the default value are used, and the new parameter is either propagated to `Canvas.paint()` (which calls `IShape.paint()`) or not.

Initializer	Default	Propagation	Result
value	used		

false	Yes		
-------	-----	--	--

```
public interface IShape {
function paint(g:Graphics, wireframe:Boolean):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics, wireframe:Boolean): void
{
for each
(
var shape: IShape in shapes) {
shape.paint(g,wireframe);
}
}
```

false No

```
public interface IShape {
function paint(g:Graphics, wireframe:Boolean):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics): void
{
for each
(
var shape: IShape in shapes) {
shape.paint(g,false);
}
}
```

true

Yes

```
public interface IShape {
function paint(g:Graphics, wireframe:Boolean = true):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics):
void
{
for each
(
var shape: IShape in shapes) {
shape.paint(g);
}
}
```

true

No

```
public interface IShape {
function paint(g:Graphics, wireframe:Boolean = true):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics):void
{
for each
(
var shape: IShape in shapes) {
shape.paint(g);
}
}
```

true

false Yes

```
public interface IShape {
function paint(g:Graphics, wireframe:Boolean = true):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics, wireframe:Boolean = true):
void {
for each
(
var shape: IShape in shapes) {
shape.paint(g,wireframe);
}
}
```

true

false No

## Changing a method signature

1. In the editor, place the cursor within the name of the method whose signature you want to change.
2. Do one of the following:
  - Press `Ctrl+F6`.
  - Choose Refactor | Change Signature on the main menu or
  - Choose Refactor | Change Signature on the context menu.
3. In the Change Signature dialog, make the necessary changes to the method signature and specify what other, related, changes are required.

You can:

- Change the method name. To do that, edit the text in the Name field.
- Change the method return type by editing the contents of the Return type field.  
Setting the method return type is only possible in PHP language version 7.1 and later. You can specify the PHP language level on the [PHP page](#) (File | Settings | Languages and Frameworks | PHP for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | PHP for macOS).
- Manage the method parameters using the table and the buttons in the Parameters area:
  - To add a new parameter, click `+` and specify the properties of the new parameter in the corresponding table row.  
When adding parameters, you may want to [propagate these parameters](#) to the methods that call the current method.

In the PHP context, when the **Change signature** refactoring is invoked from the constructor of a class, the new parameter can be initialized as a class field. To do that, use the Create and initialize class properties check box:

- When this checkbox is selected, the newly added parameter is initialized as a field. IntelliJ IDEA creates a protected field with the same name as this parameter and adds a line with the following assignment:

```
$this-><parameter_name> = <parameter_name>;
```

- When the checkbox is cleared, a parameter is added without initialization.

For example, you have the following constructor:

```
class ChangeSignatureNewParam {
    function __construct() {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
    }
}
```

If you invoke the **Change signature** refactoring from the `__construct()` method and add a new `$q` parameter, the result will depend on whether you select or clear the Create and initialize class properties checkbox:

- The Create and initialize class properties checkbox is selected:

```
class ChangeSignatureNewParam {
    private $q;
    function __construct($q) {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
        $this->q = $q;
    }
}
```

- The Create and initialize class properties checkbox is cleared:

```
class ChangeSignatureNewParam {
    function __construct($q) {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
    }
}
```

- To remove a parameter, click any of the cells in the corresponding row, and then click `-`.
- To reorder the parameters, use the `↑` and `↓` buttons. For example, if you want to put a certain parameter first in the list, click any of the cells in the row corresponding to that parameter, and then click `↑` the required number of times.
- To change the name, type, the initializer, or the default value of a parameter, make the necessary edits in the table of parameters (in the fields Name Type, Initializer and Default value respectively).

```
public interface IShape {
    function paint(g:Graphics,
        wireframe:Boolean = true):void;
}

// The function paint() in the Canvas class:

public function paint(g:Graphics):
void {
    for each
    (
        var shape: IShape in shapes) {
        shape.paint(g,false);
    }
}
```

- Propagate new method parameters (if any) along the hierarchy of the methods that call the current method.  
(There may be methods that call the method whose signature you are changing. These methods, in their turn, may be called by other methods, and so on. You can propagate the changes you are making to the parameters of the current method through the hierarchy of calling methods and also specify which calling methods should be affected and which shouldn't.)

To propagate a new parameter:

1. Click the Propagate Parameters button .
2. In the left-hand pane of the Select Methods to Propagate New Parameters dialog, expand the necessary nodes and select the checkboxes next to the methods you want the new parameters to be propagated to.  
To help you select the necessary methods, the code for the calling method and the method being called is shown in the right-hand part of the dialog (in the Caller Method and Callee Method panes respectively).

As you switch between the methods in the left-hand pane, the code in the right-hand pane changes accordingly.

3. Click OK .
4. To perform the refactoring right away, click Refactor .  
To [see the expected changes](#) and make the necessary adjustments prior to actually performing the refactoring, click Preview .

**Note** Code completion is available in the Default value field of the table in the Parameters area.

In Java, you can use the [Change Method Signature](#) refactoring to:

- Change the method name, return type and visibility scope.
- Add new parameters and remove the existing ones. Note that you can also add a parameter using a dedicated [Extract Parameter](#) refactoring.
- Reorder parameters.
- Change parameter names and types.
- Add and remove exceptions.
- Propagate new parameters and exceptions through the method call hierarchy.

On this page:

- [Examples](#)
- [Changing a method signature](#)

## Examples

The following table shows 4 different ways of performing the same Change Method Signature refactoring.

In all the cases, a new parameter `price` of the type `double` is added to the method `myMethod()`.

The examples show how the method call, the calling method (`myMethodCall()`) and other code fragments may be affected depending on the refactoring settings.

### BeforeAfter

<pre>public class MyClass {      // This is the method whose signature will be changed:      public void myMethod(int value) {         // some code here     } }  public class MyOtherClass {     public void myMethodCall(MyClass myClass) {         double d=0.5;          // Here is the method call:          myClass.myMethod(1);     } }  // We'll ask IntelliJ IDEA to update all the method calls. // We'll also specify a default value to be passed to the method.</pre>	<pre>public class MyClass {      // The new parameter price has been added:      public void myMethod(int i, double price) {         // some code here     } }  public class MyOtherClass {     public void myMethodCall(MyClass myClass) {         double d=0.5;          // The method call has changed accordingly:          myClass.myMethod(1, 0.0);     } }  // When performing the refactoring, 0.0 was specified as // the default parameter value.</pre>
--	---

```

public class MyClass {

    // This is the method whose signature will be changed:

    public void myMethod(int value) {
        // some code here
    }
}

public class MyOtherClass {
    public void myMethodCall(MyClass myClass) {
        double d=0.5;

        // Here is the method call:

        myClass.myMethod(1);
    }
}

// We'll ask IntelliJ IDEA to update all the method calls.
// We'll also ask IntelliJ IDEA to look for a variable
// of the appropriate type near the method call and pass this
// variable to the method.
// In IntelliJ IDEA, this option is called Use Any Var.

```

```

public class MyClass {

    // The new parameter price has been added:

    public void myMethod(int i, double price) {
        // some code here
    }
}

public class MyOtherClass {
    public void myMethodCall(MyClass myClass) {
        double d=0.5;

        // The method call has changed accordingly:

        myClass.myMethod(1, d);
    }
}

// Near the method call, IntelliJ IDEA has found the variable d
// which has the same type as the new parameter. As a result,
// this variable was used in the method call.

```

```

public class MyClass {

    // This is the method whose signature will be changed:

    public void myMethod(int value) {
        // some code here
    }
}

public class MyOtherClass {
    public void myMethodCall(MyClass myClass) {
        double d=0.5;

        // Here is the method call:

        myClass.myMethod(1);
    }
}

// We'll ask IntelliJ IDEA to keep the method calls unchanged but
// create a new overloading method which will call the method
// with the new signature.
// In IntelliJ IDEA, this way of handling the method calls is
// referred to as Delegate via overloading method.

```

```

public class MyClass {

    // A new overloading method has been created:

    public void myMethod(int i) {
        myMethod(i, 0.0);
    }

    // The new parameter price has been added:

    public void myMethod(int i, double price) {
        // some code here
    }
}

public class MyOtherClass {
    public void myMethodCall(MyClass myClass) {
        double d=0.5;

        // The method call has not changed:

        myClass.myMethod(1);
    }
}

// Note that the new overloading method has the old signature.
// However, it calls the method with the new signature.
// 0.0 was specified as the default parameter value
// when performing the refactoring.

```

```

public class MyClass {

    // This is the method whose signature will be changed:

    public void myMethod(int value) {
        // some code here
    }
}

public class MyOtherClass {

    // This method will also change its signature:

    public void myMethodCall(MyClass myClass) {
        double d=0.5;

        // Here is the method call:

        myClass.myMethod(1);
    }
}

// This time we'll ask IntelliJ IDEA to propagate the new
// parameter to the method call through the calling method
// myMethodCall().

```

```

public class MyClass {

    // The new parameter price has been added:

    public void myMethod(int i, double price) {
        // some code here
    }
}

public class MyOtherClass {

    // The new parameter price has propagated
    // to the method call through the calling method:

    public void myMethodCall(MyClass myClass, double price) {
        double d=0.5;

        // The method call has changed accordingly:

        myClass.myMethod(1, price);
    }
}

```

## Changing a method signature

1. In the editor, place the cursor within the name of the method whose signature you want to change.

2. Do one of the following:

- Press `Ctrl+F6`.
- Choose Refactor | Change Signature in the main menu.
- Select Refactor | Change Signature from the context menu.

Note that if you refactor a method that overrides another method, IntelliJ IDEA suggests either to modify the method from the base class, or to modify only the selected method.

3. In the [Change Signature dialog](#), make the necessary changes to the method signature and specify which other, related changes are required.

You can:

- Change the method visibility scope (access level modifier) by selecting the necessary option under Visibility.
- Change the method return type by editing the contents of the Return type field.  
Note that [code completion](#) is available in this field, and also in other fields used for specifying the types.
- Change the method name. To do that, edit the text in the Name field.
- Manage the method parameters using the controls on the Parameters tab:
  - To add a new parameter, click `+` (`Alt+Insert`) and specify the properties of the new parameter in the corresponding fields. If necessary, select the [Use Any Var option](#).  
When adding parameters, you may want to [propagate these parameters](#) to the methods that call the current method.
  - To remove a parameter, select this parameter in the table and click `-` (`Alt+Delete`).
  - To reorder the parameters, use `↑` (`Alt+Up`) and `↓` (`Alt+Down`).
  - To change the name, type, or the default value for a parameter, click this parameter in the table and make the necessary edits in the corresponding fields.
- Propagate new method parameters (if any) along the hierarchy of the methods that call the current method. (There may be the methods that call the method whose signature you are changing. These methods, in their turn, may be called by other methods, and so on. You can propagate the changes you are making to the parameters of the current method through the hierarchy of the calling methods and also specify which calling methods should be affected and which shouldn't.)

To propagate the new parameters:

1. Click  ( **Alt+G** ).
2. In the left-hand pane of the Select Methods to Propagate New Parameters dialog, expand the necessary nodes and select the checkboxes next to the methods you want the new parameters to be propagated to.  
To help you select the necessary methods, the code for the calling method and the method being called is shown in the right-hand part of the dialog (in the Caller Method and Callee Method panes respectively).

As you switch between the methods in the left-hand pane, the code in the right-hand part changes accordingly.

3. Click OK .

- Manage the method exceptions using the list of exception types and the buttons on the Exceptions tab. The procedures are similar to those used for [managing the method parameters](#) .
- Propagate new exceptions (if any) along the hierarchy of the methods that call the current method. To initiate this procedure, use  ( **Alt+X** ). In all other respects, the procedure is similar to that used for [propagating new method parameters](#) .
- Specify how the method calls should be handled. To do that, select one of the following Method calls options:
  - If you want the method calls to be **modified** , select Modify .
  - If you want to leave the existing method calls **unchanged** , select Delegate via overloading method .

4. To perform the refactoring right away, click Refactor .

To [see the expected changes](#) and make the necessary adjustments prior to actually performing the refactoring, click Preview .

The Convert Anonymous to Inner refactoring allows you to convert an anonymous class into a named inner class.

– [Example](#)

– [To inline a constructor, follow these steps](#)

## Example

BeforeAfter

<pre>public class Class {     public Interface method() {         final int i = 0;         return new Interface() {             public int publicMethod() {                 return i;}         };     } }</pre>	<pre>public class Class {     public Interface method() {         final int i = 0;         return new MyInterfaceClass(i);     } } public class MyInterfaceClass implements Interface {     private final int         i;     public MyInterfaceClass(int i) {         this.i = i;     }     public int publicMethod() {         return             i;     } }</pre>
---	---

### To inline a constructor, follow these steps

1. Place the cursor within the anonymous class to be refactored.
2. On the main menu, or on the context menu of the selection, choose Refactor | Convert Anonymous To Inner . The [Convert Anonymous To Inner dialog](#) opens.
3. In the Class name field specify the name for the new inner class.
4. In the Constructor parameters area select the variables, that will be used as parameters to the inner class constructor.
5. Click OK to create the inner class.

Convert to Instance Method refactoring is used to convert a static method to a non-static, class instance method, with a class being the type parameter of the initial method.

- [Example](#)
- [Converting a method to an instance method](#)

**Tip** This refactoring is also available from [UML Class diagram](#) .

## Example

Consider classes `MyClass` , `ClassA` and `ClassB` residing in the same package. `MyClass` contains the following code:

```
public class MyClass {
    ClassA classA = new ClassA();
    ClassB classB = new ClassB();

    static public void greatMethod(ClassA classA, ClassB classB){
        System.out.println("classA = " + classA);
        System.out.println("classB = " + classB);
    }

    public void myMethod(){
        MyClass.greatMethod(classA, classB);
    }
}
```

After refactoring, `MyClass` and `ClassB` become:

```
public class MyClass {
    ClassA classA = new ClassA();
    ClassB classB = new ClassB();

    public void myMethod(){
        classB.greatMethod(classA);
    }
}

public class ClassB {
    public void greatMethod(ClassA classA){
        System.out.println("classA = " + classA);
        System.out.println("classB = " + this);
    }
}
```

## Converting a method to an instance method

1. In the editor, place the caret on the declaration or usage of a method to be refactored. The method should be static and the types of its parameters should be the classes from the project. In other words, you cannot use such parameters types, as `String` .
2. Do one of the following:
  - On the Refactor menu, choose Convert to Instance Method .
  - Right-click the method and select Refactor | Convert to Instance Method .

**Note** The selected method must be static and must receive at least one of the classes included in the current project as a parameter.

3. The Convert to Instance Method dialog appears.
4. In the Select an instance parameter list select the class you want the method to belong to after the conversion. All the usages of this class inside the method are replaced with this .
5. To change the visibility scope of the converted method, select the new scope in the Visibility area. By default the converted method will have no scope declaration (equivalent to public) .
6. [Preview and apply changes](#) .

## Basics

The Copy refactoring lets you create a copy of a class in a different package. It can also be used to create a copy of a file, directory or package in a different directory or package.

### Performing Copy refactoring

#### To perform the Copy refactoring

1. Select the item of interest in a tool window (e.g. the Project tool window). Alternatively, open the necessary class or file in the editor.
2. Do one of the following:
  - Choose Refactor | Copy on the main menu or the context menu.
  - Press **F5** .
  - In the Project tool window, press and hold the **Ctrl** key, and drag the item to the target location.
3. In the [Copy dialog](#) that opens, specify the name and location for the copy that you are creating, and click OK .

Hiding your data and accessing it through an outward interface based on accessor methods is a good idea. Later you can change the data internals, preserving full compatibility with the code relied on the class and its available methods. The Encapsulate Fields refactoring allows you to hide your data and create the necessary accessors.

- [Example](#)
- [Performing the Encapsulate Fields refactoring](#)

**Tip** This refactoring is also available from [UML Class diagram](#) .

## Example

### BeforeAfter

```
//File Class.java
public class Class {
    public String aString;
}
```

```
//File Class.java
public class Class {
    private String aString;
    public void setaString(String aString) {
        this.aString = aString;
    }
    public String getaString() {
        return aString;
    }
}
```

```
//File AnotherClass.java
public class AnotherClass {
    public Class aClass;
    public void method() {
        aClass.aString="string";
    }
}
```

```
//File AnotherClass.java
public class AnotherClass {
    public Class aClass;
    public void method() {
        aClass.setaString("string");
    }
}
```

### To perform the Encapsulate Fields refactoring, follow these steps

1. Select a class or a specific field within the class. The way you perform selection depends on the view where you do it.
  - In the editor : position the caret at the desired field or at any place inside the class to be refactored.
  - In the Project view : select the desired class.
  - In the Structure view : select one or more fields.
2. On the main menu or on the context menu of the selection, choose Refactor | Encapsulate Fields . The [Encapsulate Fields](#) dialog box is opened, displaying all fields, detected in the selected scope.
3. In the Fields to encapsulate area check the fields you want to create accessors for.
4. In the Encapsulate area, specify whether you want to create getter or setter methods, or both.
5. To replace all field occurrences with the calls to the appropriate accessor method, in the Options area check the option Use accessor even when field is accessible .
6. In the Encapsulated fields' visibility area specify the new visibility scope for the selected fields.
7. In the Accessors' visibility area select the visibility scope for the created accessor methods.
8. [Preview and apply changes](#) .

In this section:

- [Extract Delegate](#)
  - [Extract Include File](#)
  - [Extract interface](#)
  - [Extract Method](#)
  - [Extract Method Object](#)
  - [Extract Parameter Object](#)
  - [Extract Superclass](#)
  - [Extract Constant](#)
  - [Extract Field](#)
  - [Extract Functional Parameter](#)
  - [Extract Functional Variable](#)
  - [Extract Partial](#)
  - [Extract Parameter](#)
  - [Extract Property](#)
  - [Extract Variable](#)
- 
- The way to extract constant, field, and variable refactorings are performed, depends on the setting of the Enable in-place refactoring checkbox in the [Editor](#) page of the Settings/Preferences dialog.
  - Extract refactorings are performed for the various expressions and blocks of code, including strings and substrings. Extract refactoring on substrings is supported for:
    - parts of strings with no formatting
    - parts of strings with concatenation via "+"
    - parts of strings with "%"-style formatting
    - parts of strings with "%()"-style formatting
    - new-style `str.format()` formatted strings

The Extract Delegate refactoring lets you extract some of the fields and methods of a class into a separate, newly created class. This refactoring is useful, when a class has grown too large and "does too many things". In such cases, it might be a good idea to split the class into smaller, more cohesive classes.

- [Example](#)
- [Performing the Extract Delegate refactoring](#)

## Example

### BeforeAfter

<pre>public class Foo {     private String b;     public String getInfo() {         return "(" + b + ")";     }     ... }</pre> <pre>public class Bar {     Foo foo;     String t2 = foo.getInfo();     ... }</pre>	<pre>public class Foo {     private final Info info = new Info();     public String getInfo() {         return info.getInfo();     }     ... }</pre> <pre>public class Info {     private String b;     public Info() {}     public String getInfo() {         return "(" + b + ")";     } }</pre> <pre>public class Bar {     Foo foo;     String t2 = foo.getInfo();     ... }</pre>
---	--

## To perform Extract Delegate refactoring, follow these steps

1. Open the class in the editor, or select it in the Project tool window.
2. Select Refactor | Extract | Delegate from the main or the context menu.
3. In the [Extract Class dialog](#) that opens:
  - Specify the name and package for the class to be created.
  - Selects the fields and methods to be included in the new class.
  - Click Preview to see the usages of the selected fields or methods in the [Find tool window](#) . Select the usages to be included in the refactoring and click Do Refactor .

Note that this refactoring can also be accessed from a [UML Class diagram](#) .

The Extract Include refactoring is used to extract a fragment of HTML, JSP/JSPX, JavaScript, or CSS code into a separate include file.

## To extract an include file

1. In the editor, select the code block to be extracted and choose Refactor | Extract | Extract Include File on the main menu or on the context menu of the selection.
2. In the [Extract Include File](#) dialog box that opens, specify the name of the target include file in the Name for extracted include file text box.

**Tip** Type the file name without an extension.

3. In the Extract to directory text box, specify the directory to store the include file in. Leave the predefined directory, or redefine it manually, or click the Browse button  and choose the desired folder in the Select Target Directory dialog box that opens.
4. Click OK , when ready. IntelliJ IDEA extracts the selected source code into the specified file in the target directory and generates the corresponding reference in the source file.  
If there are any duplicates for the selected fragment, IntelliJ IDEA will suggest to change them for the corresponding reference as well.

With the Extract Interface refactoring you have three options:

- Create an interface based on the methods of a class without applying the new interface immediately.
- Create an interface and apply it to the source code.
- Rename the original class, and it implements the newly created interface. In such case, IntelliJ IDEA changes all usages of the original class to use the interface where possible.

In addition, static final fields, declared in the initial class, can be moved to an interface. As a result, an interface will be created containing the specific methods and fields. Thereby, the specified class methods become implementations of the corresponding interface methods.

- [Examples](#)

- [Extracting an interface](#)

## Examples

Here we have a class, and perform Extract Interface refactoring to create an interface based on the methods of the class.

### BeforeAfter

```
// File AClass.java
class AClass {
    public static final double CONSTANT=3.14;
    public void publicMethod() { //some code here}
    public void secretMethod() { //some code here}
}

// File AClass.java
class AClass implements AnInterface {
    public void publicMethod() { //some code here}
    public void secretMethod() { //some code here}
}

// File AnInterface.java
public interface AnInterface {
    double CONSTANT=3.14;
    void publicMethod();
}
```

Another example of the Extract Interface refactoring, when the Rename original class and use interface where possible option is selected.

### BeforeAfter

```
public class FormerAClass implements AClass {
    public void publicMethod() { //some code here}
    public void secretMethod() { //some code here}
}

public interface AClass {
    double CONSTANT=3.14;
    void publicMethod();
}
```

You can extract an interface from the class that already implements another interface. Let's extract interface from the class that implements `AnInterface`. Depending on whether we want `AnotherInterface` (extracted interface) to extend the `AnInterface` (existing one) or we want source `AClass` to implement them both, we will get the following code:

Extracted Interface extends the existing one:

```
class AClass implements AnotherInterface {
    public void publicMethod() {
        //some code here
    }
    public void secretMethod() {
        //some code here
    }
}
```

Extracted Interface :

```
public interface AnotherInterface extends AnInterface {
}
```

Source class implements both interfaces.

Source class :

```
class AClass implements AnInterface, AnotherInterface {
    public void publicMethod() {
        //some code here
    }
    public void secretMethod() {
        //some code here
    }
}
```

Extracted Interface :

```
public interface AnotherInterface {  
}
```

## Extracting an interface

1. Select a class in the Project view, Structure view, or place the caret anywhere within a class in the editor.
2. On the main menu or on the context menu of the selection, choose Refactor | Extract | Interface . The **Extract Interface** dialog box appears.
3. To extract a new interface, select the Extract Interface option and specify the name for the new interface.

To rename the original class and make it an implementation of the newly created interface, select the Rename original class and use interface where possible option and specify the new name for the original class. IntelliJ IDEA will alter all original class usages to the usages of the implementing only where it is still necessary.

4. Specify the package, where the new interface will be located.
5. Select the class members you want to be listed in the interface in the Members to form interface area. The list shows all the methods of the class, as well as final static fields (constants).
6. In the JavaDoc area, select the action to be applied on the JavaDoc .
  - To leave it where it is, select the As is option.
  - To copy it to the extracted interface, select the Copy option.
  - To move it to the extracted interface, select the Move option.
7. Click Refactor to proceed.
8. Click Refactor when ready. If IntelliJ IDEA shows you a Refactoring Preview in the Find tool window, review the suggested changes. To have the interface extracted and the proposed changes applied, click Do Refactor .

**Note** If the class is used within the open project, IntelliJ IDEA proposes to replace the instances of the class with instances of the new interface. Note that if an instance references a method or field, which are not defined in the interface, it won't be suggested for replacement.

## Basics

When the **Extract Method** refactoring is invoked, IntelliJ IDEA analyses the selected block of code and detects variables that are the input for the selected code fragment and the variables that are output for it.

If there is exactly one output variable, it is used as a return value for the extracted method. In case there are multiple output variables, the Extract Method refactoring may not be applied, and the error message appears.

There are several workarounds to allow Extract Method work in this case. For example, you may introduce a special data-class that contains all output values.

**Warning!** The Extract Method refactoring has the following limitations:

- Refactoring does not work with multiple output values in automatic mode. You have to change your code before applying the refactoring.
- Refactoring does not work for a code fragment which conditionally returns from the containing method and is not placed at the end of it.

## Java example

### Before After

```
public void method() {
    int a=1;
    int b=2;
    int c=a+b;
    int d=a+c;
}
```

```
public void method() {
    int a=1;
    int b=2;
    int c=add(a,b);
    int d=add(a,c);
}
...
private int add(int a, int b) {
    return a+b;
}
```

```
public ArrayList method() {
    String[] strings = {"a","b","c"};
    ArrayList list = new ArrayList();
    for (int i=0; i < strings.length; i++)
        {list.add(strings[i]);}
    return list;
}
```

```
public ArrayList method() {
    String[] strings = {"a","ab","abc"};
    ArrayList list=add(strings);
    return list;
}
...
private ArrayList add(String[] strings) {
    ArrayList list = new ArrayList();
    for (int i=0; i < strings.length; i++)
        {list.add(strings[i]);}
    return list;
}
```

## Extracting a method

### To extract a method, follow these steps

1. In the editor, select a block of code to be transformed into a method or a function.

**Tip** The code fragment to form the method does not necessarily have to be a set of statements. It may also be an expression used somewhere in the code.

2. On the main menu or on the context menu of the selection, choose Refactor | Extract | Method or press

`Ctrl+Alt+M`.

3. In the Extract Method dialog box that opens, specify the name of the new function.

4. To create a static method, select the Declare Static check box.

5. In the Parameters area, do the following:

- Specify the variables to be passed as method parameters, by selecting/clearing the corresponding checkboxes.

If a parameter is disabled, a local variable of the corresponding type, with the initial value ... will be created in the extracted method, so that you will have to enter the initializer with an appropriate value manually.

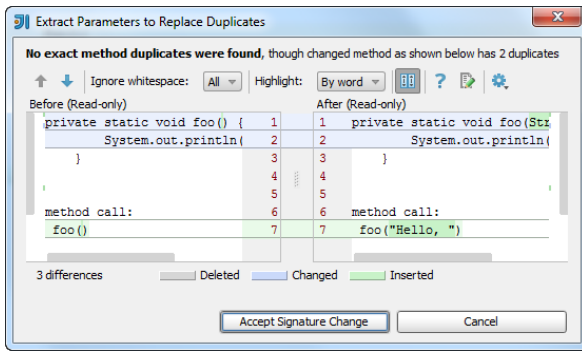

- Rename the desired parameters, by double-clicking the corresponding parameter lines and entering new names.

6. In the Visibility area define the method's visibility scope.

7. Check the result in the Signature Preview pane and click OK to create the method. The selected code fragment will be replaced with a method call. Additionally, IntelliJ IDEA will propose to replace any similar code fragments found within the current class.

## Processing duplicates

IntelliJ IDEA detects the duplicated code fragments that may accept different values as parameters and shows the following suggestion in the format of the [Differences Viewer](#) :

If you click the button Accept Signature Change, all the encountered duplicates will become highlighted, and IntelliJ IDEA will ask you for the confirmation:

Finally, after replacing the desired duplicates with the method call, you'll end up with the following code:

```
foo("Hello, ");
foo("World");

private static void foo(String x) {
    System.out.println(x);
}
```

You can also extract methods from the repetitive code fragments, which IntelliJ IDEA finds in course of the [duplicates analysis](#). The encountered duplicates display in the [Duplicates tool window](#), where you can try to replace them with method calls.

The Extract Method Object refactoring moves method into a new class, converting all the local variables to its fields, allowing you to decompose the method into other methods on the same object. It is an alternative to the [Extract Method](#) , and can be used when you have multiple return values in an extracted method.

## Example

### BeforeAfter

```
class Account {
    int gamma (int val1, ...) {
        //some computations
        return c-2*a;
    }
}

class Account {
    int gamma (int val1, ...) {
        Calculations calculations = new Calculations(val1, ...).invoke();
        int c = calculations.getC();
        int a = calculations.getA();
        return c-2*a;
    }
    private class Calculations {
        private int val1;
        ...
        private int a;
        private int c;
        public Calculations(int val1, ...) {
            this.val1 = val1;
            ...
        }
        public int getA() {return a;}
        public int getC() {return c;}
        public Calculations invoke() {
            ...//computations
            return this;
        }
    }
}
```

### To extract a method object, follow these steps

1. In the editor, select the method code block to be extracted into the object.
2. On the main menu, or from the context menu of the selection, choose Refactor | Extract | Method Object .
3. Select whether you want to create inner class, or anonymous class.

**Note** You cannot extract the method object into an anonymous class, if the selected method code block contains local variables that should be accessed individually somewhere else. In this case method object can be extracted into inner class, that will contain needed getters.

4. If you want to create an inner class, you need to specify the name for the class and the visibility scope. You can also make the class static, if needed.
5. If you want to create an anonymous class, you should specify method's name.
6. In the Parameters area select the variables that will be used as a parameters.
7. Review Signature Preview and click OK .

The Extract Parameter Object refactoring allows you to select a set of parameters to a method, and either create a wrapper class for those parameters, or use an existing compatible wrapper class. All calls to the method selected will have their parameters appropriately wrapped, and all usages of the wrapped parameter will be replaced by the appropriate calls on the newly created parameter class.

Extracting a parameter object is useful if the number of parameters passed to a method has grown too large, or if the parameters have become complex enough to deserve first-class handling as their own class. Also, it is common to wrap primitive parameters as parameter objects, thus allowing interface and implementation to be decoupled as needed.

## Example

### BeforeAfter

```
public class A {
    private void drawEdge(Graphics g, float edgeWidth,
        int x1, int x2, int y1, int y2) {
        final Graphics2D g2d = (Graphics2D) g;
        g2d.setStroke(new BasicStroke(edgeWidth));
        g.drawLine(x1, y1, x2, y2);
    }
}

public class A {
    private void drawEdge(Edge edge, Graphics g) {
        final Graphics2D g2d = (Graphics2D) g;
        g2d.setStroke(new BasicStroke(edge.getEdgeWidth()));
        g.drawLine(edge.getX1(), edge.getY1(), edge.getX2(), edge.getY2());
    }
}

public class Edge {
    private final float edgeWidth;
    private final int x1;
    ...
    public Edge(float edgeWidth, int x1, int x2, int y1, int y2) {
        this.edgeWidth = edgeWidth;
        this.x1 = x1;
        ...
    }
    public float getEdgeWidth() {
        return edgeWidth;
    }
    public int getX1() {
        return x1;
    }
    ...
}
```

## To extract a parameter object

1. Select the desired method. To do that, either open the class in question for editing, and position the caret at the method, click such method in the Structure view, or select it in the UML class diagram.
2. Choose Refactor | Extract | Parameter Object on the main menu or on the context menu of the selection.
3. In the Extract Parameter Object dialog box:
  - In the Parameter Class section, specify whether you want to create a new class, or use an existing one to wrap the parameters.
  - In the Parameters to extract list, check the parameters you want include in the new class.
  - Click Preview to make IntelliJ IDEA search for usages of the selected fields or methods, and display the refactoring preview results in the [Find tool window](#). In the preview, you can include usages into refactoring or skip them. Click Do Refactor to apply refactoring to the selected usages.

If you do not want to view usages, click Refactor. In this case, the usages will be changed immediately.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

## Basics

The Extract Superclass refactoring has two options:

- Create a superclass based on an existing class.
- Rename the original class so that it becomes an implementation for the newly created superclass. In this case, IntelliJ IDEA changes all original class usages to use a superclass where possible.

Fields and methods in the original class can be moved to the superclass. Also for a method, you can transfer only the method declaration but not the implementation declaring the method as abstract in the superclass. As a result, you will have the superclass and the original class inherited from the superclass.

## Example

### Before/After

<pre>// File Class.java public class Class {     public int varInt;     private double varDouble;     public static final int CONSTANT = 0;     public void publicMethod() {         ...     }     public void hiddenMethod() {         ...     }     public void setVarDouble(double var) {         this.varDouble = var;     }     public double getVarDouble() {         return             varDouble;     } }</pre>	<pre>// File Class.java public class Class extends SuperClass {     Int;     blicMethod() {      }     ddenMethod() {      } }  lass.java ass SuperClass {     varDouble;     final int CONSTANT = 0;     t void publicMethod();     tVarDouble(double var) {         ouble = var;     }     getVarDouble() {         Double;     } }</pre>
---	---

## Extracting a superclass

### To extract a superclass

1. Select the desired class in one of the views, or just open it in the editor.
2. On the on the main menu or on the context menu, choose Refactor | Extract | Superclass .
3. In the [Extract Superclass](#) dialog box:
  - To create a new superclass, select the Extract superclass option and specify the name for the new superclass.  
To rename the original class and make it an implementation of the newly created superclass, select the Rename original class and use superclass where possible option and specify the new name for the original class. IntelliJ IDEA will change all original class usages to the usages of the implementing class only where it is still necessary.
  - Specify the package, where the new superclass will be located.
  - In the Members to Form Superclass area, select the class members you want to be moved or delegated to the superclass.  
To leave the method implementation within the current class, and declare it abstract in the extracted superclass, select the Make Abstract checkbox.
  - In the JavaDoc area, select the action to be applied on the JavaDoc .
    - To leave it where it is, select the As is option.
    - To copy it to the extracted superclass, select the Copy option.
    - To move it to the extracted superclass, select the Move option.
4. Click Refactor to proceed.  
If the class is used within the current project, IntelliJ IDEA proposes to replace the instances of this class with the instances of the new superclass. If a class instance references a member, which is not defined in the superclass, it won't be suggested for replacement.

## Basics

The **Extract Constant** refactoring is a special case of the **Extract Field refactoring** intended to provide a fast and convenient way to create final static fields.

## Example

### Before/After

<pre>public class Class {     public void method() {         String string = "string";         ArrayList list = new ArrayList();         list.add(string);         anotherMethod(string);         ...     } }</pre>	<pre>public class Class {     @NonNull     private static final String STRING ="string";     public void method() {         ArrayList list = new ArrayList();         list.add(STRING);         anotherMethod(STRING);         ...     } }</pre>
<pre>public class Class {     public void method() {         ArrayList list = new ArrayList();         list.add("string");         anotherMethod("string");         ...     } }</pre>	<pre>public class Class {     @NonNull     private static final String STRING ="string";     public void method() {         ArrayList list = new ArrayList();         list.add(STRING);         anotherMethod(STRING);         ...     } }</pre>

## Extracting a Java constant in-place

### To extract a Java constant in-place

The **in-place refactorings** are enabled in IntelliJ IDEA by default. So, if you haven't changed this setting, the Extract Constant refactoring for Java is performed in-place, right in the editor.

1. Place the cursor within the expression or declaration of a variable to be replaced by a constant.
2. Do one of the following:
  - Press **Ctrl+Alt+C**.
  - Choose Refactor | Extract | Constant on the main menu or on the context menu.
3. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the **Up** and **Down** arrow keys to navigate to the expression of interest, and then press **Enter** to select it.

4. If more than one occurrence of the expression is found within the class, specify whether you wish to replace only the selected occurrence, or all the found occurrences with the new constant.
5. If you want the constant to be defined in a different class, select the Move to another class checkbox.
6. If necessary, change the type of the new constant.  
To move to the type, press **Shift+Tab**. Then, select the required type from the list, or edit the type in the box with the red border.

Now, to move back to the constant name, press **Tab**.

7. Specify the name of the constant. Select the name from the list or type the name in the box with a red border.

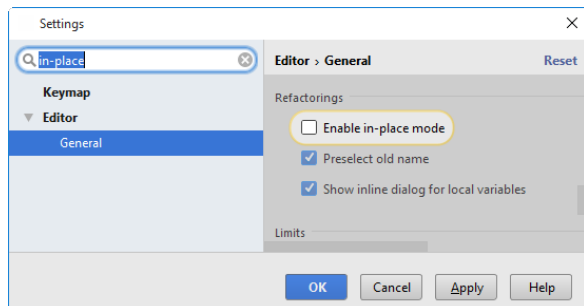

8. To complete the refactoring, press **Tab** or **Enter**.  
If you haven't completed the refactoring and want to cancel the changes you have made, press **Escape**.
9. If you have selected to move the constant definition to a different class, specify the associated settings in the **Move Members dialog**.

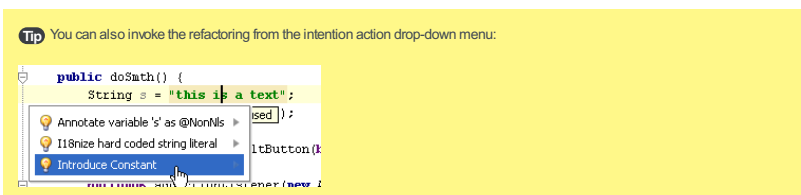

## Extracting a constant using the dialog box

### To extract a constant using the dialog box

If the Enable in-place refactorings checkbox is cleared on the Editor settings, the Extract Constant refactoring is performed by means of the [Extract Constant Dialog](#) dialog box.

1. If you are working with Java code, make sure that the [Enable in place refactorings](#) option is off in the editor settings. (By default, the Extract Constant refactorings for Java are performed [in-place](#).)
2. In the editor, select the expression or variable to be replaced with a constant, or just place the cursor within such an expression or variable declaration.
3. In the main or the context menu, choose Refactor | Extract Constant , or press `Ctrl+Alt+C` .
4. In the Expressions pop-up menu, select the expression to be replaced. Note that IntelliJ IDEA highlights the selected expression in the editor.
5. In the [Extract Constant Dialog](#) dialog that opens:
  1. Specify the name of the new constant.
  2. Select the class where the constant will be introduced. If you select an `enum` class here, use the Introduce as enum constant option to specify whether the constant should be an `enum` constant, or a usual field.
  3. In the Visibility area, select the visibility scope for the new constant.
  4. If the new constant is going to replace an existing variable, you can choose to delete the corresponding variable declaration. To do that, use the Delete variable declaration checkbox.
  5. To replace all the occurrences of the selected expression (if the selected expression is found more than once in the class), select the Replace all occurrences checkbox.
  6. In the projects configured for using annotations, you can annotate the constant of the String type as `@NonNls` to prevent it from change during possible localizations. To do so, select the option Annotate field as `@NonNls` .
7. Click OK .

## Basics

Extract Field refactoring declares a new field and initializes it with the selected expression. The original expression is replaced with the usage of the field.

## Example

### Before/After

<pre>public class Class {     AnotherClass anotherClass;     public void method() {         int a = 1;         ...         int b = a + anotherClass.intValue();         int c = b + anotherClass.intValue();     } }</pre>	<pre>public class Class {     public AnotherClass anotherClass;     private int number;     public Class() {         number = anotherClass.intValue();     }     public void method() {         int a = 1;         ...         int b = a + number;         int c = b + number;     } }</pre>
<pre>public class Class {     AnotherClass anotherClass;      public void method() {         int a = anotherClass.innerClass.i;         int b = anotherClass.innerClass.j;     } }</pre>	<pre>public class Class {     public AnotherClass anotherClass;     private AnotherClass.InnerClass aClass = anotherClass.innerClass;     public void method() {         int a = aClass.i;         int b = aClass.j;     } }</pre>

## Extracting a field in-place

### To extract a field in-place

The [in-place refactorings](#) are enabled in IntelliJ IDEA by default. So, if you haven't changed this setting, the Introduce Field refactorings are performed in-place, right in the editor:

1. Place the cursor within the expression or declaration of a variable to be replaced by a field.
2. Do one of the following:
  - Press `Ctrl+Alt+F`.
  - Choose Refactor | Introduce Field on the main menu, or on the context menu.
3. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the `Up` and `Down` arrow keys to navigate to the expression of interest, and then press `Enter` to select it.

4. If more than one occurrence of the expression is found within the class, specify whether you wish to replace only the selected occurrence, or all the found occurrences with the new constant:
5. If necessary, change the type of the new field. To move to the type, press `Shift+Tab`. Then, select the required type from the list, or edit the type in the box with the read border. Now, to move back to the field name, press `Tab`.
6. If relevant, specify where the new field will be initialized - in the current method, or in a class constructor.
7. Specify the name of the field. Select the name from the list or type the name in the box with a red border.

8. To complete the refactoring, press `Tab` or `Enter`. If you haven't completed the refactoring and want to cancel the changes you have made, press `Escape`.

Note that sometimes you may need to press the corresponding key more than once.

```

public class Class {
    AnotherClass anotherClass;
    private int number;

    public Class() {
        number = anotherClass.intValue();
    }

    public void method() {
        int a = 1;
        int b = a + number;
        int c = b + number;
    }
}

```

## Extracting a field using the dialog box

### To extract a field using the dialog box

If the Enable in place refactorings checkbox is cleared on the Editor settings, the Extract Field refactoring is performed by means of the introduce field.

1. In the editor, select the expression or variable to be replaced with a field, or just place the cursor within such an expression or variable declaration.
2. In the main menu, or the context menu of the selection, choose Refactor | Extract | Field , or press `Ctrl+Alt+F` .
3. In the Expressions pop-up menu, select the expression to be replaced. Note that IntelliJ IDEA highlights the selected expression in the editor.
4. In the [Extract Field Dialog](#) dialog that opens:
  1. Select the type of the new field from the Field of type list.
  2. Specify the name of the field.
  3. Specify where the new field should be initialized by selecting the necessary option under Initialize in .
  4. In the Visibility area, select the visibility scope for the new field.
  5. If you want the new field to be declared `final` , select the Declare final checkbox.
  6. If the new field is going to replace an existing variable, you can choose to delete the corresponding variable declaration. To do that, use the Delete variable declaration checkbox.
  7. To replace all the occurrences of the selected expression (if the selected expression is found more than once in the class), select the Replace all occurrences checkbox.
8. Click OK .

When you perform the Extract Functional Parameter refactoring, IntelliJ IDEA:

1. Analyzes the selected code fragment to find out what the method signature would be if you extracted this fragment into a new separate method.
2. Finds all functional interfaces with this method signature and suggests that you select one of them. (Only the interfaces marked with `@FunctionalInterface` or ones belonging to well-known libraries such as Guava, Apache Collections, etc. are suggested.)
3. Wraps the code fragment with an anonymous class based on the selected interface and uses this anonymous class as a parameter.
4. Where appropriate, makes related code adjustments.

– [Example](#)

– [Performing the Extract Functional Parameter refactoring](#)

## Example

BeforeAfter

<pre>@FunctionalInterface public interface Person {     public void sayHello (String s); }  public class Hello {     private void printHello () {         String s="Hello";         System.out.println(s);     }     private void printText () {         printHello();     } }</pre>	<pre>@FunctionalInterface public interface Person {     public void sayHello (String s); }  public class Hello {     private void printHello(Person person) {         String s = "Hello";         person.sayHello(s);     }     private void printText () {         printHello(new Person() {             public void sayHello(String s) {                 System.out.println(s);             }         });     } }</pre>
--	---

In this example, the refactoring is performed on `System.out.println(s);` within `Hello.printHello()`.

IntelliJ IDEA finds all functional interfaces with the appropriate method signature (`(String) -> void`) and suggests that you select one of them. (In this example, the interface `Person` is selected.)

As a result:

- The selected fragment (`System.out.println(s);`) is wrapped with an anonymous class based on the interface `Person`. This anonymous class is passed as a parameter to the call to `printHello()` within `printText()`.
- `Person` is added as a parameter to `printHello()` and the initially selected code fragment is replaced with the call to the method of the interface (`sayHello()`).

## Performing the Extract Functional Parameter refactoring

1. Select the code fragment of interest and do one of the following:
  - Press `Ctrl+Shift+Alt+P`.
  - Select Refactor | Extract | Functional Parameter from the main or the context menu.
  - Select Refactor | Refactor This from the main menu (`Ctrl+Shift+Alt+T`), and select Functional Parameter.
2. Select the desired functional interface from the list.
3. Specify the refactoring options in the [Extract Parameter dialog](#).

IntelliJ IDEA lets you extract a functional type variable.

This refactoring creates a functional expression for Java 1.8 and later versions, and an anonymous class for older versions of Java.

## Example

### Before/After

```
import java.util.List;

public class PrintAction implements Runnable {
    private List<String> data;

    public PrintAction(List<String> data) {
        this.data = data;
    }

    public void run() {
        System.out.println("Data: " + data.toString());
    }
}

import java.util.List;
import java.util.function.Function;

public class PrintAction implements Runnable {
    private List<String> data;

    public PrintAction(List<String> data) {
        this.data = data;
    }

    public void run() {
        Function<List<String>, String> presenter = (p) -> "Data: " + p.toString();
        System.out.println(presenter.apply(data));
    }
}
```

## Extracting a functional variable

**Tip** From the context menu in the editor, select Refactor | Refactor This ( `Ctrl+Shift+Alt+T` ), and select Functional Variable .

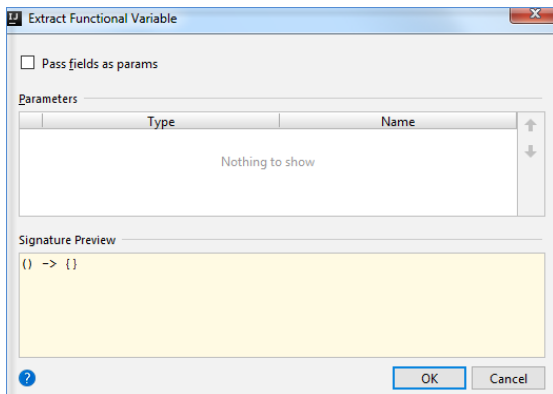

1. Select the code fragment, in this example, an argument of the `println` method.

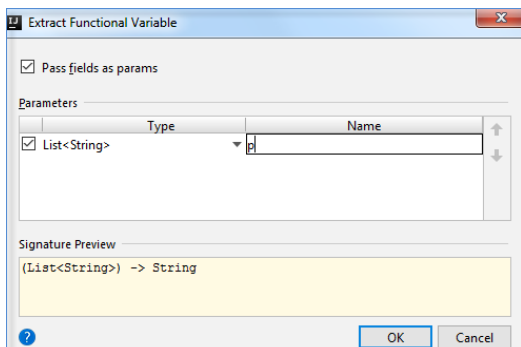

```
printAction.java x
1 import java.util.List;
2
3 class PrintAction implements Runnable {
4     private List<String> data;
5
6     public PrintAction(List<String> data) {
7         this.data = data;
8     }
9
10    public void run() {
11        System.out.println("Data: " + data.toString());
12    }
13 }
14
```

2. In the main menu, select Refactor | Extract | Functional Variable .

IntelliJ IDEA opens the Extract Functional Variable dialog.

3. When the selected code depends on instance fields, like in the example, the Pass field as params checkbox will appear and you can pass a parameter in a place of fields.

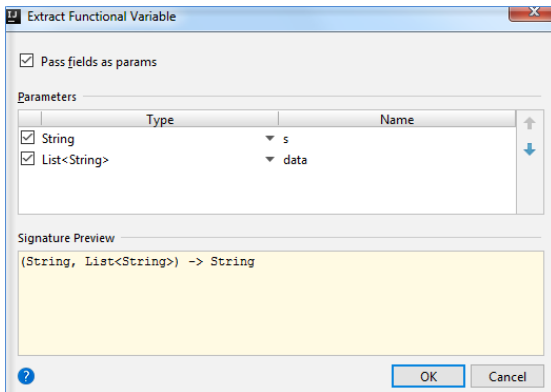

However, if for example, your selected code fragment depends on any local variable or a parameter

```

1  import java.util.List;
2
3  class PrintAction implements Runnable {
4      private List<String> data;
5
6      public PrintAction(List<String> data) {
7          this.data = data;
8      }
9
10     public void run() {
11         String s = "Data: ";
12         System.out.println(s + data.toString());
13     }
14 }
15

```

the corresponding entries would appear in the list.

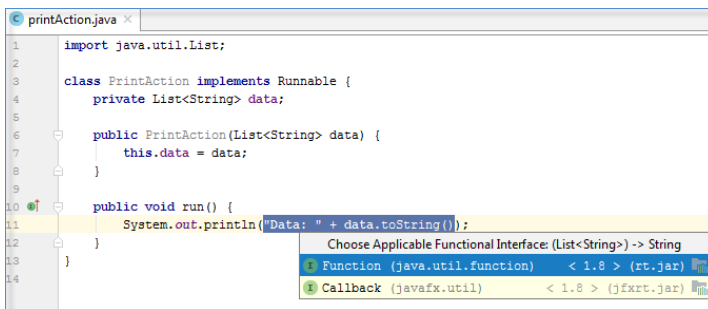

When you deselect one of the parameters in the dialog, the corresponding local values will be used instead.

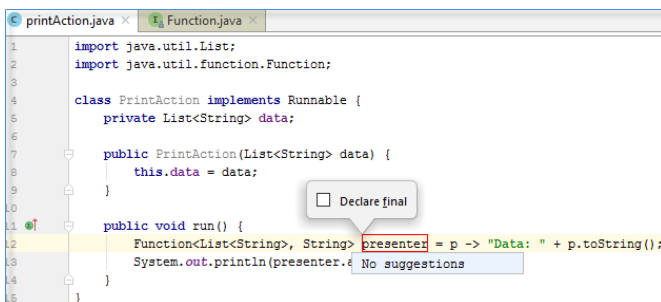

Configure your options and click OK .

4. Choose an applicable functional interface from the pop-up.

5. If you want, change a name of the extracted variable if you don't want to use the name suggested in the list.

As a result, IntelliJ IDEA creates lambda that you can use further.

```
printAction.java x  Function.java x
1  import java.util.List;
2  import java.util.function.Function;
3
4  class PrintAction implements Runnable {
5      private List<String> data;
6
7      public PrintAction(List<String> data) {
8          this.data = data;
9      }
10
11     public void run() {
12         Function<List<String>, String> presenter = p -> "Data: " + p.toString();
13         System.out.println(presenter.apply(data));
14     }
15 }
```

See also the [functional](#)

[parameter](#) refactoring.

This feature is only supported when the Ruby plugin is installed.

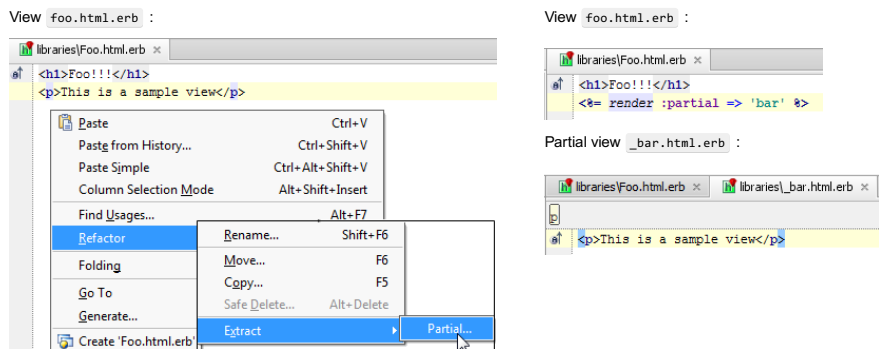

## Basics

The Extract Partial refactoring enables you to break rendering of a certain view into smaller chunks, and applies to `*.html.erb` and `*.html.haml` files.

This way, you can extract blocks of code from a view into a partial view, and replace them with a call. So doing, IntelliJ IDEA generates the name for the resulting partial view on the base of the user input in accordance with the Rails naming conventions: if the suggested partial view name is `bar`, the generated name is `_bar.html.erb` or `_bar.haml`.

## Example

### Before/After

## Extracting partial view

### To extract partial

1. Open a view in the editor.
2. Select the desired fragment of valid code. For example, in case of HTML, your selection must contain matching opening and closing tags.
3. On the main menu, or on the context menu of the selection, choose Refactor | Extract | Partial .
4. In the Extract Partial dialog box, specify the desired partial view name without extension and the leading underscore, and click OK .

The Extract Parameter refactoring is used to add a new parameter to a method declaration and to update the method calls accordingly.

This section discusses the [Extract Parameter](#) refactoring in Java.

- [Examples](#)
- [Extracting a parameter in Java in-place](#)
- [Extracting a parameter in Java using the Extract Parameter dialog](#)
- [Special notes](#)
- [Side effects](#)

## Examples

When extracting a new parameter to a method, the following two general approaches may be used depending on how the existing method calls should be handled:

- If it's possible to change all the existing method calls, a new parameter may be added to an existing method. The method calls in this case are changed accordingly, see the [first of the examples](#).
- If the existing method calls cannot be changed, a method with the existing signature is kept. The new parameter in this case is defined in a new, overloading method, see the [second of the examples](#).

In this example, the string value `"Hello, World!"` in the method `generateText()` is replaced with the new parameter `text`. The value `"Hello, World!"` is passed to the method in the updated method call `generateText("Hello, World!")`.

### BeforeAfter

```
public class HelloWorldPrinter {
    public static void print() {
        System.out.println(generateText());
    }
    private static String generateText() {
        return "Hello, World!".toUpperCase();
    }
}

public class HelloWorldPrinter {
    public static void print() {
        System.out.println(generateText("Hello, World!"));
    }
    private static String generateText(String text) {
        return text.toUpperCase();
    }
}
```

In this example a new overloading method is created and the new parameter is extracted in the definition of this method (the second of the `generateText()` methods). The signature of the existing `generateText()` method is not changed. However, the method itself has been modified. Now, it calls the new `generateText()` method and passes the value `"Hello, World!"` to it in this call. Note that the existing call of `generateText()` (in the method `print()`) is not changed.

In IntelliJ IDEA, this way of extracting a parameter corresponds to the option `Delegate via overloading method`.

### BeforeAfter

```
public class HelloWorldPrinter {
    public static void print() {
        System.out.println(generateText());
    }
    private static String generateText() {
        return "Hello, World!".toUpperCase();
    }
}

public class HelloWorldPrinter {
    public static void print() {
        System.out.println(generateText());
    }
    private static String generateText() {
        return generateText("Hello, World!");
    }
    private static String generateText(String text) {
        return text.toUpperCase();
    }
}
```

## Extracting a parameter in Java in-place

The [in-place refactorings](#) are enabled in IntelliJ IDEA by default. So, if you haven't changed this setting, the Extract Parameter refactorings for Java are performed in-place, right in the editor:

1. In the editor, place the cursor within the expression to be replaced by a parameter.
2. Do one of the following:
  - Press `Ctrl+Alt+P`.
  - Choose `Refactor | Extract | Parameter` on the main menu.
  - Choose `Refactor | Extract | Parameter` from the context menu.
3. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the `Up` and `Down` arrow keys to navigate to the expression of interest, and then press `Enter` to select it.

4. Type the parameter name in the box with a red border.

5. Select the necessary options in the Extract Parameter option box.
  - If more than one occurrence of the expression is found within the method body, you can choose to replace only the selected occurrence or all the found occurrences with the references to the new parameter. Use the Replace all occurrences checkbox to specify your intention.
  - If you don't want to change the existing method calls, select the Delegate via overloading method checkbox. For more information on how this option works, see [Examples](#) .
  - To declare the parameter `final` , select the Declare final checkbox.
6. If necessary, change the type of the new parameter. To do that, press `Shift+Tab` and edit the type in the box with the read border. (If, at this step, you want to return to editing the parameter name, press `Tab` .)
7. To complete the refactoring, press `Tab` or `Enter` .  
 If you haven't completed the refactoring and want to cancel the changes you have made, press `Escape` .

Note that sometimes you may need to press the corresponding key more than once.

## Extracting a parameter in Java using the Extract Parameter dialog

To be able to use the Extract Parameter dialog (instead of performing the refactoring [in-place](#) ), make sure that the [Enable in place refactorings](#) option is off in the editor settings.

Once this is the case, you perform the Extract Parameter refactoring as follows:

1. In the editor, place the cursor within the expression to be replaced by a parameter.
2. Do one of the following:
  - Press `Ctrl+Alt+P` .
  - Choose Refactor | Extract | Parameter on the main menu.
  - Choose Refactor | Extract | Parameter from the context menu.
3. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the `Up` and `Down` arrow keys to navigate to the expression of interest, and then press `Enter` to select it.

4. In the [Extract Parameter dialog](#) :
  1. Usually, IntelliJ IDEA sets a proper parameter type itself. If necessary, you can select another appropriate type from the Parameter of type list.
  2. Specify the parameter name in the Name field.
  3. If more than one occurrence of the expression is found within the method body, you can choose to replace only the selected occurrence or all the found occurrences with the references to the new parameter. Use the Replace all occurrences checkbox to specify your intention.
  4. To declare the parameter `final` , select the Declare final checkbox.
  5. If the expression contains a direct call to a class field that has a getter, specify the getter-related options.
  6. If the expression contains local variables, specify how these local variables will be treated in the corrected method calls.
5. [Preview and apply changes](#) .

## Special notes

The following specific issues should be mentioned:

- If you want a field to be provided as a new parameter in the method declaration, in a method call this field will be presented as a field of a class instance.
- If a class member is inaccessible (for instance, in the example above the field is private), it will be inserted in a method call but will be highlighted as an error making this file uncompileable.
- If you use for the Extract Parameter refactoring a field with a getter, you will be prompted with an extended dialog. The dialog has an option group Replace fields used in expressions with their getters :
  - Do not replace : None of the fields will be replaced with calls to the getter.
  - Replace fields inaccessible in usage context : Only the fields that cannot be directly accessed from the usage context will be replaced with calls to the getter.
  - Replace all fields : All fields will be replaced with calls to the getter.

- Applying the refactoring on a local variable will call the Extract Parameter dialog box with additional checkboxes:
  - Replace all occurrences (<number\_of\_occurrences> occurrences) : If enabled, all occurrences of the selected variable will be replaced with a parameter and the Delete variable definition checkbox is enabled. Otherwise, only the selected variable usage will be replaced with a parameter.
  - Delete variable definition : If enabled, the variable definition will be deleted.
  - Use variable initializer to initialize parameter : If enabled, the variable initializer will be used to initialize the parameter in the method call.

## Side effects

Using the Extract Parameter refactoring can have unexpected side effects if applied on class instances or expressions which are actual method parameters. For instance, in case of such code:

```
class AClass {
    int field;
    int method() {
        return field;
    }
}

class Usage {
    void method(List list) {
        int sum = 0;
        for(Iterator it = list.iterator(); it.hasNext(); ) {
            sum += ((AClass) it.next()).method();
        }
    }
}
```

The code after refactoring applied to the field `field` :

```
class AClass {
    int field;
    int method(int newfield) {
        return newfield;
    }
}

class Usage {
    void method(List list) {
        int sum = 0;
        for(Iterator it = list.iterator(); it.hasNext(); ) {
            sum += ((AClass) it.next()).method(((AClass) it.next()).field);
        }
    }
}
```

The iterator value is increased twice which is, actually, not the behavior you would expect.

However, IntelliJ IDEA can use a temporary variable successfully and resolve such cases as increment/decrement/assignment operations and the new keyword usage. For instance:

```
public int myMethod(List list) {
    return list.size();
}

public void anotherMethod() {
    myMethod(new ArrayList());
}
```

Same code after refactoring looks as follows:

```
public int myMethod(List list, int newPar) {
    return list.size();
}

public void anotherMethod() {
    final ArrayList list = new ArrayList();
    myMethod(list, list.size());
}
```

The new variable `list` was created and all parameters used for the method call are provided using this variable.

In [Maven projects](#), while editing `pom.xml`, one needs to define a property and replace the occurrences of some value - artifact version, for example, - with this property.

For these purposes, IntelliJ IDEA provides the Extract Property refactoring.

Extract Property refactoring creates a new property definition in the specified `pom.xml` file, finds all the occurrences of the selected string in the hierarchy of `pom.xml` files, and replaces them with the above property in the format: `${<property_name>}`

The Extract Property refactoring lets you move expressions and local declarations to properties.

## Examples

### Before After

In this example, artifact version is replaced with a property, which is declared in the same `pom.xml` file:

<pre>&lt;artifactId&gt;submodule&lt;/artifactId&gt;</pre>	<pre>&lt;artifactId&gt;\${submodule}&lt;/artifactId&gt; &lt;properties&gt;   &lt;submodule&gt;submodule&lt;/submodule&gt; &lt;/properties&gt;</pre>
---	---

In this example, artifact version in a `pom.xml` file is replaced with a property, which is declared in its parent `pom.xml` file:

<pre>&lt;parent&gt;   &lt;artifactId&gt;HelloWorld&lt;/artifactId&gt;   &lt;version&gt;1.0&lt;/version&gt; &lt;/parent&gt; &lt;artifactId&gt;submodule&lt;/artifactId&gt;</pre>	<p>Parent :</p> <pre>&lt;artifactId&gt;HelloWorld&lt;/artifactId&gt; ... &lt;modules&gt;   &lt;module&gt;\${submodule}&lt;/module&gt; &lt;/modules&gt; ... &lt;properties&gt;   &lt;submodule&gt;submodule&lt;/submodule&gt; &lt;/properties&gt;</pre> <p>Child:</p> <pre>&lt;parent&gt;   &lt;artifactId&gt;HelloWorld&lt;/artifactId&gt;   &lt;version&gt;1.0&lt;/version&gt; &lt;/parent&gt; &lt;artifactId&gt;\${submodule}&lt;/artifactId&gt;</pre>
---	--

## To extract a property in a pom.XML file

1. Open the desired `pom.xml` file for editing, and place the caret somewhere inside the value you want to replace.

**Tip** You can also select a certain substring; in this case the refactoring will apply to the selection.

2. Press `Ctrl+Alt+V`, or choose Refactor | Extract | Property on the context menu, or on the main menu. Note that selection will be automatically expanded up to the enclosing tags.
3. In the [Extract Property](#) dialog box, do the following:
  - In the Name field, specify the name you want to assign to the new property. IntelliJ IDEA suggests a number of suitable names. You can select one from the drop-down list, or type the desired name manually.
  - In the Project drop-down list, select the project where the new property will be declared.

Click OK .

4. The subsequent workflow depends on the specific `pom.xml` file the refactoring has been invoked from.
  - The occurrence, for which the refactoring has been invoked, will be replaced silently. If the string occurs several times, the replace usage dialog will be displayed for these occurrences. You have to specify whether you want to replace each occurrence.
  - If the `pom.xml` is a parent file and the new property will be declared in it, IntelliJ IDEA replaces the values in the parent file silently, and displays the [Find tool window](#). You have to specify whether you want to replace each occurrence.
  - If the `pom.xml` is inherited from a parent file, IntelliJ IDEA replaces the occurrence in the child file silently. This change is not propagated to the parent `pom.xml`.

In each case, IntelliJ IDEA adds new property declaration to the specified `pom.xml` file.

## Basics

The Extract Variable refactoring puts the result of the selected expression into a variable. It declares a new variable and uses the expression as an initializer. The original expression is replaced with the new variable (see the examples below).

In Java, the type of the new variable corresponds to that returned by the expression. There is an option of declaring the new variable as `final`.

To perform this refactoring, you can use:

- [In-place refactoring](#). In this case you specify the new name right in the editor.
- [Refactoring dialog](#), where you specify all the required information. To make such a dialog accessible, you have to clear the check box [Enable in-place mode](#) in the editor settings.

You can select the expression to be replaced with a variable yourself. You can as well use [smart expression selection](#). In this case IntelliJ IDEA will help you select the desired expression.

This refactoring is also available for [JavaScript](#) and [Sass](#).

## Java Examples

### Before/After

<pre>public void method() {     int a = 1;     ...     int b = a + anotherClass.intValue();     int c = b + anotherClass.intValue(); }</pre>	<pre>public void method() {     int a = 1;     ...     int number = anotherClass.intValue();     int b = a + number;     int c = b + number; }</pre>
<pre>public void method() {     int a = anotherClass.innerClass.i;     int b = anotherClass.innerClass.j; }</pre>	<pre>public void method() {     AnotherClass.InnerClass aClass = anotherClass.innerClass;     int a = aClass.i;     int b = aClass.j; }</pre>
<pre>static void printNames(final String fullName) {     System.out.println(fullName.substring(fullName.indexOf(" ") + 1));     System.out.println(fullName.substring(0, fullName.indexOf(" "))); }</pre>	<pre>static void printNames(final String fullName) {     int firstNameEndIndex = fullName.indexOf(" ");     System.out.println(fullName.substring(firstNameEndIndex + 1));     System.out.println(fullName.substring(0, firstNameEndIndex)); }</pre>

## Extracting variable in-place

### To extract a variable using in-place refactoring, follow these steps

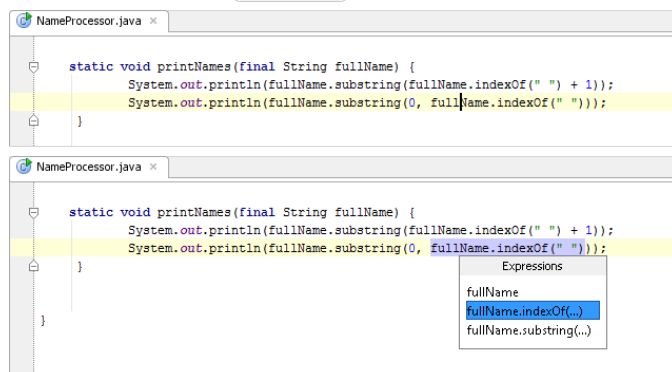

1. In the editor, select the expression to be replaced with a variable. You can do that yourself or use the **smart expression selection** feature to let IntelliJ IDEA help you. So, do one of the following:

- Highlight the expression. Then choose Refactor | Extract | Variable on the main menu or on the context menu.

Alternatively, press `Ctrl+Alt+V`.

- Place the cursor before or within the expression. Choose Refactor | Extract Variable on the main menu or on the context menu. or press `Ctrl+Alt+V`.

2. If more than one occurrence of the selected expression is found, select Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu. To select the required option, just

click it. Alternatively, use the Up and Down arrow keys to navigate to the option of interest, and press

**Enter** to select it.

3. Specify the name of the variable. Do one of the following:

– Select one of the suggested names from the pop-up list. To do that, double-click the suitable name.

Alternatively, use the Up and Down arrow keys to navigate to the name of interest, and **Enter** to select it.

– Edit the name by typing. The name is shown in the box with red borders and changes as you type. When finished, press **Enter**.

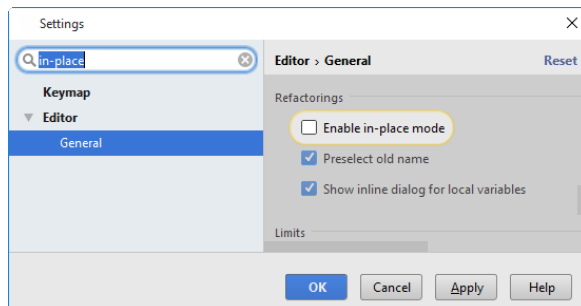

**Note** The Expressions pop-up menu contains all the expressions appropriate for the current cursor position in the editor.

When you navigate through the suggested expressions in the pop-up, the code highlighting in the editor changes accordingly.

## Extracting variable with a dialog

### To extract a variable using the dialog box

If the Enable in place refactorings check box is cleared in the Editor settings, the Extract Variable refactoring is performed by means of the [Extract Variable Dialog](#) dialog box

1. In the editor, select the expression to be replaced with a variable. You can do that yourself or use the **smart expression selection** feature to let IntelliJ IDEA help you. So, do one of the following:

– Highlight the expression. Then choose Refactor | Extract | Variable on the main menu or on the context menu.

Alternatively, press **Ctrl+Alt+V**.

– Place the cursor before or within the expression. Choose Refactor | Extract Variable on the main menu or on the context menu. or press **Ctrl+Alt+V**.

In the Expressions pop-up menu, select the expression. To do that, click the required expression.

Alternatively, use the Up and Down arrow keys to navigate to the expression of interest, and then press

**Enter** to select it.

2. In the [Extract Variable Dialog](#) dialog:

1. Specify the variable name next to Name field. You can select one of the suggested names from the list or type the name in the Name box.

2. If more than one occurrence of the selected expression is found, you can select to replace all the found occurrences by selecting the corresponding checkbox. If you want to replace only the current occurrence, clear the Replace all occurrences checkbox.

3. If you want to declare the new variable `final`, select the Declare final checkbox. (This option is available only for Java.)

4. For `ActionScript`, you can choose to introduce a constant rather than a variable. To do that, select the Make constant checkbox.

Note that `ActionScript` is not supported in IntelliJ IDEA Community Edition.

5. Click OK .

**Note** The Expressions pop-up menu contains all the expressions appropriate for the current cursor position in the editor.

When you navigate through the suggested expressions in the pop-up, the code highlighting in the editor changes accordingly.

The Generify refactoring is designed to transform existing code that does not use Generics, into the Generics-aware code. The refactoring analyzes existing code, and for each raw type creates safe and consistent parameter type.

IntelliJ IDEA tries to generate code, which is as correct as possible from the Java point of view. In other words, each context introduces some type restrictions, and the refactoring produces the best possible type, that does not contradict to the existing contexts.

## Example

### Before/After

```
public void method() {  
    List list = new LinkedList();  
    list.add("string");  
}
```

```
public void method() {  
    List<String> list = new LinkedList<String>();  
    list.add("string");  
}
```

## To generify

1. Select the level of code transformation, which can be a method, a class, a package or directory, in the Project or Structure view, or place the cursor on the class or method name in the editor. If you want to apply generics to a single code fragment, just select it in the editor.
2. On the main menu, or on the context menu of the selection, choose Refactor | Generify . The **Generify** dialog box appears.

3. Define the refactoring options. Refer to the [dialog description](#) for details.
4. **Preview and apply changes** .

```
Collection<Integer> c = new ArrayList<Integer>();  
Integer i = 10;  
c.add(i);
```

## Introduction

IntelliJ IDEA provides the following inline refactorings:

- Inline Variable refactoring replaces redundant variable usage with its initializer. See [example](#). This refactoring is opposite to the [Extract Variable](#) refactoring.

**Tip** The variable must be initialized at declaration. If the initial value is modified somewhere in the code, only the occurrences before modification will be inlined.

- Inline Method refactoring results in placing method's body into the body of its caller(s). You can opt to:
  - inline all occurrences of the method, and delete the method
  - inline only a single occurrence, and retain the method

See [example](#).

This refactoring is opposite to [Extract Method](#).

- Inline to Anonymous Class refactoring allows replacing redundant class with its contents. Starting with Java 8, the inlined anonymous classes can be converted to lambdas automatically. See [example](#).
- Inline Constructor allows compressing a chain of constructors, if one of them is a special case of another. See [example](#).
- Inline JSP/JSPX works like a regular Java inline refactoring.
- Inline Superclass refactoring results in pushing superclass' methods into the class where they are used, and removing the superclass.

## Examples

### Inline Variable

Before After

```
public void method() {
    int number = anotherClass.intValue();
    int b = a + number;
}
```

```
public void method() {
    int b = a + anotherClass.intValue();
}
```

```
public void method() {
    AnotherClass.InnerClass aClass = anotherClass.innerClass;
    int a = aClass.i;
}
```

```
public void method() {
    int a = anotherClass.innerClass.i;
}
```

### Inline Method

Before After

```
public void method() {
    int c=add(a,b);
    int d=add(a,c);
}

private int add(int a, int b) {
    return a+b;
}
```

```
public void method() {
    int c= a + b;
    int d= a + c;
}
```

```
public ArrayList method() {
    String[] strings = {"a","b","c"};
    ArrayList list=add(strings);
    return list;
}

private ArrayList add(String[] strings) {
    ArrayList list = new ArrayList();
    for (int i=0; i< strings.length; i++)
        {list.add(strings[i]);}
    return list;
}
```

```
public ArrayList method() {
    String[] strings = {"a","ab","abc"};
    ArrayList list1 = new ArrayList();
    for (int i=0; i< strings.length; i++)
        {list.add(strings[i]);}
    ArrayList list = list1;
    return list;
}
```

### Inline Constructor

Before After

```

public class Class {
    public int varInt;
    public Class() {
        this(0);
    }

    public Class(int i) {
        varInt=i;
    }

    public void method() {
        Class aClass=new Class();
        ...
    }
}

```

```

public class Class {
    public int varInt;
    public Class(int i) {
        varInt=i;
    }
    public void method() {
        Class aClass=new Class(0);
        ...
    }
}

```

## Inline Superclass

BeforeAfter

```

public class Bar {
    ...
    int calculations1() { ... }
    int calculations2() { ... }
}

class Foo extends Bar {
    int someMethod() {
        ...
        if (something > calculations1()) {
            ...
            return calculations2();
        }
        ...
    }
}

```

```

class Foo {
    ...
    int someMethod() {
        ...
        if (something > calculations1()) {
            ...
            return calculations2();
        }
        ...
    }
    int calculations1() {...}
    int calculations2() {...}
}

```

## Inline to Anonymous Class

BeforeAfter

```

import java.util.*;
public class Main {
    public class MyComparator implements Comparator<String> {
        @Override
        public int compare(String s1, String s2) {
            return 0;
        }
    }

    void sort(List<String> scores) {
        scores.sort(new MyComparator());
    }
}

```

```

import java.util.*;
public class Main {
    void sort(List<String> scores) {
        scores.sort((s1, s2) -> 0);
    }
}

```

## Performing inline refactoring

1. Place the caret in the editor at the desired symbol to be inlined.
2. Do one of the following:
  - On the main menu or on the context menu, choose Refactor | Inline .
  - Press `Ctrl+Alt+N` .
3. In the [Inline dialog](#) , that corresponds to the selected symbol, specify the inlining options.
4. [Preview and apply changes](#) .

The Invert Boolean refactoring allows you to change the sense of a Boolean method or variable to the opposite one.

**TIP** This refactoring is also available from [UML Class diagram](#) .

## Example

### BeforeAfter

```
private double a;
...
public boolean method() {
    if (a > 15 && a < 100) {
        a = 5;
        return true;
    }
    return false;
}
```

```
private double a;
...
public boolean method() {
    if (a > 15 && a < 100) {
        a = 5;
        return false;
    }
    return true;
}
```

```
boolean b = true;
...
public double method() {
    ...
    b = false;
    ...
}
```

```
boolean b = false;
...
public double method() {
    ...
    b = true;
    ...
}
```

### To invert the sense of a Boolean method or variable

1. Place the caret at the name of the method or variable to be refactored.
2. Do one of the following:
  - On the main menu choose Refactor | Invert Boolean .
  - On the context menu, choose Refactor | Invert Boolean .
3. In the Invert Boolean dialog, specify the name for the inverted method or variable.
4. [Preview and apply changes](#) .

The Make Class Static refactoring allows you to convert an inner class into a static one, and automatically corrects all references to the class in the code.

### **To make a class static**

1. In the editor, place the cursor on the name of the inner class you want to make static, or select the class in the Structure view.
2. On the main menu, or on the context menu of the selection, choose Refactor | Make Static .
3. If the class references any outer class fields, the [Make Class Static dialog](#) suggests to pass the outer class as a parameter to the inner class constructor.
4. Preview results in the [Find tool window](#) and apply changes.

The Make Method Static refactoring converts an instance method to a static one and automatically corrects all calls, implementations and overridings of the method.

**Tip** This refactoring is also available from [UML Class diagram](#).

- [Examples](#)
- [Performing the Refactoring](#)
- [Make Static refactoring for a method in a call hierarchy](#)

## Examples

### BeforeAfter

<pre>class ConnectionPool {     public int i;     public int j;     public void getConnection() {         ...     } }</pre>	<pre>class ConnectionPool {     public int i;     public int j;     public static void getConnection(ConnectionPool connectionPool) {         ...     } }</pre>
<pre>class ConnectionPool {     public int i;     public int j;     public void getConnection() {         ...     } }</pre>	<pre>class ConnectionPool {     public int i;     public int j;     public static void getConnection(int i, int j) {         ...     } }</pre>

## Performing the Refactoring

1. Select the method to be refactored in the Structure view, or right-click the method name in the editor. On the main menu, or on the context menu of the selection, choose Refactor | Make Static. The [Make Method Static dialog box](#) opens.
2. If the method references any of the containing class fields, do one of the following:
  - To pass the whole referenced object as a parameter to the method, select the Add object as a parameter with name checkbox and enter the name for the parameter.
  - To pass the referenced fields/variables as parameters to the method, select the Add parameters for fields checkbox and select the appropriate fields in the list. You can also change the order of the parameters using the Move Up and Move Down buttons.
3. If the method does not contain any references to fields or instance variables, you should only specify whether you want to replace instance qualifiers with class references.
4. To preview the results, click Preview and examine the result of the refactoring in the [Find tool window](#). Apply the changes, if no issues arise.

## Make Static refactoring for a method in a call hierarchy

In call hierarchies, if the method callers don't contain any other references to instance members, IntelliJ IDEA suggests that you make those callers static too.

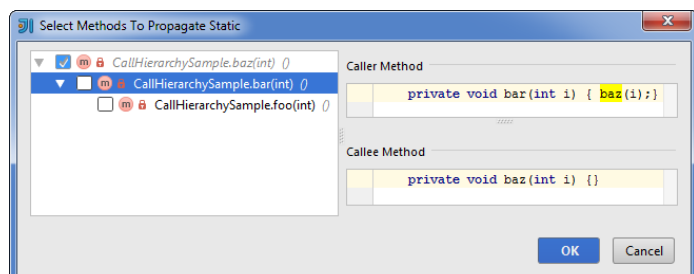

Example

### BeforeAfter

<pre>class CallHierarchySample {     private void foo(int i) { bar(i);}     private void bar(int i) { baz(i);}     private void baz(int i) { } }</pre>	<pre>class CallHierarchySample {     private static void foo(int i) { bar(i);}     private static void bar(int i) { baz(i);}     private static void baz(int i) { } }</pre>
--	---

In this example, the refactoring was performed on `baz(int i)`. All the caller methods were selected for making static too.

When performing the refactoring, the Select Methods to Propagate Static dialog is shown. This dialog lets you select the caller methods to be made static.

The Migrate refactoring allows you to easily switch between the old packages and classes used in your project and the new ones. IntelliJ IDEA comes with the default migration map. You can use it to provide Swing 1.1 support in a project that includes Swing 1.0.3 packages and classes.

**Tip** This refactoring is also available from [UML Class diagram](#).

## To perform migrate refactoring, follow these general steps

1. On the main menu, choose Refactor | Migrate . The [Package and Class Migration](#) dialog box opens.
2. Select the desired migration map from the drop-down list, or click the New button to create a new one. Edit Migration Map dialog appears.
3. Specify the name of the map, and optional map description.
4. Create a new migration description. To do that, click Add .
5. In the Edit Class/Package Migration Description dialog box that opens, specify the following options:
  - Select whether you want to migrate packages or classes.
  - Specify the old and the new names of the package or class.

Click OK to apply changes and close the dialog.

6. Create or edit as many migration descriptions as required, and click OK to apply changes and close the Edit Migration Map dialog.
7. Click Run to start migration with the selected map.

In this section:

- [Basics](#)
- [Performing Move refactoring](#)
- [Moving a package](#)

## Basics

**Tip** The **Move** refactoring is also available from [UML Class diagram](#).

Move refactorings allow you to move packages and classes between the source roots of a project, class members to other classes and inner classes to upper hierarchy levels. The move refactorings automatically correct all references to the moved packages, classes and members in the source code.

The following move refactorings are available:

- Move Package moves a package and its contents to another package or directory under the specified source root. When you move a package, you can choose between the following refactorings:
  - Move package to another package .
  - Move directory to another source root .
  - Move directory to another directory .
- Move Class refactoring enables you to:
  - Move a class to a package under the specified source root.
  - Make a class an inner class.
- Move Static Members moves a static field, method or inner class to another class.
- Move Inner to Upper Level:
  - In **Java**, this refactoring moves an inner class to a higher level.
  - In **ActionScript**, this refactoring moves out-of-package classes, functions, variables, constants and namespaces into a package. (In this case the word inner is used to refer to entities (classes, functions, etc.) that are declared **outside of packages**. The upper level means a package .)
- Move Instance Method refactoring moves an instance method to another class.
- Move File refactoring moves a file to another directory.

**Tip** The Move Package refactoring is significantly different from the other move refactorings. For corresponding instructions, see [Moving a package](#). For all the other symbols, refer to [Performing a Move refactoring](#).

## Performing Move refactoring

### To perform a Move refactoring, follow these general steps:

1. Select the symbol to be moved and do one of the following:
  - On the main menu, or on the context menu, point to Refactor, and then choose Move .
  - Press **F6** .
  - In the [Project Tool Window](#), drag the symbol to the new location.

The dialog that opens depends on the type of the selected symbol.

2. Specify the move options according to the type of the item to be moved. See option descriptions in the [Move](#) dialog box reference.
3. [Preview and apply the changes](#) .

## Moving a package

### To move a package, follow these steps:

1. Select the package in the Project tool window, and press **F6**, or just drag the selected package.
2. In the Select Refactoring dialog box, click one of the options to specify which refactoring should be performed.

- To move the whole package to another package select the first option, click OK, then specify the move options in the [Move](#) dialog box.
- To move the directory to another source root, select the second option, click OK, and specify the destination source root.
- To move the directory to another directory, select the third option, click OK, and specify the destination

directory.

- [Basics](#)
- [Example](#)
- [Pulling members up](#)

## Basics

The Pull Members Up refactoring allows you to move class members to a superclass or an interface, or interface to a superinterface.

## Example

### Before/After

<pre>// File Class.java public class Class extends SuperClass {     blicMethod() {      }      ddenMethod() {      }  }  .java ass SuperClass { t void publicMethod(); }</pre>	<pre>// File Class.java public class Class extends SuperClass {     public void publicMethod() {         ...     } }  // File SuperClass.java public abstract class SuperClass {     public abstract void publicMethod();     public void hiddenMethod() {         ...     } }</pre>
--	--

## Pulling members up

1. Select the class to be moved to a superclass or interface.
2. On the main menu or on the context menu, choose Refactor | Pull Members Up . The [Pull Members Up](#) dialog box appears.
3. Select the destination object (superclass or interface).
4. In the Members section, select the members you want to move.
5. To move a method as abstract, select the checkbox in the column Make abstract next to the method in question.
6. In the JavaDoc section, select the action to be applied on JavaDoc .
7. Click Refactor to pull the selected members to their destination.

The Push Members Down refactoring helps clean up the class hierarchy by moving class members to a subclass or a subinterface. The members are then relocated into the direct subclasses/interfaces only.

## Example

### Before/After

<pre>// File Class.java public class Class extends SuperClass {     public void publicMethod() {         ...     } }  // File SuperClass.java public abstract class SuperClass {     public abstract void publicMethod();     public void hiddenMethod() {         ...     } }</pre>	<pre>// File Class.java public class Class extends SuperClass {     public void publicMethod() {         ...     }     public void hiddenMethod() {         ...     } }  // File SuperClass.java public abstract class SuperClass {     public abstract void publicMethod(); }</pre>
--	--

## Pushing members down

1. In the editor, open the class whose members you need to push down.
2. On the main menu or on the context menu, choose Refactor | Push Members Down . [Push Members Down dialog box](#) displays the list of members to be pushed down.
3. In the Members to be pushed down area, select the members you want to move. Note that the member at caret is already selected.  
If pushing a member might cause problems, you will be notified with red highlighting. It means that, if the situation is unattended, an error will emerge after refactoring. IntelliJ IDEA prompts you with a Problems Detected dialog, where you can opt to ignore or fix the problem.
4. Select the Keep abstract checkbox to:
  - Convert the original method to abstract, and move the original method body to the new method in subclass as an abstract method implementation, if the original method is non-abstract.
  - Create the new abstract method in a subclass and the same abstract method in subclass/subinterface (with possible errors if the subclass is not abstract), if the pushed down methods are already abstract.
5. When you push down abstract methods that have JavaDoc comments, specify to how treat them in the JavaDoc section.
6. Preview and apply changes.

The Remove Middleman refactoring allows you to replace all calls to delegating methods in a class with the equivalent calls directly to the field delegated to. Additionally, you can automatically remove the classes delegating methods, which will now be unused.

This refactoring is useful if you have a class that simply forwards many of its method calls to objects of other classes, and you wish to simplify your design.

**Tip** This refactoring is also available from [UML Class diagram](#).

## Example

### Before/After

```
public class Foo {
    Bar bar;
    public Foo getImpValue() {
        return bar.getImpValue();
    }
}

public class Bar {
    private Foo impValue1;
    public Bar(Foo impValue) {
        impValue1 = impValue;
    }
    public Foo getImpValue() {
        return impValue1;
    }
}

public class Client {
    Foo a;
    Foo impValue = a.getImpValue();
}
```

```
public class Foo {
    Bar bar;
    public Bar getbar() {
        return bar;
    }
}

public class Bar {
    private Foo impValue1;
    public Bar(Foo impValue) {
        impValue1 = impValue;
    }
    public Foo getImpValue(){
        return impValue1;
    }
}

public class Client {
    Foo a;
    Foo impValue = a.getbar().getImpValue();
}
```

## To remove a middleman

1. Open the class in question in the editor, and position the caret at the name of the delegating field. Alternatively, select the delegating field in the Structure view of the desired class.
2. Choose Refactor | Remove Middleman on the main menu or on the context menu of the selection.
3. In the Remove Middleman dialog box:
  - Select whether you wish any methods which simply forward to calls to this field to be delegated. These methods will be unused by code in the current project, but may still be needed by code outside the project. You may wish to retain these delegating methods for backward compatibility.
  - Click Preview to make IntelliJ IDEA search for usages of the selected field, and display the refactoring preview results in the [Find tool window](#). In the preview, you can include usages into refactoring or skip them. Click Do Refactor to apply refactoring to the selected usages.

If you do not want to view usages, click Refactor. In this case, the usages will be changed immediately.

The Refactoring preview window may appear anyway, if the files to be affected are read-only.

In this section:

- [Basics](#)
- [Examples](#)
  - [Renaming a class](#)
  - [Renaming a method](#)
  - [Renaming a template](#)
  - [Renaming Ruby/Rails symbols](#)
- [Renaming a symbol](#)
- [Renaming a file or directory](#)
- [Important notes](#)

## Basics

Rename refactorings allow you to rename Classes, Interfaces, Enumerations and Annotations with all the references to them in the code corrected automatically.

The following rename refactorings are available in IntelliJ IDEA:

- **Rename Package** . The following usages are renamed:
  - Package statements
  - Import statements
  - Qualified names of classes
- **Rename Class** . The following usages are renamed:
  - Import statements
  - Qualified names of classes
  - Variables with the selected class type
  - Class inheritors
- **This feature is only supported when the Ruby plugin is installed.**
- **Ruby scripts** . Renaming in Ruby scripts applies to all symbols and propagates changes to all their usages across the project.
- **Ruby classes** . Results of renaming a Ruby class depends on the place of invocation and on the containing file name. First, if a Ruby class has been [created from a template](#) , the containing file name matches the specified class name. Thus, renaming a Ruby class from the editor results in generating the new file name according to the Ruby naming conventions. If the name of a containing file doesn't match class name, only the class and its usages are renamed. Second, if rename refactoring is invoked from the Project tool window, only file name will be changed; the name of the contained class will be left intact.
- **Components of Rails applications** . Renaming in Rails applications applies to the application elements (classes, controllers, actions, helpers, tests, views) and their usages. It is advisable to use the [Rails View](#) of the Project tool window, or the editor, to rename elements of the Rails applications. Rename refactoring in Rails applications has certain subtleties mentioned below:
  - On renaming an action or a view template, all associated entities are renamed, including tests. However, on renaming a test, its related entities are not renamed.
  - When renaming, keep in mind that the new name should meet Rails naming conventions; otherwise the name will not be properly recognized. It means that when you rename, for example, `MyController` to `YourController` , you only have to change `My` to `Your` , leaving the `Controller` suffix intact.
  - On renaming a controller or view , its usages in an RSpec test will only be renamed if the options Search in comments and strings is enabled.
  - When renaming Rails models , all usages are renamed too: the underlying files, classes, test classes and fixtures. IntelliJ IDEA creates a migration with the instruction to rename the corresponding table. When a field in a model is renamed, IntelliJ IDEA creates a migration with the instruction to rename the corresponding column in a table, and its foreign key, if any.
- **Named scopes** . So doing, the lines of code where the renamed scope is called as a method, are also renamed.
- **Sass selector**
- **Rename Method** . The following usages are renamed:
  - All calls of the method.
  - All overridden/implemented methods in subclasses.
- **Rename Field** .
- **Rename Function** .
- **Rename Variable** .
- **Rename Parameter** . The following usages are renamed:
  - All usages of the parameter.
  - The corresponding `param` tag in documentation comment.
- **Rename CSS color value** .
- **Rename File** .
- **Rename Directory** .
- **Rename views and references to views** in the Grails applications.

## Examples

### Renaming a class

#### Before After

```
public class MyClass {
    // some code here
}
...
public void myMethod() {
    MyClass myClass = new MyClass();
}

public class YourClass {
    // some code here
}
...
public void myMethod() {
    YourClass yourClass = new YourClass();
}
```

### Renaming a method

This feature is only supported when the Python plugin is installed.

#### Before After

##### Renaming method

```
def was_published_today(self):
    return self.pub_date.date () == datetime.date.today()

def published_today(self):
    return self.pub_date.date () == datetime.date.today()
```

### Renaming a template

This feature is only supported when the Python plugin is installed.

Rename a template:

```
urlpatterns = patterns('MyDjangoApp.polls.views',
    (r'^polls/$', 'index'),
    (r'^polls/(?P<poll_id>\d+)/$', 'detail'),
    (r'^polls/(?P<poll_id>\d+)/results/$', 'results'),
    (r'^polls/(?P<poll_id>\d+)/vote/$', 'vote'),
```

So doing, the following usages will be renamed:

```
Function to be renamed to poll_details
├─ detail()
└─ References in code to function detail (2 references in 2 files) (2 usages)
    ├─ Unclassified usage (2 usages)
    │   └─ MyDjangoApp (2 usages)
    │       └─ index.html (1 usage)
    │           (5: 37)
    │           <li><a href="{% url polls.views.detail poll_id=poll.id %}">{{ poll.id }}. {{ poll.question }}</a></li>
    └─ urls.py (1 usage)
        (9: 37) (r'^polls/(?P<poll_id>\d+)/$', 'detail'),
```

### Renaming Ruby/Rails symbols

This feature is only supported when the Ruby plugin is installed.

#### Before After

##### Renaming Ruby class with the matching file name

```
MyClass - my_class.rb      YourClass - your_class.rb
```

##### Renaming Rails method

```
def bar(a,b,c)
    return a * b + c * 123
end
def foo
    a = 0
    b = 1
    c = 2
    return bar (a,b,c)
end

def do_smth (a,b,c)
    return a * b + c * 123
end
def foo
    a = 0
    b = 1
    c = 2
    return do_smth (a,b,c)
end
```

##### Renaming Rails model

Model Library .

The following symbols should be renamed:

- Class Library
- Fixture library.yml
- Test class library\_test.rb
- Test class LibraryTest.rb
- File library.rb

Model Books .

As a result of performing the Rename refactoring, IntelliJ IDEA creates a migration. Execute the migration to have the following symbols actually renamed:

- Class Books
- Fixture books.yml
- Test class books\_test.rb
- Test class BooksTest.rb
- File books.rb

##### Renaming a scope and its usages

```
Class Word
  scope :word_length, lambda {|word_length| where :char_count => word_length}
end

assert_equal 0, Word.word_length(0).size
```

```
Class Word
  scope :word_length1, lambda {|word_length| where :char_count => word_length}
end

assert_equal 0, Word.word_length1(0).size
```

## Renaming a symbol

### To rename a symbol, follow these general steps

1. Select the item to be renamed.
  - To select a file, click the desired file in the [Project Tool Window](#).
  - To select a symbol in the editor, place the caret at the name of the symbol to be renamed.
  - To select a symbol in the [Project Tool Window](#), make sure that the members are shown, and then click the desired symbol.
  - To select a symbol in the [Structure view](#), click the desired symbol in the Structure tool window.
2. Choose Refactor | Rename on the main menu or on the context menu, or press `Shift+F6`.
3. The subsequent behavior depends on the checkbox [Enable in-place mode](#) (Settings/Preferences dialog, [Editor](#)).
  - If this checkbox is selected, the suggested name appears right below the symbol in question. You can either accept suggestion, or type a new name. However, if you press `Shift+F6` once more, IntelliJ IDEA will display the [Rename](#) dialog box with more options.
  - If this checkbox is not selected, the [Rename](#) dialog box opens immediately.

The set of controls and their names depend on the type of the symbol to be renamed.

4. If you want IntelliJ IDEA to find and rename objects related to the renamed class, whose names contain the changed string, check one or more of the following options:
  - Rename variables to rename the variables of that class type.
  - Rename inheritors to rename class inheritors.
  - Rename bound forms to rename the GUI forms bound to the class.

If you chose to rename any of the objects bound to the renamed class, IntelliJ IDEA searches for appropriate items and displays them in a sequence of dialogs, sorted by type. In each dialog you may select the items you want to change.

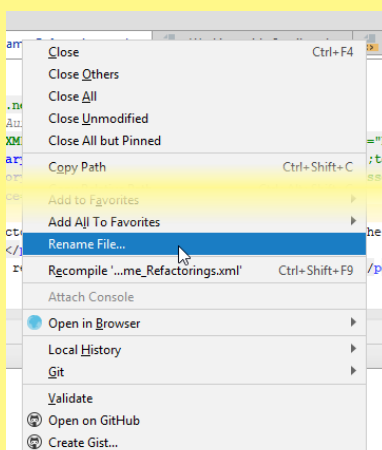

5. [Preview and apply changes](#).

## Renaming a file or directory

### To rename a file or directory

1. Select a desired file in the [Project tool window](#).
2. Choose Refactor | Rename on the main or context menu or press `Shift+F6`.
3. In Rename File dialog box that opens, specify the new file name. Select Search in comments and strings checkbox to let IntelliJ IDEA apply changes to comments and strings.
4. Press Preview to observe possible changes in [Find Tool Window](#). Press Refactor to proceed. IntelliJ IDEA finds all the occurrences of the file name and changes them respectively.

**Tip** Renaming files is also available from the editor tab:

The screenshot shows a context menu for an editor tab in IntelliJ IDEA. The menu items include: Close (Ctrl+F4), Close Others, Close All, Close Unmodified, Close All but Pinned, Copy Path (Ctrl+Shift+C), Add to Favorites, Add All To Favorites, Rename File... (highlighted), Recompile '...me\_Refactorings.xml' (Ctrl+Shift+F9), Attach Console, Open in Browser, Local History, Git, Validate, Open on GitHub, and Create Gist... A mouse cursor is pointing at the 'Rename File...' option.

So doing, the file to be renamed will be overwritten.

## Important notes

- Local variables are renamed in-place.

```
public CrocoBuilder setPaws(int paws) {  
    int pk#id = paws;  
    return this;  
}
```

This feature is only supported when the Python plugin is installed.

```
for poll_id in args:  
    try:  
        poll = Poll.objects.get(pk=int(poll_id))  
    except Poll.DoesNotExist:  
        raise CommandError('Poll "%s" does not exist' % poll_id)
```

To be able to use the Rename dialog when renaming local variables, you should [disable in-place refactoring in the editor settings](#).

- This feature is only supported when the Python plugin is installed.

When renaming Gherkin steps, mind the following limitations:

- Step definitions should not contain regular expressions
- Step names should contain alphanumeric characters only.
- A step definition should be only one in various frameworks.
- There should be a "one-to-one" mapping between a step and a step definition.

The Replace Constructor with Builder refactoring helps hide a constructor, replacing its usages with the references to a newly generated builder class, or to an existing builder class.

## Example

### Before After

### To replace a constructor with a builder class

1. Place the caret at the constructor invocation to be replaced.
2. Open [Replace Constructor with Builder](#) dialog box by choosing Refactor | Replace Constructor with Builder on the main menu, or on the context menu of the selection.

The dialog box shows the list of constructor parameters to be passed to the builder, and the suggested name of a new builder.

3. In the Parameters to pass to the builder list, optionally change the suggested setter names, and specify whether you want to initialize the generated fields in the builder.

If you specify an initial value that matches the parameter value in the constructor invocation, you can skip setter method for such parameter by selecting the **Optional Setter** checkbox.

4. Specify which builder are you going to use. If you select the **Create new** radio button, IntelliJ IDEA will generate a new builder, with the specified name, located in the specified package.

If you select the **Use existing** radio button, find the desired builder class in your project.

5. To review the intended changes and make final corrections prior to the refactoring, click **Preview** . To apply the changes immediately, click **Refactor** .

The Replace Constructor With Factory Method refactoring allows you to hide a constructor and replace it with a static method which returns a new instance of a class.

## Example

### Before/After

<pre>// File Class.java public class Class {     public Class(String s) {         ...     } }  // File AnotherClass.java public class AnotherClass {     public void method() {         Class aClass = new Class("string");     } }</pre>	<pre>// File Class.java public class Class {     private Class(String s) {         ...     }     public static createClass(String s) {         return new Class(s);     } }  // File AnotherClass.java public class AnotherClass {     public void method() {         Class aClass = Class.createClass("string");     } }</pre>
---	---

## To replace a constructor with a factory method

1. Select the class constructor.
2. Open [Replace Constructor With Factory Method dialog](#) by choosing Refactor | Replace Constructor With Factory Method on the main menu or on the context menu of the selection.
3. In the Factory method name field, specify the name for the factory method.
4. In the In (fully qualified name) field, specify the class, where the method should be created.
5. To review the intended changes and make final corrections prior to the refactoring, click Preview. To apply the changes immediately, click Refactor.

The Replace Inheritance With Delegation refactoring allows removing a class from inheritance hierarchy, while preserving the functionality of the parent. IntelliJ IDEA creates a private inner class, that inherits the former superclass or interface. Selected methods of the parent are invoked via the new inner class.

## Example

### BeforeAfter

```
// File Class.java
public class Class extends SuperClass {
    public int varInt;
    public void openMethod() {
        ...
    }
}

// File SuperClass.java
public abstract class SuperClass {
    public static final int CONSTANT=0;
    public abstract void openMethod();
    public void secretMethod() {
        ...
    }
}

// File Class.java
public class Class {
    public int varInt;
    private final MySuperClass superClass = new MySuperClass();
    public SuperClass getSuperClass() {
        return superClass;
    }
    public void openMethod() {
        superClass.openMethod();
    }
    private class MySuperClass extends SuperClass {
        public void openMethod() {
            ...
        }
    }
}

// File SuperClass.java UNCHANGED
public abstract class SuperClass {
    public static final int CONSTANT=0;
    public abstract void openMethod();
    public void secretMethod() {
        ...
    }
}
```

### To replace inheritance with delegation, follow these steps

1. Select the class to be refactored in the [Project Tool Window](#) , or open this class for editing and place the caret somewhere in the source code of the class.
2. On the main menu, or on the context menu of the selection, choose Refactor | Replace Inheritance With Delegation . The [Replace Inheritance With Delegation](#) dialog box opens.
3. In the Replace with delegation inheritance from field, select the parent object, inheritance to which will be replaced.
4. Specify the name for the field of the new inner class.
5. In the Inner class name field, specify the name for the inner class definition.
6. In the Delegate members area, select the members of the parent class, that will be delegated through the inner class.
7. To create a getter for the inner class, select the Generate getter for delegated component checkbox.
8. To review the intended changes and make final corrections prior to the refactoring, click Preview . To apply the changes immediately, click Refactor .

The Find and Replace Code Duplicates action allows you to find code repetitions similar to the selected method or constant field, and replace them with calls to the original method or constant.

## Example

### Before/After

```
public void method() {  
    int a = 1;  
    int b = 2;  
    int c = a+b;  
    int d = b+c;  
}  
...  
private int add(int a, int b) {  
    return a+b;  
}
```

```
public void method() {  
    int a = 1;  
    int b = 2;  
    int c = add(a,b);  
    int d = add(b,c);  
}  
...  
private int add(int a, int b) {  
    return a+b;  
}
```

## To find and replace code duplicates

1. Position the cursor within the method or a constant field whose duplicates you want to search for.
2. Select Refactor | Find and Replace Code Duplicates from the main or context menu.
3. In the dialog that opens, select the scope where IntelliJ IDEA shall look for code duplicates.
4. For each found code duplicate, IntelliJ IDEA will prompt you to confirm the replacement.

This refactoring allows you to extract the variable's initializer expression into a method, and replace all references to the variable with the calls to the extracted method. The declaration of the variable will be removed and the query method can be used in other methods.

Instead of `int size = getActualSize()` and using `size` throughout the code, we just operate with `getActualSize()` method. Though the resulting code has more invocations, it is much cleaner and helps identify precisely where the bottlenecks in the code can appear.

## Example

### BeforeAfter

```
public void method() {
    String str = "str";
    String aString = returnString().concat(str);
    System.out.println(aString);
}
```

```
public void method() {
    String str = "str";
    System.out.println(aString(str));
}
private String aString(String str) {
    return returnString().concat(str);
}
```

## To replace temp with query

1. In the editor, position the caret at the name of the local variable you want to be refactored.
2. On the main menu, or on the context menu of the selection, choose Refactor | Replace Temp with Query .  
[Replace Temp with Query](#) dialog box appears.  
When selecting a local variable, make sure that its value is not modified later in the code. Otherwise the error message appears.
3. Specify the name for the extracted method.
4. To declare the method static, select the Declare static check box. This option is enabled when the initial expression is static.
5. In the Parameters section, select the parameters to be used in the extracted method. The parameters are all checked by default. If unchecked, the appropriate value will be used as a local variable in the extracted method.
6. Check the result in the Signature Preview pane and click OK to create the method.

In this section:

- [Introduction](#)
- [Performing the refactoring](#)
- [Safe Delete Parameter refactoring for a call hierarchy](#)
- [Safe Delete refactoring for a method in a call hierarchy](#)

## Introduction

The Safe Delete refactoring lets you safely remove files and symbols from the source code.

To make sure that deletion is safe, IntelliJ IDEA looks for the usages of the or symbol being deleted. If such usages are found, you can explore them and make the necessary corrections in your code before the symbol is actually deleted.

**Tip** This refactoring is also available from [UML Class diagram](#).

## Performing the refactoring

1. Select the item to be deleted.
2. Do one of the following:
  - Press `Alt+Delete`.
  - Select Refactor | Safe Delete from the main or the context menu.
  - Select Refactor | Refactor This from the main menu (`Ctrl+Shift+Alt+T`), and select Safe Delete.
3. In the [Safe Delete dialog](#), select the necessary options and click OK.
4. If the refactoring is potentially unsafe, the Usages Detected dialog opens.
  - View Usages. Click this button to see where in your code the item you are about to delete is used. As a result, the [Find tool window](#) opens.  
Analyze your code and make the necessary corrections. Then click Do Refactor. (If you want to rerun the refactoring from its start, click Rerun Safe Delete. IntelliJ IDEA will check if the refactoring is safe once more.)
  - Delete Anyway. Click this button to delete the item without looking at its usages.

## Safe Delete Parameter refactoring for a call hierarchy

If a parameter is only passed through a call hierarchy and isn't used anywhere outside of that hierarchy, the Safe Delete refactoring lets you propagate the parameter deletion all along the hierarchy.

## Example

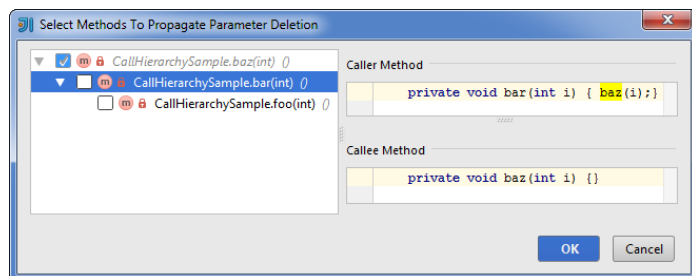

### Before/After

```
class CallHierarchySample {
    private void foo(int i) { bar(i);}
    private void bar(int i) { baz(i);}
    private void baz(int i) { }
}
```

```
class CallHierarchySample {
    private void foo() { bar();}
    private void bar() { baz();}
    private void baz() { }
}
```

In this example, the refactoring was performed on the `i` parameter within `baz(int i)`. This change was propagated to all the caller methods.

When performing the refactoring, the Select Methods to Propagate Parameter Deletion dialog is shown. This dialog lets you select the caller methods in which the parameter should be deleted.

## Safe Delete refactoring for a method in a call hierarchy

When you perform the Safe Delete refactoring for a method, IntelliJ IDEA analyzes the corresponding call hierarchy, finds the methods that may become unused and suggests that you delete those methods too.

## Example

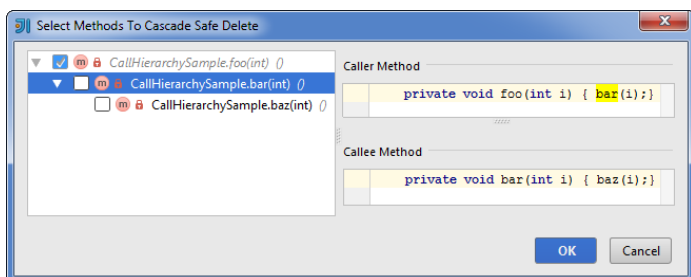

### Before/After

```
class CallHierarchySample {
    private void foo(int i) { bar(i);}
    private void bar(int i) { baz(i);}
    private void baz(int i) { }
}
```

```
class CallHierarchySample {
}
```

In this example, the refactoring was performed on the `foo(int i)` method. All the methods lower down in the call hierarchy were selected for deletion.

When performing the refactoring, the Select Methods to Cascade Safe Delete dialog is shown. This dialog lets you select the methods to be deleted.

The Type Migration refactoring allows you to automatically change a member type (e.g. from integer to string), and data flow dependent type entries, like method return types, local variables, parameters etc. across the entire project. It also lets automatically convert variable or method return type between arrays and collections. If any conflicts are found IntelliJ IDEA warns you about them.

**Tip** This refactoring is also available from [UML Class diagram](#).

## Example

f: int -> String

### BeforeAfter

```
int f;
void bar(int i) {}
void foo() {
    bar(f);
}
```

```
String f;
void bar(String i) {}
void foo() {
    bar(f);
}
```

I<String> -> I<Integer>

### BeforeAfter

```
interface I<T> {
    T foo(T t);
}

class A implements I<String> {
    String myString;
    public String foo(final String s) {
        if (s == null) {
            return
                myString;
        }
        return s;
    }
}
```

```
interface I<T> {
    T foo(T t);
}

class A implements I<Integer> {
    Integer myString;
    public Integer foo(final Integer s) {
        if (s == null) {
            return
                myString;
        }
        return s;
    }
}
```

myResult: ArrayList<String> -> String[]

### BeforeAfter

```
public class ResultContainer {
    private ArrayList<String> myResult;
    public String[] getResult() {
        return myResult.toArray(new String[myResult.size()]);
    }
}
```

```
public class ResultContainer {
    private String[] myResult;
    public String[] getResult() {
        return myResult;
    }
}
```

## To change type, follow these steps

1. In the editor, place the caret on the type to be refactored.
2. On main menu, choose Refactor | Type Migration, or press `Ctrl+Shift+F6`.
3. In the Type Migration dialog box, specify the new type and scope where to look for the usages.
4. Click Preview and review the items that will be affected. If needed, exclude usages from refactoring. To do that, right-click usage in the [Type Migration Preview](#) and select Exclude. When done, click Migrate.

Use Interface Where Possible refactoring delegates execution of the specified methods, derived from a base class/interface, to an instance of an ancestor class or an inner class, implementing the same interface.

## Example

### Before After

<pre>// File Class.java public class Class implements Interface {     public void publicMethod() {         ...     }     public void hiddenMethod() {         ...     } }</pre>	<pre>// File Class.java UNCHANGED public class Class implements Interface {     public void publicMethod() {         ...     }     public void hiddenMethod() {         ...     } }</pre>
<pre>// File Interface.java public interface Interface {     int CONSTANT=0;     void publicMethod(); }</pre>	<pre>// File Interface.java UNCHANGED public interface Interface {     int CONSTANT=0;     void publicMethod(); }</pre>
<pre>// File AnotherClass.java public class AnotherClass {     Class firstClass;     Class secondClass;     public void method() {         firstClass.publicMethod();         firstClass.hiddenMethod();         secondClass.publicMethod();         if (secondClass instanceof Class) {             ...         }         ...     } }</pre>	<pre>// File AnotherClass.java MODIFIED public class AnotherClass {     Class firstClass;     Interface secondInterface;     public void method() {         firstClass.publicMethod();         firstClass.hiddenMethod();         secondInterface.publicMethod();         if (secondInterface instanceof Interface) {             ...         }         ...     } }</pre>

## To use interface where possible, follow these steps

1. Select a class whose methods should be delegated to its parent class or interface. To do that, place the caret on this class in the editor or in the [Project Tool Window](#).
2. On the main menu or on the context menu of the selection, choose Refactor | Use Interface Where Possible.
3. In the [Use Interface Where Possible](#) dialog box, select the parent object that will replace the usages of the current class.
4. To replace the current class name in `instanceof` statements, check the option Use interface/superclass in instanceof.  
Note that if you use `instanceof` statements and leave this checkbox unselected, you may receive erroneous code, such as:

```
if (secondInterface instanceof Class)
```

This code will compile, but may produce undesired results.

5. To review the intended changes and make final corrections prior to the refactoring, click Preview. To continue without preview, click Refactor.  
The Rename variables dialog box appears. It lists the occurrences of the class that may be replaced by the superclass or the interface selected. Select the usages you want to replace, and (optionally) specify new names for each of them.
6. Click OK to continue. If you have previously clicked the Preview button, the Preview window will appear now.

The Wrap Return Value refactoring allows you to select a method, and either create a wrapper class for its return values, or use an existing, compatible wrapper class. All returns from the method selected will be appropriately wrapped, and all calls to the method will have their returns unwrapped.

Wrapping a method's returns are useful, if your design changes in such a way that you want a method to return more information than originally planned. After wrapping, the wrapper class can be extended, allowing more data to be returned from the method. Also, it is common to wrap primitive return values, thus allowing interface and implementation to be decoupled as needed.

**Tip** This refactoring is also available from [UML Class diagram](#).

## Example

### Before/After

```
class Order {
    String customer;
    String getCustomer() {
        return customer;
    }
}
```

```
class Order {
    String customer;
    Customer getCustomer() {
    }
}

class Customer {
    String id;
    Customer(String id) {
        this.id=id;
    }
}
```

### To wrap a return value, follow these steps

1. Open the desired class in the editor and place the caret at the method whose returns you wish to wrap.
2. Choose Refactor | Wrap Return Value on the main menu, or on the context menu of the selection. Alternatively, select the desired method in the Structure views, and trigger refactoring from there.
3. In the [Wrap Return Value dialog box](#) specify the name and package for the new wrapper class, or select an existing compatible wrapper class.
4. Preview and apply changes.

In this part:

- Documenting Source Code in IntelliJ IDEA
  - [Basics](#)
  - [Python documentation](#)
  - [RDoc support](#)
  - [YARD support](#)
  - [HEREDOC support](#)
- [Enabling Creation of Documentation Comments](#)
- [Creating Documentation Comments](#)
- [Generating JavaDoc Reference for a Project](#)

## Basics

IntelliJ IDEA provides convenient features for creating documentation comments.

Documentation comments in your source code are available for the [Quick Documentation Lookup](#) and open for review on pressing `Ctrl+Q`.

In Java files, IntelliJ IDEA creates stubs of documentation comments on typing the opening tag and pressing `Enter`.

If this feature applies to the methods, `@param` tags are created for each parameter declared in the method signature, `@return` tag is created if the method is not void, and `@throws` tags are created for each exception statement.

When you [create additional tags](#), IntelliJ IDEA provides code completion that suggests the possible tag names.

If a certain tag has multiple values, the same code completion provides the list of available values. Smart type code completion suggests the list of classes that are appropriate for the specific exception.

## Python documentation

The following features are only supported, when Python plugin is installed!

Documentation comments can be created in accordance with the syntax, selected in the [Python Integrated Tools](#) page of the Settings/Preferences dialog, for example, [reStructuredText](#) or [epytext](#).

If this feature applies to a function, IntelliJ IDEA generates tags, depending on the selected docstring format, for example:

- For reStructuredText: `:param` tags for each parameter declared in the function signature, and `:return` tag.
- For epytext: `@param` tags for each parameter declared in the function signature, and `@return` tag.

So doing, the tags in [reStructuredText](#) and [epytext](#) markup are highlighted accordingly.

If [configured](#), the documentation comment stubs can be generated with `type` and `rtype` tags.

In the Python files, IntelliJ IDEA recognizes the documentation comments represented as [Python docstrings](#).

Before you start, make sure that the required docstring format, for example, `epytext` or `reStructuredText`, is selected in the [Python Integrated Tools](#) page of the Settings/Preferences dialog.

Also note that IntelliJ IDEA captures custom roles from `conf.py`. When configuring the directory that contains `*.rst` files, point to the directory with `conf.py` ([Python Integrated Tools | Path to the directory with \\*.rst files](#)).

The following features are only supported, when Ruby plugin is installed!

## RDoc support

[RDoc](#) tags are completed:

[RDoc](#) highlighting in documentation comments can be enabled or disabled. To enable it, select the checkbox Highlight RDoc and ruby syntax in comments in the [Appearance](#) page of the editor settings.

## YARD support

[YARD](#) tags are completed:

- YARD directives complete in places where methods could be defined;
- Type annotations complete where applicable (assignments, before block vars);
- `param/return/etc.` tags complete before methods, inside directive docstrings, before `attr_reader/writer/accessor`

## HEREDOC support

Besides documentation comments in the RDoc and YARD formats, IntelliJ IDEA supports HEREDOCs. This is especially useful, if you are writing large blocks of text.

For example, consider the following:

```
class Heredoc
  def message
    <<-HEREDOC
Hello, World:)
Take a look at the recent post in our blog.
Stay tuned.
HEREDOC
  end
end
puts Heredoc.new.message
```

If you perform run, the lines between <<-HEREDOC and HEREDOC appear in the [Run tool window](#) .

**Note** IntelliJ IDEA suggests a [Rubyintention action](#) that converts <<-HEREDOC to squiggly<<-HEREDOC. This intention works with Ruby 2.3 and higher.

**Warning!** Note that this section refers to JavaScript, Java, Python and the other languages that have special beginning of documentation comments.

This section does not refer to Ruby.

## Enabling documentation comments

1. Open the Editor | General | Smart Keys page of IntelliJ IDEA settings (`Ctrl+Alt+S`).
2. In the Enter section, select or clear Insert documentation comment stub check box.
- 3.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

For Python, scroll to the Insert type placeholders in the documentation comment stub option and select or clear the check box as required. Refer to [the option description](#) for details.

On this page:

- [Creating documentation comments for a method or function](#)
- [Creating tags](#)
- [Creating and fixing doc comments](#)
- [Creating documentation comments for Ruby methods](#)
- [Creating documentation comments for Python functions](#)
- [Example of Python comment](#)
- [Fill Paragraph action](#)
- [Clickable comments](#)

## Creating documentation comments for a method or function

### To create a documentation comment for a method or function

1. Place the caret **before** the declaration.
2. Type the opening block comment `/**` , and press `Enter` .
3. Add meaningful description of parameters and return values.

Please note the following:

- IntelliJ IDEA checks syntax in the documentation comments and treats it according to the Error settings.
- If the entered text contains HTML tags, the closing tag will be automatically added after typing `>` , provided that this behavior is [enabled](#) in the editor settings.
- When typing in a documentation comment, the caret automatically moves to an expected position. For example:

```
/**
 * <ul>
 * <li>[caret]
 * [caret after Enter]
 * </li>
 * </ul>
 */
```

## Creating tags

### To create tags in a documentation comment block

1. In a comment block, select the desired empty line and type `@` or (for Python and Ruby languages) : character.
2. Press `Ctrl+Space` , or just wait for Code Completion to display the suggestion list:

3. Select a tag from the suggestion list. For example, you can specify the parameters type, or return type.
4. If a certain tag has several values, press `Ctrl+Space` after the tag, and select the desired value from the suggestion list. For example, IntelliJ IDEA suggests to select the desired parameter name.

```
function count(param1, param2)
}/**
 * @param param1
 * @param param2
 */
{}
```

## Creating and fixing doc comments

**Warning!** Note that this section refers to JavaScript, Java, Python and the other languages that have special beginning of documentation comments.

This section does not refer to Ruby.

Documentation comment can be created with the dedicated action [Fix Doc Comment](#) . It can be invoked by means of [Find Action](#) command.

Press `Ctrl+Shift+A` , with the caret somewhere within a class, method, function, or field, which should be documented, and enter the action name [Fix Doc String](#) . The missing documentation stub with the corresponding tags is added. For example:

```

/**
 *
 * @param userInput
 * @return
 */
static boolean processRepeatConversion (@NotNull String userInput) {
boolean repeatConversion = false;
if (((userInput.equals("y")) || (userInput.equals("Y")))) {
repeatConversion = true;
}
return repeatConversion;
}
}

```

The next case lays with fixing problems in the existing documentation comments.

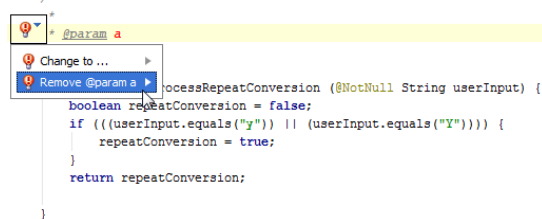

For example, if a method signature has been changed, IntelliJ IDEA highlights a tag that doesn't match the method signature, and suggests a quick fix.

For JavaScript, IntelliJ IDEA suggests an intention action UpdateJSDoc comment. You can also press `Ctrl+Shift+A`, and type the action name:

```

public class MetersToInchesConverter {
/**
 * @param a
 */
processRepeatConversion (@NotNull String userInput) {
boolean repeatConversion = false;
if (((userInput.equals("y")) || (userInput.equals("Y")))) {
repeatConversion = true;
}
return repeatConversion;
}
}

```

**Tip** The action Fix doc comment has no keyboard shortcut bound with it. You can [configure keyboard shortcut](#) of your own.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## Creating documentation comments for Ruby methods

### To create documentation comments for a Ruby method

1. Place the caret on an empty line before the declaration of the method you want to document.
2. Type the beginning of a doc comment (#), or just press `Ctrl+Slash`.
3. Press `Ctrl+Space`, and choose the desired tag from the suggestion list. Then press `Ctrl+Space` again, and choose the desired parameter name:

### To create documentation comments for a Ruby method using intention action, do one of the following

- Place the caret anywhere within the method you want to document, press `Alt+Enter`, and choose Add `@return` tag. The documentation comment with the `@return` tag is created. Specify the return type.

- Place the caret at the parameter you want to document, press `Alt+Enter`, and choose Add `@param` tag. The documentation comment with the `@param` tag for the selected parameter is created. Specify the parameter type.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Creating documentation comments for Python functions

### To create documentation comment for a Python function

1. Place the caret **after** the declaration of a function you want to document.
2. Type opening triple quotes, and press `Enter` , or `Space` .
3. Add meaningful description of parameters and return values.

**Tip** Mind the following:

- Generation of docstrings on pressing `Space` after typing opening triple quotes only works when the checkbox Insert pair quote is cleared in the page [Smart Keys](#) of the editor settings.
- If you rename a parameter of a function, IntelliJ IDEA will correspondingly update the tag in documentation comment.

### To create documentation comment for a Python function using intention action

1. Place the caret somewhere within the function you want to document.
2. Press `Alt+Enter` to show the available intention actions.
3. Choose Insert documentation string stub :

IntelliJ IDEA generates documentation comment stub according to docstring format, selected in the [Python Integrated Tools](#) page.

## Example of Python comment

Consider the following function:

```
def handle(self, myParam1, myParam2):
```

In the [Python Integrated Tools](#) page, select Epytext . Then type the opening triple quotes and press `Enter` or `Space` . IntelliJ IDEA generates documentation comment stub:

```
...
@param self:
@param myParam1:
@param myParam2:
@return:
...
```

Then select reStructuredText , type the opening triple quotes and press `Enter` or `Space` . IntelliJ IDEA generates documentation comment stub:

```
...
:param self:
:param myParam1:
:param myParam2:
:return:
...
```

## Fill Paragraph action

Fill Paragraph action is supported for Java comments. This action creates soft wraps in comments. To make use of this action, follow these steps:

1. Place the caret somewhere inside a comment in a class.
2. Do one of the following:
  - On the main menu, choose Edit | Fill Paragraph
  - Press `Ctrl+Shift+A` , in the pop-up frame, type Fill Paragraph , and then press `Enter` ,

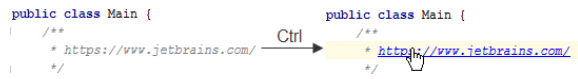

## Clickable comments

If a documentation comment contains a hyperlink, you can make it clickable.

To do that, do one of the following:

- Keep the `Ctrl` key pressed and hover your mouse pointer over the hyperlink:

```
public class Main {  
|  /**  
|   * https://www.jetbrains.com/ → Ctrl → * https://www.jetbrains.com/  
|   */  
}
```

- Press `Ctrl+B`.

IntelliJ IDEA provides a front-end to the standard JavaDoc utility for generating JavaDoc reference for your project. This feature is available from the editor and from the project tool window.

## To generate project documentation

1. On the main menu, choose Tools | Generate JavaDoc . Generate JavaDoc dialog is opened.
2. In the Generate JavaDoc dialog, specify the following options:
  - Select scope (whole project or a certain project with subpackages).
  - Specify the output directory, where the generated documentation will be placed.
  - Use the slider to define the level of visibility of members to be included in the generated documentation.
3. Specify the other JavaDoc options. Refer to the topic [Generate JavaDoc Dialog](#) for description of controls.
4. Click OK .

**Note** For language injections to be available, the IntelliJLang plugin must be enabled. This plugin is bundled with the IDE and enabled by default.

You can inject a language (such as HTML, CSS, XML, SQL, RegEx, etc.) into a string literal in your code and, as a result, get comprehensive coding assistance when editing that literal.

- [Example: Injecting HTML. Opening a fragment editor](#)
- [Accessing language injection functions](#)
- [Ways to inject a language](#)
- [Using language injection comments](#)
- [Using the @Language annotation](#)
- [Accessing injection settings](#)
- [Using language injection prefixes and suffixes](#)

### Example: Injecting HTML. Opening a fragment editor

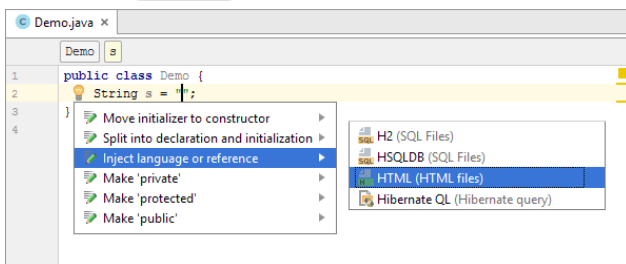

To get an impression of how language injections work:

1. Create a Java class and open that class in the editor.
2. Within the class body, type:

```
String s = "";
```

3. Place the cursor between the quotation marks.

4. Click  or press `Alt+Enter`, select Inject language or reference, and then select HTML (HTML files).

5. Type:

```
<body><h1>Hello, World!</h1></body>
```

When typing, note that auto-completion for HTML tags is now available. Also note how the HTML code is highlighted.

6. Let's now open a fragment editor for the injected HTML code: press `Alt+Enter` and select Edit HTML Fragment.

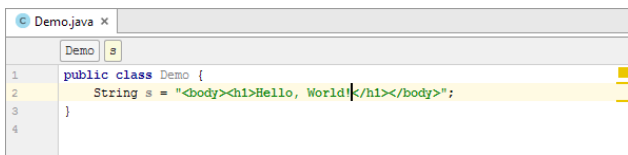

Here is the result:

You can use the fragment editor as an alternative (or in addition) to editing injected string literals in the "main editor".

7. To complete the example, let's cancel the injection: switch to the main editor, press `Alt+Enter` and select Un-inject Language/Reference.

Note that the text between the quotation marks has become green which is the default color for string values. This indicates that the value in the quotation marks is now treated simply as text.

```
1 public class Demo {
2     String s = "<body><h1>Hello, World!</h1></body>";
3 }
4
```

Don't close the editor yet. Later in this topic, we'll use our Java class for showing other language injection features.

## Accessing language injection functions

Most of the functions related to language injections are accessed through a "light bulb menu" (💡 or `Alt+Enter`).

## Ways to inject a language

You can inject a language by using:

- Inject language or reference `command`. You have already seen that in [Example: Injecting HTML. Opening a fragment editor](#). This way of injecting a language is temporary: the string literal stays injected for a limited period of time.
- `// language=<language_ID>`, see [Using language injection comments](#).
- `@Language("<language_ID>")`, see [Using the @Language annotation](#).

## Using language injection comments

To inject a language by means of an injection comment, on a separate line preceding the one that contains the target string literal, add:

```
// language=<language_ID>
```

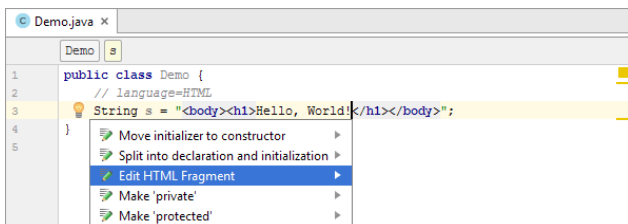

e.g.

```
// language=HTML
```

NOTE: The syntax of the comments should be appropriate for the language that you are using. So you may want to use `# language=...` or `-- language=...` rather than `// language=...`.

Example

1. On the line preceding `String s = "...";`, type `// language=HTML`.
2. Check the light bulb menu (`Alt+Enter`).

```
1 public class Demo {
2     // language=HTML
3     String s = "<body><h1>Hello, World!</h1></body>";
4 }
5
```

As you can see, HTML has been injected into the string literal.

3. Remove the commented line (e.g. `Ctrl+Y`) to come back to the previous state.

## Language IDs

The language IDs, generally, are intuitive, e.g. MySQL, RegExp, XML, HTML. If not sure about the language ID, use the suggestion list for the inject language or reference command. What precedes the opening parentheses there is the language IDs.

See also, [Using language injection prefixes and suffixes](#).

## Using the @Language annotation

In Java code, you can use the `@Language("language_ID")` annotation.

To be able to use this annotation: 1) the `annotations.jar` (or `annotations-java8.jar`) file should be included in your module dependencies and 2) the `import org.intellij.lang.annotations.Language;` statement should be added to your class file. For both these tasks, IntelliJ IDEA provides the intention actions as shown in the Example that follows.

In other respects, the `@Language` annotation works similarly to the injection comments.

Example

1. On the line preceding `String s = "...";`, type `@Language("HTML")`.  
If you haven't used this annotation in your project yet:
2. To add `annotations.jar` to the module dependencies: place the cursor within `Language`, press `Alt+Enter` and select Add 'annotations' to classpath.

In the dialog that opens, just click OK .

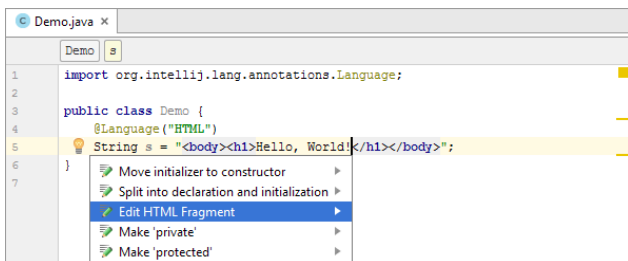

3. If IntelliJ IDEA suggests adding the import statement, just press `Alt+Enter` . Otherwise, press `Alt+Enter` and select Import class .

In both cases, the result will look something like this:

4. Place the cursor within the string literal and check the light bulb menu (`Alt+Enter`) to see that HTML has been injected.

5. Remove the `@Language("HTML")` line to return to the previous state (`Ctrl+Y`) .

## Accessing injection settings

To access the language injection settings:

1. Open the Settings / Preferences dialog (e.g. `Ctrl+Alt+S` ).
2. Go to the Language Injections page: Editor | Language Injections .

For more info, see [Language Injections page](#) .

## Using language injection prefixes and suffixes

Injecting a language may be accompanied with adding a prefix and a suffix. The prefix is added before the injected fragment, and the suffix - after the fragment.

Adding the prefix and the suffix is "imaginary". It doesn't change the actual string value. The prefix and the suffix act as a "wrapper" and their main purpose is to turn the injected fragment into a syntactically complete language unit. In this way, you give IntelliJ IDEA a broader context for validating the injected code fragment.

When editing your code, you can see the prefix and the suffix only in the fragment editor; the prefix and the suffix are not shown in the main editor.

The prefix and the suffix can be included in the injection comment whose complete form is

```
// language=<language_ID> prefix=<prefix> suffix=<suffix>
```

where the prefix and the suffix are optional.

## Example

In this example, we'll remove the opening and closing `<body>` tags from the injected code fragment and add these tags to the injection comment as the prefix and suffix.

1. Remove the opening and closing `<body>` tags: e.g. place the cursor within the injected fragment, press `Ctrl+Shift+Delete` and select Remove Enclosing Tag body.
2. On the line preceding `String s = "...";`, type `// language=HTML prefix=<body> suffix=</body>`
3. For the injected fragment, open the fragment editor.

The screenshot shows two windows from an IDE. The top window, titled 'Demo.java', contains the following Java code:

```
1 public class Demo {
2     // language=HTML prefix=<body> suffix=</body>
3     String s = "<h1>Hello, World!</h1>";
4 }
5
```

The bottom window, titled 'HTML Fragment (Demo.java:85).html', shows the fragment editor with the following HTML code:

```
1 <body><h1>Hello, World!</h1></body>
```

Compare the fragments shown in the main and in the fragment editors.

IntelliJ IDEA suggests various ways of navigation between the IDE components and within source code. IntelliJ IDEA's smart editor makes it possible to navigate across the source code using the code structure rather than plain scrolling. You can find your way in the source code using the method calls, declarations, errors, changes etc.

In this part:

- [Navigating with Bookmarks](#)
- [Navigating Between Open Files and Tool Windows](#)
- [Navigating Between IDE Components](#)
- [Navigating Between Methods and Tags](#)
- [Navigating Between Test and Test Subject](#)
- [Navigating from Stacktrace to Source Code](#)
- [Navigating to Action](#)
- [Navigating to Braces](#)
- [Navigating to Class, File or Symbol by Name](#)
- [Navigating to Custom Folding Regions](#)
- [Navigating to Declaration or Type Declaration of a Symbol](#)
- [Navigating to Super Method or Implementation](#)
- [Navigating to File Path](#)
- [Navigating to Line](#)
- [Navigating to Next/Previous Change](#)
- [Navigating to Next/Previous Error](#)
- [Navigating to Recent](#)
- [Navigating to Navigated Items](#)
- [Navigating with Breadcrumbs](#)
- [Navigating with Favorites Tool Window](#)
- [Navigating with Navigation Bar](#)
- [Navigating with Structure Views](#)

On this page:

- [Introduction](#)
- [Navigating within the current file](#)
- [Navigating across a project](#)

## Introduction

The editor of IntelliJ IDEA provides two types of bookmarks:

- Anonymous bookmarks, indicated by check signs ✓ in the left gutter. The number of anonymous bookmarks is unlimited.
- Bookmarks with mnemonics indicated by **b** or **g** icons in the left gutter. There can be only 10 numbered and 26 lettered bookmarks within a project.

All bookmarks are indicated with the black streaks in the marker bar:

Once created, the bookmarks enable you to easily jump to the desired location within a file, or across the entire project.

## Navigating within the current file

### To navigate through the bookmarks within the current file, do one of the following

- On the main menu, choose `Navigate | Bookmarks | Next/Previous Bookmark`. The order of visiting bookmarks depends on their order in the collection of bookmarks in the [Bookmarks dialog](#).
- Click the black streak in the marker bar.

## Navigating across a project

### To navigate across a project using numbered bookmarks

- Use `Ctrl+Number` where the <number> corresponds to the desired bookmark.

### To navigate among all bookmarks in a project, do one of the following

- On the main menu, choose `Navigate | Bookmarks | Show Bookmarks`, or press `Shift+F11`. In the [Bookmarks dialog](#), select the target bookmark, and press `Enter`.

For your convenience, the target code preview is shown in the right pane of the dialog box.

- In the [Favorites tool window](#), select the desired bookmark in the Bookmarks list, and then double-click the bookmark entry, or press `F4`. The corresponding file opens in the editor, with the caret at the beginning of the bookmarked line.

This section describes how to:

- [Create and delete bookmarks with mnemonics](#)
- [Toggle bookmarks](#)
- [View project bookmarks](#)
- [Delete bookmarks](#)
- [Change the order of bookmarks](#)

## Creating bookmarks with mnemonics

### To create a bookmark with mnemonics, follow these steps:

1. Place the caret at the desired line of code in the editor.
2. Press `Ctrl+F11` (alternatively, choose `Navigate | Bookmarks | Toggle Bookmark With Mnemonic` on the main menu), then press one of the keys 0-9 or A-Z.

## Toggling bookmarks

### To toggle an anonymous bookmark on the current line, do one of the following:

- On the main menu, choose `Navigate | Bookmarks | Toggle Bookmark`.
- Press `F11`.

## Viewing bookmarks

### To view all bookmarks in a project, do one of the following:

- On the main menu, choose `Navigate | Bookmarks | Show Bookmarks`.
- Press `Shift+F11`.

## Deleting bookmarks

### To delete bookmarks in a project, follow these steps:

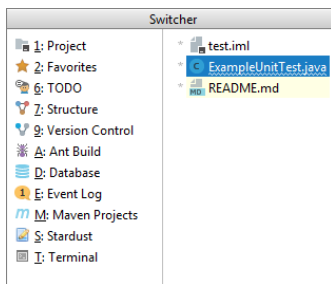

1. Open the Bookmarks dialog (`Navigate | Bookmarks | Show Bookmarks`, or `Shift+F11`).
2. Select bookmarks and press `Delete`.

## Changing order of bookmarks

### To change the order of bookmarks

1. Open the Bookmarks dialog (`Navigate | Bookmarks | Show Bookmarks`, or `Shift+F11`).
2. Select the desired bookmark.
3. Use `Move Up` (`↑`, `Ctrl+Up`) and `Move Down` (`↓`, `Ctrl+Down`) buttons to shift the bookmark in the desired direction.

IntelliJ IDEA suggests a handy way to switch between files opened in the editor, split editor tabs, and tool windows (docked or floating). This is similar to application switchers in different operating systems. The switcher consists of two columns: the left one displays a list of tool windows, and the right one displays a list of files. If more than one file is currently opened in the editor, they are listed. If no files are currently opened, or there is just one tab, the switcher shows recently opened files (the currently opened file is marked with an asterisk).

To switch between files or tool windows:

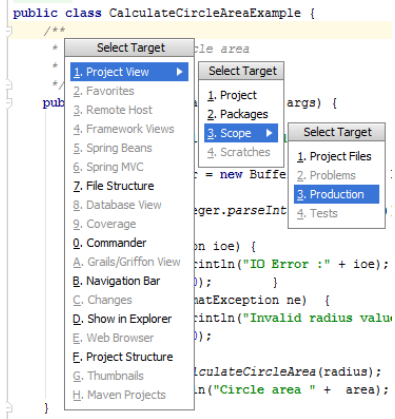

1. Press `Ctrl+Tab` .
2. Keeping the first key (`Ctrl` on Windows/Linux or `⌘` on macOS) pressed, use the following keys:
  - `Left` and `Right` to switch between the lists of tool windows and files.
  - `Up` and `Down` arrow keys, `Tab` or `Shift+Tab` to go up and down the list in both panes.
  - `Delete` or `Backspace` to close the editor tab where the selected file is opened and remove the selected file from the list.
3. Release the `Ctrl` / `⌘` key. The corresponding file or tool window gets the focus, and the switcher pop-up disappears.

Suppose you have selected a file or member in one of the tool windows, and would like to quickly locate it in another IDE component. The Select Target pop-up menu helps you move the focus to the selected component of IntelliJ IDEA, the file system, etc.

## To navigate to the desired component

1. On the main menu select **Navigate** and click **Select In**, or press **Alt+F1**.  
The **Select Target** pop-up menu shows up.

2. Use the arrow keys or the mouse pointer to select the desired component. If your target is the Project tool window, you can select the desired view:

**Tip** You can also double-click selected file or member in one of the tool windows or press **Enter** to open it in the editor.

Since your source code can contain numerous methods, it is convenient to navigate to the beginning of the next or previous method. In the Web contents, this feature enables navigating between tags.

### To navigate to the next or previous method or tag

- On the main menu, choose Navigate | Next Method / Previous Method respectively.
- Use `Alt+Up` / `Alt+Down` keyboard shortcuts.

For JavaScript code inside HTML files this behavior depends on the caret location. If the caret rests inside a JavaScript block, this means of navigation enables jumping between JavaScript functions. If the caret rests on a `<script>` tag, then navigation is performed between the tags.

To improve the visibility of your source code by having a line added automatically between adjacent methods, choose the Show Method Separators option in the [Appearance](#) page of the editor settings.

On this page:

- [Overview](#)
- [Jumping from a test to its test subject](#)
- [Jumping from a class or file to its test](#)

## Overview

Testing support in IntelliJ IDEA provides the ability to navigate between a test and the test subject.

For information on common testing procedures, see [Testing](#) .

For language-and framework-specific guidelines, see , [Testing Frameworks](#) , [Testing JavaScript](#) , [Testing Node.js](#) , and [Language and Framework - Specific Guidelines](#) .

## Jumping from a test to its test subject

1. Open the desired test class in the editor.
2. On the main menu or on the context menu of the editor, choose [Navigate | Test Subject](#) . Alternatively, press `Ctrl+Shift+T` .

The test subject for the current test class opens in the dedicated tab of the editor and gets the focus.

## Jumping from a class or file to its test

1. Open the desired class in the editor.
2. On the main menu or on the context menu of the editor, choose [Navigate | Test](#) . Alternatively, press `Ctrl+Shift+T` .

If more than one test is associated with the test subject, select the desired one from the pop-up list. The test for the current class opens in the dedicated tab of the editor and gets the focus.

**Note** If a test class doesn't exist, you will be prompted to create one as described in the section [Creating Tests](#) .

You can easily navigate from the stack trace in the Run tool window to the source code that causes problems.

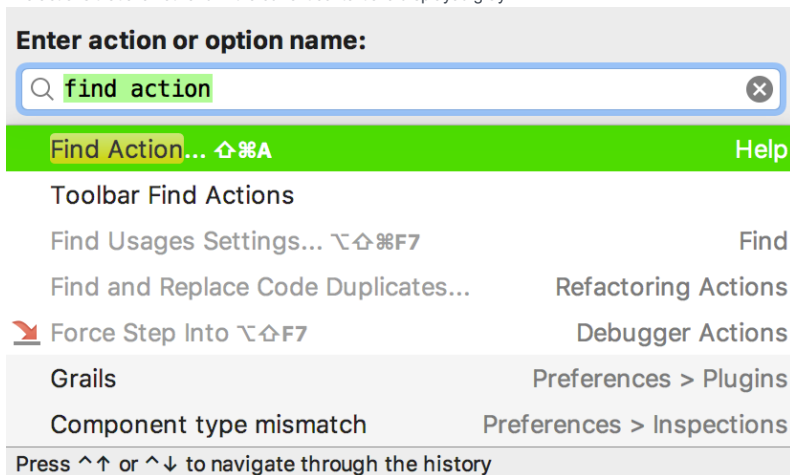

### **To navigate from the stack trace to a line of code**

- In the Run tool window scroll to the desired stack trace line and click the link to the source file in question. The source file opens in the editor.

IntelliJ IDEA helps you quickly find the desired action, without digging through the menus and toolbars. The concept action covers the commands of the main menu and various context menus, commands performed through the toolbar buttons of the main toolbar and tool windows.

## To find an action

1. Choose Help | Find Action on the main menu or press `Ctrl+Shift+A`. The pop-up window that opens, shows the suggestion list of matching names. By default, this list includes the menu commands only. If you want to include the non-menu commands in the suggestion list, press `Ctrl+Shift+A` once more.
2. Start typing the desired action name. As you type, the suggestion list displays the matching names of actions. The actions that are not valid in the current context are displayed gray.

3. Double-click the desired entry in the suggestion list, or select it using the arrow keys and press `Enter`.

This way you can invoke the actions that are not mapped to keyboard shortcuts in certain schemes (for example, scroll to top, scroll to bottom, or Emacs actions, like kill rings, sticky selection, or hungry backspace).

These actions are not mapped to certain keyboard shortcuts, neither they appear in the menus. If necessary, configure keyboard shortcuts for these actions as described [here](#).

On this page:

- [Navigating to the borders of a code block](#)
- [Navigating to the borders of the closest higher code block](#)

## Navigating to the borders of a code block

### To navigate to the borders of a code block, do one of the following:

- To navigate to the code block start, press `Ctrl+Open Bracket`, with the caret anywhere inside the code block.  
The caret jumps to the opening brace of the current code block.
- To navigate to the code block end, press `Ctrl+Close Bracket`, with the caret anywhere inside the code block.  
The caret jumps to the closing brace of the current code block.
- To toggle between code block start or end, press `Ctrl+Shift+M`.  
You can also invoke this action ( Move Caret to Matching Brace ) with a [Search Everywhere](#) or [Go to Action](#) functionality:

## Navigating to the borders of the closest higher code block

### To navigate to the borders of the closest higher code block, do one of the following:

- To jump to the higher code block start, press `Ctrl+Open Bracket`, with the caret at the [current code block opening brace](#).
- To jump to the higher code block end, press `Ctrl+Close Bracket`, with the caret at the [current code block closing brace](#).

**Tip** Practically, you can just press `Ctrl+Open Bracket` or `Ctrl+Close Bracket` as many times as you need, until the caret is positioned at the start or end of the desired code block.

On this page:

- [Overview](#)
- [Navigating by name](#)
- [Tips and tricks](#)

## Overview

Navigate commands enable you to quickly jump to the desired classes, files, or symbols specified by names. IntelliJ IDEA suggests a look-up list of matching names, from which you can select the desired one, and open it in the editor. This navigation honors CamelCase and snake\_case capitalization. Refer to the [tips](#) for detailed list of available techniques.

## Navigating by name

To navigate to a class, file, or symbol with the specified name:

1. On the main menu, point to **Navigate**, and then choose **Class**, **File**, or **Symbol** respectively, or use the following shortcuts:

- Class: `Ctrl+N`
- File (directory): `Ctrl+Shift+N`
- Symbol: `Ctrl+Shift+Alt+N`

2. In the pop-up window, start typing the desired name.

So doing, you can enter characters located anywhere inside the desired name. As you type, the suggestion list shrinks, displaying the matching names only.

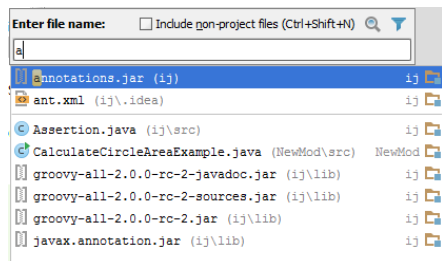

- **Class** :

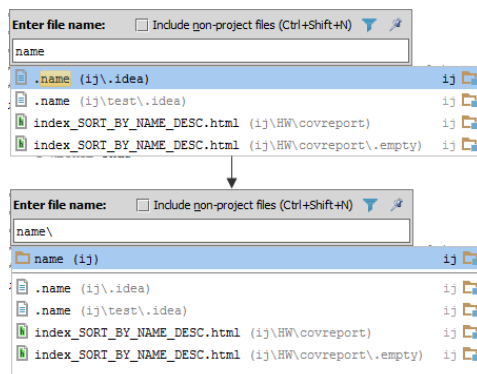

It is also possible to navigate directly to the specified anonymous class. It is enough to specify class name and the anonymous class number, delimited with `$` character:

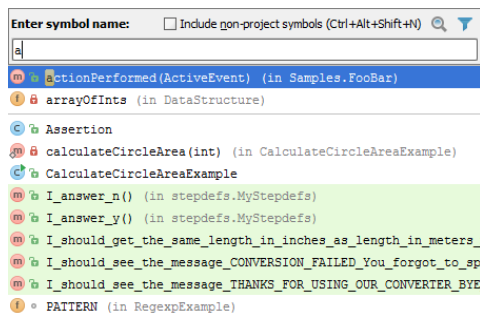

- **File** :

- **Directory** : use the same `Ctrl+Shift+N` shortcut as for file navigation, and type the name of the directory you are looking for, the pattern name ending with `/` or `:`:

- **Symbol** :

3. Click the desired entry in the suggestion list, or select it using the arrow keys, and press `Enter`.

## Tips and tricks

While working in the navigation pop-up window, use the following helpful techniques:

- Narrow down the search scope by selecting the file types to search in. Just click the filter , and clear the checkboxes next to the file types you are not interested in.
- Include non-project files in the look-up list and thus make available matching files from SDKs and libraries.
- If the look-up list is too long, type more characters to shrink it, or click the ellipsis sign at the end of the list, to reveal its next portion.
- Type the initial letters of the **CamelHumps** names, for example:

Note that IntelliJ IDEA automatically recognizes **CamelHumps** and matches them to the lower case letters.

- Type any letters separated with spaces for **snake\_case** names, for example:

- In the navigation to file pop-up window, type letters delimited with slashes to denote nested directories:

- Type line number after a file name, delimited with a colon, to navigate to the specified line:

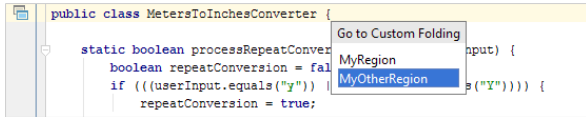

- Use `*` wildcard to represent any number of characters, though it is quite enough to type characters located in the middle of the desired name.
- If while typing in one of the Navigate to Class/File/Symbol pop-up windows you notice that you need another one, just invoke the necessary dialog box. The text you have already entered will not disappear.
- Press `Alt+F1` to invoke the Select Target pop-up window, and choose the desired IDE component.
- Note that for the projects under version control, the entries in the look-up list are color coded according to their status:

- When there is a **detached editor frame** with a certain file, you can opt to open this file in the main IntelliJ IDEA frame by pressing `Enter`, or activate the detached frame by pressing `Shift+Enter`.

If there are code folding comments in your file (see [Using code folding comments](#) ), you can navigate to corresponding folding regions like this:

1. Select Navigate | Custom Folding or press `Ctrl+Alt+Period` .
2. Select the target folding region. (The regions in the list are identified by their descriptions.)

```
public class MetersToInchesConverter {  
    static boolean processRepeatConversion(MyRegion input) {  
        boolean repeatConversion = false;  
        if (((userInput.equals("y")) || MyOtherRegion ("Y")))) {  
            repeatConversion = true;  
        }  
    }  
}
```

On this page:

- [Introduction](#)
- [Important note](#)
- [Navigating to the declaration of a symbol](#)
- [Navigating to the type declaration of a symbol](#)

## Introduction

While editing your source code, you might need to navigate to the location where a particular named code reference (a symbol) has been first declared. Navigate | Declaration command enables you to navigate back to the initial declaration of a symbol from any place in the source code, even if it is from inside another class, or comment.

## Important note

Navigate | Declaration/Type Declaration

- Applies to the symbols of source code, CSS, HTML or XML tags and attributes, DTD and schema elements and attributes, and references in comments.
- Does not apply to the primitive types.

## Navigating to the declaration of a symbol

1. Place the caret at the desired symbol in the editor.

2. Do one of the following:

- On the main menu, choose Navigate | Declaration .
- Press `Ctrl+B` .
- Click the middle mouse button.
- Keeping `Ctrl` for Windows or Linux users or `⌘` for macOS users pressed, point to the symbol, and click, when it turns to a hyperlink. You can also see declaration at the tooltip while keeping `Ctrl` for Windows or Linux users or `⌘` for macOS users pressed.

```
public class DataBean1 {  
    Map root java.util  
    String n public interface java.util.List<E> extends java.util.Collection<E>  
    private List listt;
```

`⌘` for macOS users pressed.

**Tip** Annotation types are marked in the declaration tooltips with the `@` character:

```
[untitled2] aaa  
}/** public @interface MyAnno  
@MyAnno
```

## Navigating to the type declaration of a symbol

1. Place the caret at the desired symbol in the editor.

2. Do one of the following:

- On the main menu, choose Navigate | Type Declaration .
- Press `Ctrl+Shift+B` .
- Press the `Ctrl+Shift` for Windows and Linux users, or `⌘+⇧` for macOS users keys and hover your mouse pointer over the symbol. When the symbol turns to a hyperlink, click it without releasing `Ctrl+Shift` for Windows and Linux users, or `⌘+⇧` for macOS users keys. The type declaration of the symbol opens in the editor. You can also see the declaration at the tooltip while keeping `Ctrl+Shift` for Windows and Linux users, or `⌘+⇧` for macOS users pressed.

```
this.name = n java.lang  
}  
public final class java.lang.String extends Object  
implements java.io.Serializable, java.lang.Comparable<java.lang.String>, java.lang.CharSequence  
public String getName() {  
    return name;
```

IntelliJ IDEA provides an easy way to navigate up and down through the hierarchy of methods. If a method is overridden / implemented by a certain method, or overrides / implements some method itself, it is marked with an icon in the gutter area of the editor. When the mouse cursor hovers over such icon, the method information is displayed as the tooltip:

- : This method implements a method required by an implemented interface or extended abstract class.
- : This method of an interface or an abstract class is implemented by one or more descendants.
- : This method overrides a method defined by its superclass.
- : This method or field is overridden / implemented by one or more subclasses.

Use these icons, shortcuts, or menu commands to navigate to the corresponding points of origin.

## Navigating through the hierarchy of methods

To navigate up and down through the method hierarchy, do one of the following:

- Click the gutter icon and select the desired ascendant or descendant class from the list.
- On the main Navigate menu, choose Super Method , or Implementation(s) respectively.
- Press `Ctrl+U` or `Ctrl+Alt+B` for the super method or implementation respectively.

On this page:

- [Overview](#)
- [Navigating to a file path](#)
- [Viewing file path](#)

## Overview

It may be helpful to open a file in a file manager (for example, in the Windows Explorer, if Windows is your OS), or the Finder. IntelliJ IDEA allows you to easily navigate to any part of a file path, right from the editor.

## Navigating to a file path

### To navigate to a file path from the editor

1. Hold `Ctrl` / `⌘` and click the relevant tab in the editor.
2. In the drop-down list, select the element you need.

The file manager shows the selected file or directory.

## Viewing file path

To just view the path to a file, place the mouse pointer over the tab where the file is opened.

Navigate | Line command is the most basic way to navigate to the line with the specified number.

## To navigate to a line in the editor

1. On the main menu, choose `Navigate | Line`, or press `Ctrl+G`.
2. In the `Go To Line` dialog box that appears, IntelliJ IDEA shows the current line and offset delimited by a colon. Type the target line number and, optionally, an offset, and then click `OK`.

The current caret position (line number and offset) is displayed in the `Status Bar`. You can click it to open the `Go To Line` dialog box.

If you edit a file that is under version control, IntelliJ IDEA provides several ways to move back and forth with the updates. In particular, you can use the navigation commands, keyboard shortcuts, and the change markers.

**To navigate to the next/previous change in the editor, do one of the following:**

- On the main menu, choose `Navigate | Next / Previous Change`.
- Use keyboard shortcuts `Ctrl+Shift+Alt+Down` or `Ctrl+Shift+Alt+Up`.
- Point to a [change marker](#), and click the arrow up  or arrow down  buttons.

**To navigate to the place of your last edit, do one of the following:**

- On the main menu, choose `Navigate | Last Edit Location`
- Use keyboard shortcut `Ctrl+Shift+Backspace`.

On this page:

- [Introduction](#)
- [Configuring error navigation](#)
- [Navigating between errors or warnings](#)

## Introduction

Another method of code navigation is to **move between found errors and warnings** . The caret is positioned immediately before the code issue.

You can configure the way IntelliJ IDEA navigates between code issues: it can either jump between all code issues or skip minor issues and only navigate between detected errors.

## Configuring error navigation

### To configure the error navigation

1. Right click the [Validation Side Bar](#) .
2. On the context menu, choose one of the available navigation modes:
  - To have IntelliJ IDEA skip warnings, infos, and other minor issues, choose Go to high priority problems only .
  - To have IntelliJ IDEA jump between all detected code issues, choose Go to next problem .

## Navigating between errors or warnings

### To navigate between errors or warnings, do one of the following

- On the main menu, choose Navigate | Next / Previous Highlighted Error .
- Use keyboard shortcuts `F2` and `Shift+F2` respectively.

On this page:

- [Navigating to a recently opened file](#)
- [Navigating to a recently edited file](#)
- [Navigating to the last/next edit location](#)
- [Using multi-selection in the lists of recent files](#)

## Navigating to a recently opened file

### To navigate to a recently opened file

1. On the main menu, choose View | Recent Files or press `Ctrl+E`.
2. From the Recent Files pop-up window that opens select the desired file.

## Navigating to a recently edited file

### To navigate to a recently edited file

1. On the main menu, choose View | Recently Changed Files or press `Ctrl+Shift+E`.
2. From the Recently Edited Files pop-up window that opens select the desired file.

**Tip** The recently opened or recently modified files are selected from the history list. The number of entries in the history list is configurable in the Recent file limit field in the [Editor](#) settings page.

- Navigating to recent files applies to the search results as well. By pressing `Ctrl+E` in the [Find](#) tool window, you can have the list of recent search results shown.

## Navigating to the last/next edit location

### To jump to the latest edit location

- Do one of the following:
  - On the main menu, choose Navigate | Last Edit Location.
  - Press `Ctrl+Shift+Backspace`.

### To jump to the next edit location

- On the main menu, choose Navigate | Next Edit Location.

This action is not bound to any shortcut. An interested user can do it as described in the section [Configuring Keyboard Shortcuts](#).

## Using multi-selection in the lists of recent files

### To use multi-selection in the lists of recent files

- To select non-adjacent files, use `Ctrl` / `⌘` + mouse click.
- To select adjacent files, use `Shift` / `⇧` + mouse click.

You can go back and forth along the items that have already been navigated to. This feature applies to the items reached using all navigation commands except for the simplest ones, such as arrow keys, Page Up, Page Down, Home and End.

## To navigate to the navigated items

Do one of the following:

- On the main menu, choose **Navigate | Back / Forward** .
- Use keyboard shortcuts `Ctrl+Alt+Left` , or `Ctrl+Alt+Right` .
- On the main toolbar, click  or  .

**Note** On a macOS computer, you can also use the three-finger right-to-left and left-to-right swipe gestures.

Breadcrumbs help you navigate through your source code. They show the names of classes, variables, functions, methods and tags in the file opened in the active editor tab:

A screenshot of a breadcrumb trail in an IDE. It consists of three rectangular buttons with rounded corners, separated by vertical lines. The first button contains the text 'DataStructure', the second contains 'EvenIterator', and the third contains 'next()'. The 'next()' button is highlighted with a yellow background, indicating the current position in the code.

To jump to an element in the source code, click the breadcrumb with its name.

## Configuring breadcrumbs

By default breadcrumbs are shown at the bottom of the editor. To move or hide them, right-click a breadcrumb and click Breadcrumbs | Top or Breadcrumbs | Don't show .

You can also do that on the [Breadcrumbs page](#) ( File | Settings | Editor | General | Breadcrumbs for Windows and Linux or IntelliJ IDEA | Preferences | Editor | General | Breadcrumbs for macOS):

1. Select the checkboxes next to the languages in which you want to have breadcrumbs shown.
2. Choose where to show breadcrumbs (at the top or at the bottom of the editor).
3. To suppress breadcrumbs, clear the Show breadcrumbs checkbox.

The [Favorites tool window](#) consolidates the views of the project's favorite items, bookmarks and breakpoints. Choosing the appropriate [viewing mode](#) for this tool window helps you have all information at hand, and navigate through the items with ease.

**To jump from an item in the Favorites tool window to the file in the editor, do one of the following**

- Double-click the selected item.
- On the context menu of the selected item, choose Jump to Source .
- Press **F4** .

The corresponding file opens in the editor. In case of a bookmark or a breakpoint, the caret rests at the beginning of the line with this bookmark or breakpoint.

Use the [Navigation Bar](#) as a handy tool to find your way across the project.

### To navigate to a file using the Navigation bar

1. Press `Alt+Home` to activate the Navigation bar.
2. Use the arrow keys or the mouse pointer to locate the desired file.
3. Double-click the selected file, or press `Enter` to open it in the editor.

**Tip** To jump to Java methods, use [breadcrumbs](#) .

Use the Structure pop-up window or the Structure tool window to quickly jump to the desired member of a file in the editor. The Structure views provide quick navigation for all supported file types.

Besides that, navigation with the Structure pop-up window is also available for [diagrams](#) .

## To navigate to a member in the editor

1. Choose Navigate | File Structure on the main menu or press `Ctrl+F12` .
2. In the File Structure pop-up window that opens select the Narrow down the list on typing checkbox and start typing the desired member name.  
You can include the members, inherited from the parent classes, by checking the option Show inherited members or pressing `Ctrl+F12` again.

3. Use the navigation keys to select the desired node. Then do one of the following:
  - If the cursor rests on a top or intermediate node (for example, class `c` or element `<>`), double-click this node or press `Enter` to expand it in the Structure pop-up, or press `F4` to jump to its declaration in the editor.
  - If the cursor rests on a leaf node (for example, a member `m`, `i` or lowest-level element `<>`), double-click this node or press `Enter` to jump to its declaration in the editor.

In the case of an inherited member, the respective parent class opens in the editor.

You can also use the [Structure](#) tool window (`Alt+7` ). This view is flexibly configurable and useful for many tasks, apart from navigation. However, the File Structure pop-up window is the easiest way for quick navigation.

IntelliJ IDEA provides extensive search and replace capabilities, which includes basic search and replace, search and replace in paths, finding usages, code-aware structural search and more. Some of the replacement facilities (like renaming classes and members) are performed by means of [refactorings](#) .

All the search commands can be found under the Find node of the Edit menu.

In this part you will learn how to:

- [Find and replace](#) text in the current file.
- [Find specific word](#) .
- [Search and replace across the project](#) .
- [Find usages](#) .
- [Highlight usages](#) .
- [View usages of a symbol across the project, and jump to the desired usage](#) .
- [Work with the search results](#) .
- [Perform structural search and replacement using a template](#).

IntelliJ IDEA lets you find and replace text strings in an active editor.

## Search through the current file

1. From the main menu, choose Edit | Find | Find , or press **Ctrl+F** . The search pane appears on top of the active editor.
2. If necessary, specify the [search options](#) .
3. In the search field, start typing the search string:

As you type, the first occurrence of the search string after the current cursor position is selected; the other occurrences are highlighted in the editor. In addition, the matching occurrences are marked in the right gutter with stripes.

```
race = function() {
  var runners, winner;
  winner = arguments[0]; runners = 2 <= arguments.length ? __slice.call(arguments, 1)
  return print(winner, runners);
};
```

4. To search for a multi-line fragment, click **↵** in the search box or press **N/A** .

5. [Explore the search results](#) .

**Tip** To turn on the multiline mode, press **N/A** .

To return to a single-line mode, press **Delete** .

## Replace in the current file

1. From the main menu, choose Edit | Find | Replace , or press **Ctrl+R** . The search and replace pane appears on top of the active editor.
2. If necessary, specify the [search and replace options](#) .
3. In the search field, start typing the search string. As you type, the matching occurrences are highlighted in the editor, and a Replace pop-up dialog box opens at the first occurrence, suggesting to replace the current occurrence, or all of them, with an empty string.
4. Start typing the replacing string.
5. [Explore the search results](#) , and, using the buttons of the replace dialog box, replace occurrences as required. See [Search and replace options](#) below.

## Working with search results

- To initiate a new search, do one of the following (depending on the current focus):
  - If the editor has the focus, press **Ctrl+F** .
  - If the search field has the focus, press **Ctrl+A** .

In both cases, the existing search string will be selected, and you can start typing a new one.

- To jump between occurrences, do one of the following:
  - Press **Shift+F3** (jump to previous selection) or **F3** (jump to next selection).
  - Use the **↑** or **↓** buttons in the Search pane.
  - Click the gutter stripes.
- The search pane shows the number of found occurrences. If no matches are found, the search pane becomes red:

- Use the recent search history: with the search pane already open, click **Q** to show the list of recent entries.
- Use Code completion in the Find and Replace panes. Start typing a search string, press **Ctrl+Space** , and select the appropriate word from the suggestion list.
- With the Find and Replace pane already opened, use **Ctrl+R** or **Ctrl+F** to toggle between panes. Thus, the search and replace strings are preserved.
- To cancel the operation and close the pane, press **Escape** .
- Use **multiple selection** ( **multiselection** ). For example, if a certain string has been highlighted as a search result, it is possible to add an occurrence of this string to multiple selection by clicking **⇧** ( **Alt+J** ), delete an occurrence from multiple selection using **⇧** ( **Shift+Alt+J** ), or add all found occurrences to multiple selection using **⇧** ( **Ctrl+Shift+Alt+J** ).

## Search and replace options

ItemDescriptionSearch/Replace

	Click this button to show the history of the recent entries.	Search, replace
	Click this button to clear the search field.	Search, replace
	Click these buttons to navigate through the occurrences of the search string.	Search, replace
	Click this button to add the next found occurrence to a multiple selection.	Search
	Click this button to remove the found occurrence from a multiple selection.	Search
	Click this button to create a selection that contains all the found occurrences.	Search
	Click this button to show search results in the <a href="#">Find tool window</a> .	Search, replace
Match Case	If this checkbox is selected, IntelliJ IDEA will distinguish between upper and lowercase letters while searching.	Search, replace
Regex	If this checkbox is selected, the search string will be perceived as a <a href="#">regular expression</a> , and the replacement preview is shown in a tooltip.	Search, replace
Words	if this checkbox is selected, IntelliJ IDEA will search for whole words only, that is, for character strings separated with spaces, tabs, punctuation, or special characters.  This checkbox is disabled, if the Regular expressions checkbox is selected.	Search, replace
Preserve Case	If this checkbox is selected, IntelliJ IDEA retains the case of the first letter and the case of the initial string in general. For example, <i>MyTest</i> will be replaced with <i>Yourtest</i> if you specify <i>yourtest</i> as the replacement.  This checkbox is disabled, if Regular expressions checkbox is selected.	Replace
In Selection	If this checkbox is selected, search and replacement will be confined to the selected text only.	Replace
Replace	Click this button to replace the current occurrence and proceed to the next one.	Replace
Replace all	Click this button the replace all found occurrences in the current file, or in the selection.	Replace
Exclude/Include	Click Exclude button to skip the current occurrence and exclude it from the Replace all operation. The button for this occurrence changes to Include .	Replace
	Click this button to invoke the list of additional options. Checking the corresponding option confines the search to the specified scope, while the other occurrences are ignored.	Search, replace

## Introduction

IntelliJ IDEA extends search and replace capability to the entire project, specific module, or any directory with its nested hierarchy. Explore search results in the preview tab or in the [Find tool window](#).

## Finding a piece of text in all the files within the specified path

1. On the main menu, choose `Edit | Find | Find in Path`, or press `Ctrl+Shift+F`.
2. In the Find In Path dialog, specify the following options:
  - Start entering the text. Type the text explicitly, or specify a pattern using a regular expression, or select a previously used piece of text or a pattern from the recent entries' drop-down list.  
If you specify the search pattern through a regular expression, use the `$n` format in back references (to refer to a previously found and saved pattern).
  - Search scope ( project , module , directory, or custom scope).

- Search options (case sensitivity, whole words, and regular expressions).

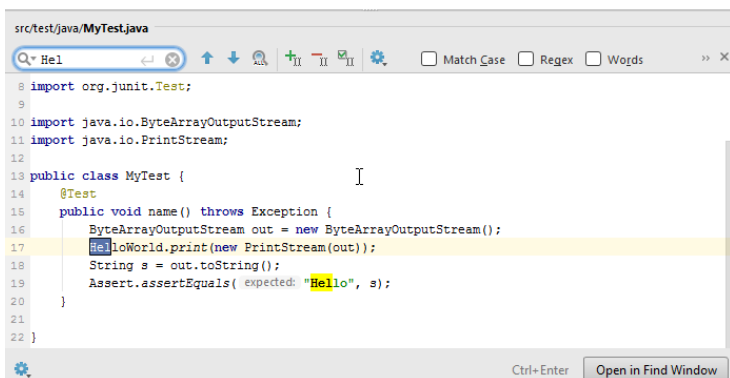

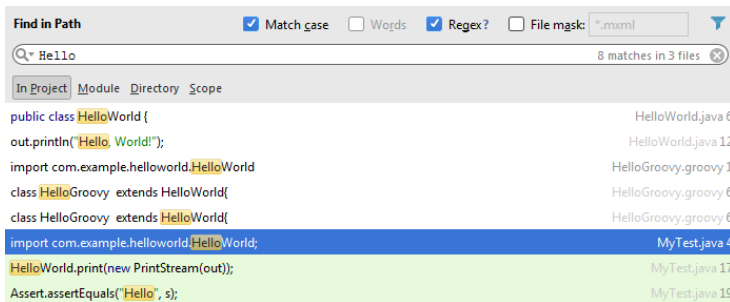

- Context search options.

The results are displayed in the preview area.

3. Edit the selected result right in the preview editor as it is a functional editor where actions such as `Find` (`Ctrl+F`) or `Find Next` (`F3`) are available without leaving the Find in Path window.

Press `Enter` to open the selected result in the editor.

Click `Open in Find Window` (`Ctrl+Enter`) to see all of the results in the Find tool window.

**Tip** If the search takes too much time, click `Background` in the search progress window. In this case the search progress is indicated in the Status bar.

**Tip** When invoked for the second (and subsequent) time, the dialog opens with the scope that has been selected previously. For example, if the scope has been `Directory`, the next time you invoke the dialog, the scope again will be `Directory`.

## Replacing a piece of text in all the files within the specified path

1. Do one of the following:
  - On the main menu, choose `Edit | Find | Replace in Path`.
  - Press `Ctrl+Shift+R`.
  - Being in the Find In Path dialog box, press `Ctrl+Shift+R` to switch to Replace In Path dialog box.
2. In the Replace In Path dialog, specify the search and replace strings, the search options, and the scope. Type the search

and replacement text explicitly, or specify patterns using regular expression, or select a previously used piece of text or a pattern from the recent history drop-down list.

- If you specify the search and/or replacement text through a regular expression, use the `$n` format in back references (to refer to a previously found and saved pattern).
- To use a backslash character `\` in a regular expression, escape the meaningful backslash by inserting **three extra backslashes** in preposition: `\\` .

3. Click Replace in Find Window . IntelliJ IDEA displays the encountered occurrences of the search string in the **Find tool window** , selects the first occurrence and opens the file with this occurrence in the editor and moves the focus to it.

At the same time, IntelliJ IDEA opens the Replace Usage dialog box, with the full path to the encountered occurrence in the title bar:

Do one of the following:

- To have the selected occurrence replaced, click **Replace** .
- To preserve the selected occurrence and move to the next one, click **Skip** .
- To have all the occurrences of the search string in the currently active tab replaced, click **Replace All in This File** .
- To preserve the occurrences of the search string in the currently active tab (any) and move to the next file, click **Skip to Next File** .
- To have all the detected occurrences replaced, click **All Files** .
- To switch to the manual mode, click **Preview** . The Replace Usage dialog box closes and the focus moves to the Find tool window. Do one of the following:
  - Browse through the list of detected occurrences, select the ones you want to replace and then click **Replace Selected** .
  - To have all the occurrences changed click **Replace All** .

## toggling between the Find and Replace

- To switch from the Find In Path to Replace In Path window, press `Ctrl+Shift+R` .
- To switch from the Replace In Path to Find In Path window, press `Ctrl+Shift+F` .

This command lets you find occurrences of the current word independently on its structural meaning — it can be anything in your document: an identifier or a keyword in the code, a word in a string literal or a comment, an XML tag or attribute, or even a number. If any matches are found, you can quickly navigate between them.

Note that this command is case-sensitive.

### **To find the word at caret, do one of the following**

- On the main menu, choose Edit | Find | Find Word At Caret .
- Use `Ctrl+F3` keyboard shortcut.

### **To navigate between the occurrences of the word at caret**

1. Press `F3` to go to the next occurrence.
2. Press `Shift+F3` to go to the previous occurrence.

Search for usages is an important part of the code analysis, which enables you to clarify dependencies. IntelliJ IDEA suggests several types of search for usages:

- [Finding Usages in Project](#)
- [Finding Usages in the Current File](#)
- [Highlighting Usages](#)
- [Viewing Usages of a Symbol](#)
- [Viewing Recent Find Usages](#)

IntelliJ IDEA provides different search options depending on whether you are searching for usages of a class, method, field, parameter, or throw statements, and extends search for usages to the files in supported languages. For example, in CSS, XML and HTML files you can search for the usages of styles, classes, tags and attributes.

Search for usages extends to the [Cucumber step definitions](#) as well.

Explore search results in the [Find tool window](#).

## Finding usages of a symbol in a project

1. Select a symbol to find usages for. To do that, place the caret within the desired symbol in the editor, or click the symbol in the [Project Tool Window](#). You can also select symbol in the UML Class diagram
2. Do one of the following:
  - On the main menu, choose Edit | Find | Find Usages
  - Choose Find Usages on the context menu
  - Press `Alt+F7`.
3. In the [Find tool window](#), explore search results. Use the  button to represent search results in meaningful groups by type of usage.

While analyzing the search results, you can at any time open the [search options dialog box](#) by clicking  in the [Find tool window](#) or by pressing `Ctrl+Shift+Alt+F7`.

## Finding usages of implemented and overridden methods

In the PHP context, IntelliJ IDEA also applies the [Find Usages](#) functionality to implemented and overridden methods.

Consider the following example:

1. Create an interface, an abstract class that implements it, and two classes that extend the abstract class:
  1. Create an interface `MyInterface` with a `foo()` method.
  2. Create an abstract class `MyAbstractClass` that implements `MyInterface`.
  3. Create a class `MyClass` that extends `MyAbstractClass` and implement the `foo()` method required by the interface and overrides the methods of the parent class.
  4. Create a class `MyClassWithDelegate` that extends `MyClass` and implement `foo()` with a delegate.
  5. Create variables `$b` and `$c` that call `foo()` from `MyClass` and `MyClassWithDelegate` respectively.

```
<?php
interface MyInterface {
    //press Alt-F7 on foo() here
    public function foo();
}

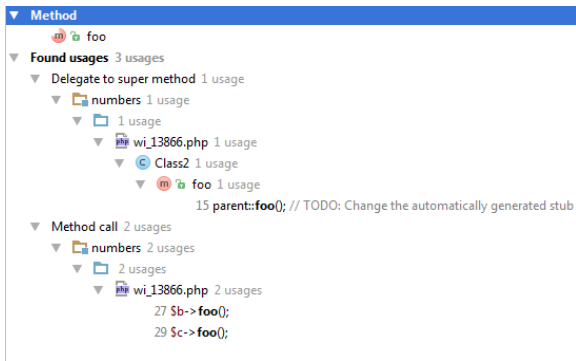

abstract class MyAbstractClass implements MyInterface {
    public function foo () {
        // TODO: Implement foo() method.
    }
}

class MyClass extends MyAbstractClass {
    public function foo() {
        parent::foo(); // TODO: Change the automatically generated stub
        echo "foo";
    }
}

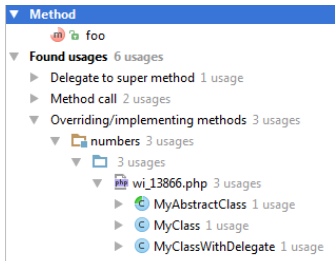

class MyClassWithDelegate extends MyClass {
    public function foo() {
        foo();
    }
}

$b = new MyClass();
$b->foo();
$c = new MyClassWithDelegate();
$c->foo();
```

2. From `MyInterface`, invoke **Find Usages** for `foo()` by pressing `Alt+F7` or choosing `Edit | Find | Find Usages` on the main menu. By default, IntelliJ IDEA shows only delegates to the super method and method calls:

3. To find also the methods that implement or override the base method, click  in the **Find tool window**. Then in the **Find Usages. Method Options** dialog that opens, select the **Include overloaded methods** checkbox and click **Find**. As a result, all the usages of the `foo()` method are found in all the classes that implement or extend `MyInterface`:

## To find usages of a symbol in the current file

1. Click the desired symbol in the editor, or in the Structure view.
2. On the main menu, choose Edit | Find | Find Usages in File , or press `Ctrl+F7` . The encountered usage is highlighted in the editor.

For a field, you can specify whether you want to search for its accessor methods in the Search Accessors dialog box.

On this page:

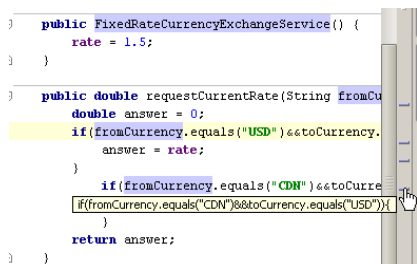

- [Introduction](#)
- [Activating automatic highlighting of usages](#)
- [Highlighting usages of a symbol in the current file](#)
- [Navigating among usages](#)
- [Removing highlighting](#)

## Introduction

The search command Highlight Usages in File ( `Ctrl+Shift+F7` ) makes it possible to visualize usages of a symbol in the current file.

In particular, it is possible to highlight implemented methods of interfaces.

All found usages of a symbol in the current file are highlighted and color-coded, as defined in the [Color Scheme](#) settings page, to represent read or write access to the symbol. In addition to the highlights of occurrences in text, the stripes of the same colors appear in the marker bar, accompanied with tooltips.

The behavior of usage highlighting is configurable: you can make IntelliJ IDEA show usages of a symbol at caret automatically, or invoke it with a command.

## Activating automatic highlighting of usages

1. Open the Settings/Preferences dialog box ( File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS ), and click General under the Editor node.
2. On the [General](#) page that opens, select the Highlight usages of element at caret checkbox in the Highlight on Caret Movement area.

## Highlighting usages of a symbol in the current file

1. Place the caret at the selected symbol in the editor. If automatic usages highlighting is enabled, see all its occurrences in the current file highlighted. Otherwise, proceed to the next step.
2. On the main menu, choose Edit | Find | Highlight Usages in File , or press `Ctrl+Shift+F7` .

**Tip** If you turn Power Save mode on, the usages are not highlighted.

To highlight overridden methods:

1. In a class that implements one or more interfaces, place the caret at the `implements` keyword in the class declaration.
2. On the main menu, choose Edit | Find | Highlight Usages in File , or press `Ctrl+Shift+F7` . A list of implemented interfaces shows up:

3. Select the interface, whose methods you want to highlight, and press `Enter` .

## Navigating among usages

To navigate among usages, do one of the following:

- Click on a stripe in the marker bar to navigate to the respective usage location.
- Use the `F3` and `Shift+F3` keyboard shortcuts to navigate to the next and previous usages respectively.

## Removing highlighting

To remove highlighting of usages, press `Escape` .

Using the Show Usages function, you can bring up a list of the usages of a symbol across the whole project. So doing, the pop-up window with the list of usages of a symbol features a toolbar with the following buttons:

#### Icon/Tooltip/Shortcut/Description

	Merge usages from the same line	Merge usages of the symbol from the same line.
	Show read access	Show read access to the symbol.
	Show write access	Show write access to the symbol.
	Show import statements	Show usages in the import statements.
	Group by file structure	If this button is pressed, the found usages show under the corresponding method nodes.
	Settings.../ <code>Ctrl+Alt+S</code>	Open the <a href="#">Find Usages</a> dialog box for the selected symbol where you can change the search options.
	Open Find Usages tool window/ <code>Alt+F7</code>	Click this button to pin the Show Usages pop-up window and show usages in the Find Usages tool window.

**Tip** In addition to the ability of viewing usages, you can use this function as a quick means of navigation.

## To view the usages of a symbol across the project

1. Place the caret at the desired symbol in the editor.
2. On the main menu, choose Edit | Find | Show Usages , or press `Ctrl+Alt+F7` .
3. Examine and analyze the detected occurrences of a symbol:
  - Use the toolbar buttons to present search results in the desired way.
  - To jump from search results to a line of source code, click the desired entry.
  - To close the list, press `Escape` .

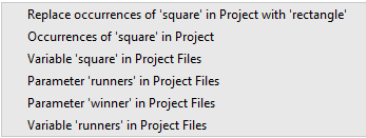

4. If necessary, customize the search options in the [search options dialog box](#) . To invoke the dialog box, do one of the following:
  - In the Show Usages pop-up window, click  .
  - Press `Ctrl+Shift+Alt+F7` .

With IntelliJ IDEA you can easily navigate to the recent search results if any find usages action took place during the IntelliJ IDEA session.

## To view recent find usages

1. Select Edit | Find | Recent Find Usages on the main menu.
2. Select the required search item from the submenu of the recent search results.

Replace occurrences of 'square' in Project with 'rectangle'  
Occurrences of 'square' in Project  
Variable 'square' in Project Files  
Parameter 'runners' in Project Files  
Parameter 'winner' in Project Files  
Variable 'runners' in Project Files

The selected search shows in the Find tool window.

Structural Search and Replace ( SSR ) performs search and replace in the supported languages code across the whole project, taking advantage of the IntelliJ IDEA's awareness of the syntax and code structure of the supported languages.

IntelliJ IDEA finds, and if required, replaces fragments of source code, using the [search templates](#) .

Structural Search and Replace is helpful when you need to browse through or modify an extensive code base, find changes in libraries, explore the source code for specific constructs, or refactor the source code.

**Tip** To see the list of supported languages, open the dialog box [Structural Search and Replace Dialogs](#) and click the drop-down list File type .

In this section:

- [Search Templates](#)
- [Structural Search and Replace - General Procedure](#)
- [Creating and Editing Search Templates](#)
- [Structural Search and Replace Examples](#)

**Search templates** are the essential part of [Structural Search and Replace](#) feature. Like [Live templates](#), the search templates consist of plain text and one or more **template variables**.

A valid search or replacement template represents one of the following Java constructs:

- Expression, for example `new SomeExpression()`
- Statement, or sequence of statements, for example `q = 1;`
- Class designator, for example `class Booking implements Serializable`
- Line or block comments, for example `/** Created in IntelliJ IDEA */`.
- `@Modifier` annotations.

IntelliJ IDEA provides a collection of predefined search templates, that match the various statements, expressions, classes and their members, XML and HTML constructs, and more. You can use these templates for structural search and replace, and also as a basis for creating your own search templates.

The search templates make use of the variables, which are the strings surrounded with `$` characters, for example `$expression$`. Symbols in the source code, `String` literals, and comments can be referred to by means of variables.

Variables in a template are subjected to certain constraints that help you refine your search and limit it to the desired matches:

- **Text constraints** are text patterns to match against. These constraints can be plain text, or regular expressions, and can contain references to symbols.
- **Number of occurrences** defines how many sequential elements (in a parameter, declaration or statement list) a variable can include and whether a variable is required to be present in a pattern or not. If the number of occurrences is 1, only one symbol can match the variable. If the number of occurrences is null, it means that an element could be missing.
- **Expression constraints** apply semantic conditions to the search, for example locate the symbols that are read or written to.
- **Script constraints** are used when items to search for are more than a plain match. If you are looking for certain language constructs (for example, constructors with the specified number of parameters, or members with the specified visibility modifiers), apply constraints described as Groovy scripts.

In search templates, the following simplifications can be used:

- Method body can be omitted.
- If no access modifier is indicated, any access modifier will be honored.
- Short class names (instead of fully qualified names) are used in the templates and constraint fields.
- Using `class $Class$` as a template, results in finding anonymous classes as well.
- Templates for comments and documentation comments should contain variables and constructs with correct comment and JavaDoc syntax.

This section outlines the general SSR procedure. Refer to the section [Structural Search and Replace Examples](#) for typical use cases.

### To find and replace source code structurally, follow these general steps:

1. On the main menu, choose `Edit | Find | Search Structurally` , or `Edit | Find | Replace Structurally` .
2. In the dialog box that opens, define the [search template](#) . In brief, defining a search template involves the following steps:
  - Type the desired construct in the Search template text area, or use one of the pre-defined search templates by clicking the Copy existing template button.
  - Specify the constraints to be imposed on the variables within the search template. To do that, click the Edit variables button. All the variables contained in the search template are listed in the Variables pane of the [Edit Variable](#) dialog box.

Refer to the section [Creating and Editing Search Templates](#) for the detailed description of procedure.

3. In case of the structural replace, specify the replacement pattern, and define variable constraints as required.
4. Specify the search and replace options, in particular, the number of occurrences to be matched, and the type of files to be analyzed.
5. Specify the scope to perform the structural search and replace in. To do that, click the down arrow in the Scope list, and select one of the pre-defined scopes, or click the ellipsis button, and configure the desired scope in the [Scopes](#) dialog box.
6. Click `Find` . The detected occurrences are displayed in the [Find tool window](#) . Please note that in case of replacement, you can select the desired matches in the search results and click the `Preview Replacement` button. The corresponding occurrence is highlighted in the source code.

You can create [search and replace templates](#) from scratch, just typing the code in the text area of the [Structural Search / Replace](#) dialog box. However, there is a collection of the predefined search templates that you can use as prototypes for your own templates. All custom templates appear in the list of existing search templates, under the node User defined .

To create a search template, follow these general steps:

- On the main menu, choose Edit | Find | Search Structurally .
- Do one of the following:
  - Type the code of your template in the Search template text area.
  - Click the Copy existing template button, and in the Existing Templates dialog box, select the desired template as a prototype. The source code of the selected template appears in the Search template text area, where you can change it as required.
  - If you need to configure the template variables, click the Edit variables button. [Edit Variables](#) dialog box appears. In the Variables column, select a variable you want to configure, and specify the constraints that will apply to this variable. See the dialog [reference page](#) for the detailed description of constraints.
- Repeat the process for the other variables, as required, apply changes and close the dialog box.
- Click the Save Template button.
- In the Save Template dialog, type the name of the new template, and click OK .

**Tip** You can create a new template in the Existing Templates dialog. To do that, click the  button on the toolbar. This opens the Structural Search dialog, with the empty template field. To define the custom template, follow the steps described above.

On this page:

- [One statement](#)
- [Method call](#)
- [If statement](#)
- [Search in comments and/or string literals](#)
- [Search for constructors of the class](#)
- [Add try/catch/finally code](#)
- [Finding all descendants of a class or all classes that implement a certain interface](#)
- [Finding all such methods](#)
- [Using @Modifier for finding package local and instance methods](#)
- [Using 'Contained in Constraints' field in a search](#)
- [Searching for XML and HTML tags, attributes, and their values](#)
- [Using script constraints](#)

## One statement

```
$Statement$;
```

Increasing the number of occurrences count to a certain number, you can find sequences of statements that contain up to the specified number of elements.

## Method call

```
$Instance$.MethodCall($Arguments$)
```

This template matches method call expressions. If the number of occurrences is zero, it means that a method call can be omitted.

## If statement

```
if ($Expr$) {  
    $ThenStatements$;  
}  
else {  
    $ElseStatements$;  
}
```

## Search in comments and/or string literals

Consider one wants to find comments or literal containing 'foo'. Search template would be like `$SomethingWeWantToFind$` or `"$SomethingWeWantToFind$"`. In case one wants to find comments/string containing some particular words (say, foo as a word), this should be specified as a text constraint.

## Search for constructors of the class

The search template **Constructors of the class** with default variable settings lets you find only one constructor in each class within the specified scope. If the class has several constructors then to find more than one, you need to set the Maximum count option of **Occurrences** count to **Unlimited** in the `$Class$` variable. For more information, see [Edit Variable Dialog](#).

Note that the class declarations will also be included into the find occurrences' list.

## Add try/catch/finally code

If one wants to replace a statement with a `try/catch/finally` construct, the following pair of search and replace templates can be suggested. The search template is:

```
$Statements$;
```

with a certain maximum number of occurrences specified as a constraint.

The replacement template is:

```
try {  
    $Statements$;  
}  
catch(Exception ex) {  
}
```

## Finding all descendants of a class or all classes that implement a certain interface

Consider the following search templates:

```
class $Clazz$ extends $AnotherClass$ {}
```

or

```
class $Clazz$ implements $SomeInterface$ {}
```

As the text constraint for the variables `$AnotherClass$` or `$SomeInterface$`, specify the name of the base class or implemented interface.

## Finding all such methods

To look for the different implementations of the same interface method, use the following search template:

```
class $a$ {  
    public void $show$();  
}
```

Specify text constraint for the `$show$` variable, and enable the option `This variable is the target of the search`.

## Using @Modifier for finding package local and instance methods

IntelliJ IDEA suggests pre-defined templates for the package local and instance fields of a class. These templates make use of the `@Modifier` annotation, which helps describe search target, when there is no way to express it using the natural language means.

However, if you need to search for package local or instance methods, you will have to create the corresponding search templates yourself, applying the `@Modifier` annotation.

To specify criteria for finding all methods with the visibility modifiers package local and instance, use the following search template:

```
class  
$Class$ {  
    @Modifier("packageLocal") @Modifier("Instance") $ReturnType$ $MethodName$($ParameterType$ $Parameter$);  
}
```

## Using 'Contained in Constraints' field in a search

The existing example uses the following template:

```
LOG.debug($params$);
```

Placing `if(' _a' { ' _st*'; }` where `_a` and `_st` are variables and `*` denotes zero or more occurrences in `Contained in Constraints` field and selecting `Invert condition checkbox of Complete Match variable` will result a search of logging statements that are not contained in the `if` statement.

## Searching for XML and HTML tags, attributes, and their values

The simplest template to search for a tag is `<$a$ />`

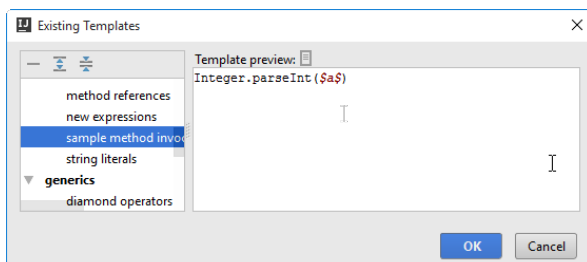

By placing constraints on the variable `$a$`, you can specify which tags you want to find. For example, if you specify the text/regexp constraint `app.+`, you'll find the tags whose names start with `app`.

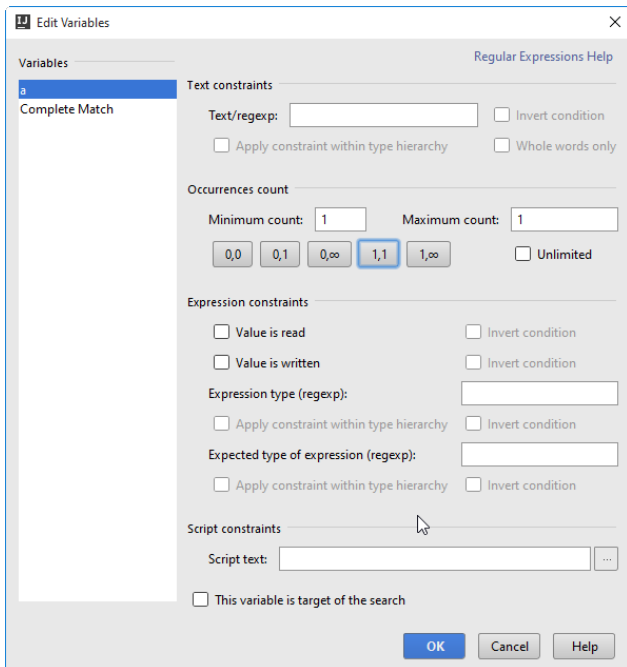

A more versatile template for searching in XML and HTML is `<$tag$ $attribute$="$value$"/>`. By using this template with properly specified search settings and constraints, you can find practically anything that may occur in XML or HTML. For example, if you specify the text/regexp constraint `width` for the variable `$attribute$`, you'll find all the tags that have the `width` attribute.

## Using script constraints

IntelliJ IDEA structural search lets you use advanced constraints that cannot be specified using UI.

See the following template as an example:

The constraint is specified using Groovy scripting language and IntelliJ IDEA PSI API for the language you are searching. The Groovy constraint is applicable to any language to which the structural search can be applied.

The search results display in the [Find tool window](#) . The results of each search display in a separate tab.

Using the controls and the context menu commands of this tool window as well as the main menu, you can:

- Navigate [to source code](#) .
- [Exclude and include](#) search results in refactoring.
- Add selected search results [to favorites](#) .
- Show the results of the [recent find usages](#).
- Perform [version control](#) operations using the specific VCS, associated with the parent directory of the usage.
- [Hide excluded search results](#) from showing them in the Find tool window ( [Alt+Delete](#) ) .

IntelliJ IDEA lets you search for files, actions, classes, settings, elements of the UI using the Search Everywhere dialog.

1. Double-press **Shift** to open the Search Everywhere dialog.

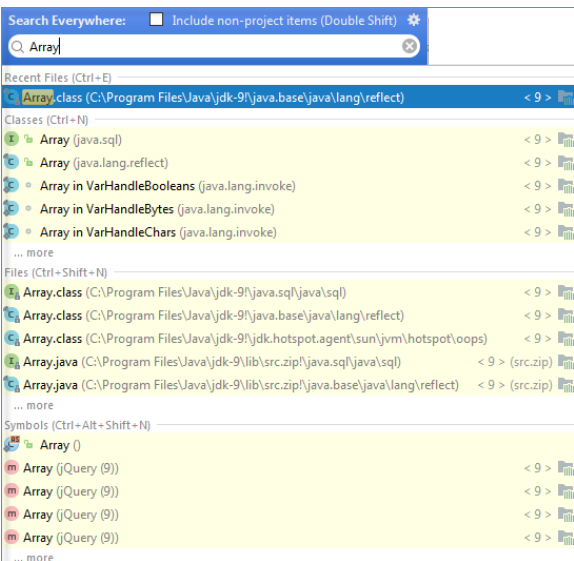

Pressing double **Shift** again will select the Include non-project items checkbox and the list of search results will extend to non-project related items.

Clicking the  icon will enable you to configure a scope for your search.

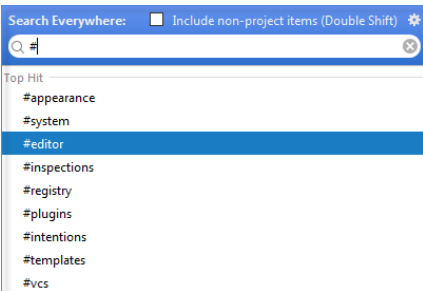

2. Start typing your query. You can see that IntelliJ IDEA lists the results dividing them into sections where your query is found (classes, actions, files, symbols, etc.)

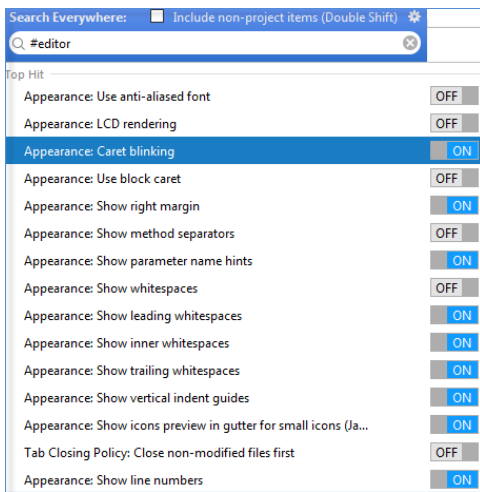

Press **Tab** to move the selection to more... or to the first element of the next section. Press **Up** or **Down** to navigate between the elements in the list.

3. If you need to see the history of your searches, put caret in the search field (at the 0 position) and press **left arrow key**.
4. Type **#** to see the list of settings that you can quickly access. Select the one you need and press **Enter**.

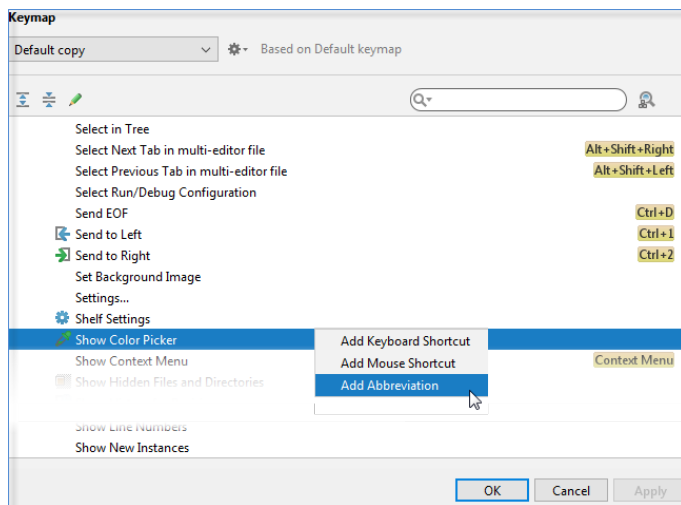

As a result, IntelliJ IDEA gives you a quick access to the selected setting and its options.

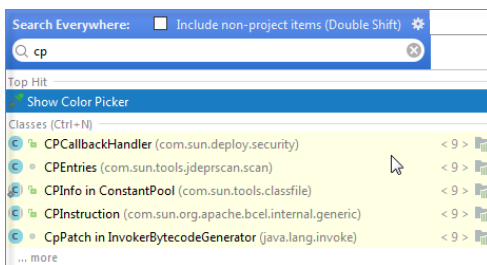

5. You can search for abbreviations. You can assign a short code for the action and use the Search Everywhere dialog to search for such element and quickly access it. For example, assign an abbreviation for *Color Picker* .

1. Open Settings | Keymap and from the options on the right select Other | Show Color Picker .
2. From the context menu, select Add abbreviation .

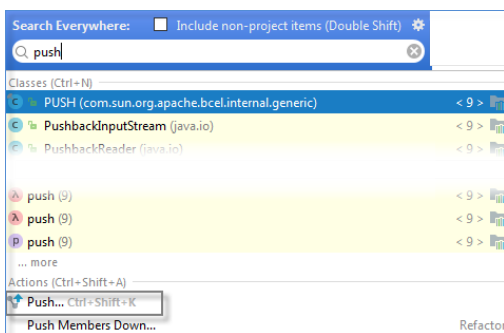

3. In the dialog that opens, specify the abbreviation you are going to use, for example, "cp" and click OK .

IntelliJ IDEA adds the abbreviation to the item and when you type "cp" in the Search Everywhere dialog, IntelliJ IDEA will display the item to which you've assigned your abbreviation. Press Enter to access the Color Picker dialog.

6. You can search for actions. For example, you can search for a VCS action and access its dialog.

In the Search Everywhere dialog, in the search field, type, for example, *push* .

IntelliJ IDEA displays the result in the Action section, IntelliJ IDEA also displays a shortcut `Ctrl+Shift+K` against the action that lets you access the Push dialog.

You can use a shortcut located against the Action section to narrow your search to the specified action and options where the name of the action is mentioned.

Enter action or option name:

- Push... Ctrl+Shift+K**
- Push ITDs In... Refactor
- Push Members Down... Refactor
- Move and Push Alt+Shift+P
- Goto Alt+Shift+G
- Allow force push Settings > Git
- Conditional can be pushed inside branch expre... Settings > Inspections
- Auto-update if push of the current branch was... Settings > Git
- Zen HTML: !!!xs (<!DOCTYPE html PUBLIC "-//W3...  ON
- Settings Repository Settings > Plugins
- Missing Constrains in ConstraintLayout Settings > Inspections

Press Ctrl+Up or Ctrl+Down to navigate through the history

IntelliJ IDEA facilitates quick and easy access to the API documentation, which you can view immediately in the editor or in an external browser. To gain access to the API documentation from within your project, make sure to attach archives or directories that contain sources of the library classes.

This section describes how to use the view parameter information feature, display context information or JavaDoc references, and see definitions of the symbols:

- [Viewing Definition](#)
- [Viewing Inline Documentation](#)
- [Viewing External Documentation](#)
- [Viewing Method Parameter Information](#)

On this page:

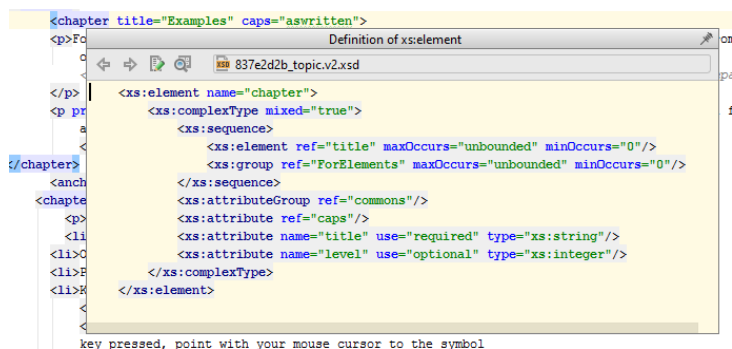

- Basics
- Viewing the definition of a symbol at caret
- Toolbar of the quick definition lookup

## Basics

Quick Definition Lookup makes it possible to view definition of a symbol (tag, class, method/function, field, etc.) in a pop-up window.

For markup languages, IntelliJ IDEA retrieves definitions of symbols from the specified DTD or schema. For details, see [XML](#).

## Viewing the definition of a symbol at caret

Do one of the following:

- On the main menu, choose View | Quick Definition.
- Press `Ctrl+Shift+I`.
- Keeping the `Ctrl` key pressed, point with your mouse cursor to the symbol of interest, so that it turns to a hyperlink, with the definition of the symbol displayed in a tooltip. Clicking this hyperlink results in opening the respective definition page in the editor.

Quick definition tooltip shows hyperlinks to the symbols involved.

When you move your mouse pointer within the tooltip, a pin button  appears. If you pin the tooltip, documentation for the symbol at caret is displayed in the [Documentation Tool Window](#).

## Toolbar of the quick definition lookup

Use the icons on the toolbar of the pop-up window to navigate to the source code of the definition and view its usages.

### IconKeyboardAction shortcut

	<code>Shift+Alt+Left</code>	Navigate to the previous/next screen in the definition pop-up window after using hyperlinks in the definition.
	<code>Shift+Alt+Right</code>	
	<b>Note</b> On a macOS computer, you can also use the three-finger right-to-left and left-to-right swipe gestures.	
	<code>F4</code>	Open the source code of the definition for editing, and close the quick definition lookup window. If IntelliJ IDEA cannot find the appropriate sources in your project, it will try to decompile the code. In this case the <a href="#">JetBrains Decompiler</a> dialog with legal information is displayed.
	<code>Ctrl+Enter</code>	Open the source code of the definition, and preserve the quick definition lookup window opened. If IntelliJ IDEA cannot find the appropriate sources in your project, it will try to decompile the code. In this case the <a href="#">JetBrains Decompiler</a> dialog with legal information is displayed.

## Basics

Quick Documentation Lookup helps you get quick information for any symbol or just method signature information, provided that this symbol has been supplied with documentation comments in the applicable format.

IntelliJ IDEA recognizes inline documentation created in accordance with [Javadoc](#) markup.

In this case, such documentation is properly rendered in the Quick Documentation Lookup window:

For [markup languages](#), IntelliJ IDEA retrieves reference from the language specification according to the [Document Type](#) setting.

The URLs and e-mail addresses specified in the documentation comments for methods are also properly rendered. Clicking a hyperlink opens the corresponding URL in an external browser; clicking an e-mail address opens the default mail client.

## Viewing quick documentation

### To view documentation for a symbol at caret, do one of the following

- On the main menu, choose View | Quick Documentation Lookup.
- Press `Ctrl+Q`.
- Provided that the checkbox [Show quick doc on mouse move](#) in the editor settings is selected, just move your mouse pointer over the desired symbol.

When you explicitly invoke code completion, then quick documentation for an entry selected in the suggestion list can be displayed automatically. The behavior of quick documentation lookup is configured in the [Code Completion](#) page of the Settings/Preferences dialog.

**Tip**

### To change the font size of quick documentation, do one of the following

- Click  in the upper-right corner of the quick documentation window, and move the slider.
  - Rotate the mouse wheel while keeping the `Ctrl` key pressed.
- Note that for this feature to work, you have to enable it in the [General](#) page of the editor settings.

Refer to the section [Zooming in the Editor](#) for details.

## Documentation window

The Documentation pop-up window helps navigate to the related symbols via hyperlinks, and provides a toolbar for moving back and forth through the already navigated pages, changing font size, and viewing documentation in an external browser.

When pinned, the Documentation pop-up window turns into the [Documentation tool window](#), with the corresponding sidebar icon, and more controls.

To switch between the Documentation pop-up window and the [Documentation tool window](#), use `Ctrl+Q`.

### IconShortcutDescription

	<code>Left</code> or <code>Right</code>	Switch to the previous or next documentation page (e.g. after using hyperlinks).
	<code>Shift+F1</code>	View external documentation in the default browser.
	<code>F4</code>	Switch to the item (e.g. source) that corresponds to the documentation page currently shown.
		Turn the Auto-update from source option on or off. When the option is on, the information in

---

the tool window is synchronized with your navigation in the editor and other places in the UI.

Click this icon to show the font size slider. Move the slider to increase or decrease the font size in the quick documentation window as required.

**Tip** For information on retrieving inline documentation in the JavaScript or PHP context, see [JavaScript Documentation Look-Up](#) and [PHPDoc Comments](#) respectively.

External documentation makes it possible to get additional information for the symbols at caret. In contrast to the [quick documentation](#), this feature shows the documentation in an external browser, which helps study the symbol in more detail, navigate to related symbols, and retain the information for further reference.

External documentation becomes available for viewing when properly configured in the [module structure](#). For example, in the [module paths](#), you can add a path to a JavaDoc file, or a link to documentation; or specify a documentation URL for a library.

**To view documentation for a symbol at caret in an external browser, do one of the following:**

- On the main menu, choose View | External documentation .
- Press `Shift+F1` .
- While in the [Quick Documentation Lookup window](#), click  .

On this page:

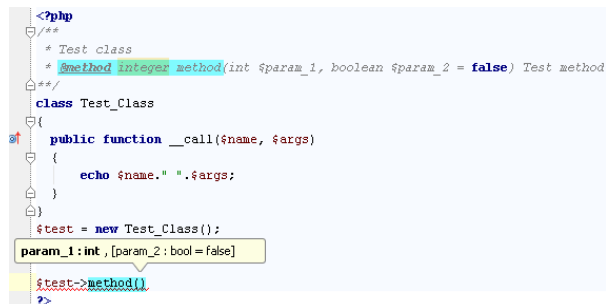

- [Parameter hints for methods](#)
- [Parameter hints for constructors](#)
- [Configuring the behavior of parameter hints](#)

## Parameter hints for methods

Place the caret anywhere within the call of the desired method or function and choose View | Parameter Info on the main menu or press `Ctrl+P`.

In the PHP context, parameter information for methods defined through the `@method` [phpDocumentor tag](#) is also available:

## Parameter hints for constructors

In the PHP context, IntelliJ IDEA prompts you about the parameter type when a constructor is called. Place the caret anywhere within the call of the desired constructor and choose View | Parameter Info on the main menu or press `Ctrl+P`. The parameter type is shown in a tooltip:

When you type the parameter value, it is prepended with the parameter from the constructor:

## Configuring the behavior of parameter hints

Open the [Code Completion page](#) ( Settings | Editor | General | Code Completion for Windows and Linux or IntelliJ IDEA | Preferences | Editor | General | Code Completion for macOS) and configure the following options in the Parameter info section:

1. To have a complete method or function signature shown rather than a list of required types, select the Show full signatures checkbox.

Make sure to include the required third-party [libraries](#) in the project source path. Otherwise, names of the parameters will not be displayed.

2. To have the list of parameter types for the called method or function shown automatically after a certain delay, select the Auto pop-up (in ms) checkbox and specify the time period in milliseconds.

## Overview

i18n support with IntelliJ IDEA falls into the following major aspects:

- Internationalization , which involves extracting strings out of your source code and presenting them as properties that are further referenced in the source code.
- Localization , which means translating these properties into the target languages.

## i18n-related features

IntelliJ IDEA provides helpful features that simplify working on software internationalization and localization issues. These features are:

- Individual [encoding](#) for files and directories.
- [Dedicated file type](#) for storing properties.
- Advanced editing assistance for properties files.
- Auto-detection of [resource bundles](#) .
- Code inspections related to internationalization issues; intention actions, and quick fixes.
- Dedicated editor for performing [mass actions](#) within resource bundles.

## Prerequisites

i18n support is available for the Django applications.

- `gettext` utilities are downloaded and installed on your machine.
- `locale` directory is created in the project root.
- Django is the project template language.

On this page:

- [Basics](#)
- [Properties file features](#)

## Basics

The properties files are text files with the `.properties` extension, containing pairs of keys and values, that can be accessed and rendered in the UI.

These files are marked with the icon .

IntelliJ IDEA also recognizes properties files in XML format. They are marked with the icon .

## Properties file features

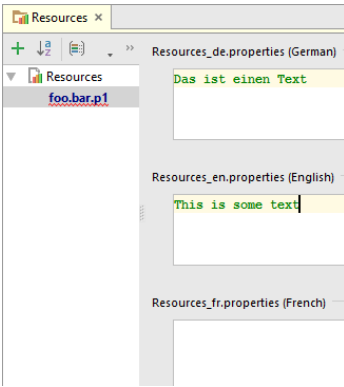

IntelliJ IDEA supports the following features for the properties files:

- Action for [creating new resource bundles](#).
- Ability to work with XML-based properties files.
- Actions for combining and dissociating properties files.
- Syntax `key - delimiter - value`. IntelliJ IDEA uses `=` (equal sign) or `:` (colon) as a delimiter.

For example, if you want a field label to read "Your name.", you might create a pair in a properties file like this:

```
nameLabel=Your name:
nameLabel: "Your name:"
```

- Error highlighting for errors like missing locale records, or duplicate property keys and invalid escape sequences:

- Inspection and quick fix for detecting and removing duplicate keys in properties files:

- Referencing properties from Java files and Ant build files.

- Code completion for property keys:

- Inspection and quick fix for detecting and creating the missing property keys and values:

- Goto Declaration (`Ctrl+B`) to navigate from a reference to a key to its declaration:

- Finding usages of the currently selected property.
- Refactoring for properties includes Rename, Move, Copy, Safe Delete, and Migrate.
- [Structure view](#) for properties files:

- **Quick Definition Lookup** for properties files: if an action calls a property, you can view the property definition by pressing

Ctrl+Shift+I :

On this page:

- [Basics](#)
- [Creating resource bundles](#)
- [Combining or dissociating properties](#)

## Basics

Resource bundle is a set of [properties files](#) that have same base name with different language-specific suffixes. A resource bundle contains at least two properties files with similar base name, for example `file_en.properties` and `file_de.properties`.

IntelliJ IDEA recognizes resource bundles, and marks them with the icon .

IntelliJ IDEA supports the following features for the resource bundles:

- [Action for creating new resource bundles](#).
- [Actions for combining and dissociating](#) properties files.
- Dedicated [Resource Bundle Editor](#).
- Error highlighting for the missing properties or values.
- Refactoring for resource bundles includes [Rename](#), [Move](#), [Copy](#) and [Safe Delete](#).

## Creating resource bundles

### To create a new resource bundle, follow these steps

1. In the Project tool window, choose the directory where the new resource bundle should be created.
2. Do one of the following:
  - Press `Alt+Insert`.
  - On the context menu of the selection, choose `New | Resource Bundle`
  - On the main menu, choose `File | New | Resource Bundle`
3. In the dialog box that opens, do the following:
  - Specify the base name of the resource bundle.
  - If necessary, select the checkbox `Use XML-based properties files`.
  - Add the required locales. To do that, click `+` and type the comma-separated suffixes of the required locales.
  - Click `OK` when ready.

The new node Resource Bundle '<base name>' appears in the [Project Tool Window](#):

## Combining or dissociating properties

By default, when a new resource bundle is created, it shows joined. You can dissociate it and show the properties files only.

### To dissociate a resource bundle

1. Right-click the resource bundle you want to dissociate.
2. On the context menu, choose `Dissociate Resource Bundle <base name>`.

### To combine several properties files into a resource bundle

1. Select the properties files to be combined.
2. Right-click the selection.
3. On the context menu, choose `Combine to Resource Bundle`.
4. Specify the base name of a resource bundle.

Resources include [properties files](#) , images, DTDs, and XML files. These files are located under the Classpath of your application, and are usually loaded from the Classpath by means of the following methods:

- `ResourceBundle.getBundle()` for the property files and resource bundles
- `loadResourceAsStream()` for icons and other files

When building an application, IntelliJ IDEA copies all resources into the output directory, preserving the directory structure of the resources, relative to the source path. The following file types are recognized as resources by default:

- `.properties`
- `.xml`
- `.html`
- `.dtd`
- `.tld`
- `.gif`
- `.png`
- `.jpeg`
- `.jpg`

The pattern of recognized resource files is represented as a regular expression and configurable in the [Compiler dialog](#) .

Using Resource pattern setting, you can add your own file extensions and create custom list of resources.

Standard Java API is designed to use ISO 8859-1 encoding for the properties file.

To use other encodings, feed them as escape sequences and Unicode. The other option is to define the default encoding for `.properties` files on the project level and use different API that can read properties files in the encoding you have defined.

## To configure default encoding for properties files

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Editor | File Encodings .
2. Do one of the following:
  - To have the special mode turned on when symbols are stored in a properties file as escape sequences but displayed as normal letters, check the option Transparent native-to-ascii conversion . This option is helpful when the properties files are encoded in ISO 8859-1. It is recommended to use this approach, if you don't have any special reasons to change encoding.
  - In the field Default encoding for properties files , select the encoding that will be used for all properties files in project.

On this page:

- [Basics](#)
- [Creating locales](#)
- [Editing locales](#)

## Basics

The [properties files](#) are used to store localization strings. IntelliJ IDEA enables you to create new properties files, and detects the existing ones.

## Creating locales

### To create properties files

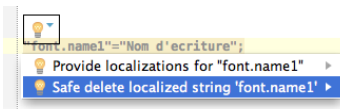

1. Right-click a directory where you would like to create a properties file.
2. On the context menu of the target directory, choose New | File .
3. In the New File dialog box, type the file name with the corresponding extension, and click OK . Note that you can also create nested directories under `locales` , and add new properties files there.

**Tip** If you create several files with the same name and different locale suffixes (for example, `myProperty_en`, `myProperty_fr` etc.), such properties files will be [recognized as a resource bundle](#) .

## Editing locales

While editing properties files, use the following techniques:

- Syntax highlighting : Keywords, delimiters, values and comments are highlighted. You can configure the color scheme in the [Color Scheme](#) page of the Settings/Preferences dialog.
- Code inspection detects unused strings and suggests to fix the problem immediately:

- Expand word : Start typing, and press `Alt+Slash` to go through the existing strings.

On this page:

- [Resource bundle editor basics](#)
- [Invoking properties editor for a resource bundle](#)
- [Editing property keys and values](#)
- [Tips and tricks](#)

## Resource bundle editor basics

Once you create several `.properties` files with the same name, differing by locale suffix, IntelliJ IDEA automatically recognizes them and groups in the Project view into a Resource Bundle.

## Invoking properties editor for a resource bundle

### To invoke properties editor for a resource bundle, do one of the following:

- In the Project tool window, right-click a resource bundle and choose Jump to Source .
- Select a resource bundle in the Project tool window, and press `F4` .
- Open for editing a `.properties` file that is a part of a bundle, and at the lower edge of the editor, click Resource Bundle tab:

## Editing property keys and values

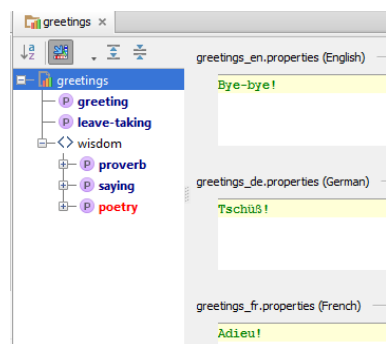

### To edit property keys, follow these general steps

1. Open for editing the desired `*.properties` file.
2. Add, change, or delete keys as required. The changes are reflected in the Resource Bundle editor.

For changing values, use the resource bundle editor that enables you to edit an entire set of property files at a time. IntelliJ IDEA takes care of creating respective records in each file of the bundle.

### To edit a property value

1. Select property key in the left pane of the resource bundle editor.
2. In the target locale frame, edit the value as required. The respective `.properties` file will change accordingly.

## Tips and tricks

- The properties missing values, or omitted in one of the `.properties` files are red-highlighted.
- All escaped characters in the `*.properties` files in the format `\uxxxx` , are displayed in the resource bundle editor as un-escaped unicode literals.

Vice versa, if a non-ASCII character is entered in the resource bundle editor, it is reflected in the underlying `*.properties` file as a corresponding escaped character in the format `\uXXXX` .

For example, if the `*.properties` file contains a property value

```
Was ich nicht wei\u00df, macht mich nicht hei\u00df
```

then the resource bundle editor will show

```
Was ich nicht weiß, macht mich nicht heiß
```

Resource bundle editor itself does not perform any conversion. To have escape sequences properly resolved in properties files, select the checkbox `Transparent native-to-ascii conversion` in the [File Encoding](#) page of the `Settings/Preferences` dialog.

- It is possible to encode non-ascii symbols using both upper- and lower-case hex symbols (e.g. `\u00E3` vs `\u00e3` ). Upper case is used by default. To use lower case, set `'idea.native2ascii.lowercase'` property in the `bin/idea.properties` file to true.

Refer to the section [Tuning IntelliJ IDEA](#) for details.

On this page:

- [Introduction](#)
- [Extracting string literals](#)
  - [Extracting string literals using ResourceBundle](#)
  - [Extracting string literals using custom resource bundle class](#)

## Introduction

Having [enabled](#) code inspection that highlights hardcoded string literals, you can proceed with extracting these literals into your properties files. For this purpose, IntelliJ IDEA provides special intention action `i18nize hard coded string literal`.

This section considers two possible ways of accessing resource bundle:

- Using the `java.util.ResourceBundle` utility class
- Using `custom utility class`

## Extracting string literals

### Extracting string literals using ResourceBundle

#### To extract a string literal using java.util.ResourceBundle

1. Specify resource bundle that will be used to store the extracted literals. In particular, you can add the following statement to your source code:

```
private static ResourceBundle <field name> =  
getBundle("<bundle name>");
```

For example:

```
private static ResourceBundle myBundle =  
getBundle("com.intellij.fontChooser.FontChooser");
```

**Note** You can skip this step and specify the desired resource bundle expression immediately in the `i18nize Hard Coded String Literal` dialog box.

2. Click the highlighted string, press `Alt+Enter`, and in the list of intention actions choose `i18nize hard coded string literal`:

3. In the `i18nize Hard Coded String Literal` dialog box specify the target properties file, the property key and value, and the resource bundle expression.  
If the `ResourceBundle` field has been declared in the source code (as shown in the step 1), IntelliJ IDEA suggests its name by default. If you haven't declared this field in the source code yet, you can still define the desired expression immediately in the dialog box. To do that, enter a valid expression of the `ResourceBundle` type in the Resource bundle expression field.

Note that `basic code completion` works in this field. Type class name, and press `Ctrl+Space` after period to select method:

Choose the desired method from the suggestion list, and press `Ctrl+Space` once more to fill in the parentheses:

After that, type the package and resource bundle name in quotes:

- Click OK . The line with hardcoded string literal is replaced. For example, if the resource bundle has been declared in the source code, the following line will be created:

```
private String greeting = myBundle.getString("hello");
```

If the resource bundle has been defined in the dialog, the result will be:

```
private String greeting = ResourceBundle.getBundle
("com.intellij.fontChooser.FontChooser").getString("hello");
```

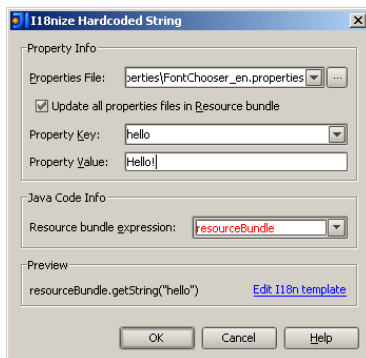

## Extracting string literals using custom resource bundle class

### To extract a string literal using custom resource bundle class

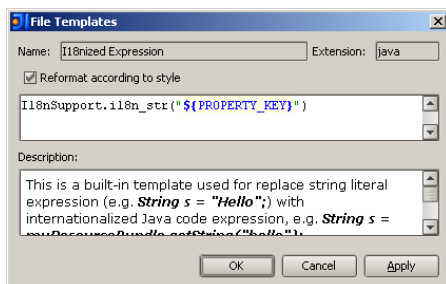

- Make sure that `redist/annotations.jar` archive that resides under your IntelliJ IDEA installation, is added to the module dependencies.
- Create a new class in your project, and type the following code:

```
import org.jetbrains.annotations.PropertyKey;
import org.jetbrains.annotations.NonNls;
import java.util.ResourceBundle;
import java.text.MessageFormat;
public class I18nSupport {
    @NonNls
    private static final ResourceBundle bundle = ResourceBundle.getBundle ("com.
    public static String i18n_str
        (@PropertyKey(resourceBundle ="com.intellij.FontChooser")
        String key,Object... params){
        String value =bundle.getString(key);
        if (params.length >0) return MessageFormat.format(value, params);
        return value;
    }
}
```

- In a class that contains hardcoded string, click the highlighted string, press `Alt+Enter` , and in the list of intention actions choose `i18nize hard coded string literal` . The `I18n-ize String Literal` dialog box shows that resource bundle expression is missing:

- Click `Edit i18n template` link. In the `File Template` dialog box, change the `I18nized Expression` to point to the method of your custom resource bundle class:

Click OK to save the updated template and close the dialog box.

**Warning!** This change is global, and affects all projects!

- In the `Preview` section of the `I18n-ize String Literal` dialog box, see the suggested substitution, and click OK .

The source code changes:

```
private String greeting = I18nSupport.i18n_str("hello");
```

Your source code can contain hardcoded literals which you would like to recognize and further [extract to properties](#) . To highlight hardcoded literals in the editor, use Internationalization code inspections.

## To enable recognizing hardcoded string literals

1. Open the [Settings dialog](#) .
2. In the Project Settings , select Editor | Inspections to open [Inspections](#) dialog box.
3. Select the desired profile, and locate the node Internationalization issues .
4. Check the option Hard coded strings , which will cause the hardcoded string literals to be highlighted in the editor.

**Note** Note that you can configure severity of this inspection and specify when the hardcoded strings should be recognized. For example, you can opt to skip the content of `toString()` method, or the literals without alphabetic characters.

5. Apply changes and close the dialog. Now the editor will highlight the hardcoded string literals, as shown below:

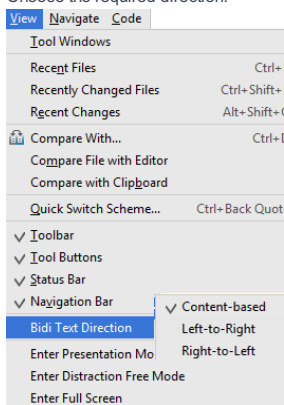

```
JFrame frame = new JFrame("Font Chooser");  
frame.setContentPane(new F{Hard coded string literal: 'Font Chooser' more... (Ctrl+F1)}  
frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
```

IntelliJ IDEA enables you to choose the base direction to render the strings and tokens (for example, in the properties files), containing bidirectional text, like a mix of English and Hebrew or Arabic.

## To choose the direction of rendering strings

1. On the menu View, point to the node BiDi Text Direction.

2. Choose the required direction:

By default, the direction of rendering is content-based, which means that text direction is defined by the text with which the string begins. For example, if the string starts with English, then the base direction of text is LTR.

However, it is also possible to always use either LTR or RTL as the base direction.

So doing, the string literals change their view:

This feature is only supported in the Ultimate edition.

In this part:

- Working with Diagrams
  - [Basics](#)
  - [Features](#)
- [Working with Java module dependency diagrams](#)
- [Configuring Default Settings for Diagrams](#)

- [Viewing Members in Diagram](#)
- [Viewing Siblings and Children](#)
- [Viewing Ancestors, Descendants, and Usages](#)
- [Editing Module Dependencies on Diagram](#)
- [Navigating Through a Diagram Using Structure View](#)

**Tip** IntelliJ IDEA implements the UML diagrams functionality with a bundled plugin, which can be completely disabled by clearing the UML Support check box on the the Plugins page of IntelliJ IDEAsettings ( [Ctrl+Alt+S](#) ).

## Basics

UML modeling support provided by IntelliJ IDEA involves two aspects:

- Reverse engineering , which involves drawing a UML model on the base of the existing code base. Such model helps you get an [overview](#) of the classes and packages that comprise your application, relationships between them, explore libraries, and view dependencies.
- Forward engineering , which enables you to design and create a visual model, and populate it with [node elements](#), [members](#) and [relationships](#) . IntelliJ IDEA automatically generates source code and keeps it synchronized with the model.

UML model in IntelliJ IDEA is represented by a Class diagram in standard notation.

IntelliJ IDEA enables using UML class diagrams to analyze Java, ActionScript/Flex, PHP, and Maven applications, and the structure of the databases and tables. Besides that, you can explore changes committed to VCS.

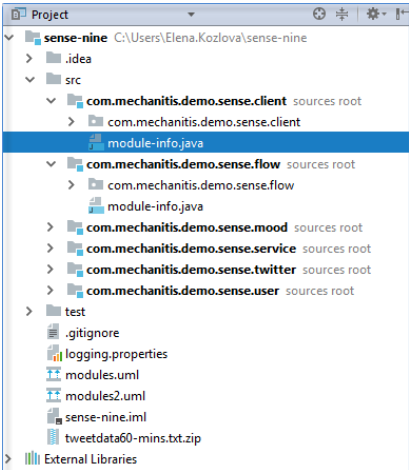

## Features

In IntelliJ IDEA, Class diagram features:

- Ability to view UML model as a diagram in a [separate editor tab, in a pop-up window](#) , or as a [preview](#) .
- Ability to invoke UML class diagram from the Project , Structure , Database , Maven , Version Control tool windows, the History tab of the Version Control tool window, and Navigation bar.  
In the editor, one can view class diagram for the whole class, or for a symbol at caret.
- Navigation from a diagram element to the underlying source code.
- Highlighting [siblings and children classes and packages](#) .
- Refactorings ([Rename](#) , [Type Migration](#) , [Move](#) , [Safe Delete](#) , [Extract Class](#) , [Invert Boolean](#) , [Remove Middleman](#) , [Inline](#) , [Encapsulate](#) , [Migrate](#) , [Change Signature](#) , [Make Static](#) , [Convert to Instance Method](#) , [Introduce Parameter Object](#) , [Wrap Return Value](#) )
- Navigation to [class, file or symbol by name](#) and to the [last edit location](#) .
- Viewing class or package information at the tooltip, and [quick documentation lookup](#) .
- [Viewing changed classes](#) as a UML Class diagram.
- Quick hierarchy view in a [UML Class diagram pop-up window](#) .
- [Viewing subtypes, super classes and classes from signatures](#) .
- Ability to [find usages](#) of a node element or member.
- ability to [configure default settings](#) for UML Class diagram.

IntelliJ IDEA lets you view and manage diagrams for Java modules that are part of the [Jigsaw project](#), which comes with JDK 9, so make sure you have the latest JDK 9 Early Access build installed to view and manage such diagrams.

## Viewing a Java module diagram

- 

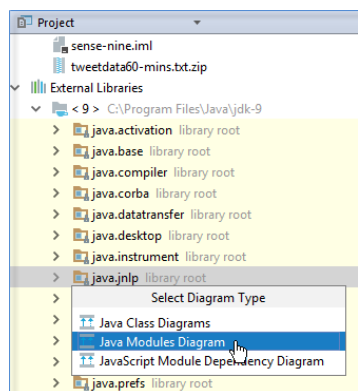

The screenshot shows the 'Project' tool window in IntelliJ IDEA. The project is named 'sense-nine'. Under the 'src' directory, there are several source roots for modules: 'com.mechanitis.demo.sense.client', 'com.mechanitis.demo.sense.flow', 'com.mechanitis.demo.sense.mood', 'com.mechanitis.demo.sense.service', 'com.mechanitis.demo.sense.twitter', and 'com.mechanitis.demo.sense.user'. There are also files like 'module-info.java', 'test', '.gitignore', 'logging.properties', 'modules.uml', 'modules2.uml', 'sense-nine.iml', and 'tweetdata60-mins.txt.zip'. The 'External Libraries' section is visible at the bottom.

Note that IntelliJ

IDEA allows only one Java module per one IntelliJ IDEA module.

- In the Projects tool window select an item (module/project) for which you want to create a diagram.
- Right-click the selected item and from the context menu select Diagram | Show Diagram . Alternatively, open the `module-info.java` file in the editor and from the context menu select Show Diagram .
- From the list that opens, select the Java Module Diagram type. IntelliJ IDEA displays a diagram with modules and its dependencies.

You can also select a JDK module and using the context menu or pressing `Ctrl+Shift+Alt+U` ,

The screenshot shows the 'External Libraries' section in the IntelliJ IDEA Project tool window. A context menu is open over the 'java.jnlp' library root, showing options like 'Select Diagram Type', 'Java Class Diagrams', 'Java Modules Diagram', 'JavaScript Module Dependency Diagram', and 'java.prefs library root'. The 'Java Modules Diagram' option is highlighted.

create a diagram for this module.

## Analyzing a Java module diagram

IntelliJ IDEA lets you view and analyze modules and its dependencies (named and automatic modules). You can easily recognize those modules since they each have a different color.

- IntelliJ IDEA modules - `com.mechanitis.demo.sense.client`
- named modules (contain `module-info.java`) - `java.xml`
- automatic modules - `websocket.common`

A connection between modules and dependencies is shown using arrows. With bold arrows IntelliJ IDEA displays a connection between modules and transitive dependencies. So you can always see what gets pulled in with the module.

## Managing a Java module diagram

IntelliJ IDEA lets you manage your diagram performing basic diagram actions such as jumping to the source code, find usages, etc.

For more information, please see [Diagram Reference](#), but check the following useful actions:

- You can jump to the source code - select the desired item and press `F4`
- You can quickly locate a module or a library if you have too many items in your graph - press `Ctrl+F` and from the list that opens, select the element you're looking for.

- You can view usages of the diagram element in the project files - select the desired element and press `Ctrl+Alt+F7`

Default options for the UML Class diagram help define the elements to be shown in diagram, visibility level of the node elements and members, layout, and more. These settings apply to any newly created UML Class diagram. Once a UML Class diagram is open, you can change its display settings as required, using the diagram toolbar and context menu.

Refer to the section [Diagrams](#) for the detailed description of controls.

### **To configure default settings for diagrams**

1. Open [Settings](#) , and under the Tools node, click [Diagrams](#) .
2. In the [Diagrams](#) page of the Settings dialog box, choose node you want to configure settings for, and then select the checkboxes to define the elements to be shown or hidden in diagram, for example, class members, or visibility level.
3. Select the checkboxes that define the Class diagram appearance and behavior: default layout, behavior after layout, and the possibility to view colored links.
4. Apply changes.

On this page:

- [Basics](#)
- [Opening a UML class diagram](#)
- [Tips and tricks](#)

**Tip** IntelliJ IDEA implements the UML diagrams functionality with a bundled plugin, which can be completely disabled by clearing the UML Support check box on the the Plugins page of IntelliJ IDEA settings ( `Ctrl+Alt+S` ).

## Basics

You can invoke UML class diagram from different places:

- From the various tool windows.
- From the Navigation bar.
- From the Structure tool window.
- From the editor.

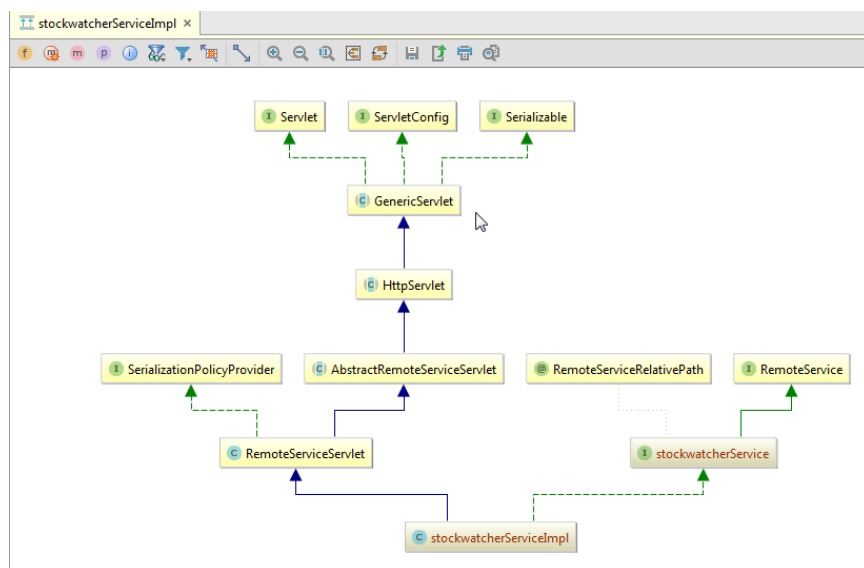

IntelliJ IDEA displays UML diagrams in two modes:

- In a pop-up window.
- In a separate editor tab.

## Opening a UML class diagram

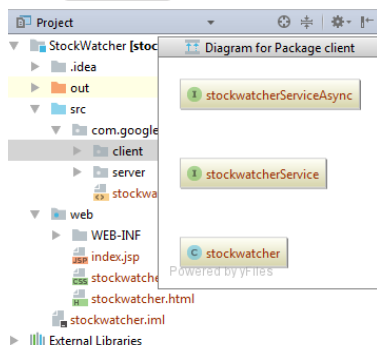

1. Select the desired item, or open it in the editor.
2. Do one of the following:
  - On the context menu of the selection, click **Diagram**, and on the submenu, select the way you want to view the model: **Show Diagram** or **Show Diagram Pop-up**.
  - Press `Ctrl+Shift+Alt+U` or `Ctrl+Alt+U`.

The diagram is displayed in the editor tab or in the pop-up window:

## Tips and tricks

- You can open a UML class diagram without using your pointing device. Consider such a workflow: press `Alt+Home`, then press `Ctrl+Alt+U`.
- It is possible to view a UML class diagram of a Java package. Just select a Java package in the Project tool window, and press `Ctrl+Alt+U`:

You can add the existing node elements to the background of the UML Class diagram, using the context menu action, or drag-and-drop technique.

If there are relationships between the node elements in model, and the added element, these relationships will be displayed in diagram.

On this page:

- [Adding node elements](#)
- [Dragging node elements](#)
- [Adding notes](#)

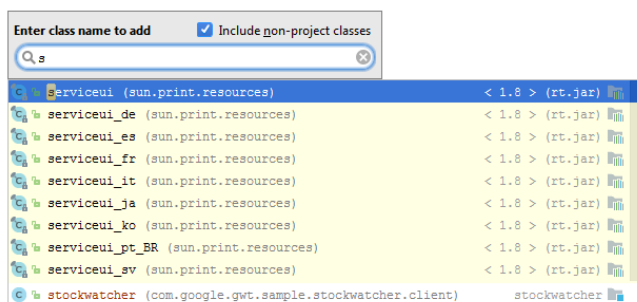

## To add a node element to a UML Class diagram

1. Do one of the following:

- Right-click the diagram background, on the context menu, point to **New**, and next choose the type of element to be added.
- Press **Space**.

2. In the Enter class name to add dialog box, start typing the desired class name. IntelliJ IDEA automatically displays suggestion list with matching names.

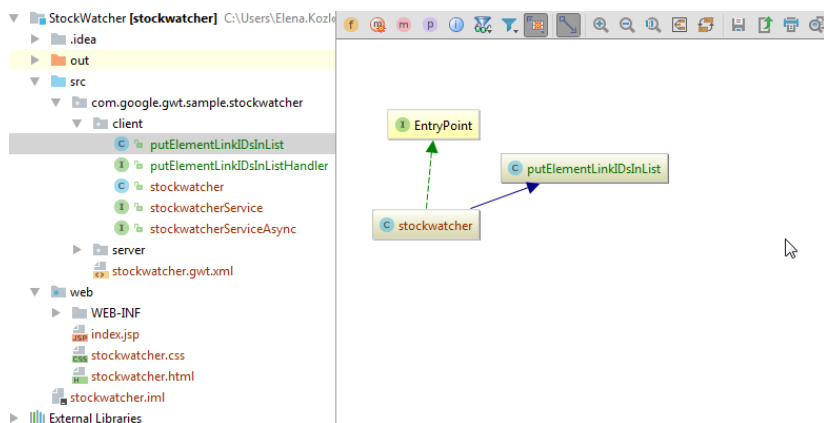

Note that you can include classes outside the scope of your project, by selecting the **Include non-project classes** checkbox.

3. Select the desired class from the suggestion list, and press **Enter**.

## To add a node element using drag-and-drop technique

1. Select one or more desired elements in the Project tool window.
2. Drag selection to the diagram background.

## To add a note to a node element

1. Right-click a node element, which you would like to comment.
2. On the context menu, choose **New | Note**.
3. In the text box, type the desired text. Note that **Enter** starts a new line in the text box. To complete a note, click **OK**, or press **Ctrl+Enter**.

You can populate your model with [node elements](#) (classes, interfaces and enumerations), and delete them from diagram, or from your project. When a node element is created in a UML Class diagram, the corresponding stub file is created in the current package.

In a similar way, IntelliJ IDEA helps create [members](#) (fields, methods, or constructors) in the node elements.

It is also possible to clarify the contents of diagrams with notes, which are created same way.

## To create a node element in a UML Class diagram

1. Do one of the following:
  - Right-click the diagram background, or a package where a new node element should be created. Next, on the context menu, point to **New**, and choose element type from the submenu.
  - Press **Alt+Insert**, and choose element type from the pop-up frame.
2. Specify the element name, or type the contents of a note, and click **OK**.

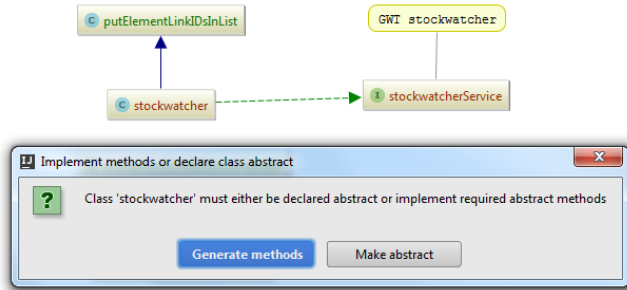

## To create a member in a node element

1. **Select** a node element in a diagram.
2. Do one of the following:
  - On the context menu of the selection, point to **New**, and then choose the member type on the submenu.
  - Press **Alt+Insert**, and choose member type from the pop-up frame.
3. Depending on the selected member type ([field](#), [constant](#), [method](#), or [constructor](#)), specify the member name and the other parameters. See preliminary results in the Preview pane of each dialog.

For creating relationship links between node elements, IntelliJ IDEA provides a special mode, in which drag-and-drop technique can be used for drawing links. As a link is created, the corresponding extends / implements clause is generated in the underlying source code. So doing, the extends link is represented with a solid line, and the implements link is represented with a dotted line.

### To create a link between node elements

1. Make sure that  is pressed on the diagram toolbar.
2. Draw a link from the source to a target node.
3. Specify whether the target class should be declared abstract, or implement required abstract methods:

### To delete a link

1. Select a link between two node.
2. Press  .
3. In the dialog box that opens, confirm deletion:

IntelliJ IDEA suggests two ways of deleting elements from diagram:

- Remove node elements from view, while leaving the underlying source code intact. This option can be helpful, if you want to explore a certain group of nodes, and remove the unnecessary ones from view.
- Delete node elements from project.

### To remove elements from view

1. In the diagram, select one or more elements to be deleted.
2. Press `Delete` .

### To delete elements from project

1. In the diagram, select the element to be deleted.
2. Use the [Safe Delete refactoring](#) (`Alt+Delete`) to delete selected classes from project.

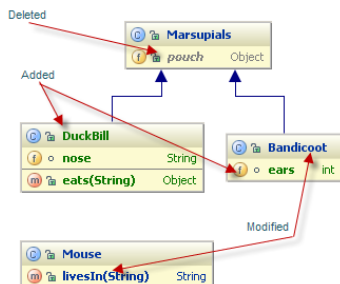

For the modules under version control, you can usually view the list of changed files in the Changes tool window. If you want to evaluate how your changes affect the model, use UML Class diagram. This view presents the complete picture of changes, including relationships between the modified classes.

For this purpose, IntelliJ IDEA provides the action [Show changed classes](#), which is available from the editor, Project tool window, and the Local Changes tab of the Version Control tool window.

Moreover, IntelliJ IDEA helps you analyze how the changes affect a model across revisions, and provides the action [Compare all classes from revision on UML](#).

Changes in Class diagram are color-coded:

- Green for added elements.
- Gray for deleted elements.
- Blue for modified elements.

## To view changes in UML Class diagram

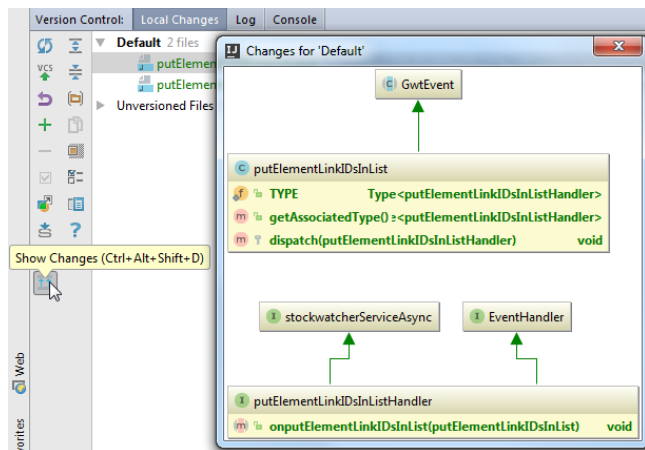

1. In the [Local Changes](#) tab of the Version Control tool window, select the desired changelist from the suggested popup:

Note that if there is only one changelist, the popup won't show up.

2. Do one of the following:

- In the toolbar of the [Local](#) tab, click , or press `Ctrl+Shift+Alt+D`.
- On the context menu of the editor or the Project tool window, choose [Diagrams | Show Changes](#), or press `Ctrl+Shift+Alt+D`.

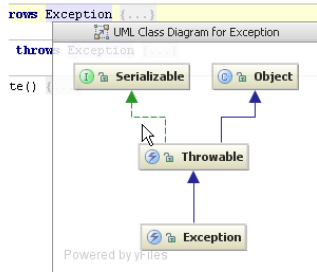

The diagram opens in a pop-up window. Double-click a node to view changes in a Differences viewer.

## To view changes in revisions as UML Class diagram

1. In the [History](#) tab of the [Version Control tool window](#), select the desired revision.
2. Click , or press `Ctrl+Shift+D`. The diagram opens in a pop-up window.

IntelliJ IDEA helps you view the complete hierarchy of the selected type.

So doing, you can modify the contents of the UML Class diagram, to show ancestor or descendant classes, types used in method signatures, and perform all actions that are available for UML Class diagrams.

## To view class hierarchy as a UML Class diagram

1. Open the desired class in the editor, and place the caret at the type you want to see hierarchy for.
2. Do one of the following:
  - On the context menu, point to Diagrams , and then choose Show Diagram , or Show Diagram Popup
  - Press `Ctrl+Shift+Alt+U` or `Ctrl+Alt+U`

**Tip** You can view type hierarchy for any class selected in the Project tool window

By default, the diagrams show node elements only. However, you can show members too.

## To show members in diagram

1. Press `Ctrl+Shift+Alt+U` to open a diagram.
2. Do one of the following:
  - On the diagram toolbar, click the [buttons](#) that correspond to the members you want to show.
  - Right-click the diagram background, and on the context menu, point to the Show Categories command, and then choose the category to be shown or hidden.

**Note** As you choose a Show Categories command, the state of the corresponding toolbar button changes accordingly.

IntelliJ IDEA can smartly tell the nodes that belong to the same package from the extraneous ones.

## To highlight sibling nodes

1. **Select** a node element in diagram.
2. Start navigating through the diagram. So doing, the classes and packages that reside in different packages, are automatically grayed out.

- To show ancestor and descendant types
- To find usages of a diagram element

## To show ancestor and descendant types

1. Open [UML Class diagram](#) for the desired class or package.
2. [Select](#) a node element in diagram.
3. On the context menu, choose one of the following commands, or press keyboard shortcuts:
  - Go to | Implementation [Ctrl+Alt+B](#)
  - Show Parents [Ctrl+Alt+P](#)
4. If there are several classes available, select the desired one from the pop-up list:

The selected class will be added to the UML Class diagram, with the corresponding relationship links:

## To find usages of a diagram element

1. [Select](#) a diagram element.
2. On the context menu of the selection, select the desired [Find Usages](#) command.

IntelliJ IDEA provides an additional way to explore and change module dependencies using UML class diagram of a module.

### To change module dependencies

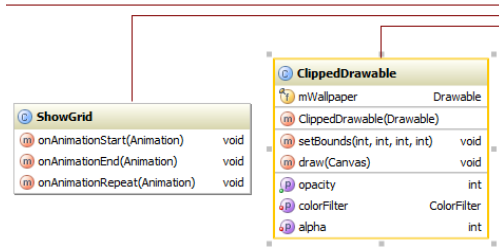

1. Right-click a module node in the Project tool window, or in the Navigation bar.
2. On the context menu, choose Diagrams | Show Diagram .
3. Press `Alt+Insert` .
4. Choose Add Dependency on the pop-up menu.

## To navigate through a diagram, follow these general steps

1. Press `Ctrl+F12` . The menu of diagram elements pops up.

2. Use the arrow keys to select the desired diagram element, and press `Enter` . The selected diagram node element becomes active.

3. Press `Enter` once more. The first member of an element gets the focus.

4. The following actions are available:

- Pressing `Enter` toggles the focus between a diagram element and its members.
- When a diagram element has the focus, use the arrow keys to jump between elements.
- When a member has the focus, use the vertical arrow keys to navigate through an element to the desired member.
- Having selected an element or a member, [navigate to the underlying source code](#) .

To run or debug your code in IntelliJ IDEA, you can use numerous run/debug configurations. Each run/debug configuration represents a named set of run/debug startup properties. When you perform run, debug, or test operations with IntelliJ IDEA, you always start a process based on one of the existing configurations using its parameters.

IntelliJ IDEA comes with a number of run/debug configuration types for the various running, debugging and testing issues. You can create your own run/debug configurations of specific types.

Each run/debug configuration type has its own default settings. Whenever a new run/debug configuration of the respective type is created, it is based on these default settings.

## Temporary configuration

A [temporary run/debug configuration](#) is automatically created every time you choose Run <item\_name> or Debug <item\_name> for an item without a permanent configuration. Temporary configurations can be saved as permanent.

Temporary configurations are marked with semi-transparent icons and are managed same way as the permanent configurations.

By default, 5 temporary configurations are allowed per project. You can change this limit via the [Edit Configurations](#) dialog.

## Permanent configuration

A [permanent run/debug configuration](#) is explicitly created for a particular class or method. If there is no permanent configuration for an item, IntelliJ IDEA automatically creates a temporary configuration for it, when you choose Run <item\_name> or Debug <item\_name> on the context menu of this class or method.

## Default run/debug configuration settings

The default run/debug configuration settings are listed in the Run/Debug Configurations dialog under the Defaults node. They denote the settings that are used when new run/debug configurations are created.

You can set the default settings for a specific configuration type that will become applicable to any run/debug configuration of this type created later. Changing defaults does not affect the existing run/debug configurations.

The process of editing per-type default configuration settings is described in [Changing Run/Debug Configuration Defaults](#) .

The process of creating or editing custom run/debug configurations is described in [Creating and Editing Run/Debug Configurations](#) .

## Overview

With the Navigation bar visible ( View | Navigation Bar ), the available [run/debug configurations](#) are displayed in the run/debug configuration selector in the Run area:

IntelliJ IDEA provides the [Run/Debug Configuration](#) dialog box as a tool for handling run/debug configurations: create configuration profiles or change the default ones.

IntelliJ IDEA suggests the following ways to create a run/debug configuration:

- [Create a run configuration manually](#) on the base of the default one, or using the [Run/Debug Configuration](#) dialog box.
- [Save a temporary run configuration](#) .
- Specify the target application server during module creation. IntelliJ IDEA will generate a run/debug configuration of the corresponding type.

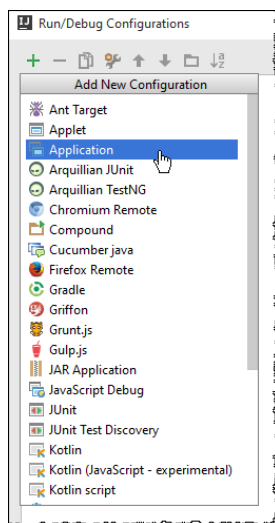

Also, the Run/Debug configuration can be deleted automatically for the deleted/obsolete targets, if this capability is enabled. See details [here](#) .

**Note** , that this capability is applicable only to those configurations that had being created automatically by CLion.

## Creating a run/debug configuration

To create a run/debug configuration, follow these steps:

1. Open the [Run/Debug Configuration](#) dialog box by doing one of the following:
  - On the main menu, choose Run | Edit Configurations .
  - With the Navigation Bar visible ( View | Navigation Bar ), choose Edit Configurations from the selector of run/debug configurations.
  - Press `Shift+Alt+F10` , then press `0` to display the Edit Configuration dialog box or select the configuration from the pop-up window and press `F4` .
2. In the [Run/Debug Configuration](#) dialog box, click `+` on the toolbar or press `Alt+Insert` . The drop-down list shows the default run/debug configurations. Select the desired configuration type.

The fields that appear in the right pane display the default settings for the selected configuration type.

3. For the new run/debug configuration:
  - Specify its name in the Name text box. This name will be shown in the list of the available run/debug configurations.
  - Specify whether you want to make IntelliJ IDEA check execution status of the instances of the same run/debug configuration. If you want to make sure that only one instance of the run/debug configuration is currently executed, select the checkbox `Single instance only` . In this case, a confirmation dialog box will show up every time you try to launch run/debug configuration, when one instance of the same type is still running.  
If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.  
If this checkbox is not selected, you can launch as many instances of the runner as required. As the result, each runner will start in its own tab of the Run tool window.
4. In the Before launch section, define whether you want to compile the modified sources, and run an Ant or Maven script.
5. In the Configuration tab, [specify the class](#) that contains the `main()` method, VM options, program arguments, working directory and other configuration-specific settings.
6. In the Logs tab, specify the options that control [output logs](#) produced while running or debugging application.  
In particular, specify whether IntelliJ IDEA will display the [standard output and standard error output](#) to the console.

7. For the various servers, set up the deployment and startup/connection options.
8. For the applications and tests, click the Code Coverage tab (for example, [in applications run/debug configuration](#) ), and specify the options that define [code coverage measurement](#) for testing purposes.
9. Specify additional parameters depending on the configuration type. Refer to the descriptions of run/debug configuration parameters below the [Run/Debug Configurations Dialog](#) section.
10. Apply the changes and close the dialog box.

**Note** If you want to change the settings of the default run/debug configuration, expand the Defaults node, select the desired configuration type, and modify it as required. See [Changing Run/Debug Configuration Defaults](#) for details.

**Tip** To use an existing configuration as a template, create its copy by clicking the Copy button  on the toolbar, then change it as required.

## Editing an existing run/debug configuration

To change an existing run/debug configuration:

- On the main menu, choose Run | Edit Configurations .
- With the Navigation Bar visible ( View | Navigation Bar ), choose Edit Configurations from the run/debug configurations selector.
- Press `Shift+Alt+F10` , then press `0` to display the Edit Configuration dialog box or select the configuration from the pop-up window and press `F4` .

In the corresponding run/debug configuration dialog box, change parameters as required.

## Managing multiple run configurations

You can manage multiple run configurations at once in a dedicated dashboard. For example, you start, pause and stop several applications, track their status, and examine application-specific details.

To enable the dashboard:

1. Click **Edit Configurations** from the run/debug configurations selector.
2. Select **Defaults** from the list in the left-hand section.
3. Under the **Run Dashboard Types** section, click **+** and select the necessary run configuration type. You can add multiple configuration types one by one.
4. Apply the changes and close the dialog.

To show or hide the dashboard, go to View | Tool Windows and click **Run dashboard** .

If necessary, you can hide the tree section on the dashboard and view configurations on dashboard tabs. To do so, click the **Show Configurations** icon on the left toolbar on the **Run dashboard** , or press `Ctrl+Shift+T` .

On this page:

- [Introduction](#)
- [Configuring defaults](#)

## Introduction

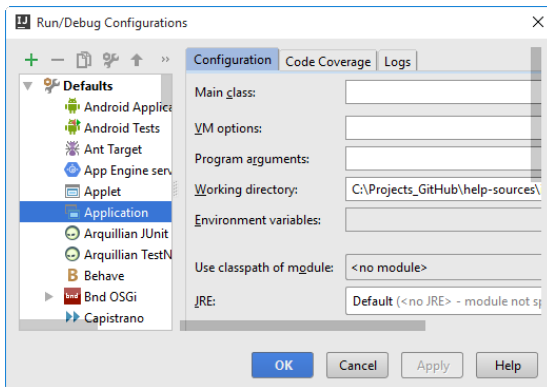

For a run/debug configuration of a particular type, you can set up the default values for one or more parameters and save them as a template for further usage. In this case, the next time when you create a new configuration of that type, the corresponding fields of the dialog will already contain the specified values.

Note that changing the default values **does not affect** the already existing run/debug configurations.

## Configuring defaults

To set up the default values for a run/debug configuration, follow these steps:

1. In the left-hand pane of the run/debug configuration dialog, expand the Defaults node.
2. From the drop down list under the Defaults node, select the desired configuration type. The corresponding configuration template appears in the right-hand pane.
3. Specify the desired parameters of the right pane and click Apply to save the template.

**Tip** The Name, Share and Single instance only fields are not available for the default run/debug configurations.

## Introduction

Sometimes you might need to run or debug a certain class with the `main()` method without creating a dedicated run configuration. In this case, you can use the temporary [run configuration](#) provided by IntelliJ IDEA.

Temporary run/debug configuration is added to the list of available configurations and works same way as the [permanent run/debug configuration](#). You can change its settings using the [Run/Debug Configuration](#) dialog box and optionally save it as permanent.

## Creating a temporary run/debug configuration

1. Select the desired class with the `main()` method in the Project view or open it in the editor.

2. Do one of the following:

- On the context menu, choose Run <name> or Debug <name> .
- Press `Ctrl+Shift+F10` .

IntelliJ IDEA creates a temporary configuration, which appears in the Run/Debug Configuration selector when the run or debug session is over.

## Saving a temporary run/debug configuration

- In the Run/Debug Configuration selector, choose Save <configuration name> .
- In the Run/Debug Configuration dialog box, click  .
- On the context menu of the editor or Project view, choose Save <configuration name> .

On this page:

- [Introduction](#)
- [Creating folders of run/debug configurations](#)
- [Deleting folders](#)
- [Changing order of folders](#)

## Introduction

When there are too many run/debug configurations of the same type, you can put them into directories, and thus make them visually distinguishable.

Folders are used to organize run/debug configurations. When not needed, they can be deleted, and the run/debug configurations grouped under those folders will be moved under the root of the corresponding run/debug configuration type.

Once grouped, the run/debug configurations appear in the drop-down list under the corresponding folders:

## Creating folders of run/debug configurations

1. Open the [Run/Debug Configuration](#) dialog box by doing one of the following:
  - On the main menu, choose Run | Edit Configurations .
  - With the Navigation Bar visible ( View | Navigation Bar ), choose Edit Configurations from the selector of run/debug configurations.
  - Press `Shift+Alt+F10` , then press `0` to display the Edit Configuration dialog box or select the configuration from the pop-up window and press `F4` .
2. In the [Run/Debug Configuration](#) dialog box, click  on the toolbar. A new empty folder is created.
3. Specify the folder name in the text field to the right, or accept the default name.
4. Select the desired run/debug configuration of a certain type, and move under the target folder. This can be done in one of the following ways:
  - Use drag-and-drop.
  - Use the  and  toolbar buttons.
  - Press `Alt+Up` or `Alt+Down` .
5. Apply changes. Note that if a folder is empty, it will not be saved.

## Deleting folders

1. In the [Run/Debug Configuration](#) dialog box, select a folder to be deleted.
2. On the toolbar, click  . The selected folder is deleted silently. Any run/debug configurations grouped under this folder, are moved under the root of the corresponding type.
3. Apply changes.

## Changing order of folders

1. In the [Run/Debug Configuration](#) dialog box, select one of the folders within a certain run/debug configuration type.
2. Do one of the following:
  - On the toolbar, click  or  .
  - Press `Alt+Up` or `Alt+Down` .

The selected folder moves one position up or down.
3. Apply changes.

After the dialog box is closed, groups of run/debug configurations in the run/debug configurations selector on the main toolbar appear in the order achieved by moving folders up or down within the type.

This section describes the procedures that are common for the various types of applications:

- [Running Applications](#)
- [Rerunning Applications](#)
- [Reviewing Results](#)
- [Stopping and Pausing Applications](#)
- [Setting Configuration Options](#)
- [Setting Log Options](#)
- [Viewing Running Processes](#)

For the details related to running applications in the supported frameworks, refer to [Language and Framework - Specific Guidelines](#)

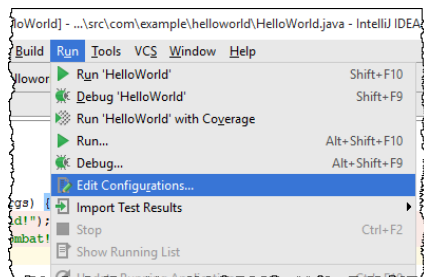

On this page:

- [Introduction](#)
- [Running an application](#)
- [Running a class with main\(\) method](#)

## Introduction

IntelliJ IDEA enables running entire applications as well as [classes with the main\(\) method](#).

IntelliJ IDEA makes use of the settings defined in a [Run/Debug Configuration](#). All the run configurations that exist in a project, are available in the Select Run/Debug Configuration drop-down list.

If you want to see the list of all currently running applications, select Run | Show Running List from the main menu. Refer to the [Viewing Running Processes](#) section for details.

Note that after you've started a run session, the  icon that marks the [Run tool window](#) and in the Run/Debug Configuration Selector toggles to  to indicate that the run process is active.

**Note** If the options that launch build or tools before running were enabled in a [Run/Debug configuration](#), IntelliJ IDEA runs the build or tools, and after success will run the application. Otherwise, the program will start immediately.

## Running an application

- Do one of the following:
  - In the left gutter, click the icon , and choose the desired command.
  - On the main toolbar, select the desired run configuration, and:
    - Choose Run | Run from the main menu.
    - Click .
    - Press `Shift+F10`.
  - Press `Shift+Alt+F10`, select the desired run configuration from the pop-up menu, and press `Enter`.

From this pop-up menu you can:

- Invoke the Edit Configuration dialog.
- Edit the selected configuration before launch (`F4`).
- Instantly delete a configuration (`Delete`).
- Switch from run to debug and vice versa (hold `Shift`).
- Access a previously selected configuration (`1`).
- Access context-dependent configuration (`2` or `3`).

This pop-up menu can also be quickly accessed by pressing `F9`, when you're not running any debug session.

## Running a class with main() method

- Open the class in the editor and do one of the following:
  - In the left gutter, click the icon , and choose the desired command.
  - Choose Run <method name > on the context menu
  - Press `Ctrl+Shift+F10`
- Select the class in the Project tool window and choose Run <method name > on the context menu of the selection.

You can re-run an application if its tab is still opened in the [Run](#) window. The program re-runs with the initial settings.

1. In the Run window, select the tab where the desired application is opened.
2. In the toolbar of the Run window, click the Rerun button  , or press `Ctrl+F5` .

**Tip** If you want to re-run without loosing focus in the editor tab you are working in, press `Shift+F10` .

You can review any output from your running applications in the Run window console. The output from each application is displayed in its own tab of the [Run](#) tool window, named after the corresponding [run/debug configuration](#).

If you re-run an application, the new output overwrites the contents of the tab. To preserve the output of an application, even if you re-run it, [pin](#) the output tab.

## Introduction

In the [Run](#) tool window, you can stop a program, or pause its output. If a program is stopped, its process is interrupted and exits immediately. When program output is paused, the program continues running in the background, but its output is suspended.

## Stopping a program

1. In the Run tool window, click the Stop button  on the toolbar, or press `Ctrl+F2`.
2. To close the active tab, click the Close button , or press `Ctrl+Shift+F4`.

## Suspending the program output

- In the Run tool window, click the Pause button  on the toolbar.

Note that the button is not available for [Run/Debug Configuration: Node.js](#), [Run/Debug Configuration: Attach to Node.js/Chrome](#), and [Run/Debug Configuration: NUnit](#).

Configuration options include VM settings, arguments that should be passed to the program, working directory, classpath and SDK. Refer to the [Run/Debug Configuration](#) dialog for detailed description of the fields.

## To define Configuration options of a run/debug configuration

1. Click Configuration tab of the Edit Run/Debug Configuration dialog.
2. In the Main class field, specify the class that contains the `main()` method. To do that, type the fully qualified name manually, or click the ellipsis button and select the desired class from the Choose Main Class dialog.

In the Choose Main Class dialog, you can locate the desired class using one of the following ways:

- Click the Project tab, and select class with the `main()` method from the project tree view.
- Click the Search by Name tab and start typing the class name. As you type, the list of available classes narrows down to match your entry.

Click OK, or press `Enter` when ready.

3. In the VM options field, type optional VM arguments, for example the heap size, garbage collection options, file encoding, etc. If the line of VM arguments is too long, click  and type the text in the editor dialog.
4. In the Program parameters field, type optional list of parameters that should be passed to the `main()` method through the array of its arguments.
5. In the Working directory field, specify the current directory that your application will use while running.
6. In the Use classpath and SDK of module field, select the desired module from the list of modules existing in the project.

Use Logs tab in the Run/Debug Configuration dialogs to configure the way log files, generated by an application or server, are displayed in the console.

If your application or server generates log files, the default entries will be automatically added to the log file list in the Run/Debug Configuration dialog.

## To configure Logs options

1. In the [Run/Debug Configuration](#) dialog box, click Logs tab. The table Log files to be shown in console displays the list of log files (if any).
2. Click [+](#). [Edit Log Files Aliases Dialog](#) dialog is displayed.
3. In the Alias field, type the alias name to show in the list of log entries. In the Log File Location field, type the fully qualified name of the log file, or specify its location by pressing the ellipsis button. Select whether you want to show all or last file coverable by pattern. Click OK to close the dialog.
4. Activate the log entry. To do that, select the checkbox in the Is Active column.
5. To skip the previous content, select the checkbox in the Skip Content column.

**Note** If you are using third-party logging tools, you might want to make the message's output that mimics a standard linkage to the source code as for stacktrace line (at `<fully-qualified-class-name>.<method-name>(<file-name>:<line-number>)`). For that, add specific Conversion Pattern to your log.xml configuration file.

For example, in a log4j Conversion Pattern this would be `<param name="ConversionPattern" value="%-5p - [%-80m] - at %c.F:n"/>`.

IntelliJ IDEA makes it possible to view all the running applications. The command Show Running List of the menu Run is only enabled if there are active applications. If no applications are active, the command is greyed out.

## Viewing the list of running applications

– On the main menu, choose Run | Show Running List .

A popup listing all active applications is displayed in the top-right corner of the editor.

**Tip** Same is also valid for debugging.

A subprocess can be entered in the course of debugging.

## Overview

This section describes the procedures that are common for various types of applications. For details on debugging applications in the supported frameworks, refer to [Language and Framework - Specific Guidelines](#) .

IntelliJ IDEA provides a full range of facilities for debugging your source code:

- Breakpoints in Java.
- Breakpoints in JavaScript.
- Multiple simultaneous debugging sessions.
- Customizable breakpoint properties: conditions, pass count, etc.
- [Frames](#) , [variables](#) , and [watches](#) views in the debugger UI.
- Runtime [evaluation of expressions](#) .

If you want to see the list of all currently debugging applications, select Run | Show Running List from the main menu. Refer to the [Viewing Running Processes](#) section for details.

## General debugging steps

1. [Configure](#) the dependencies and libraries to be passed to the compiler and generate the debugging information.
2. Configure common debugger behavior, including [stepping speed](#) , [class reloading policy](#) , or [scrolling of the editor canvas](#) .
3. [Configure the debugger engine](#) .
4. To debug [CoffeeScript](#) , [TypeScript](#) , and [Dart](#) code, you need to generate a [source map](#) for it. This will set the correspondence between lines in your original code and in the generated JavaScript code. If no source map is generated, your breakpoints will not be recognized and processed correctly.
5. [Define a run/debug configuration](#) for the application to be debugged.
6. Create [breakpoints](#) in the source code.
7. [Launch](#) a debugging session.
8. [Pause or resume](#) the debugging session as required.
9. During the debugger session, [step through the breakpoints](#) , [evaluate expressions](#) , change values on-the-fly [examine suspended program](#) , [set watches](#) , [reload classes](#) , and [customize views](#) .

**Note** See [Compiling CoffeeScript to JavaScript](#) , [TypeScript](#) , and [Using Pub](#) for details.

After you've started a debug session, the  icon that marks the [Debug tool window](#) toggles to  to indicate that the debug process is active.

Note that IntelliJ IDEA lets you debug decompiled code in the same way as your normal source files, provided that it contains line number attributes.

In this section:

- [Debug](#)
- [Useful debugger shortcuts](#)
- [Breakpoints](#)
  - [Breakpoint details and condition](#)
  - [Field breakpoints](#)
  - [Action breakpoints](#)
  - [Temporary breakpoints](#)
  - [Disable breakpoints](#)
- [Debugger session](#)
  - [Smart step into](#)
  - [Drop frame](#)
  - [Run to cursor](#)
  - [Mark instance](#)
  - [Evaluate expression](#)
  - [Reload changes and hot swapping](#)
- [Remote debug](#)
- [Settings](#)

## Debug

After you have configured a [run configuration](#) for your project, you can launch it in debug mode by pressing `Shift+F9`.

In the [Debug tool window](#) you can see the list of frames and threads with their states, variables and watches. When you select a frame, you see the variables corresponding to the selected frame.

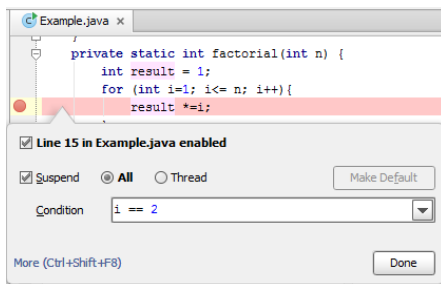

## Useful debugger shortcuts

- [Toggle breakpoint](#): `Ctrl+F8`
- [Resume program](#): `F9`
- [Step over](#): `F8`
- [Step into](#): `F7`
- [Stop](#): `Ctrl+F2`
- [View breakpoint details/all breakpoints](#): `Ctrl+Shift+F8`
- [Debug code at caret](#) `Shift+F9` (e.g if you stay within the main method), or `Shift+Alt+F9`

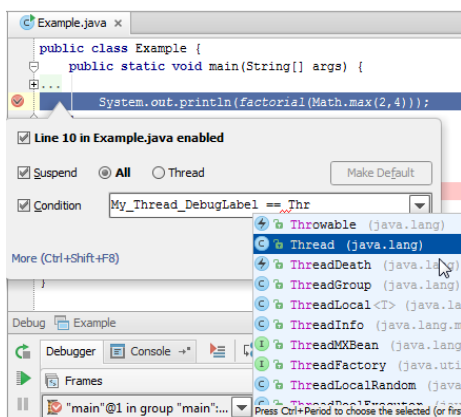

## Breakpoints

### Breakpoint details and condition

If you want to change details of a breakpoint, press `Ctrl+Shift+F8`. Here you can specify the breakpoint conditions.

If you have any instance marked with a label, you can use it in the condition expression as well:

To see all breakpoints in the project (with more advanced settings), press the same shortcut `Ctrl+Shift+F8` again.

```
Example.java x
public class Example {
    static int maxFactorial;

    public static void main(String[] args) {
        ... */
        System.out.println(factorial(Math.max(2,4)));
        System.out.println(maxFactorial);
    }

    private static int factorial(int n) {
        int result = 1;
        for (int i=1; i<= n; i++){
            result *=i;
        }
        return result;
    }
}
```

Refer to the section [Enabling, Disabling and Removing Breakpoints](#) for details.

## Debugger session

### Smart step into

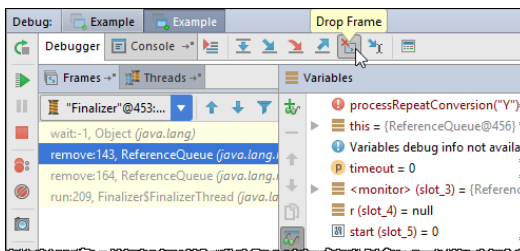

Sometimes it happens that you stay at a line and want to step into a particular method but not the first one that will be invoked. In this case use Smart step into by pressing `Shift+F7` to choose a particular method. This is a great time-saver.

Refer to the section [Choosing a Method to Step Into](#) for details.

### Drop frame

In case you want to "go back in time" while debugging you can do it via Drop Frame action. This is a great help if you mistakenly stepped too far. This will not revert the global state of your application but at least will get you back by stack of frames.

The icon  is described in the [Debug tool window](#) reference.

### Run to cursor

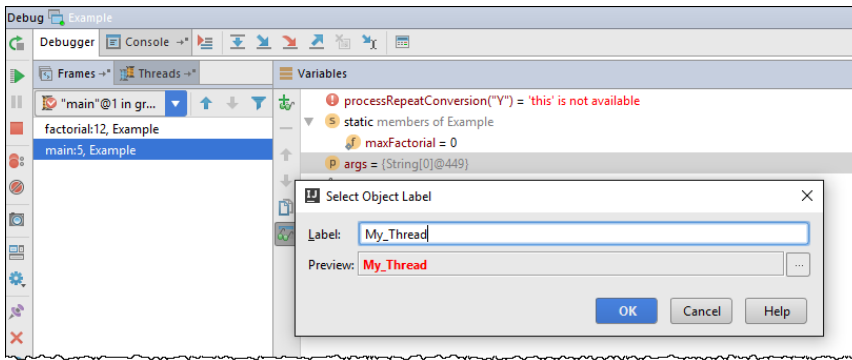

Sometimes you need to resume the program and stop at another line of code, without adding another breakpoint. Easy: just press `Alt+F9`.

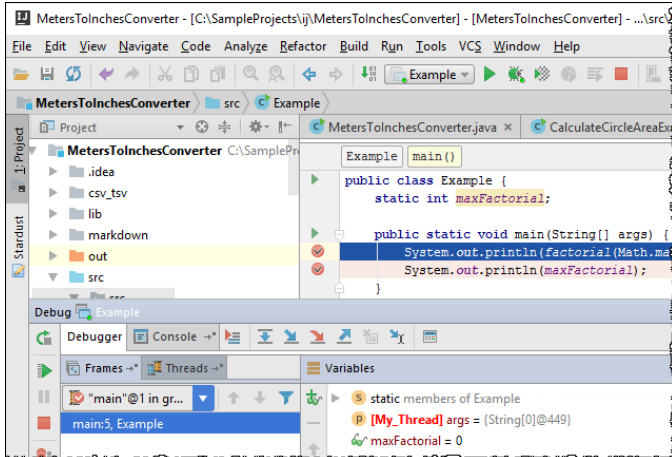

The icon  is described in the [toolbar reference](#) of the Debug tool window.

### Mark instance

If you want a particular instance to be always recognized while debugging, you can mark it with a colored label via `F11` or the context menu in the [Variables](#) and [Watches](#) tabs.

The next time this instance appears in Watches, Variables or Evaluate expression, you will see the label:

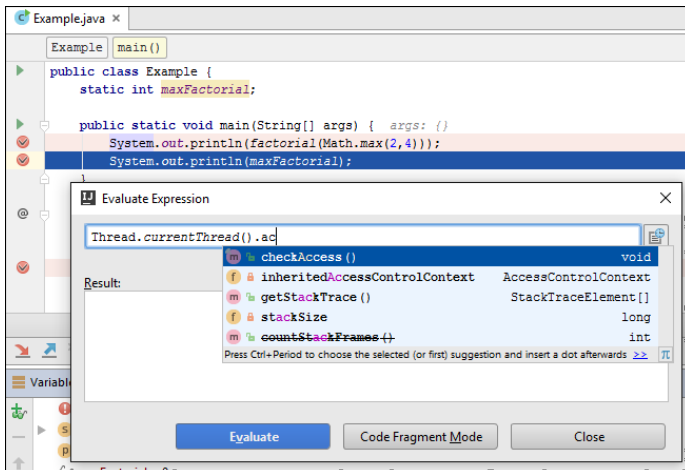

### Evaluate expression

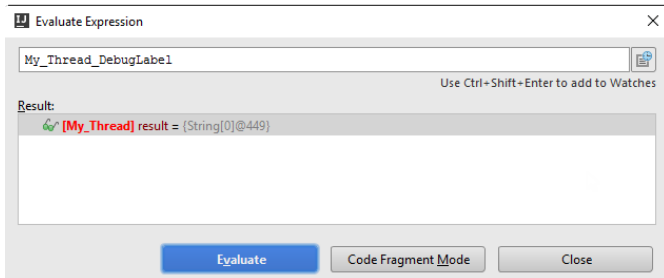

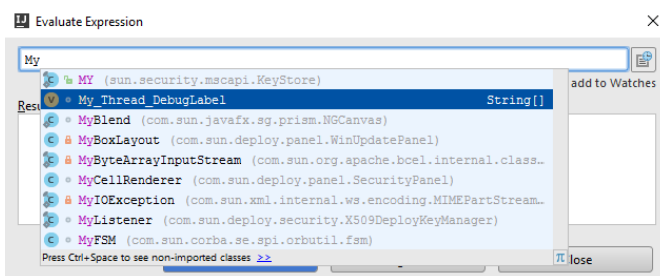

While in debug mode, you can **evaluate any expression** by pressing `Alt+F8`.

This tool provides code completion just as in the editor so it's very easy to enter any expression:

If you have any instances marked with labels, code completion will offer you its names so you can evaluate them:

Refer to the section [Evaluating Expressions](#) for details.

## Reload changes and hot swapping

Sometimes it happens that you need to insert minor changes in your code without shutting down the process. Since Java VM has such a feature as [HotSwap](#), the IDE handles these cases automatically and offers you to [reload the changed classes](#) whenever you compile the changed classes while in debug mode.

Keep in mind that Java VM's HotSwap has a number of constraints and does not support reloading of static fields and methods.

## Remote debug

The final thing you definitely should know about debugging in IntelliJ IDEA is Remote debug. Remote debug means attaching debugger to a process which is already running on a specific port on your or any other's host. This way you can attach the debugger to your application server which is running standalone.

To create a remote configuration, [go to Edit configurations](#) and add [Remote run configuration](#). Make sure to specify the correct host and port before you run this configuration.

## Settings

If you want to change the default debugger settings, choose [Debugger](#) in IntelliJ IDEA Settings/Preferences.

Breakpoints are source code markers used to trigger actions during a debugging session.

In this part:

- [Types of Breakpoints](#)
- [Breakpoints Icons and Statuses](#)

On this page:

- [Introduction](#)
- [Line breakpoint](#)
- [Temporary Line breakpoint](#)
- [Method breakpoint](#)
- [Exception breakpoint](#)
- [Field watchpoint](#)
- [JavaScript / Flex /PHP breakpoints](#)

## Introduction

IntelliJ IDEA lets you create breakpoints of several types. Each breakpoint type supported by IntelliJ IDEA addresses different debugging needs and has its own individual settings.

Breakpoints are triggered when the program reaches the specified line of source code, before it is executed. The line of code that contains a set breakpoint, is marked with a red stripe; once such line of code is reached, the marking stripe changes to blue .

Once set, a breakpoint remains in project until removed. Breakpoints can only be set on executable lines of code. Comments, declarations of fields or methods, and empty lines are not valid locations for breakpoints.

**Tip** If a file with breakpoints has been modified externally, for example, updated from a version control repository, or changed in an external editor, so that line numbers are changed, then the breakpoints will be moved accordingly. Note that IntelliJ IDEA should be running at the moment of such modification; otherwise, such changes will pass unnoticed.

## Line breakpoint

These breakpoints are assigned to lines of source code and are used to target a particular section for debugging.

## Temporary Line breakpoint

These breakpoints are assigned to lines of source code and are used to target a particular section for debugging. When hit, such breakpoints are immediately removed.

## Method breakpoint

Method breakpoints act in response to the program entering or exiting a particular method. They let you target your debugging sessions by method you wish to investigate, rather than by line number. Method breakpoints let you follow the program flow at the method level as well as check entry and exit conditions. Note that using method breakpoints can slow down the application you are debugging.

## Exception breakpoint

IntelliJ IDEA provides exception breakpoints for Java and JavaScript.

**Exception breakpoints** are triggered when the specified exception is thrown. Unlike the line breakpoints, which require specific source references, exception breakpoints apply globally to the exception condition, rather than to a particular code reference.

With PHP **Exception Breakpoints** , you can initiate the debugger at the start of the script and break on your own breakpoints or whenever an error or Exception of a given type occurs. PHP Exception breakpoints do not require configuring Xdebug for working in the **Just-In-Time** mode by setting `xdebug.remote_mode` to `jit` , see [Debugging in the Just-In-Time Mode](#) for details.

## Field watchpoint

Field watchpoints allow you to react to any access or modification of specific instance variables. For example, if at the end of a complicated process you are ending up with an obviously wrong value on one of your fields, then setting up a field watchpoint may be the quickest way to determine the origin of the fault.

## JavaScript / Flex /PHP breakpoints

JavaScript, Flex, and PHP breakpoints are identical to line breakpoints in Java.

These breakpoints are assigned to particular lines of JavaScript or PHP source code. They can be set in `*.html` files as well as in `*.js` or `*.php` files and are used to target a particular section of code for debugging.

On this page:

- [Basics](#)
- [Breakpoint states and icons](#)

## Basics

When a breakpoint is set, the editor displays a breakpoint icon in the gutter area to the left of the affected source code. A breakpoint icon denotes status of a breakpoint, and provides useful information about its type, location, and action.

The icons serve as convenient shortcuts for managing breakpoints. Clicking an icon removes the breakpoint. Successive use of **Alt** - click on an icon toggles its state between enabled and disabled. The settings of a breakpoint are shown in a tooltip when a mouse pointer hovers over a breakpoint icon in the gutter area of the editor.

## Breakpoint states and icons

The table below summarizes the possible breakpoint states:

Status	Line	TemporaryExceptionMethodField	Description
<b>JavaScript</b>			
<b>Flex</b>			
Enabled			Shown at design-time or during the debugging session when the class with such breakpoint is not yet loaded.
Valid	NA		Shown at run-time when the breakpoint is recognized by the debugger as set on an executable code line.
Invalid	NA		Shown when the breakpoint is set on a commented or non-executable line indicating that such breakpoint would not be hit.
Disabled			Indicates that nothing happens when the breakpoint is hit.
Conditionally disabled			This state is assigned to breakpoints when they depend on another breakpoint to be activated.

When the button is pressed in the toolbar of the [Debug](#) tool window, all the breakpoints in a project are muted, and their icons become grey: .

In this section:

- [Accessing Breakpoint Properties](#)
- [Configuring Breakpoints](#)
- [Creating Line Breakpoints](#)
- [Creating Exception Breakpoints](#)
- [Creating Field Watchpoints](#)
- [Creating Method Breakpoints](#)
- [Enabling, Disabling and Removing Breakpoints](#)
- [Moving Breakpoints](#)
- [Named Breakpoints](#)
- [Navigating Back to Source](#)
- [Working with Groups of Breakpoints](#)

On this page:

- [Introduction](#)
- [Viewing all breakpoints](#)
- [Viewing properties of a breakpoint](#)

## Introduction

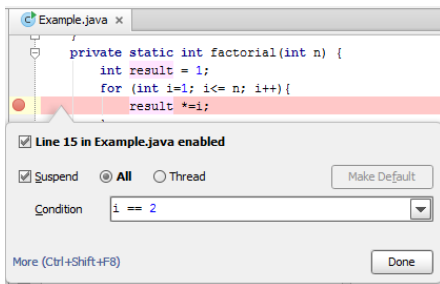

To view the whole list of the breakpoints in the current project, use the [Breakpoints](#) dialog box. For each individual breakpoint in the list, you can view and change its properties as required.

## Viewing all breakpoints

- On the main menu, choose Run | View Breakpoints .
- Press `Ctrl+Shift+F8` .
- In the toolbar of the [Debug tool window](#) , click  .
- Breakpoints are visible in the [Favorites](#) tool window.

## Viewing properties of a breakpoint

- Right-click a breakpoint icon in the left gutter of the editor.

On this page:

- [Basics](#)
- [Configuring breakpoints](#)

## Basics

For a breakpoint, you can configure the following properties:

- Actions to be performed upon hitting a certain breakpoint.
- Suspend policy, which defines whether the application should be suspended upon hitting the breakpoint.
- Dependencies on other breakpoints.
- Conditions defining when a breakpoint is hit.

IntelliJ IDEA suggests the following way to change the breakpoints properties:

- Using the [Breakpoints](#) dialog box, for a breakpoint selected in the list.
- Using breakpoint icon in the left gutter

## Configuring breakpoints

1. Do one of the following:

- Right-click a breakpoint in the left gutter, and then click the link More or press `Ctrl+Shift+F8`.
- Open the Breakpoints dialog box as described on page [Accessing Breakpoint Properties](#) and select the desired breakpoint in the list.
- In the [Favorites](#) tool window, select the desired breakpoint, and click .

Note that the pop-up window shows less options than the [Breakpoints](#) dialog box. To show hidden options, click More .

2. Define the actions to be performed by IntelliJ IDEA on hitting breakpoint:

- To notify about the reaching of a breakpoint with a text message in the debugging console, select the Log message to console check checkbox.  
To evaluate an expression in the context of a breakpoint and display its value in the debugging console, check the option Evaluate and log , and enter a valid expression in the option field.

This feature lets you obtain information about your running application without having to suspend its execution.

- To set a breakpoint the current one depends on, select it from the Disabled until selected breakpoint hit drop-down list. Once dependency has been set, the current breakpoint is disabled until selected one is hit.
  - Choose Disable again radio button to disable the current breakpoint after selected breakpoint was hit.
  - Choose Leave enable radio button to keep the current breakpoint enabled after selected breakpoint was hit.
- Enable suspending an application upon reaching a breakpoint by selecting the Suspend checkbox, and then select one of the option buttons to specify the way a running program will be paused. For more information on the Suspend options, refer to [Breakpoints](#) dialog reference.
- To set the break condition, enable condition by selecting the appropriate checkbox, and enter the desired expression in the Condition field.  
If the expression evaluates to true , the user-selected actions are performed. If the evaluation result is false , the breakpoint does not produce any effect.

3. The following options are defined in the [Breakpoints](#) dialog box (if you edit properties of a particular breakpoint, click More ):

- To limit breakpoint hits only with particular object instances using instance IDs, check the Instance filters option and type the instance ID value, or click the ellipsis button and specify instance ID in the Instance Filters dialog.
- To define breakpoint behavior with regards to particular classes, select the Class Filter checkbox and specify the class filter. Type the class filter manually or click the Browse button  and create the class filter definition in the [Class Filters](#) dialog box that opens.
- To define the number of times a breakpoint is reached but ignored, select the Pass count checkbox and specify the number of passes the breakpoint should be skipped before it is hit.  
For more information, refer to the [Breakpoints](#) dialog reference.

On this page:

- [Basics](#)
- [Creating line breakpoints in the editor](#)
  - [Important notes](#)
- [Creating temporary line breakpoints](#)
- [Deleting line breakpoints](#)

## Basics

A **line breakpoint** is a breakpoint assigned to a specific line in the source code.

Line breakpoints can be set on executable lines. Comments, declarations and empty lines are not valid locations for the line breakpoints.

## Creating line breakpoints in the editor

1. Place the caret on the desired line of the source code.
2. Do one of the following:
  - Click the left gutter area at a line where you want to toggle a breakpoint.
  - On the main menu, choose Run | Toggle Line Breakpoint .
  - Press `Ctrl+F8` .

## Important notes

- For the lambda expressions, you can set multiple breakpoints within a single line. To do this, click the left gutter area at a line where you want to set a breakpoint. A drop-down list will appear where you can select which method(s) you want to set

a breakpoint at:

IntelliJ IDEA highlights each of the lambda expressions as you move the mouse over the options.

- If you want to set a line breakpoint in the default class constructor, it is enough to set a line breakpoint on the first line of this class, since the default constructor is mapped to it:

```
class A { // set a breakpoint on this line
}
```

- When one sets a breakpoint on a [folded method](#) , a line breakpoint is set on the first executable line after method declaration.

## Creating temporary line breakpoints

1. Place the caret on the desired line of the source code.
2. Do one of the following:
  - On the main menu, choose Run | Toggle Temporary Line Breakpoint .
  - Press `Ctrl+Shift+Alt+F8` .

## Deleting line breakpoints

Do one of the following:

- In the [Breakpoints](#) dialog box, select the desired line breakpoint, and click  .
- In the editor, locate the line with the line breakpoint to be deleted, and click its icon in the left gutter.
- Place caret on the desired line and press `Ctrl+F8` .

1. On the main menu, choose Run | View Breakpoints , or press `Ctrl+Shift+F8` .
2. In the [Breakpoints](#) dialog box that opens, click `+` .
3. Select Java Exception Breakpoint or JavaScript Exception Breakpoint from the drop-down list.
4. In the Choose Exception Class dialog box, specify the desired exception class from the library, or from the project, and click OK .  
IntelliJ IDEA returns you to the Breakpoints dialog box.
5. Configure the new exception breakpoint as described in [Configuring Breakpoints](#) .

Field watchpoints  help you target your debugging search to specific instance variables.

On this page:

- [Creating field watchpoints using the Breakpoints dialog](#)
- [Creating field watchpoints using the editor](#)
- [Creating field watchpoints from the Debug tool window](#)
- [Deleting field watchpoints](#)

## Creating field watchpoints using the Breakpoints dialog

### To create a field watchpoint using the Breakpoint dialog

1. On the main menu, choose Run | View Breakpoints , or press `Ctrl+Shift+F8` .
2. In the **Breakpoints** dialog box that opens, click **+** .
3. Select Field Watchpoint from the drop-down list:

4. In the Add Field Watchpoint dialog box that opens, specify the following:
  - Fully qualified name of a class that contains the desired field. You can type it manually, or click  , and find the desired class by name, or from the project.
  - Field name. You can type it manually, or click  and select the desired field from the list of fields in the selected class.

## Creating field watchpoints using the editor

### To create a field watchpoint from the editor

1. Open the desired class in the editor, and locate the field you want to create a watchpoint for.
2. `Alt+click` on the left gutter at the field declaration line.

## Creating field watchpoints from the Debug tool window

### To create a field watchpoint from the Debug tool window

1. During the debugging session, open the Variables tab.
2. Select the desired field and choose Add Field Watchpoint on the context menu.

## Deleting field watchpoints

### To delete a field watchpoint

1. In the **Breakpoints** dialog box, select the desired field watchpoint, and click **-** .
2. In the editor, locate the line with the watchpoint to be deleted, and click its icon in the left gutter.

On this page:

- [Introduction](#)
- [Creating method breakpoints](#)
- [Deleting method breakpoints](#)

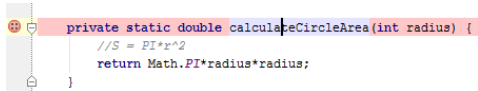

## Introduction

[Method breakpoints](#) let you follow the program flow at the method level.

## Creating method breakpoints

### To create a breakpoint using the editor

1. Place the caret inside the method where you want to toggle a method breakpoint.
2. On the main menu, choose Run | Toggle Method Breakpoint . Method breakpoint appears at the method declaration.

```
private static double calculateCircleArea(int radius) {  
    //S = PI*r^2  
    return Math.PI*radius*radius;  
}
```

A balloon appears, informing you about the possible slow-down of the debugging process:

Alternatively, just click the left gutter at the method declaration.

### To create a method breakpoint using the Breakpoints dialog

1. On the main menu, choose Run | View Breakpoints , or press `Ctrl+Shift+F8` .
2. In the [Breakpoints](#) dialog box that opens, click `+` .
3. Select Method Breakpoint from the drop-down list.
4. In the Add Method Breakpoint dialog box, specify the class name pattern, including the package name, and the name of the desired method.

When a debugging session starts, the application will pause in all classes with the names matching the specified pattern, at the specified method.

## Deleting method breakpoints

### To delete a method breakpoint

1. Click the method breakpoint icon  in the left gutter.
2. On the main menu, choose Run | Toggle Method Breakpoint .

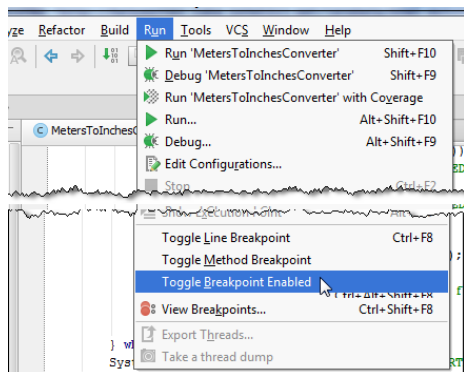

On this page:

- [Toggling between the enabled and disabled state of a breakpoint](#)
- [Disabling a breakpoint temporarily in the editor](#)
- [Enabling a temporarily disabled breakpoint in the editor](#)
- [Removing a breakpoint](#)
- [Removing all breakpoints of a certain type](#)

## Toggling between the enabled and disabled state of a breakpoint

When you temporarily disable or enable a breakpoint, its icon changes from  to  and vice versa.

1. Place the caret at the desired line with a breakpoint.
2. Do one of the following:
  - On the main menu, choose Run | Toggle Breakpoint Enabled :

- Right-click the desired breakpoint icon, select or deselect the <breakpoint name> enabled checkbox, and then click

- Done .
-  -click on the breakpoint icon.

**Tip** Alternatively, [open the Breakpoints dialog box](#) , select the desired breakpoint, and select or clear the checkbox to its left.

## Disabling a breakpoint temporarily in the editor

When you temporarily disable a breakpoint, its icon changes from  to  .

Alternatively, open the Breakpoints dialog box, as described on page [Accessing Breakpoint Properties](#) , select the desired breakpoint, and clear the checkbox next to it or the Line <line number> in <file name> checkbox in the right-hand pane.

## Enabling a temporarily disabled breakpoint in the editor

When you enable a temporarily disabled breakpoint, its icon changes from  to  .

1. Place the caret at the desired line with a breakpoint.
2. Do one of the following:
  - Right-click the desired breakpoint icon, select the Line <line number> in <file name> checkbox in the pop-up dialog box that opens, and then click Done .
  - With the  key pressed, click the breakpoint icon.

Alternatively, open the Breakpoints dialog box, as described on page [Accessing Breakpoint Properties](#) , select the desired breakpoint, and select the checkbox next to it or the Line <line number> in <file name> checkbox in the right-hand pane.

## Removing a breakpoint

- [Open the Breakpoints dialog box](#) , select the desired breakpoint, and click  .
- Click the breakpoint icon in the left gutter of the editor.

## Removing all breakpoints of a certain type

1. On the main menu, choose Run | View Breakpoints , or press  .
2. In the [Breakpoints](#) dialog, press the left arrow key to select the desired category.
3. Press  .  
All breakpoints of a certain type will be deleted.

To move a breakpoint, drag-and-drop it to the target line.

**Note** Field/Method breakpoint can be dragged to another field/method declaration only.

On this page:

- [Introduction](#)
- [Editing breakpoint description](#)
- [Searching for a breakpoint using its name](#)

## Introduction

IntelliJ IDEA makes it possible to add a name or a short description to a breakpoint to facilitate search.

## Editing breakpoint description

1. [Open the Breakpoints dialog](#).
2. Right-click a breakpoint you are interested in.
3. On the context menu, choose Edit description.
4. In the Edit Description dialog box, type the desired description.

The specified description shows in italic next to the address of a breakpoint in the [Breakpoints](#) dialog:

## Searching for a breakpoint using its name

1. [Open the Breakpoints dialog](#).
2. Start typing the name (description) of the desired breakpoint.

The breakpoint with the matching description gets the focus.

To jump from the Breakpoints dialog to the breakpoint source code, follow these steps:

1. Open the Breakpoints dialog by pressing `Ctrl+Shift+F8`.
2. To open the file with the selected breakpoint for editing, press `F4`.

On this page:

- [Introduction](#)
- [Creating groups of breakpoints](#)
- [Moving breakpoints to another group, or out of a group](#)
- [Toggling a group of breakpoints](#)

## Introduction

IntelliJ IDEA makes it possible to organize breakpoints in groups, for example, to mark out breakpoints for a specific problem. This is done in the [Breakpoints dialog](#) .

## Creating groups of breakpoints

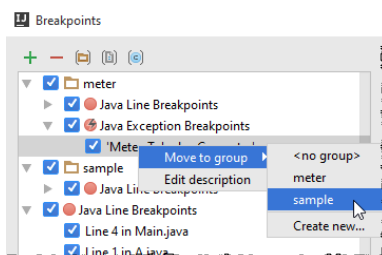

1. In the [Breakpoints dialog](#) , right-click one or more breakpoints you are interested in.
2. On the context menu, point to the command `Move to group` , and then on the submenu, choose `Create new...` :

3. In the New Group dialog box, type the name of the new group. The selected breakpoint moves to the newly created group.
4. Optionally, you can right-click a group of breakpoints and select `Set as default` from the popup menu. All newly created breakpoints will be automatically added to this group.

## Moving breakpoints to another group, or out of a group

1. In the [Breakpoints dialog](#) , right-click one or more breakpoints you are interested in.
2. On the context menu, point to the command `Move to group` , and then on the submenu, choose the desired group name:

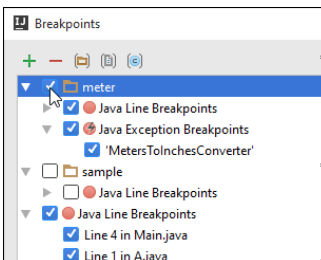

The breakpoints in question move to the selected group.

1. In the [Breakpoints dialog](#) , right-click one or more breakpoints within a group.
2. On the context menu, point to the command `Move to group` , and then on the submenu, choose `<no group>` .
3. The selected breakpoints move to a node according to their [type](#) .

## Toggling a group of breakpoints

Using groups of breakpoints, it is possible to toggle all breakpoints within a group in a single click.

- Select or clear the checkbox to the left of a group name:

## Introduction

IntelliJ IDEA supports debugging for Java and Groovy applications, classes, and files. The debugging functionality is incorporated in IntelliJ IDEA, you only need to configure its settings.

Depending on the plugins enabled, IntelliJ IDEA can also support debugging for other languages, for example, JavaScript, Flex or PHP.

IntelliJ IDEA supports debugging applications running on the built-in or an external web server. Debugging can be performed only using [Google Chrome](#) and other browsers of the **Chrome** family.

## Configuring debugger settings

### To configure settings required for debugging, perform the following general steps

1. In the Project Structure dialog ( `Ctrl+Shift+Alt+S` ), configure the roots, dependencies and libraries to be passed to the compiler.
2. In the Settings/Preferences dialog box, configure the debugger options:
  - Under the Build, Execution and Deployment section, click [Debugger](#), and configure the debugger options.
  - Under the Build, Execution and Deployment section, point to [Compiler](#) node, click [Java Compiler](#), or [RMI Compiler](#), and select the checkbox Generate debugging info.

On this page:

- [Before debugging](#)
- [Debugging an application](#)

## Before debugging

- [Configure debugger options](#) .
- [Specify the roots, dependencies and libraries to be passed to the Debugger](#) .
- [Set breakpoints](#) in the source code.
- If necessary, create or modify the corresponding [Run/Debug configuration](#) .

The debug session starts with the selected run/debug configuration. Note that several debug processes can be launched simultaneously.

When debugging an application in IntelliJ IDEA, keep in mind that

- If the Make module before running/debugging/reloading option has been selected, IntelliJ IDEA first compiles all modified sources in your project.
- IntelliJ IDEA proceeds with debugging, if compilation reports no errors.
- If the code has not been compiled before debugging, the source and class files might be out of sync.
- If you specify the `-classpath` option in the VM Options field, the selected module classpath will be overridden.
- If you debug a JavaScript source, IntelliJ IDEA opens a browser for the HTML file with your script in a separate frame.

## Debugging an application

### To start debugging an application, do one of the following

- Select the run/debug configuration to execute, and then do one of the following:
  - Click  icon in the left gutter, and then choose .
  - Click  on the toolbar.
  - Choose Run | Debug on the main menu.
  - Press `Shift+F9` .
- Press `Shift+Alt+F9` , select the configuration from the pop-up menu, and press `Enter` .

Note that after you've launched a debug session, the  icon that marks the [Debug Tool Window](#) toggles to  to indicate that the debugging process is active.

On this page:

- [Introduction](#)
- [Pausing the debugger session](#)
- [Resuming the debugger session](#)

## Introduction

When a breakpoint is hit, or when a running thread or an application is paused manually, the debugging session is suspended.

## Pausing the debugger session

Do any of the following:

- On the main menu, choose Run | Pause Program .
- Click  on the Debug toolbar.  
Note that the button is not available for [Run/Debug Configuration: Node.js](#) , [Run/Debug Configuration: Attach to Node.js/Chrome](#) , and [Run/Debug Configuration: NUnit](#) .

## Resuming the debugger session

Do any of the following:

- On the main menu, choose Run | Resume Program .
- Click  on the Debug toolbar.
- Press  .

On this page:

- [Introduction](#)
- [Reloading changed classes](#)
- [Configuring reloading behavior](#)

## Introduction

You can reload classes changed during debugging without need to restart the entire application using the HotSwap mechanism.

At the moment due to original limitations of Java SDK the HotSwapping is possible ONLY if a method body is altered. In all other cases (like changing method or class signature), the class reload is impossible and the corresponding error message appears.

## Reloading changed classes

### To reload changed classes

1. Do one of the following:
  - On the main menu, choose Run | Reload Changed Classes .
  - On the main menu, choose Build | Compile "class\_name" to recompile an altered class during debug.
2. In the Reload Changed Classes dialog box, confirm reloading. Results are displayed in the [Messages tool window](#) .

## Configuring reloading behavior

### To configure reloading behavior

1. On the main menu, choose File | Settings , and under Build, Execution, Deployment expand the Debugger node.
2. Open [HotSwap](#) page.
3. Click one of the radio buttons in the group Reload classes after compilation . You can opt to always reload classes, reload after confirmation, or never do it.

On this page:

- [Basics](#)
- [Examining a suspended thread](#)
- [Navigating between frames](#)
- [Exporting threads](#)

## Basics

When a breakpoint is hit, or a program execution is manually [suspended](#), you can [examine](#) your application by analyzing frames.

A frame corresponds to an active method or function call. A frame stores the local variables of the called method or function, the arguments to it, and the code context that enables expression evaluation.

All currently active frames are displayed on the Frames pane of the [Debug](#) tool window, where you can [switch](#) between them and analyze the information stored therein.

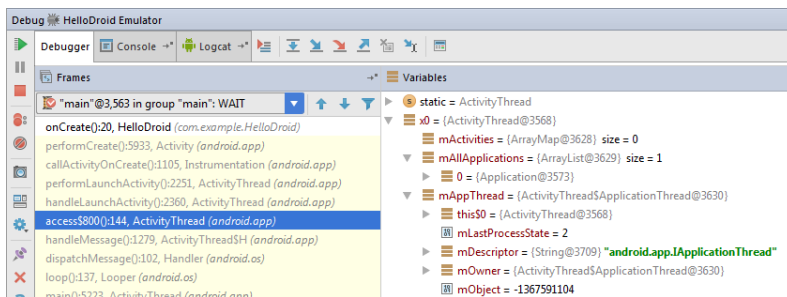

## Examining a suspended thread

### To examine frames of a suspended thread

1. Select a thread from the thread selector drop-down list on top of the Frames pane. The list of frames is displayed:

2. Select a frame from the Frames list. The Variables pane shows all the variables available to the method call in this frame, so you can further explore them.

## Navigating between frames

Do one of the following:

- Use up and down arrow buttons on the toolbar.
- Use [Up](#) and [Down](#) shortcuts.

You do not need to perform any actions to navigate to the frame's source code. IntelliJ IDEA automatically jumps to the source code of the selected frame in the editor.

## Exporting threads

If you need to get a report on the status of all the threads, you can export threads information.

### To export threads

1. Right-click anywhere in the Frames tab and select [Export Threads](#) from the context menu, or select [Run | Export Threads](#) from the main menu.
2. To save a report as a text file, specify the path to the file in the [Export Threads](#) dialog and click [Save](#).
3. To copy it to the Clipboard, click [Copy](#).

When a frame is selected in the list, all the values available to this frame's method call are displayed in the Variables pane of the Debug tool window, so you can further explore them. This section describes the ways to simplify examining these values:

- [Evaluating Expressions](#)
- [Adding, Editing and Removing Watches](#)
- [Inspecting Watched Items](#)
- [Setting Labels to Variables, Objects and Watches](#)
- [Navigating to Source Code from the Debug Tool Window](#)

On this page:

- [Basics](#)
- [Limitations](#)
- [Evaluating expressions or code fragments in a stack frame](#)
- [Evaluating arbitrary expressions](#)
- [Evaluating expressions in the editor](#)

## Basics

IntelliJ IDEA enables you to evaluate expressions and code fragments in the context of a stack frame currently selected in the [Frames pane](#) of the [Debug tool window](#).

In addition to regular expressions, you can also evaluate operator expressions, lambda expressions, and anonymous classes.

The following evaluation modes are available:

- **Expression Mode** for evaluating single-line expressions.
- **Code Fragment Mode** for evaluating short code portions. You can evaluate declarations, assignments, loops and `if/else`.

Besides, IntelliJ IDEA provides a way to [quickly evaluate](#) an expression at caret or a selection in the editor.

## Limitations

While using the Expression Evaluation feature, be aware of the following:

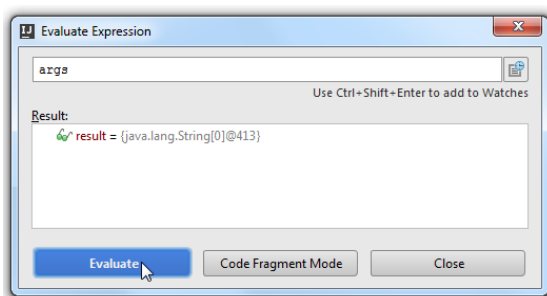

- A method can be invoked within the Expression Evaluation dialog only if the debugger has stopped at a breakpoint, but has not been paused.
- Expression Evaluation can only be "single-level". In other words, if IntelliJ IDEA stops at a breakpoint within a method called from the Expression Evaluation, you cannot use the Expression Evaluation feature again.
- If a method invoked within Expression Evaluation has a breakpoint inside its body, this breakpoint will be ignored.

**Tip** Note that in certain operating systems the key and mouse combinations may not work as described here. In this case, it's necessary to tweak the operating system's keymap. For example, if you are using Ubuntu, mind the windows manager, whose [shortcuts conflict](#) with that of IntelliJ IDEA.

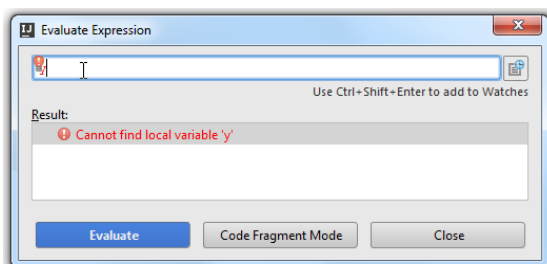

## Evaluating expressions or code fragments in a stack frame

To evaluate an expression or a code fragment in a stack frame, do the following:

1. In the [Frames](#) pane, select the thread where you want an expression to be evaluated.
2. Invoke the [Evaluate Expression](#) command in one of the following ways:
  - On the main menu, choose Run | Evaluate Expression
  - On the context menu of the editor, choose Evaluate Expression
  - Press `Alt+F8`
  - Click  on the [Stepping toolbar](#) in the [Debug tool window](#).
3. Select an evaluation mode. If you want to evaluate a code fragment, click the Code Fragment Mode button.
4. Depending on the selected mode, type the expression or statements to evaluate in the text field and click Evaluate.

If the specified expression cannot be evaluated, the possible reason is briefly described in the Result pane of the dialog box.

**Tip** If you have [assigned a label](#) to a variable, object, or watch, you can reference it by this label as if it were a local variable `<label-name>_DebugLabel1` defined in the same context where the expression is evaluated. IntelliJ IDEA also displays this label in the completion suggestion list.

## Evaluating arbitrary expressions

1. Open the **Evaluate Expression** dialog box in one of the following ways:

- Choose **Run | Evaluate Expression** on the main menu.
- Press **Alt+F8**.
- To evaluate a specific variable, select it on the **Variables pane** of the **Debug tool window**, then choose **Run | Evaluate Expression** or press **Alt+F8**.

2. In the Evaluate Expression dialog box, specify the expression you want to evaluate. Do one of the following:

- In the Expression field, type the expression in question or choose one of the previously evaluated expressions from the drop-down list.  
If you have selected a specific variable on the Variables pane, this variable will be displayed in the Expression text box.
- To evaluate a code fragment, click the Code Fragment Mode button and fill in the Code Fragment text box.  
To return to the original mode, click the Expression mode button.

3. Click the Evaluate button. The Result read-only field shows the evaluation output. If the specified expression cannot be evaluated, the Result field explains the reason.

## Evaluating expressions in the editor

During a debugger session, the value of any expression is shown in the tooltip every time you hover your mouse pointer over it. If an expression contains children, clicking **+** expands the node and displays all children.

You can also use the Quick Evaluate expression functionality that lets you view the value of an expression using the keyboard only.

There are two ways to evaluate an expression quickly:

1. By using the Show value tooltip on code selection functionality:

- In the **Debugger | Data Views** settings page, enable the Show value tooltip on code selection option.
- Select a code fragment with the mouse, or by pressing **Ctrl+W**. A tooltip with the expression value automatically appears under the selection and changes each time you change the selection.

2. By manually invoking the tooltip with the expression value:

- Place the caret at the desired location, or select an expression to be evaluated.
- Choose **Run | Quick Evaluate Expression** on the main menu, or press **Ctrl+Alt+F8**. The tooltip with the expression value appears under the selected expression.

On this page:

- [Introduction](#)
- [Accessing the Watches pane](#)
- [Creating watches](#)
- [Editing watches](#)
- [Deleting watches](#)

## Introduction

If you want to evaluate a number of variables or expressions in the context of the current frame, and view all of them simultaneously, you can create **watches** for them. The values of the expressions are updated with each step through the application, but are only visible when the application is suspended. Unlike the [Expression Evaluation feature](#), these expressions are persisted as the part of your project.

This section describes how to add items to watches, change and remove watches.

## Accessing the Watches pane

By default, the Watches pane is hidden and the watches are shown in the [Variables pane](#).

- To have the Watches pane displayed separately and view the configured watches in it, release the Show watches in Variables tab toggle button  on the toolbar of the Variables pane. By default, the button is pressed.
- To hide the Watches pane and view the watches in the Variables pane, press the  toggle-button on the toolbar of the Watches pane.

## Creating watches

Do one of the following:

- In the [Watches](#) pane, click , or just press `Insert`.
- On the [Variables](#) pane, in the Inspection window, or in the [Evaluate Expression](#) dialog box, right-click the desired item and choose Add to Watches on the context menu.
- Select the desired item in the Variables pane and drag it to the Watches pane.
- Select item in the editor, right-click it and select Add to Watches on the context menu.

**Tip** You can navigate from a backtrace in the Watches pane to the respective line of the source code. To do that, right-click a line of backtrace, and choose Jump to Source on the context menu, or just press `F4`.

## Editing watches

To change the expression represented by a watch, right-click the desired watch and select Edit on the context menu.

## Deleting watches

- In the Watches pane, select a watch to be deleted.
- On the context menu, choose Remove Watch, or press `Alt+Delete`.

On this page:

- [Introduction](#)
- [Accessing the Watches pane](#)
- [Inspecting references](#)

## Introduction

IntelliJ IDEA helps inspect any variables or watches item in its own window. For example, if you need to examine several references in detail, you can open an inspection window for each of them. So doing, a separate window is created for each variable or watch reference and all of its child references.

The inspection windows are non-modal, and you can launch as many as of them required. All changes of the references are immediately reflected in the corresponding inspection windows.

## Accessing the Watches pane

By default, the Watches pane is hidden and the watches are shown in the [Variables pane](#).

- To have the Watches pane displayed separately and view the configured watches in it, release the Show watches in Variables tab toggle button  on the toolbar of the Variables pane. By default, the button is pressed.
- To hide the Watches pane and view the watches in the Variables pane, press the  toggle-button on the toolbar of the Watches pane.

## Inspecting references

1. Select the item to be inspected on the Variables or Watches pane.
2. On the context menu, choose Inspect .

On this page:

- [Introduction](#)
- [Settings and removing labels](#)

## Introduction

You can add your own label to a variable, object, or watch and then reference it as if it were a local variable `<label-name>_DebugLabel` defined in the same context where the expression is evaluated. IntelliJ IDEA also displays these labels in suggestion pop-up lists for code completion in the [Evaluate Expression](#) dialog box.

## Settings and removing labels

### To set a label

1. Select the desired watch in the list
2. Select Mark Object on the context menu or press `F11`. The Select object label dialog box opens.
3. Specify the label name.
4. Click the Browse button  to change the label color. Click OK when ready.

To remove a label, right-click the item and select Unmark Object on the context menu, or select the item in the list and press `F11`.

### **To navigate to the source code, do one of the following:**

- Select the desired item in the [Variables](#) tab and press `F4` .
- Right-click an item in the Variables tab, and select Jump to Source from the context menu.

### **To navigate to an object's source**

- Select an item in the Variables or Watches tab and press `Shift+F4` .
- Right-click an item in the Variables or Watches tab, and select Jump to Object Source from the context menu.

On this page:

- [Introduction](#)
- [Customizing Threads view](#)
- [Customizing Data view](#)
- [Custom type renderers](#)
  - [Rendering objects](#)
  - [Disabling custom type renderers](#)
  - [Switching between type renderers](#)

## Introduction

While exploring frames and their content, you might want to customize the way data is displayed. This section describes how to set such options.

## Customizing Threads view

You can organize the way threads are shown in the list according to your needs.

### To customize Threads view

1. Right-click anywhere in the Frames tab and choose Customize Threads View .
2. Specify viewing options. They are described in detail [here](#) .

## Customizing Data view

You can organize the way data is shown in the Variables tab according to your needs.

### To customize data view

1. Right-click anywhere in the Variables tab and select Customize Data Views .
2. Specify viewing options. They are described in detail [here](#) .

## Custom type renderers

You can also specify your own type renderers instead of the default ones. They provide you the ability to customize how objects are displayed in the debugger, offering "logic-oriented" presentation of data vs. structure-oriented as it is by default.

## Rendering objects

### To render objects view

1. Open the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Debugger and select Type Renderers .
2. Click **+** to create a new renderer.
3. Specify the renderer name, the object class to which it applies, and which expressions to use while rendering.  
For details on rendering options refer to [options description](#) .
4. Define the appearance of the expanded node.
5. Click OK .

## Disabling custom type renderers

### To disable custom type renderer

1. Open the Settings dialog ( `Ctrl+Alt+S` ), click Debugger and select Type Renderers .
2. Select the type renderer to be disabled in the list and clear the checkbox next to its name in the list.  
Even if the type renderer is disabled, you can temporary switch to it while stepping through the program using the View as option.
3. Click OK .

## Switching between type renderers

While stepping through the application in the Debug tool window, you can temporary switch between renderer schemes.

### To switch between type renderers

1. Right-click the object instance in the Variables or Watches tab of the Debug tool window.
2. In the context menu, click View as , and then select the renderer from the list of the applicable type renderers.

When a program is suspended, the source file, associated with the current execution point, is opened in the editor. The current execution point (the next line to be executed) is marked with a blue line.

You can visit the other files, and then return to the current execution point using the actions described in this section.

### **To find the current execution point, do one of the following**

- On the main menu, choose Run | Show Execution Point .
- Press `Alt+F10` .
- Click  on the [stepping toolbar](#) of the Debug tool window.

In this section:

- Stepping Through the Program
  - [Introduction](#)
  - [Stepping through the program](#)
  - [Tips and tricks](#)
- [Choosing a Method to Step Into](#)
- [Improving Stepping Speed](#)

## Introduction

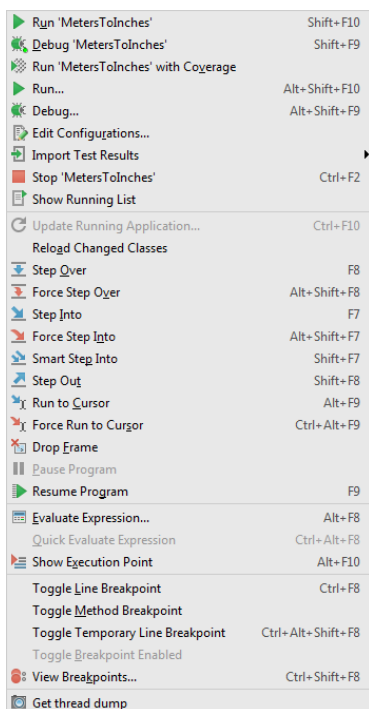

When a breakpoint is reached or your program is [suspended](#) , the [Debug](#) tool window becomes active and enables you to get control over the program's execution. For this purpose, you can use the Run menu commands, or the icons on the [stepping toolbar](#) of in the Debug tool window.

Each stepping action advances the [execution point](#) to the next execution location, depending on the action you choose.

## Stepping through the program

Do one of the following:

- On the main Run menu, or on the editor's context menu, choose one of the <stepping command>

- Use the [keyboard shortcuts](#) .
- Use the buttons in the [stepping toolbar](#) of the Debug tool window.

## Tips and tricks

- The Force Step Into command  enables you to step into a method of a class not to be stepped into , for example, a standard Java SDK class .

The classes, stepping into which is suppressed, are specified on the [Stepping](#) page of the [Settings/Preferences](#) dialog box.

- The Force Step Over command  enables you to jump over the method call ignoring the breakpoints on the way.
- The Force Run to Cursor command  enables you to jump to the cursor position ignoring existing breakpoints on the way.

When you reach a line with calls of several methods, you can choose the method you want to step into.

**Tip** If you choose a method of a class stepping into which is suppressed on the [Stepping](#) page of the [Settings](#) dialog box, the suppression is overridden as when you invoke the Force Step Into command.

## To choose a method to step into

1. On the main menu, choose Run | Smart Step Into or press `Shift+F7`.
2. In the pop-up window, choose the desired method from the list.

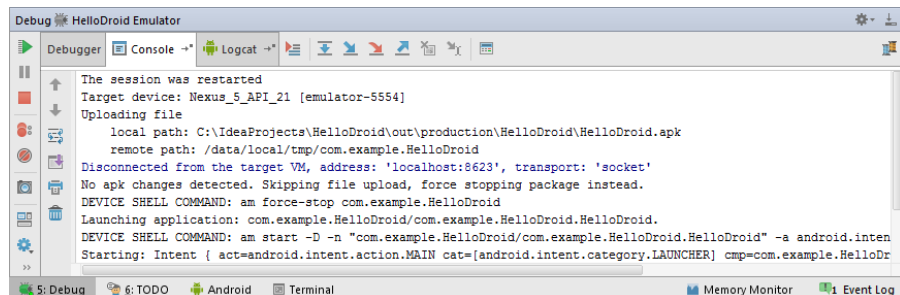

## To improve stepping speed, follow these recommendations

- Try avoiding method and field breakpoints.
- If the Watch method return values option is enabled in Debug Toolbar | Settings , disable it.
- Turn off Alternate view for Collections classes by clearing the Enable alternative view for Collections classes checkbox at the [Data Views](#) page of the [Debugger](#) settings.
- Turn off the 'ToString' mode on the IDE level by clearing the Enable 'toString' object view checkbox on the [Data Views](#) page of the [Debugger](#) settings.
- Simplify the conditions for breakpoints and watchpoints, especially the frequently hit ones.
- Use filters (e.g., for class instances).
- During the debugging session, switch to a view with fewer elements.

The information on a debugging session is displayed in the dedicated tabs of the **Debug** tool window named after the selected run/debug configuration.

For each session, use the **Console** tab to view the debugger messages and application output, and the **Debug** tab to monitor threads and frames.

When displaying and modifying local variables or watches values, IntelliJ IDEA uses the **Default Encoding** setting for the current project or the **IDE encoding** if no encoding is specified at the project level. The same setting is used when showing the PHP console script output.

## Monitor debugger overhead

The debug process is part of the runtime and, therefore, may impact performance. Every evaluation of an expression, or stepping over the code use the same memory as the debugged application, and may cause large overhead.

IntelliJ IDEA lets you view this overhead so that you can quickly detect what causes it and reduce it by removing unnecessary breakpoints, disabling automatic evaluation of expressions, turning off async stacktraces, etc.

To invoke the Overhead pane, click the  icon in the top-right corner of the Debug tool window:

Name	Hits	Time (ms)
<input checked="" type="checkbox"/> Show Method Return Values	258	23.000
<input checked="" type="checkbox"/> Capture point at java.lang.Thread.start	203	20.000
<input checked="" type="checkbox"/> Line 15 in FutureTest (my)	162	18.500
<input checked="" type="checkbox"/> Capture point at java.util.concurrent.CompletableFuture.supplyAsync	37	9.000
<input checked="" type="checkbox"/> Capture point at java.util.concurrent.CompletableFuture.thenRunAsync	1	1
<input checked="" type="checkbox"/> myFutureTest.main	1	1
<input checked="" type="checkbox"/> Line 19 in FutureTest (my)	1	1
<input checked="" type="checkbox"/> Capture point at java.util.concurrent.CompletableFuture.thenAcceptAsync	1	0
<input checked="" type="checkbox"/> Capture point at java.util.concurrent.CompletableFuture.runAsync	1	0
<input checked="" type="checkbox"/> toString renderer	2	0

On this page:

- [Basics](#)
- [Enabling inline debugging](#)
- [Viewing inline debugging results](#)

## Basics

The **inline debugging** functionality facilitates the debugging procedure, as it lets you view the value of variables used in your source code right next to their usage, without having to switch to the [Variables pane](#) of the [Debug tool window](#).

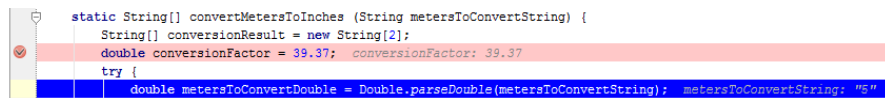

## Enabling inline debugging

To enable the **inline debugging** functionality, do one of the following:

- In the [Debug tool window](#) toolbar, click the Settings icon  and select the Show Values Inline option from the popup menu.
- Open the [Data Views](#) page of Setting/Preferences dialog, and select the checkbox Show values inline.

## Viewing inline debugging results

If this option is enabled, when you launch a debug session and **step** through the program, the values of variables are displayed at the end of the lines where these variables are used.

```
static String[] convertMetersToInches (String metersToConvertString) {
    String[] conversionResult = new String[2];
    double conversionFactor = 39.37; conversionFactor: 39.37
    try {
        double metersToConvertDouble = Double.parseDouble(metersToConvertString); metersToConvertString: "5"
    } catch (Exception e) {}
}
```

On this page:

- [Introduction](#)
- [Attaching to local process](#)

## Introduction

**Attach to local process** feature allows you to debug a project which you are developing in IntelliJ IDEA, but (for some reasons) are not able to launch directly from your IDE.

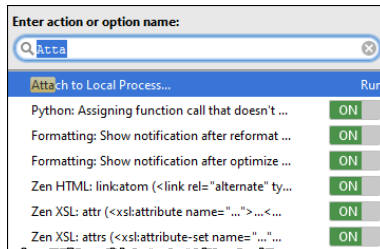

## Attaching to local process

### To attach to a local process, follow these general steps:

1. Launch the process intended for debugging. You can do it from operating system or using the IntelliJ IDEA terminal.
2. To find the process to attach to, do one of the following:
  - On the main menu, choose Run | Attach to Local Process :

- On the main menu, choose Help | Find Action or press `Ctrl+Shift+A` . In the list of actions that appears, find the desired action by typing the first letters, and select it:

3. From the list of available processes that appears, select the desired process. Simplify your search by typing the first letters of its name or PID

4. Proceed with [debugging](#) the same way as you usually do it in IntelliJ IDEA ([set breakpoints](#) , [step through](#) , [pause and resume](#) the process, [evaluate expressions](#) etc.)
5. When finished, detach the process: select the Run | Stop or click the Stop the process button  of the [Debug Tool Window](#) .

## Overview

Debugging is one of the most powerful tools in any developer's arsenal. It gives us a unique insight into how a program runs and allows us to gain a much deeper understanding of the piece of code we debug. It allows us to trace running code and inspect the state and the flow of the execution. As part of that, it gives us the illusion of a sequential flow. This is very intuitive and powerful but also may be misleading as most modern applications are multithreaded.

"Debugging" suggests we deal with bugs but this is actually a misnomer. The information we get from debugging is useful even when there is no problem with the code. Finding bugs just happens to be a very common use case for the knowledge we can get from a debug session.

The IntelliJ IDEA debugger offers a rich experience that helps us to easily debug anything from the simplest code to complex multithreaded applications.

Before we start, a word of caution: debugging is a very powerful tool but it does come with a cost. The debug process is part of the runtime and therefore affects it. Every evaluation of an expression happens using the same memory of the debugged application, and can modify and potentially corrupt the state. During this tutorial, bear in mind that debugging is an intrusive approach that may affect the outcome of the debugged application. We will explore a few ways to minimize its impact and sometimes even exploit it. The timing of execution is also very different when you debug code compared to running it. The minimal debug tracking overhead in itself may already be enough to change the timing of events and therefore the application behaviour. Every [breakpoint](#) or log is a possible synchronization point, and stepping obviously changes the timings significantly. As we are about to see, this becomes a critical issue in multithreaded environments, when sometimes reproducing a bug depends on a very specific sequence of events.

Last point to remember is that debugging is not a substitute for understanding the code. In fact, the only way to learn from a debug session is to constantly compare the information the debugger shows us with our expectations from the code and how we think it "should" behave. Before starting a debugging session we must have some knowledge of what we're trying to achieve by it. If we're looking for a bug, we need to roughly know what is incorrect, i.e. what is different from the expected behaviour or state. In most cases we will also have some initial assumption as to why things are wrong. This will dictate how our debugging session should be conducted. When we debug, we must always compare that information with our expectations, and pay close attention when the code deviates from these expectations.

This is the point where debugging is so effective.

This is the point where we learn.

In this tutorial we try to dive deeper into debugging techniques and assume you are already familiar with the basic concepts such as:

- [Line breakpoints](#) to suspend the JVM or thread.
- [Stepping](#) .
- [Classes configured to be skipped](#) .
- [Force to step into](#) "skipped code".
- [Evaluating Expressions](#)
- Using a [watch](#)
- Defining a [type renderer](#)

## Debugging code that was compiled without the debug flag

Code that was compiled without the debug flag cannot be debugged. There is no way to step into this code. When the debugger encounters such code during a debugging session, it will step over that part of code.

Line breakpoints are also not possible to define and hit. However, this is where the [Method Breakpoint](#) might save us, as we can still define in IntelliJ IDEA a breakpoint to stop before entry or exit from a specific method, even if the method itself was compiled without the debug flag.

When viewing the state, since the actual variables within the method cannot be inspected, we will see a warning message instead.

## Debugging without source code

If we don't have the source to specific code, IntelliJ IDEA will still decompile the class and show our steps in the decompiled source. This is very helpful, but note that the generated decompiled class may look different from the original, and if the lines do not match, debugging in decompiled code may be confusing. Always try to obtain the source code of the classes you want to step into.

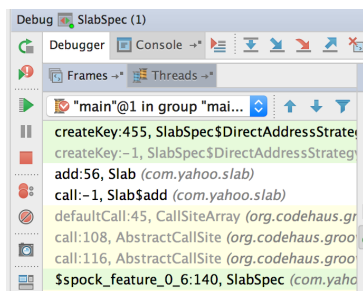

## Detecting unexpected state or flow

This section covers what to do if we know where things have already gone wrong, but don't know why.

## Exploring the call frames

A Line Breakpoint should be enough for most cases of detecting the cause behind an unexpected call or call with

unexpected parameter values to a method. If we're not sure where it's being called from, we can put the breakpoint inside the method. When the VM is suspended, click on the previous [call frames](#) to view the call stack and inspect the state in each scope to see how we got here.

## Drop frames

If we stepped too far and want to go back up the stack to then re-execute the code, we can use the [Drop Frame](#) feature. It's a useful feature, but also potentially dangerous: we must be aware that re-executing the code will execute the same instructions twice, and if those instructions modify state we might end up in a corrupted state, and certainly in a scenario that would not happen in a normal run under the same conditions. To make the impact of Drop Frame obvious, consider this simple program:

```
public class DropFrameDemo
{
    private static int state = 0;

    public static void main(final String[] args)
    {
        modifyStateBasedOnParameter(state);
        modifyStateBasedOnStaticField();
    }

    // dropping frame within this method,
    // and executing again will print state = 2
    private static void modifyStateBasedOnStaticField()
    {
        state++;
        System.out.println("state = " + state);
    }

    // dropping frame from within this method,
    // and executing again will print state = 1
    private static void modifyStateBasedOnParameter(final int parameter)
    {
        state = parameter + 1;
        System.out.println("state = " + state);
    }
}
```

Breaking inside `modifyStateBasedOnParameter()` will not impact the state because IntelliJ IDEA remembers the parameter values passed in to that frame and will not recalculate those. However, breaking inside `modifyStateBasedOnStaticField()` will make the `state` field equal '2'. A value which is impossible under a normal run of `main()`.

## Detecting unexpected flow by method

**Note** In older versions of IntelliJ IDEA a method breakpoint significantly slows down the execution.

Since version 2017.1 the method breakpoint is actually emulated by line breakpoints and so is just as fast.

An alternative to having a line breakpoint defined within the problematic method is to define a [Method Breakpoint](#). This type of breakpoint is not attached to a source code line number, but to the entry and exit of a call to a method. It is especially useful in two main cases:

- When a method is defined by an interface and we want to breakpoint in **all** implementations of it.
- When we don't have the source code, only a decompiled version, and we still want to inspect the ins and outs of a method call, without any confusing differences in line numbers between the compiled class and the decompiled source code.

## Detecting unexpected object state

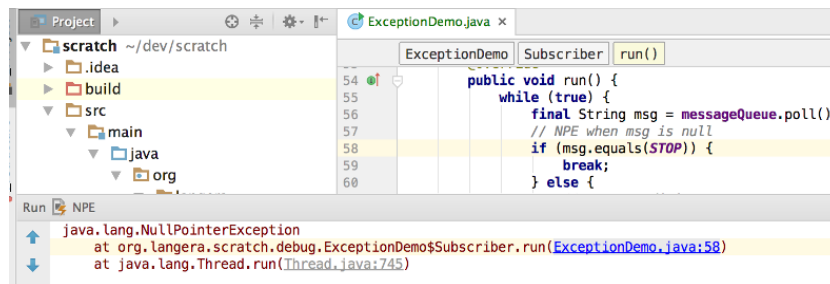

**Note** A field watchpoint is a type of breakpoint that slows down execution significantly and should be used with care, especially in multithreaded applications where a change in timing can affect the scenario.

Sometimes its hard to figure out the exact flow that caused a field to get to some unexpected state. In those special cases

we can use a breakpoint that will be hit anytime the program either read from or write to a specific field. see [Field Watchpoint](#).

## Detecting unexpected exception thrown

Although not strictly a debugging feature, when we want to investigate why an exception was thrown, we can [analyse the exception stack trace](#) and quickly get to the line of code that generated that exception. From there the combination of Line Breakpoint and Stepping is usually enough to figure out what is wrong.

Sometimes however, the exception is wrapped in another exception or caught and swallowed by the catch block. All we see are its side effects (perhaps a log) but not its stack trace. For that we can use an [Exception Breakpoint](#).

## Debugging Asynchronous flow

Reactive programming is increasingly popular and with the help of many frameworks and libraries out there, developers are writing a lot more asynchronous code.

The flow in an asynchronous application is a major challenge for debugging tools and the developers who use them. The execution jumps between frames and makes it harder to understand and follow the code.

Stepping forward is the easier bit. We can insert breakpoints at different points in the code and regardless of the executing thread, see the progress from one code snippet to the next.

When doing that, pay attention to whether a breakpoint suspends just a thread or the entire application. The decision is based on the goal of the debugging session. If you want to check the state of all threads and see what thread has progressed and what thread might be unnecessarily waiting, you can freeze the entire system at this point and view call frames and stack traces of all threads.

If you're debugging a specific action, you can suspend just one thread and let the rest of the system keep working.

## Async Stacktraces

The real pain with asynchronous debugging starts when we want to look back from a specific point in the code and understand how we got here. Consider the example of asynchronous code below (using JDK's `CompletableFutures`):

```
private void asyncExample() throws InterruptedException, ExecutionException
{
    final CompletableFuture<String> future = supplyAsync(() -> "F").thenApplyAsync(this::append_oo);
    System.out.println(future.get());
}

private String append_oo(String str)
{
    return str + "oo";
}
```

When we stop inside the method `append_oo` we can see that the stack trace gives us very little information.

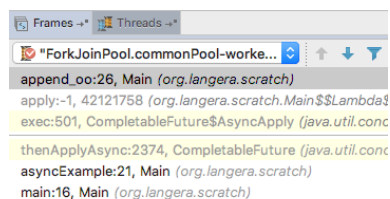

Specifically, we can't see the future applied above it nor can we see the `asyncExample` method that for us started it all.

In an asynchronous context, stack traces will only show us a very limited picture and what we really need is the flow of information between the threads or the combined stack traces of all threads that got us to this point (also known as the causality chain).

IntelliJ IDEA provides a way to view those Async stacktraces .

While in a debugging session, IntelliJ IDEA will capture stacktraces and will show them later when viewing the stacktrace of the next part of the asynchronous flow:

Or even clearer when we filter the external libraries:

The stacktraces to capture and the point to insert them needs to be configured in the debugger preferences under [Async Stacktraces](#).

IntelliJ IDEA needs to know the class name and the method to appear at the top of the stack trace which we need to capture. In our example `java.util.concurrent.CompletableFuture.thenApplyAsync`. The debugger also needs to know the position in the other stack trace where we want to insert the captured stack trace. In our example it is `java.util.concurrent.CompletableFuture$AsyncApply.exec`.

In order to match the two stack traces we also needs two keys - one for each context which will point to the same value when one stack trace is indeed the next logical step in our async chain. In our example the key expression we can use is `param_0` (parameter 0 - the method reference we pass into `thenApplyAsync`). It will be matched with `fn` - the variable inside `java.util.concurrent.CompletableFuture$AsyncApply` that holds the function in the second call frame.

**Build, Execution, Deployment > Debugger > Async Stacktraces**

	Capture class name	Capture metho...	Capture k...	Insert class name	Insert...	Insert...
<input checked="" type="checkbox"/>	java.util.concurrent.CompletableF...	supplyAsync	param_0	java.util.concurrent.CompletableFuture\$AsyncS...	run	f
<input checked="" type="checkbox"/>	javax.swing.SwingUtilities	invokeLater	param_0	java.awt.event.InvocationEvent	dis...	run...
<input checked="" type="checkbox"/>	java.util.concurrent.CompletableF...	thenApplyA...	param_0	java.util.concurrent.CompletableFuture\$AsyncA...	exec	fn

This should be [configured in the debugger settings](#) once and configuration for common async frameworks such as `CompletableFuture` used here will be provided.

## Debugging multithreaded applications

Multithreaded applications are the biggest challenge to debug. These applications are not deterministic and much harder to control. The illusion of a sequential flow we get from stepping in a debug session does not help either and can be misleading.

When investigating issues that can be concurrency bugs, we need to try to step less and fine-tune our breakpoints more. This is because a lot of the concurrency bugs depend on a specific interaction between different threads, and an intrusive debugging session will interfere with that. We'll show how using various [Breakpoint properties](#) allows us to limit the interference to a minimum. The other important topic is controlling and [switching between different threads](#) in the application. We'll go through some examples of debugging different concurrency bugs to demonstrate how IntelliJ IDEA's features help with this.

**Tip** Always name your threads in multithreaded applications according to their function. It simplifies both logging and debugging.

## Controlling a breakpoint

IntelliJ IDEA [debugger properties](#) allow us to control the actions taken when a breakpoint is triggered. Some of them define an action, and others are there to add further conditions on whether to take the action at all. This fine level of control of the breakpoints is critical for concurrency bugs, because most will only be reproduced when threads interact in a very specific way. Any interference of the breakpoints may prevent us from reproducing the bug.

## Breakpoint actions

Deciding on the breakpoint action depends on what we want to achieve in the debugging session.

If we can define the condition or point in the code where we can get more insight from viewing the entire system state, we should [suspend the entire VM](#).

Sometimes, [suspending only one thread](#) and not the whole VM is preferable. This is especially true when the application is part of a larger system and suspending the VM will cause either an overflow of messages waiting to be served, or request timeouts that end up breaking the entire system. When we have many worker threads, it is better to keep almost all working and focus on just one thread which is interesting to us.

When we deal with a concurrency bug, any suspension of execution may prevent us from reproducing the bug. We can opt to make the breakpoint not suspend anything, just [log](#) either a message or a value of a particular expression to the console, then inspect the log. This works well when we have a strong theory about what exactly are we looking for.

## Restrict breakpoint with conditions

Apart from being convenient, breakpoint conditions let us minimize the intrusive nature of the debugging session. They allow us to limit the breakpoint actions to only what we see as absolutely essential.

**Note** The conditions themselves have an overhead and are being evaluated every time the breakpoint is hit.

[Conditional expressions](#) are the most widely used condition. They allow us to trigger the breakpoint only when our application reaches a specific state. Ideal if we can define an expression that captures the exact point when things start to go wrong.

[Pass count](#) is useful in code that is being run many times, either an event handler or a loop and the interesting scenario we're after only manifests itself after a specific number of passes.

We use this when the code is being hit many times but only the first case is interesting. The [Remove Once Hit](#) option is especially useful in two scenarios:

- When the breakpoint action is to log rather than suspend, which means we don't have the ability to remove or disable the breakpoint after it was hit.
- When the code is executed by many threads and we only want to suspend one of them.

A very useful feature. Its obvious use is as a filter to triggering a breakpoint in a scenario where we're interested in a visit to a method, or a specific state in the code only after another state was reached. But as well as that, we can use it to reproduce a particular concurrency issue, as it can help us suspend threads and control which thread reaches which particular line in the code and in which order.

**Tip** Instance filtering uses instance ID, and therefore needs to be set when the application is already running.

Allows us to [filter](#) triggering by class or specific instance.

## Debugging long running scenarios

[Method Breakpoint](#) and [Field Watchpoint](#) slow down code execution considerably. When executing the same code a huge number of times, even [conditional breakpoints](#) slow down the processing enough for it to be noticeable. This is a real issue because the scenario of an event handler processing millions of events is fairly common (think of replaying a journal file or processing huge production log files) and evaluating a breakpoint condition inside that event handling code can slow down the system to an unusable state. To overcome that, assuming we can modify running code, we can improve the speed by employing a little trick we shall call "breakpoint in code". This trick is very useful when we debug processing of millions of events where only one causes a problem and we have no idea in advance which is the problematic one, and can save us a lot of waiting for a conditional breakpoint to be triggered. The fastest code is the executed code that was compiled and optimized by the JVM. We want to use that fact and so, instead of writing a condition on a breakpoint, we introduce it to our executed code in a way that we can manipulate later. We then debug without any breakpoint, thus running in the fastest way a debugging session can run, and introduce a breakpoint while the code is running only when we actually know we will hit it.

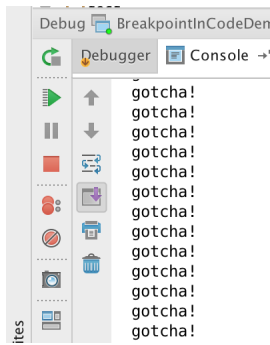

## Breakpoint in code

1. We introduce a loop to the code with our condition. This means we enter the loop only if the interesting state occurs. We then print something to the console so we will know when the code has entered the loop. Because the loop does not change any state, once we enter the loop we will stay inside it.

```
while (bugCondition(msg))
{
    System.out.println("gotcha!");
    try
    {
        Thread.sleep(1000);
    }
    catch (InterruptedException e)
    {
        //ignore
    }
}
```

**Tip** The sleep here is just to avoid bombarding the console with "gotcha!" messages.

2. At this point we initiate the debug session, sit and wait for the "gotcha!" to appear. The console will show us we "hit" the "breakpoint".

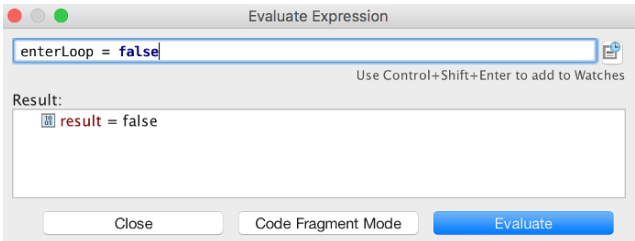

- When the "gotcha!" does appear, we introduce a real line breakpoint inside the loop. The breakpoint will be hit and suspend the VM or thread. Now we can inspect the event and its state. If inspecting is not enough, the last thing to do is to make our code exit the loop. There are two options to do that.
  - We can take advantage of the Evaluate Expression intrusive nature to evaluate a code fragment that will actually modify the loop condition to false. This is easily done if we use a field or variable as the condition of the loop, since we can then modify its value.

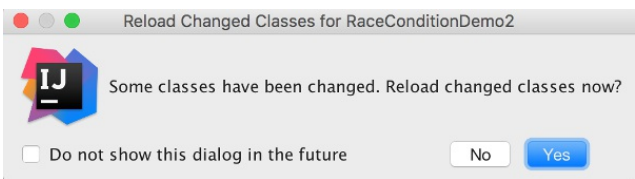

```

boolean enterLoop = bugCondition(msg);
while (enterLoop)
{
    System.out.println("gotcha!");
    try
    {
        Thread.sleep(1_000);
    }
    catch (InterruptedException e)
    {
        //ignore
    }
}

```

- We can exit the loop by using another feature of a debugging session, HotSwap . This allows us to modify the running code during debugging, compile it and then IntelliJ IDEA will hot swap the debugged classes with the new version. All we need to do is change the loop condition to 'false'. By default, IntelliJ IDEA will detect that a class has a new version and will ask us whether to reload the class with the new version.

Once the new version is loaded, the new loop condition will make the code exit the loop and we can continue debugging from that point. You can either put another breakpoint after the loop to suspend the execution again or just step through the 'false' loop condition.

**Note** Remember to delete this code after debugging. You should also have a failing test for the real feature to remind you to never commit it by mistake.

### Looking for a race condition

A race condition is a common issue in multithreaded applications. Multiple threads access and modify the same state, potentially corrupting it or causing undesired flow. A race condition can be a very subtle bug and is usually hard to reproduce. That is because it only occurs when the threads execute the code in a very specific order. Other execution orders will look fine and not cause any issues.

When looking for a race condition among threads, our debug run must start as minimally intrusively as possible to not interfere with the execution order. Once we gain some information or have an assumption on what the execution order is that will cause the bug, we can also use the debug features to reproduce it using a [dependency between breakpoints](#) .

### Detecting race condition resulting in a corrupted state

**Tip** If you suspect a race condition, start by debugging without any breakpoints just to make sure you can still reproduce the issue in the debug mode.

Sometimes race conditions only occur once in every ten or a hundred runs of the system. If we suspect there is a race condition in our multithreaded code, we must always make sure that the intrusive nature of the debugging session does not make the issue non-reproducible. For example, here we've created a system of publishers and subscribers, however all our subscribers share a primitive (and not a thread-safe) counter to count the total number of consumed messages.

```
private class Subscriber implements Runnable
{
    @Override
    public void run()
    {
        while (true)
        {
            String msg = messageQueue.poll();
            if (msg != null)
            {
                if (msg.equals(STOP))
                {
                    break;
                }
                else
                {
                    // race condition right here!
                    counter++;
                }
            }
        }
    }
}
```

Once we've made sure the issue can be reproduced in the debug mode, we try setting a [breakpoint with logging](#) instead of suspending the program execution. Here again, just the fact we are logging from all threads to the same console may "synchronize" the threads in such a way that will "solve" the bug. We need to be sure we can still reproduce it even if now it might take more attempts. Logging the suspected state can narrow down our options and allow us to see that the problem is not with the number of calls to the method but with the counter field.

## Avoiding debugger overhead

A race condition such as the one in our previous example will, on most machines, turn out to be a "subtle" race condition. By "subtle" we mean that any modification or change to the runtime environment can "fix" it. Remember that the origin of the bug is the fact that advancing a primitive counter is not an atomic operation.

```
// race condition right here!
counter++;
```

To reproduce the bug we need two threads, both reading the same value: the "second" thread must read the value before the "first" one updates it and flushes its CPU cache. Easy enough to create on multi-core machines during a normal run, but almost impossible to reproduce in a debugging session.

Logging, via a breakpoint, at that same point synchronizes the threads, as they all need to write to the same log. This also flushes the CPU caches of all threads, as writing to the log is atomic. In short, it prevents us from reproducing the bug. Suspending either the VM or the thread cannot help us here either, as we can't separate the two instructions (reading the counter value and incrementing it) to break between them. At this point, we need to make some assumptions then prove or refute them. Since we cannot use any breakpoints, our only hope is that we can change the actual executed code and introduce new code that will be compiled and therefore will interfere less.

This is very much a last resort option. A good pattern to help us here is a trace buffer.

## Trace buffer

We can introduce an internal buffer and store the interesting values in this buffer. Think of it as a localized, very efficient in memory log. We must make sure that:

- We have a buffer per thread, and those buffers are isolated so this does not introduce new concurrency issues.
- Because the buffer is per thread, it does not need to be thread safe and must not be thread-safe. This is because we want to avoid introducing any synchronization points.
- The values we insert must not be references to a real state that can change, but copies or log messages.
- The introduced code is as minimal as possible, to minimize its effect on the running code.
- We print or log the contents of the buffers only after the execution has ended, to avoid making the logging action a synchronization mechanism between threads. Another option is to only store the values in the trace buffer, then inspect its contents by putting a breakpoint after the critical part of the code has finished executing.

```

private class Subscriber implements Runnable
{
    private int index = 0;
    private final int[] traceBuffer = new int[NUMBER_OF_SUBSCRIBERS_AND_PUBLISHERS * 100];

    @Override
    public void run()
    {
        while (true)
        {
            String msg = messageQueue.poll();
            if (msg != null)
            {
                if (msg.equals(STOP))
                {
                    break;
                }
                else
                {
                    traceBuffer[index++] = counter;
                    // race condition right here!
                    counter++;
                }
            }
        }
    }
}

```

For example, here we introduced a primitive `int` array large enough for all messages, and in order to prove our suspicion of a bug in the counter, we store just the counter values before advancing it. Yes, it may not be the exact value advanced by the counter, but it will prove our assumption if the same counter value is reported by several threads. After all events are completed, we can inspect the trace buffers and find the duplicates.

## Detecting a race condition resulting in unexpected flow control

```

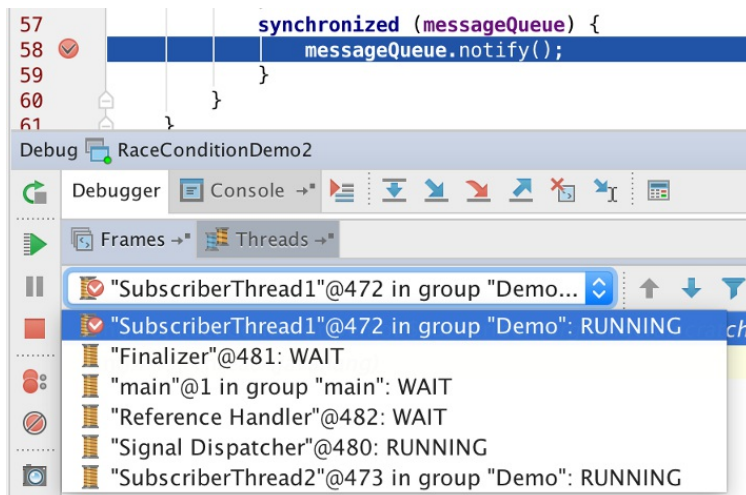

private class Subscriber implements Runnable
{
    @Override
    public void run()
    {
        String msg;
        while (true)
        {
            msg = messageQueue.poll();
            if (msg != null)
            {
                if (msg.equals(STOP))
                {
                    break;
                }
                // else do something
            }
        }
        // Will NOT work with multiple subscribers, as main thread will
        // wake up when the first subscriber is done.
        // Using a CountdownLatch here is a much better approach.
        synchronized (messageQueue)
        {
            messageQueue.notify();
        }
    }
}

```

In this example we have another race condition, but the contended shared state is not directly visible and is only deduced by what seems like a wrong flow control: the first subscriber will wake up the main thread, which will exit even if the second thread is still processing a message. We can't inspect or print the waiting thread in a 'trace buffer' in this case, but we can inspect the position of various threads when we suspend the entire application.

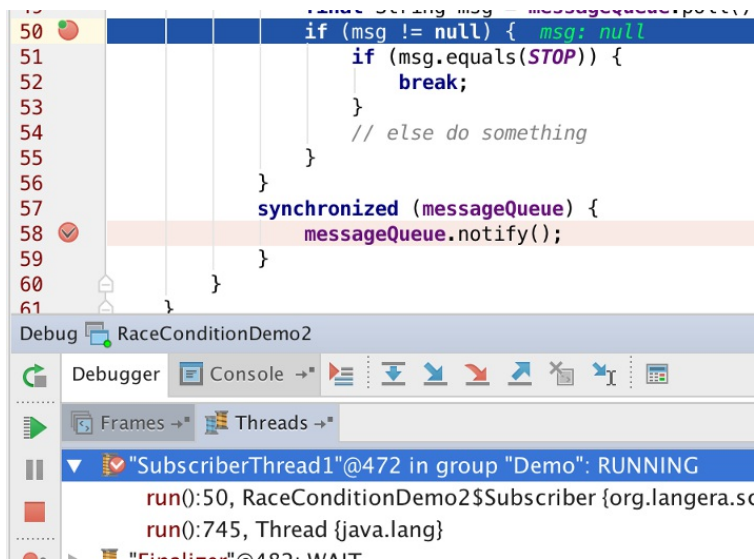

1. First, we can suspend the main thread after it wakes up. We can see that sometimes one of the subscriber threads is still marked running. This allows us to assume the problem's origin is in the fact that the `notify()` method is called too soon.

2. We can suspend only one of the subscriber threads. That will cause the other thread to notify the main thread. This will prove to us the problem can happen in any subscriber and is in its logic.
3. To be sure, we can suspend the entire VM earlier, just before a subscriber notifies the main thread. We can then inspect the status of the two subscriber threads and prove that one of them is still polling, while the other has already finished and is about to notify the main thread it's done.

In this screen capture, we can see from inspecting the threads that both are marked 'RUNNING', which means that while the first is about to notify the main thread it is done (inside the synchronized block), the other can still be processing messages.

4. To prove our assumption beyond any doubt we can also put a breakpoint inside the polling loop of the subscribers. We make that breakpoint depended on the previous breakpoint just before we notify the main thread we're done. Hitting the dependant breakpoint (as shown below) proves our theory.

## Detecting a deadlock

A deadlock occurs when two threads will conflict in such a way that both are preventing each other from working at all. Once they occur, deadlocks are easy to spot by looking at the frames of all threads. We can do this by using `Thread dump`. This feature is also [available when running](#). If we know we're chasing a deadlock, the running mode is even preferable to debugging. This is because we will not interfere at all with the execution this way, and the snapshot will be the output of a Java thread dump of the application. A thread dump can detect deadlocks and warn about them. For example, in the dump below we can see the process found 1 deadlock between the `PublisherThread` (which is stuck in line 44) and `SubscriberThread` (in line 78).

```
Found one Java-level deadlock:
=====
"PublisherThread":
  waiting for ownable synchronizer 0x000000076abf45a0, (a java.util.concurrent.locks.ReentrantLock$NonfairSync),
  which is held by "SubscriberThread"
"SubscriberThread":
  waiting for ownable synchronizer 0x000000076abf4570, (a java.util.concurrent.locks.ReentrantLock$NonfairSync),
  which is held by "PublisherThread"

Java stack information for the threads listed above:
=====
"PublisherThread":
  at sun.misc.Unsafe.park(Native Method)
  - parking to wait for <0x000000076abf45a0> (a java.util.concurrent.locks.ReentrantLock$NonfairSync) <6 internal calls>
  at org.langer.a.scratch.debug.DeadlockDemo$Publisher.run(DeadlockDemo.java:44)
  at java.lang.Thread.run(Thread.java:745)
"SubscriberThread":
  at sun.misc.Unsafe.park(Native Method)
  - parking to wait for <0x000000076abf4570> (a java.util.concurrent.locks.ReentrantLock$NonfairSync) <6 internal calls>
  at org.langer.a.scratch.debug.DeadlockDemo$Subscriber.run(DeadlockDemo.java:78)
  at java.lang.Thread.run(Thread.java:745)

Found 1 deadlock.
```

1. In this example, we can see that both threads are stuck waiting for a lock, which means that another thread is not freeing those locks. We can also see that both are waiting for different locks, as the synchronizer id is different. Even more informative is the deadlock summary at the top that tells us what thread holds each lock. We can see that the two deadlocked threads are holding the lock the other thread is trying to obtain.

**Tip** Always name your threads in multithreaded applications according to their function. Anyone needing to look at a thread dump later, will thank you.

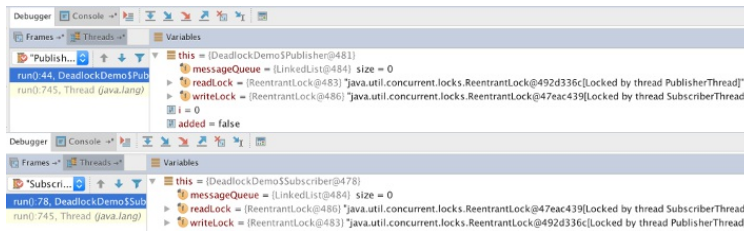

2. This should already give us plenty of information on how the deadlock occurs. If it is still unclear how our code reached a deadlock, we can then try debugging with breakpoints just before we hit the lines provided by the thread dump. When we have a theory of what is wrong, we can try reproducing the scenario by using the [dependency between breakpoints](#).
3. We can now create a Suspend Thread breakpoint on one of those threads and verify, using another thread dump snapshot, the other thread reached its deadlock position.

Now

we can inspect the state just before one of the threads gets deadlocked.

4. Another option is to put suspend thread breakpoints on both threads and switch between them. Inspecting the states of the `Publisher` and `Subscriber` in this example will show us the confusion that caused the deadlock.

5. When we inspect our lock instances we can see that the concurrent code was actually correct, but we confused the read lock and write lock when we passed them to the two objects. Look at the lock instances ids in the image above.
6. Indeed, when we then inspect the constructions (where we injected those locks) we can see the bug:

```
ThreadGroup threadGroup = new ThreadGroup("Demo");

new Thread(threadGroup, new Subscriber(messageQueue, readLock, writeLock), "SubscriberThrea

//passing locks in the wrong order will cause deadlock between publisher and subscriber
new Thread(threadGroup, new Publisher(messageQueue, writeLock, readLock), "PublisherThread"
```

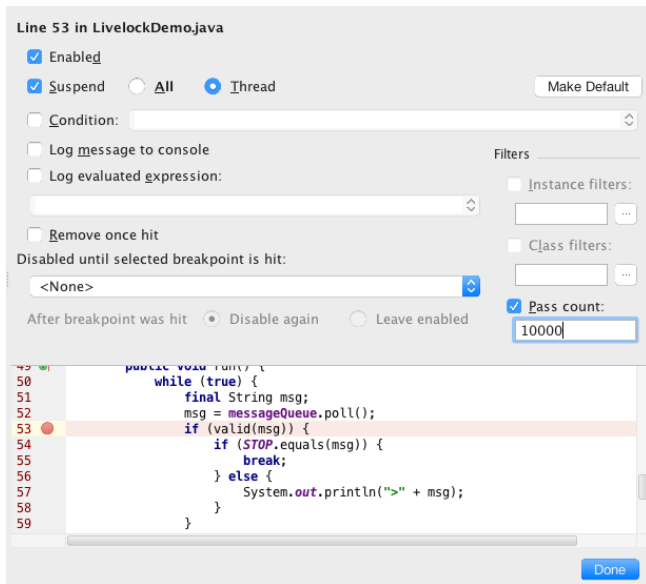

## Detecting a livelock

A livelock is a scenario where threads are not blocked, but still unable to make a progress. From the outside, a livelock should behave just like a deadlock, but because the threads are not blocked, the snapshot (thread dump) will not alert us on any deadlock.

1. One strategy to try before starting debugging, is to repeat the Thread Dump several times then compare the stack traces for various threads. This should give us a clear view of the problematic areas in the code, in most cases a loop that the code cannot escape from.

2. If we're still unsure, we can use a Pass Count with a large number that we assume will only be reached in a livelock situation.

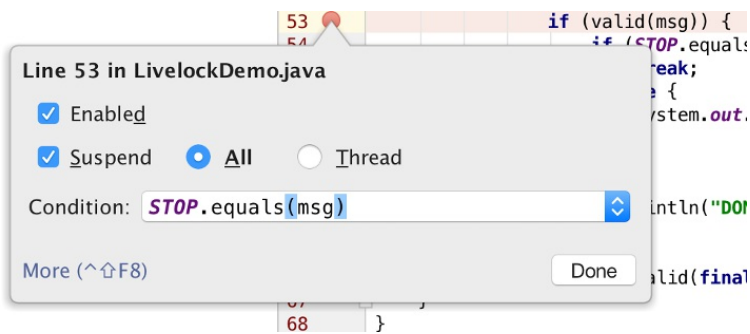

We can also Step

through the code and verify exactly what area of code is being executed repeatedly but not progressing.

- At this point we can use a Conditional Expression to capture the point in the execution when we enter the livelock situation (i.e when the application reaches a state that will prevent it from escaping the executed code block).

In this example, we assume that the STOP message failed to break us from the loop, so either it was never sent or that it was not handled so we'll introduce a breakpoint with a condition that looks for a STOP message.

- Our breakpoint is hit, meaning the STOP message was sent but not handled.

- We step in, inspect the state with Evaluate Expression and find the bug. The 'valid' method does not think STOP is a valid message and puts us in this livelock scenario.

IntelliJ IDEA provides support for several language-specific [testing frameworks](#) . This section covers the issues that are common for all the supported testing frameworks:

- [Configuring Testing Libraries](#)
- [Creating Tests](#)
- [Creating Test Methods](#)
- [Creating Run/Debug Configuration for Tests](#)
- [Performing Tests](#)
- [Monitoring and Managing Tests](#)

- [Tutorial: Test Driven Development](#)

On this page:

- [Introduction](#)
- [Adding test libraries](#)

## Introduction

The libraries for JUnit and TestNG are shipped with IntelliJ IDEA, but are not included in the classpath of your project or module by default. Consequently, when a test class is created, the references to the `TestCase` class or test annotations are not resolved.

To add the necessary library to the classpath, you can use the general procedure of [adding a dependency to a module](#). The corresponding libraries are located in the following directories:

- JUnit libraries ( `junit.jar` and `junit-4.11.jar` ): `<IntelliJ IDEA directory>\lib`.
- TestNG library ( `testng-jdk15.jar` ): `<IntelliJ IDEA directory>\plugins\testng\lib`.

IntelliJ IDEA can add the necessary library to the classpath automatically. The corresponding features are available when [creating a test for a class](#) or when [writing the code for a test](#).

## Adding test libraries

### To add a test library to the classpath when creating a test for a class

1. In the editor, place the cursor within the line containing the class declaration.
2. Press `Alt+Enter` to view the available [intention actions](#).
3. Select Create Test.
4. In the Create Test dialog, to the right of the text informing you that the corresponding library is not found, click Fix.

### To add a test library to the classpath when writing the code for a test

1. In the source code of a test class, place the cursor within an unresolved reference to `TestCase` or annotation.
2. Press `Alt+Enter` to view the available [intention actions](#).
3. Select Add <library> to classpath.

On this page:

- [To create a test class using the intention action](#)
- [To create a test class using navigation](#)

## To create a test class using the intention action

To create test cases for the supported testing frameworks, you can use the Create Test [intention action](#).

1. Open the class you want to create a test for in the editor, and place the cursor on the class name.
2. Press `Alt+Enter` to invoke the list of available intention actions.
3. Choose Create Test from the list.

4. In the [Create Test dialog](#):

- a. Select the testing library to be used.

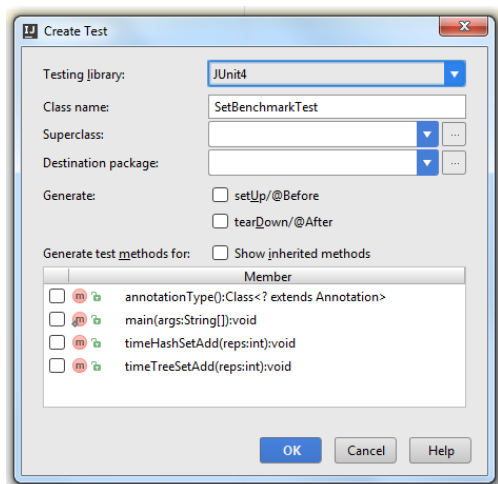

If the selected library is missing from your module, click the Fix button. The corresponding library will be automatically added to the module libraries.

- b. Define the name and location of the test class to be generated.

- In the Class name field, specify the name of the stub test class to be generated.
- In the Superclass field, IntelliJ IDEA suggests the appropriate super class for JUnit3. For JUnit 4 and TestNG, this field is blank.
- In the Destination package field, define where the generated test class should be placed.

- c. Specify whether you want the `setUp()` / `tearDown()` methods (for JUnit), or the `@Before` / `@After` annotations to be generated.

- d. In the table that shows the list of all methods of the source class, select the ones you want to generate test methods for.

## To create a test class using navigation

1. Open the class you want to create a test for in the editor, and place the cursor on the class name.
2. Do one of the following:
  - On the main menu, choose `Navigate | Test`.
  - On the context menu, choose `Go to | Test`.

If the target test doesn't exist, you will be prompted to create it. Refer to [Navigating Between Test and Test Subject](#) for details.

To create stub test methods in JUnit test classes, you can use the IntelliJ IDEA code generation feature.

**Note** To create a test class with a complete set of test methods and fixtures, use the [Create Test](#) intention action.

## Creating a stub test method in a JUnit test class

1. Open the corresponding JUnit test class in the editor.
2. Place the cursor where you want a new test method to be generated.
3. Press `Alt+Insert` and select Test Method from the Generate menu.

On this page:

- [Introduction](#)
- [Creating run/debug configuration for tests](#)

## Introduction

You can run your tests (test cases, test suites, etc.) using run/debug configurations, in the way similar to running ordinary applications.

To create the necessary run/debug configurations, you can use the general procedure (see [Creating and Editing Run/Debug Configuration](#)) or various shortcuts available in IntelliJ IDEA. Using these shortcuts (implemented as context menu commands) you can create the run/debug configurations for:

- An individual test case.
- All tests in a directory or a package.
- Selected test classes which may be located in the same or different directories, packages or modules.  
This option is available only for JUnit.
- An individual test method.

**Note** You can run your tests even without creating the run/debug configurations for them. To do that, use the Run ([Ctrl+Shift+F10](#)) or the Debug command in corresponding context menus.

As a result, temporary run/debug configurations will be generated which you can then save.

## Creating run/debug configuration for tests

### To create a run/debug configuration for tests, follow these general steps:

1. To start creating the run/debug configuration, open the context menu for the item or items of interest and select the appropriate Create command. So, depending on what you want to create the run/debug configuration for, do one of the following:
  - If you want to create the run/debug configuration for an individual test, or all tests in a directory or a package:
    1. Right-click the corresponding test class, directory or package in the [Project Tool Window](#).
    2. Select the Create ... command from the context menu.  
The command name depends on your current selection in the Project tool window and may look something like:
      - Create "All Tests" for a source or test directory.
      - Create "Tests in '<package\_name>'" for a package.
      - Create "<test\_name>" for a test class.
  - If you want to create the run/debug configuration for selected tests:
    1. Select the tests of interest in the [Project Tool Window](#).
    2. Right-click one of the selected tests to open the context menu.
    3. In the context menu, select Create "<first\_test\_name> and <n> more".
  - If you want to create the run/debug configuration for a test method:
    1. Open the test class containing the method of interest in the editor.
    2. To open the context menu, right-click somewhere within the method code.
    3. In the context menu, select Create "<method\_name>()".

**Note** A similar context menu command is available for the whole test class in the editor. To open the context menu for the class, right-click somewhere outside the area occupied by the code of the methods (for example, in the line containing the class declaration).

2. In the dialog that opens, specify the run/debug configuration parameters and click OK. For more information, see the corresponding dialog description for [JUnit](#) or [TestNG](#).

**Tip** To distinguish between the context menu commands for JUnit and TestNG, the following icons are used:

-  for JUnit.
-  for TestNG.

On this page:

- [Introduction](#)
- [Running or debugging a test](#)

## Introduction

Generally, IntelliJ IDEA runs and debugs tests in the same way as other applications, by running the run/debug configurations [you have created](#) . When doing so, it passes the specified test classes or methods to the test runner.

In many cases, you can initiate a testing session from a context menu. For this purpose, the Run and Debug commands are provided in certain context menus. For example, these commands are available for a test class, directory, or a package in the [Project Tool Window](#) . They are also available for a test class or method you are currently working on in the editor.

If you run a test for which there is no permanent run/debug configuration a temporary configuration is created. You can then save such a configuration using the [Run/debug configuration](#) dialog, if you want to reuse it later.

The tests run in the background, so you can execute several tests at the same time.

Each running configuration gets its own tab in the [Run tool window](#) (the [Test Results tab](#) ). One tab can aggregate several tests.

## Running or debugging a test

### To run or debug a test, follow these general steps:

To start running or debugging a test, you can use the main toolbar, or a context menu in the Project tool window or in the editor:

- Using the main toolbar:

1. Select the necessary run/debug configuration from the list on the main toolbar.

2. Click Run  or Debug  to the right of the list. (Alternatively, choose Run | Run ( [Shift+F10](#) ) or Run | Debug ( [Shift+F9](#) ) from the main menu.)

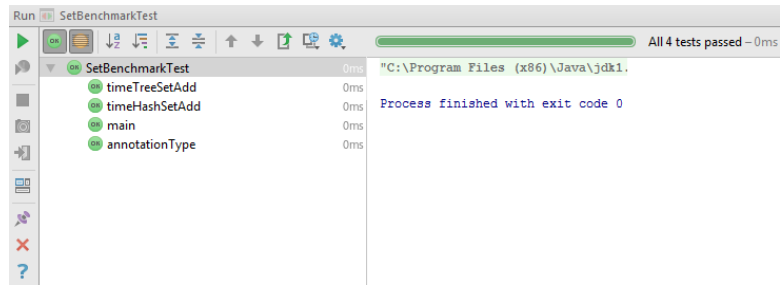

**Tip** To see the list of available run or debug configurations and to quickly select the one you want, you can use the following keyboard shortcuts: [Shift+Alt+F10](#) for the run configurations, or [Shift+Alt+F9](#) for the debug configurations.

- Using a context menu:

Right-click a test class in the Project tool window, or open it in the editor, and right-click the background. On the context menu, choose Run < class name> or Debug... .

**Tip** For a test method, open the class in the editor and right click anywhere in the method. The context menu suggests the command Run / Debug <method name> .

Test progress and results display in the dedicated **test runner tabs** of the Run tool window.

You can **rerun**, **terminate**, and **suspend** execution of tests same way as you do it for running applications. In addition to the common running actions, in the test runner you can:

- Navigate through the list of test cases using arrow keys.
- Navigate between failed tests using the **↓** and **↑** buttons or **Ctrl+Alt+Up** or **Ctrl+Alt+Down** keyboard shortcuts.
- View the total number of tests being run in the current session. The summary information is displayed in a message line on the top of the tool window. After completion of the tests, the message informs you about the number of failed tests and elapsed time.
- View testing progress in the progress bar.
- Show or hide information about the passed tests, using the **✔** button.
- Show the ignored tests in the tree view of all tests within the current run/debug configuration or test class using the **🚫** button.
- Navigate from the stack trace to the problem location in the source code by clicking the hyperlink in the Output pane.
- Enable and disable the following functionality by clicking the cog button **⚙** and selecting the relevant items from the context menu:
  - Monitoring execution of the current test.
  - Have the first failed test selected automatically upon completing the suit.
  - Navigating to the stack trace.
  - Automatic scrolling to the source code.
  - Have the corresponding source code opened at exceptions.
  - Have statistic shown in the Statistics pane.

On this page:

- [Overview](#)
- [Viewing statistics](#)
- [Important note](#)
- [Viewing the results of previously run tests](#)

## Overview

Depending on the selected node in the tree view of tests, the Test Runner displays information on the various levels. In the Test Runner, you can view statistics of the tests, navigate to stacktrace, show or hide successful tests, and more.

Use the [Testing toolbar](#) to control visual representation of the test results.

## Viewing statistics

The Statistics tab shows information about the elapsed time and memory usage of each test.

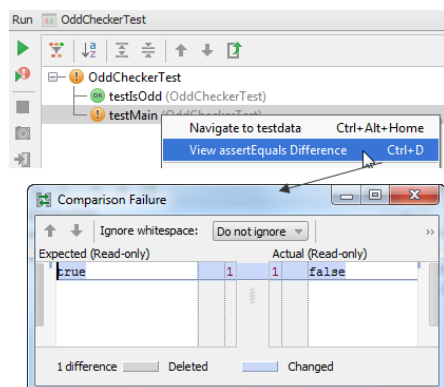

To view statistics, click  on the Testing toolbar to reveal the drop-down menu, and then click the Show Statistics check command.

The values displayed in the Statistics tab are not accurate and only give an approximate estimate of the test performance. For example, if a garbage collector works during the test run, the memory usage shown in the Statistics tab is wrong.

## Important note

If a unit test contains string `assertEquals` failures, the test runner provides the ability to view differences between the compared strings. Choose the View assertEquals Difference on the context menu of the failed test that contains `assertEquals`, and explore differences in the [Differences viewer](#):

## Viewing the results of previously run tests

The results of a test session can be saved in two ways:

- Click  to have the results of the selected test saved in a file. In the [Export Test Results](#) that opens, specify the file to save the output in and the format in which the data will be saved. If you want to view the test results later, choose the **XML** format.
- IntelliJ IDEA keeps track of test sessions and saves test results in its internal memory. Click  to view the test results that you previously saved in an XML file or the results that IntelliJ IDEA has kept in its internal history. The pop-up menu that opens shows a list of internally saved results of test sessions, each item is supplied with the name of the run configuration and a time stamp.

- To view the results of a testing session from the IntelliJ IDEA history, select the item with the suitable run configuration and time stamp.
- To load the previously exported results, choose Import from file and then choose the required XML file in the dialog box that opens.

The loaded test results are shown in the tab and the name of the corresponding run configuration is displayed on the title bar. To re-run the tests from the loaded session, click .

## Introduction

You can repeat your test session, or individual tests without leaving your [test runner tab](#) of the Run tool window. The tests are performed again using the same run configuration as in the initial run.

## Rerunning a testing session

Do one of the following:

- Click the rerun button  on the toolbar of the Run tool window.
- Use `Ctrl+F5` keyboard shortcut.

Note that you can [rerun the tests automatically](#).

## Rerunning an individual test

1. In the testing tab of the test runner, right click a test case node or a test.
2. On the context menu, choose Run <test target> .

## Rerunning a failed test

1. In the testing tab of the test runner, select a failed test.
2. In the [Run toolbar](#) , click Rerun Failed Tests .

## Debugging a failed test

1. In the [Test Runner tab](#) , press `Shift` and click Rerun Failed Tests .
2. Select Debug from the Restart Failed Tests popup.

The tests that have failed will be rerun in the debug mode.

You can abort a running test session at any time. So doing, all tests that are current running will stop immediately. The icons of the tests in the test runner reflect the statuses of the tests (passed, failed, aborted, or never run).

### **To stop a testing session, do one of the following**

- On the toolbar of the test runner, click the stop button .
- Use `Ctrl+F2` keyboard shortcut.

On this page:

- [Viewing the list of recently performed tests](#)
- [Rerunning the selected test](#)
- [Performing failed test](#)
- [Jumping to the test declaration](#)

## Viewing the list of recently performed tests

If some tests were already performed, one can view them in a popup list.

### To view the list of recent tests, do one of the following:

- Use [Fine Action](#) or [Search Everywhere](#) , and type the word "recent".
- Press `Ctrl+Shift+Semicolon`

IntelliJ IDEA displays the list of recently performed tests, which includes successful test run configurations, and individual failed test.

## Rerunning the selected test

### To rerun a test

1. Select the desired test from the suggestion list.
2. Press `Enter` to rerun the selected test.

## Performing failed test

### To perform a failed test

1. Select the desired failed test.
2. Click ▶
3. On the submenu, click the desired test run configuration, or press `Enter` .

## Jumping to the test declaration

### To navigate to the declaration of the selected test

1. Select the desired test from the suggestion list.
2. Press `F4` to navigate to its declaration.

In this section:

- Code Coverage
  - [Basics](#)
  - [Prerequisite](#)
  - [Running with code coverage](#)
  - [To use code coverage in project, follow these general steps](#)
- [Configuring Code Coverage Measurement](#)
- [Running with Coverage](#)
- [Viewing Code Coverage Results](#)
- [Managing Code Coverage Suites](#)
- [Generating Code Coverage Report](#)

## Basics

Measuring code coverage is available for testing, applications, and application server run/debug configurations.

The code coverage measuring can be performed using the following runners:

- IntelliJ IDEA code coverage runner (recommended).
- [EMMA](#) open-source toolkit. Note that EMMA is not supported by the author any more, and works with Java 7 only when frame validation turned off (pass `-noverify` to the process).
- [JaCoCo](#) .

IntelliJ IDEA code coverage runner enables multi-mode analysis:

- Sampling mode enables collecting line coverage with negligible slow-down.
- Tracing mode enables accurate collection of the branch coverage, with the ability to track tests, view [coverage statistic](#) , and get additional information on each covered line.

For the other runners, only sampling mode is available.

Code coverage results are reflected in the dedicated [Coverage tool window](#) , in the Project view of the [Project Tool Window](#) , and in the editor. The tool windows show the following information:

- For a directory: the percentage of the covered classes and lines.
- For a class: the percentage of the covered methods and lines.

When a file is opened in the editor, each line is highlighted with regard to its code coverage status:

- Lines executed during simulation are marked green.
- Lines not executed during simulation are marked red.
- Covered lines with conditions are marked yellow in the tracing mode.

The coverage measurement results comprise a coverage suite . You can have the results of a new simulation merged with any existing suite. In this case, a line will be considered covered if it is covered by at least one of the simulations.

A coverage suite is generated every time a test or application with code coverage measurement is executed. It is possible to have an unlimited amount of coverage suites.

## Prerequisite

Make sure the **Code Coverage** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) . If the plugin is disabled, the code coverage tabs will not be visible in the run/debug configuration dialogs.

## Running with code coverage

### To use code coverage in project, follow these general steps

1. Specify how you want to [process the coverage results](#) .
2. [Create tests](#) for the target code, if you are going to measure code coverage for testing.
3. [Configure code coverage measurement](#) in the desired run/debug configuration.
4. [Run with coverage](#) , using the dedicated command on the main menu Run | Run with Coverage , or  .
5. Once the run with coverage has been executed, you can
  - Use the [various coverage suites](#) .
  - [View code coverage data](#) .
  - [Generate code coverage report](#) .

IntelliJ IDEA makes it possible to configure the various aspects of code coverage measurement. In this section:

- [Configuring the way coverage suites are processed](#)
- [Configuring code coverage measurement options](#)
- [Changing colors of the coverage highlighting](#)

## To configure code coverage behavior

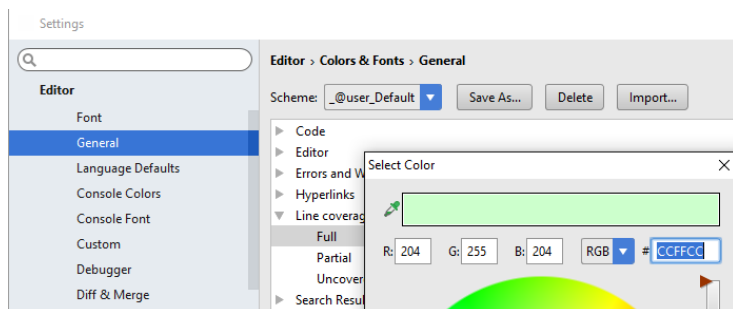

1. Open the [Settings/Preferences dialog box](#) , and then click Coverage under Build, Execution, Deployment . The [Coverage](#) page opens.
2. Define how the collected coverage data will be processed:
  - To have the Code Coverage dialog box shown every time you launch a new run configuration with code coverage, choose Show options before applying coverage to the editor .
  - To discard the new code coverage results, choose Do not apply collected coverage .
  - To discard the active suites and use the new one every time you launch a new run configuration with code coverage, choose Replace active suites with the new one .
  - To have the new code coverage suite appended to the active suites every time you launch a new run configuration with code coverage, choose Add to active suites .
3. Define the behaviour of the [Coverage](#) tool window when an application or test is run with coverage:
  - To have the Coverage tool window opened automatically, select the Activate Coverage View checkbox.
  - To open the Coverage tool window manually, clear the Activate Coverage View checkbox.

## To configure code coverage options

1. Open the [Edit Run/Debug Configuration](#) dialog box, add the desired run/debug configuration, and click the Code Coverage tab.
2. In the Code Coverage tab, define the following options:
  - From the Choose coverage runner drop-down list, select the desired code coverage runner. The available options are:
    - EMMA
    - IntelliJ IDEA
  - Choose the options for the selected runner:
    - For the EMMA runner, only the Sampling mode is available.
    - For the IntelliJ IDEA runner, you can choose between the Sampling or Tracing modes.
  - Specify the scope to measure code coverage for. Do one of the following:
    - To specify a class, click the Add Class button.
    - To specify a package, click the Add Package button.
  - To have code coverage statistic collected for folders with tests as well, select the Enable Coverage in Test Folders checkbox.

## To configure code coverage colors

1. Open the [Color Scheme](#) page of the editor settings. Alternatively, just click  in the statistics pop-up.
2. Expand Colors and Fonts node, and select General .
3. In the list of textual components, select the required type of coverage, for example, Full , Partial or Uncovered , and then choose the desired colors:

IntelliJ IDEA provides a dedicated action that allows you to perform run with code coverage measurement. The code coverage data are processed according to the option selected in the [Coverage](#) page of the Settings/Preferences dialog box.

## To run with code coverage measurement

1. Do one of the following:
  - Open the desired file in the editor, and choose Run <name> with coverage on the context menu. When running tests with coverage, note that you can run the entire test class, or each individual test method, depending on the caret location.
  - Select the desired run/debug configuration, and then on the main menu choose Run | Run <run/debug configuration name> with coverage .
  - On the main toolbar, click  . This will launch the selected run/debug configuration.
2. If the Show options before applying coverage to the editor checkbox has been selected in the [Coverage](#) page of the Settings/Preferences dialog box, choose whether you want to replace the active coverage suites, or add the collected data to the active suites, or do not want not apply coverage data. You can also opt to skip this dialog in the future.  
In case any other option has been selected, the respective action will be performed silently.
3. [Explore the collected coverage data](#) in the [Coverage Tool Window](#) .

Viewing code coverage helps you detect pieces of your source code that are not affected by simulation.

## To view code coverage results

1. Do one of the following:
  - Run the desired class with coverage , select suite to show , and open class in the editor.
  - On the main menu, choose Analyze | Show Code Coverage Data .
  - Press `Ctrl+Alt+F6` .
2. View coverage results:
  - In the Project tool window:

- In the dedicated Coverage tool window :

Element	Class, %	Method, %	Line, %
Main	0% (0/1)	0% (0/2)	0% (0/2)
MetersToInchesConverter	100% (1/1)	50% (2/4)	16% (5/30)
OddChecker	0% (0/1)	0% (0/4)	0% (0/6)

3. Open in the editor the files you want to explore.
4. Use the color indicators in the left gutter to detect the uncovered lines of code.

5. To find out how many times a line has been hit, click the line in the gutter area.

The pop-up window that opens shows the statistic for the line at caret. For lines with conditions, the pop-up window also provides statistic:

Use the following toolbar buttons:

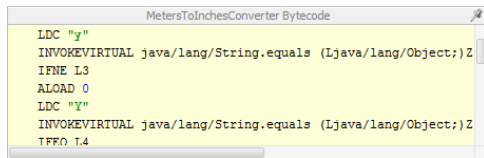

- : jump to the next/previous groups of covered or uncovered lines.
- : view JUnit tests that cover the line at caret.

The test that covers the line at caret, is shown in a pop-up window:

- This button is only available in the Tracing mode, and with the Track per test coverage checkbox selected.
- When pinned, this pop-up window converts into the Find tool window .

-  : show byte code of the current class in a pop-up window:

```
MetersToInchesConverter Bytecode
LDC "y"
INVOKEVIRTUAL java/lang/String.equals (Ljava/lang/Object;)Z
IFNE L3
ALOAD 0
LDC "y"
INVOKEVIRTUAL java/lang/String.equals (Ljava/lang/Object;)Z
IFEQ L4
```

- This button is only available, when Byte Code Viewer plugin that comes bundled with the product, is enabled.
- When pinned, this pop-up window converts into the Byte Code Viewer.
-  : open the [Color Scheme](#) settings, where you have to choose the node Line Coverage .
-  : hide coverage information.

6. Create missing tests, as described in the section [Creating Tests](#) .

IntelliJ IDEA provides a tool to select coverage suites for showing or hiding, adding and removing suites.

On this page:

- [Accessing the Choose Coverage Suite](#)
- [Selecting coverage suites to show](#)
- [Hiding coverage suites](#)
- [Adding coverage suites from disk](#)

## Accessing the Choose Coverage Suite

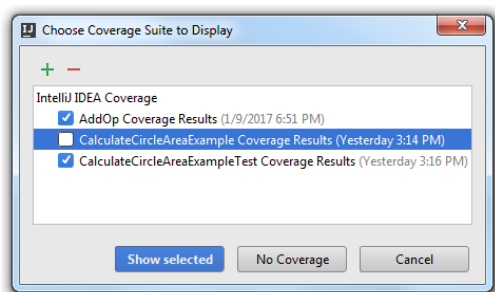

### To open the Choose Coverage Suite to Display dialog box, do one of the following

- On the main menu, choose Analyze | Show Coverage Data .
- Press `Ctrl+Alt+F6` .

## Selecting coverage suites to show

### To select coverage suites to show

1. Open the Choose Coverage Suite to Display dialog box, as described above.
2. In the Choose Coverage Suite to Display dialog box, select the checkboxes next to the desired suites.

3. Click Show selected . The dialog box closes.
4. Open in the editor the classes, for which the coverage suites have been selected, and explore the coverage results.

## Hiding coverage suites

### To hide coverage suites

1. Open the Choose Coverage Suite to Display dialog box, as described above.
2. In the Choose Coverage Suite to Display dialog box, select the checkboxes next to the suites you want to hide.
3. Click No coverage . The dialog box closes. The coverage results are not shown for the target classes.

## Adding coverage suites from disk

### To add or delete a coverage suite

Consider a situation when a file that contains code coverage information, has been obtained from the build server. You can load this file from disk and make it available for review. Also, you can bring for examination the coverage suite that has been produced some time ago.

On the other hand, IntelliJ IDEA allows you to remove unnecessary coverage suites.

1. Open the Choose Coverage Suite to Display dialog box, as described above.
2. Add new suites or delete the existing ones:
  - Click `+` , and select the desired `*.es` file in the file chooser dialog.
  - Select one or more suites in the list, and click `-` . The selected suite will be deleted from the list, and from storage.

IntelliJ IDEA suggests two ways of generating HTML reports on the base of the code coverage measurement results: using the menu command, or using the [Coverage tool window](#) .

## To generate a code coverage report

1. Do one of the following:
  - On the main menu, choose Analyze | Generate Coverage Report .
  - In the toolbar of the [Coverage tool window](#) , click  .
2. In the Generate Coverage Report dialog box that opens, specify the target directory where the generated report will be stored, and optionally select the checkbox Open generated HTML in browser .
3. Click Save . IntelliJ IDEA will store the generated report to the specified location, and also open it in the default browser, if the corresponding checkbox has been selected.

Please note that if you are going to save a code coverage report for one of the [multiple projects opened in the same window](#) , it is important to check the suggested target location, because IntelliJ IDEA suggests the previously used location.

On this page:

- [Introduction](#)
- [Prerequisites](#)
- [Creating Your First Test](#)
- [Writing the Test Body](#)
- [Running the Tests](#)
- [Implementing the Code](#)
- [Iterate](#)
- [Summary](#)

## Introduction

Whether you like to write your tests before writing production code, or like to create the tests afterwards, IntelliJ IDEA makes it easy to create and run unit tests. In this tutorial we're going to show how to use IntelliJ IDEA to write tests first ([Test Driven Development or TDD](#)).

## Prerequisites

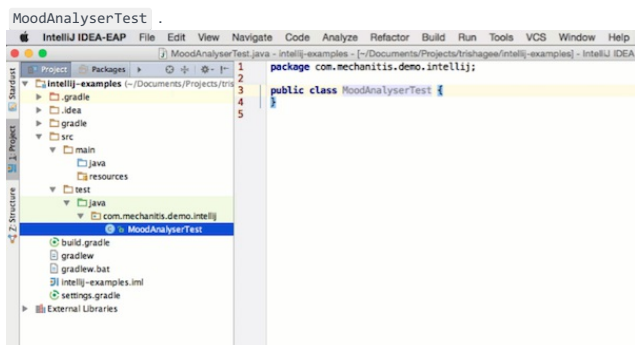

This tutorial assumes the following prerequisites:

- You have [created a Java project](#) in IntelliJ IDEA.
- You have folders for production and test code, either [created manually](#) or from when you [created the project](#).
- You have JUnit 4 on the classpath, either by [adding a test library](#), or adding a dependency in [Gradle](#) or [Maven](#).
- Your source and test roots are [correctly configured](#) - source roots will appear as blue folders, test folders will have a green background.
- You have [created the packages](#) you want in your project.

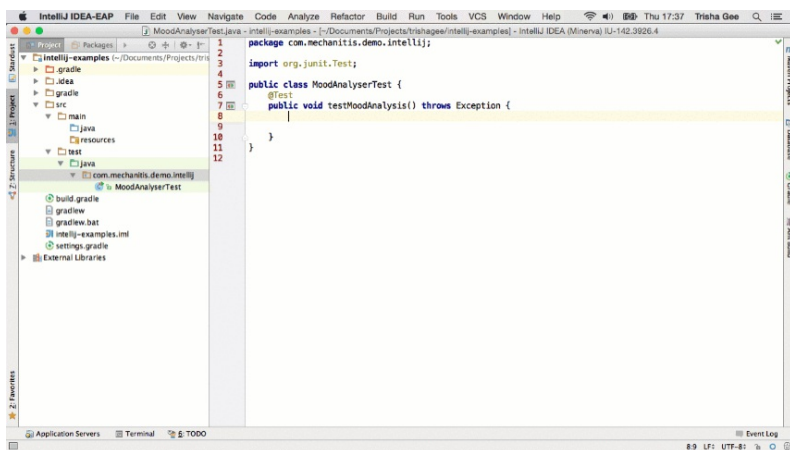

## Creating Your First Test

Given that we're writing our tests first without necessarily having the classes we're testing available to us yet, we'll create our first test via the project panel.

1. Right click on the package you want to create the test in and select New | Java Class .
2. Enter the test name - given we're testing using JUnit, this will likely be [Something]Test, for example

3. With the cursor placed somewhere inside the class's curly braces, press `Alt+Insert` .
4. Select Test Method | JUnit 4 from the menu. This will create a test method with the default template. Fill in a name for the test, press enter and the cursor will end up in the method body.

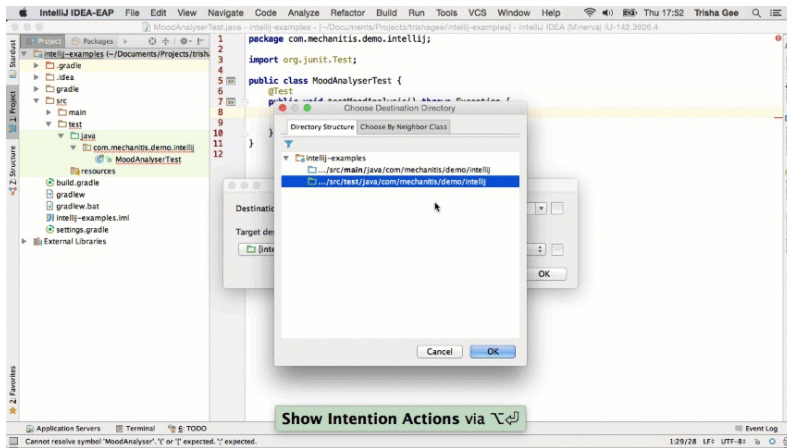

You can alter the [default test method template](#) - for example, if you wish to change the start of the method name from `test` to `should` .

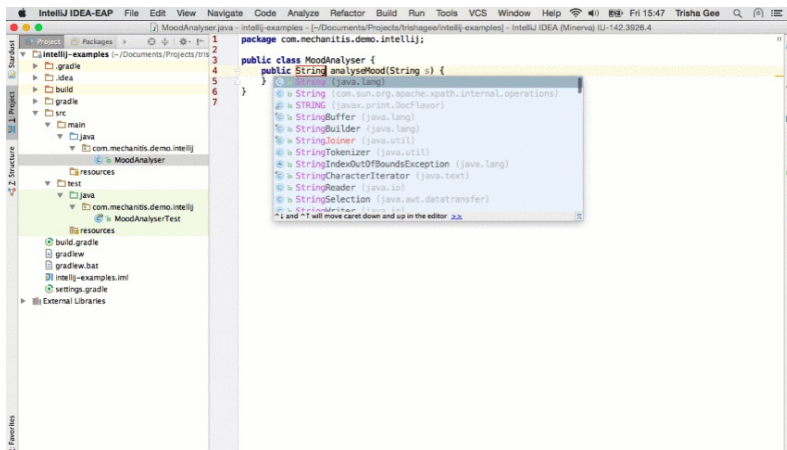

## Writing the Test Body

It may seem counter-intuitive to write test code for classes and methods that don't exist, but IntelliJ IDEA makes this straightforward while keeping the compiler happy. IntelliJ IDEA can create classes and methods for you if they don't already exist.

1. Write your tests describing what you want to achieve, pressing `Alt+Enter` on any classes that don't exist and selecting "Create class '[ClassName]'". This will give you a minimum implementation that keeps the compiler happy.

2. Continue writing the test body, including names of methods that you need that don't exist, again you can use `Alt+Enter` and select "Create method '[methodName]'" to have IntelliJ IDEA create a bare skeleton method.

As always, you can use IntelliJ IDEA's [refactoring tools](#) to create variables to store results in, and IntelliJ IDEA will import the most appropriate classes for you, if the correct libraries are on the classpath.

## Running the Tests

When following a TDD approach, typically you go through a cycle of [Red-Green-Refactor](#). You'll run a test, see it fail (go red), implement the simplest code to make the test pass (go green), and then refactor the code so your test stays green and your code is sufficiently clean.

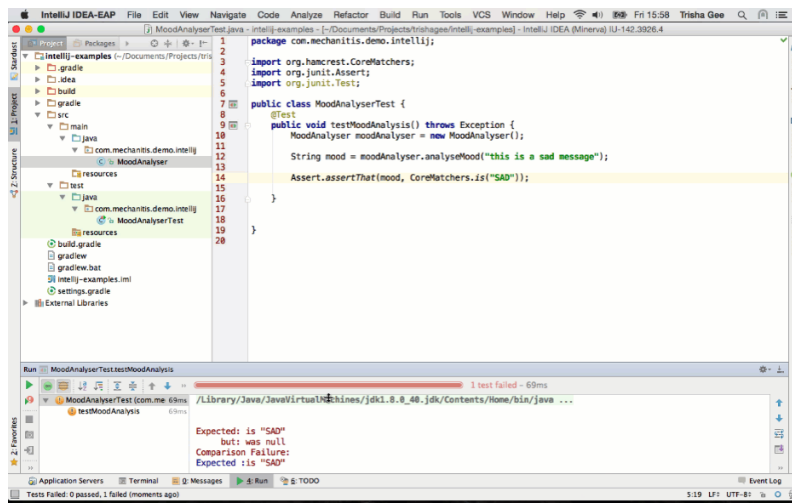

The first step in this cycle is to run the test and see it fail.

Given that we've used IntelliJ IDEA's features to create the simplest empty implementation of the method we're testing, we do not expect our test to pass.

- From inside the test, press `Ctrl+Shift+F10` to run this individual test.

The results will be shown in the [run dialog](#). The test name will have an icon next to it - either red for an exception, or yellow for an assertion that fails. For either type of failure, a message stating what went wrong is also shown.

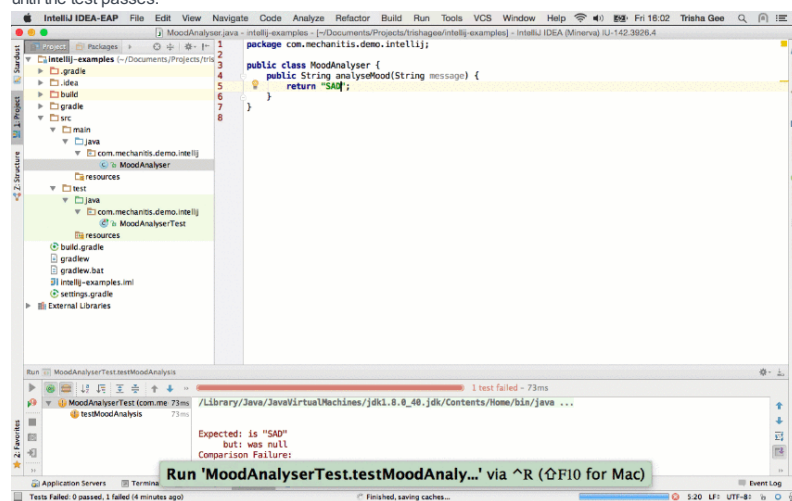

## Implementing the Code

The next step is to make the tests pass, which means implementing the simplest thing that works.

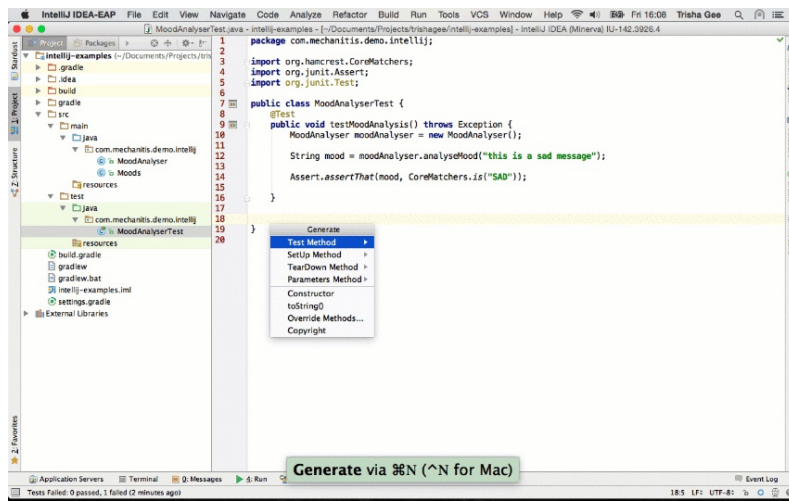

1. You can navigate to the code being tested using the usual methods - clicking through on the method name, pressing `Ctrl+Alt+B` while the cursor is on the method name, or pressing `Ctrl+Shift+T` to switch between the test and the production code.
2. Make the change to the method to make the test pass. Often with TDD, the simplest thing that works might be hard-coding your expected value. We will see later how iterating over this process will lead to more realistic production code.
3. Re-run the test, using `Shift+F10` to re-run the last test.
4. See the test pass - the icon next to the test method should go green. If it does not, make the required changes until the test passes.

## Iterate

Developing code is an iterative process. When following a TDD-style approach, this is even more true. In order to drive out more complex behaviour, we add tests for other cases.

1. In your test class, use `Alt+Insert` again to create a new test method.
2. Pick a second test case that specifies more requirements of the method you're testing. Remember that you can use IntelliJ IDEA's features to create classes and methods to keep the compiler happy.
3. Run this second test case, showing that it fails for the correct reason.
4. Change the code in the method being tested to make this test pass.
5. Re-run both the tests by pressing `Ctrl+Shift+F10` inside the test class, not inside a single method, and see that both tests now pass. If either test fails, make the changes needed to the code to ensure the tests pass.

## Summary

Writing your first test in a test-first style takes a small amount of setup - creating the test class, creating the test methods, and then creating empty implementations of the code that will eventually become production code. IntelliJ IDEA automates a lot of this initial setup.

As you iterate through the process, creating tests and then making the changes required to get those tests to pass, you build up a comprehensive suite of tests for your required functionality, and the simplest solution that will meet these requirements.

This section describes how to:

- [Configure compiler settings](#) .
- [Compile source files, modules or packages](#) .
- [Make a module](#) .
- [Make](#) or [rebuild](#) a whole project.
- [Work with the results of compilation](#) .
- [Package a Java module into a JAR file](#) .

Note that the way the module dependencies are ordered may be very important for the compilation to succeed. See [Configuring projects](#) .

The Java builder of IntelliJ IDEA builds, or brings together source files, external libraries, properties files and configurations to produce a living application. The builder uses a compiler that works according to the Java specification.

The compiler treats encountered problems as errors and warnings. Unlike errors, the warnings do not prevent successful compilation. Both warnings and errors are reported in the Messages window.

The following key principles underlie the notion of compilation:

- All compilation tasks are performed in a separate process, fully independent from the main IDE's process, to get rid of the "out of memory" and other resources contention.
- Java compiler is used "in-process" via Java API for better performance and more flexible annotation processors management.
- Compilation is automatically triggered by events from the file system of the IDE, if [such option is enabled](#) .

To build your project, you do not have to leave your editing environment: with IntelliJ IDEA you can compile, build and run your source code straight away.

Note that the way the module dependencies are ordered may be very important for the compilation to succeed. See [Configuring projects](#) .

In this part:

- [Compilation Types](#)
- [Supported Compilers](#)
- [Build Process](#)

IntelliJ IDEA suggests several ways of compiling and building applications. The corresponding commands are available in the Build menu.

- Compile <compilation\_scope>. All the source files in the specified scope are compiled. The scope in this case may be a file, a package, etc. Refer to the section [Compiling Target](#) for details.
- Build Project. All the source files in the entire project modified since the last compilation, are compiled. Dependent source files, if appropriate, are also compiled. Additionally, the tasks tied to the compilation or build process on the modified sources are performed. For example, EJB validation is performed, if the corresponding option is enabled on the [Validation page](#) . Refer to the section [Building Project](#) for details.
- Build Module. Compiles recursively are all the source files which have been modified since the last compilation in the selected module, as well as in all the modules it depends on. Refer to the section [Building Module](#) for details.
- Rebuild Project. All the source files in the project are recompiled. This may be necessary when the classpath entries have changed, for example, SDKs or libraries being used added, removed or altered. Refer to the section [Rebuilding Project](#) for details.

Currently IntelliJ IDEA supports the following Java compilers:

- Javac. This compiler is taken from the Java [SDK](#) currently assigned to the project.
- Eclipse. IntelliJ IDEA comes bundled with the Eclipse compiler.
- [Ajc](#). This compiler is not included in IntelliJ IDEA distribution and should be downloaded separately.  
To use the compiler in IntelliJ IDEA, you also need to download, install, and enable the **AspectJ Support** plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Besides that, IntelliJ IDEA supports compilers for Flex, [Groovy](#), [Android DX](#). The corresponding plugins should be also downloaded, installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

Build process includes the following steps:

- Compiling source code in the source path of a module and placing results to the output path.
- Compiling source code in the test path of a module and placing results to the test output path.
- Creating copies of the resource files in the output path.
- Reporting problems in the Messages tool window.

With IntelliJ IDEA you can build your applications using [Ant](#) , [Maven](#) or [Gradle](#) .

- [Compilation output locations](#)
- [Specifying compilation output folders](#)
- [Configuring compiler settings](#)

## Compilation output locations

There are individual compilation output folders for your [sources](#) and [test sources](#) , and for each of your [modules](#) .

By default, the results of compilation are output to:

- Sources: `<ProjectFolder>/out/production/<ModuleName>`
- Tests: `<ProjectFolder>/out/test/<ModuleName>`

At the project level, you can change the `<ProjectFolder>/out` part of the output path. If you do so (say, specify some `<OutputFolder>` instead of `<ProjectFolder>/out` ) but don't redefine the paths at the module level, the compilation results will go to `<OutputFolder>/production/<ModuleName>` and `<OutputFolder>/test/<ModuleName>` .

At the module level, you can specify any desirable compilation output location for the module sources and tests individually.

## Specifying compilation output folders

The compilation output folders are specified in the Project Structure dialog ( [File | Project Structure](#) ).

Project default folder. Select [Project](#) . In the Project compiler output field, specify the corresponding path.

Module output folders. Select [Modules](#) , select the module of interest, and select [Paths](#) . The controls that you want are in the upper part, under [Compiler output](#) .

## Configuring compiler settings

You can modify the list of recognized resources, exclude certain paths from compilation, select the desired compiler, configure annotation processing, etc.

1. [Open the Settings / Preferences dialog](#) (e.g. `Ctrl+Alt+S` ).
2. On the [Compiler page](#) (the Build, Execution, Deployment section), you may want, for example, to modify the regular expression that describes the extensions of the files to be recognized as resources (the Resource patterns field). Use semicolons ( `;` ) to separate individual patterns. See the [list of wildcard characters and examples](#) .
3. On the [Excludes page](#) , specify the files and folders that shouldn't be included in compilation. Use `+` to add items to the list.  
Note:
  - If an excluded path is a dependency of the source code being compiled, this path will be included in compilation and processed by the compiler as required.
  - If a file contains errors and fails to compile, but it is not important for the current project state, or if you want to skip some files and not to include them in the output directory, you can exclude such files from compilation.
4. On the [Java Compiler page](#) , check if the compiler being used is the one that you want. If necessary, select a different compiler.

**Tip** If you are not happy with the version of the Eclipse compiler bundled with IntelliJ IDEA you can replace this compiler directly in the IntelliJ IDEA distribution with the one you've downloaded from the [Eclipse download page](#) . Note, however, that the name of the corresponding archive should match the pattern `ecj-*.jar`

5. On the [Annotation Processors page](#) , [configure the annotation processing parameters](#) .
6. Apply the changes and close the dialog.

On this page:

- [Compiling all source files in a target](#)
- [Tips and tricks](#)

## Compiling all source files in a target

### To compile all source files in the specified target

1. Select a file, module, or package.
2. On the main menu, choose Build | Rebuild 'target' , or press `Ctrl+Shift+F9` .

## Tips and tricks

### When performing compilation, note that:

- When called from the editor, this method compiles the current file.
- You can compile any module separately. All modules the current one depends on will be compiled as well.

### To cancel the process, do one of the following:

- Middle-click on the progress bar
- Click 
- Press `Ctrl+F2` , and select the process from the pop-up menu.

On this page:

- [Making a module](#)
- [Cancelling build](#)

## Making a module

### To make a module

1. Select the desired module, or any source file or directory within this module.
2. On the main menu choose Build | Make Module 'name' .

## Cancelling build

### To cancel the process, do one of the following:

- Middle-click on the progress bar
- Click 
- Press `Ctrl+F2` , and select the process from the pop-up menu.

On this page:

- [Making a project](#)
- [Cancelling build](#)

## Making a project

### To make a project, do one of the following

- On the main menu choose Build | Build Project 'name' .
- Press `Ctrl+Shift+F9` .

## Cancelling build

### To cancel the process, do one of the following:

- Middle-click on the progress bar
- Click 
- Press `Ctrl+F2` , and select the process from the pop-up menu.

Before packaging a Java module into a JAR file, you need to configure a JAR artifact. See [Working with Artifacts](#) .

## To build a JAR file from a module

1. On the main menu, choose Build | Build Artifact .
2. From the drop-down list, select the desired artifact of the type JAR .

**Tip** The list shows all the artifacts configured for the current project. To have all the configured artifacts built, choose the Build all artifacts option.

## To rebuild a project

- On the main menu choose Build | Rebuild Project .

## To cancel the process, do one of the following:

- Middle-click on the progress bar
- Click 
- Press `Ctrl+F2` , and select the process from the pop-up menu.

IntelliJ IDEA reports compilation and building results in the [Messages tool window](#) that displays information about the errors and warnings, providing each type of problem with its own icon and a pair of numbers that represent the row and column, where the problem occurred. In addition, the Messages tool window lets you jump from the error message to the actual location in the source code.

This section describes how to:

- [Jump from an error message to the respective problem location in the source code](#) .
- [Navigate through the list of error messages](#) .
- [Save compilation report as a text file](#) .

## To jump from an error message to the problem location in the source code

Do one of the following:

- Double-click the error message.
- When Autoscroll to Source  button is released, it is enough to single-click the error message.
- On the context menu of the error message choose Jump to Source .
- Press  .

## To navigate through the list of error messages in the Messages window

Do one of the following:

- Click  or  buttons in the toolbox of the Messages window.
- Press  or  .

## To save compilation results in a text file

1. In the toolbox of the Messages window, click the Export to Text  button, or press  .
2. In the Export Preview dialog, specify the target file, and click Save .

**Tip** Use the Copy button to place selected fragments of the error report to the Clipboard.

To be able to compile an application, you need to specify a build JDK. A build JDK can be configured on a project level. If you have a complex project, you may want to configure different JDKs for different modules.

This topic explains how IntelliJ IDEA selects a build JDK if multiple JDKs are defined, and how to configure them:

- [How does IntelliJ IDEA know which JDK to use?](#)
- [Configuring build JDK](#)

## How does IntelliJ IDEA know which JDK to use?

This section explains the algorithm of choosing a build JDK by IntelliJ IDEA if multiple JDKs are configured on the per-module basis. IntelliJ IDEA does the following to determine which JDK to use for compilation:

- IntelliJ IDEA checks all JDKs used in the project (i.e. the JDKs defined on both the project and module levels).
- IntelliJ IDEA calculates the latest of these JDKs. This is necessary to make sure that all modules can be compiled.
- If the version of the latest JDK configured is lower than 1.6, the JDK version used for running IntelliJ IDEA will be used. This limitation is related to the fact that the compiler API used by IntelliJ IDEA for building projects is supported starting from JDK 1.6.
- Although a specific version of the compiler will be used (in accordance with the selected JDK version), each separate module will be compiled using javac's cross-compilation feature against the libraries of the JDK defined for this particular module in the project settings. This protects you from a situation when a module is compiled against newer libraries than those for which dependencies are set.

## Configuring build JDK

1. Open the [Project Structure dialog](#).
2. Do one of the following:
  - To set a build JDK for an entire project, select Project in the left pane. On the right, under Project SDK, select the required SDK from the drop-down list.
  - To set a build JDK for a specific module, select Modules in the left pane, then select the required module in the central pane and specify a JDK in the Module SDK drop-down list.

If you haven't created any projects before and specified the path to the JDK, click [New](#), select JDK and browse for the JDK installation folder in the [dialog that opens](#).

Note that you can also override the project- or module-level JDK settings for a particular debug or testing session by editing the appropriate [Run/Debug Configuration](#).

In this section:

- Annotation Processors Support
  - [Basics](#)
  - [Annotation profiles](#)
- [Configuring Annotation Processing](#)

## Basics

If you use some custom annotation processors in your project to generate sources and files, validate code and produce warnings, IntelliJ IDEA enables you to easily invoke these processors as a part of the [compilation process](#) .

IntelliJ IDEA allows you to:

- Obtain annotation processors right from the project classpath, or from the specified location.
- Adjust the set of modules which should be covered by annotation processing of a certain profile.
- Store annotation processing results relative to the specified location.
- Perform annotation processing.

When processing annotations is [enabled](#) , the annotations are processed by the compiler in course of compilation.

## Annotation profiles

Annotation processing is performed on the base of the annotation profiles .

A profile is a set of configuration options for annotation processing (use of the annotation processor, location of the annotation processing output, specific annotation processors and their parameters).

The default profile always exists. All the modules comprising a project by default use this profile. When new profiles are created, modules can be associated with them. Thus, several modules can be grouped to use one type of annotation processing.

On this page:

- [Creating annotation profile](#)
- [Associating a module with a profile](#)
- [Configuring annotation profile](#)

## Creating annotation profile

### To create an annotation profile

1. In the [Annotation Processors](#) page, click **+**.
2. In the Create new profile dialog box, specify the [profile](#) name.

To delete a profile, select it in the list, and click **-**. So doing, all modules, associated with this profile, are moved to the default profile.

The default profile cannot be deleted.

## Associating a module with a profile

### To associate a module with an annotation profile

By default, all the modules of a project are associated with the default profile.

1. Select a module in the list of modules under a profile.
2. Click , or press **F6**.
3. From the drop-down list, select the target profile to move the selected module to.

## Configuring annotation profile

### To configure annotation processing for a profile, follow these steps

1. In the [Annotation Processors](#) page, select the desired annotation profile.
2. Enable processing annotations by selecting the corresponding checkbox.
3. Do the following:
  - Choose location of the annotation processors. You can opt to use annotation processor from the classpath, or specify its location by choosing it from the [Select Path](#) dialog box.
  - In the Directory name field, type the name of the directory where the annotation processor output will be stored. If the field is left blank, the files generated by the annotation processor will be stored under the project output directory. When the name is specified, the directory with this name will be created under the content root after automatic annotation processing during compilation.
  - Specify the fully-qualified names of the processors to be launched. If nothing is specified, then IntelliJ IDEA will launch all the processors detected in the specified location.
  - Specify additional parameters to be passed to the annotation processors.

On this page:

- [What is an artifact?](#)
- [Working with artifact configurations](#)
- [Building artifacts](#)
- [Build options \(Build, Rebuild, etc.\)](#)
- [Running JAR artifacts](#)
- [Deploying artifacts to application servers and cloud platforms](#)
- [Examples](#)

See also, [Project Structure / Artifacts](#) .

## What is an artifact?

An artifact is an assembly of your project assets that you put together to test, deploy or distribute your software solution or its part. Examples are a collection of compiled Java classes or a Java application packaged in a Java archive, a Web application as a directory structure or a Web application archive, etc.

An artifact can be an archive file or a directory structure that includes the following structural elements:

- Compilation output for one or more of your modules
- Libraries included in module dependencies
- Collections of resources (web pages, images, descriptor files, etc.)
- Other artifacts
- Individual files, directories and archives.

## Working with artifact configurations

Artifacts are generated according to artifact configurations. The artifact configurations are managed in the Project Structure dialog ( [File | Project Structure | Artifacts](#) ).

The key part of configuring an artifact is specifying the artifact structure and contents on the [Output Layout tab](#) .

## Building artifacts

You can initiate building an artifact yourself: [Build | Build Artifacts](#) .

You can as well build an artifact by executing a run/debug configuration:

In the corresponding run/debug configuration, add the `Build <ArtifactName>` artifact task to the Before launch task list. The artifact will be built automatically when you execute the run/debug configuration ( [Run | Run](#) or [Run | Debug](#) ).

Including the Build artifact task in a run/debug configuration makes sense when the run/debug configuration somehow uses the corresponding artifact, e.g. starts the application packaged in a JAR artifact or deploys a WAR or EAR artifact to an application server.

By default, an artifact, when built, is placed into the `out/artifacts/<artifact_dir>` folder.

## Build options (Build, Rebuild, etc.)

When building an artifact ( [Build | Build Artifacts](#) ), you have the following options:

- Build. When used for the first time, the whole artifact is built. Each next time you use this option, only the part of the artifact affected by the changes you have made since the last build is built and added to the output folder.
- Rebuild. Build the whole artifact as if for the first time. Technically, this is [Clean](#) followed by [Build](#) .
- Clean. Delete all the contents of the artifact output directory.
- Edit. Edit the [artifact configuration](#) .

## Running JAR artifacts

To run Java applications packaged in Java archives (JARs), IntelliJ IDEA provides the JAR Application run configurations. To create such a run configuration:

1. Open the Run/Debug Configurations dialog (e.g. [Run | Edit Configurations](#) ).
2. Click [+](#) and select JAR Application .

## Deploying artifacts to application servers and cloud platforms

Many of the artifact formats (e.g. WAR, Exploded WAR, EAR, Exploded EAR) are suitable for deployment to application servers and cloud platforms. Here is how you deploy such artifacts:

1. In a server or cloud run/debug configuration, specify the artifact to be deployed. (Use the Deployment tab or field.)
2. Execute the run/debug configuration or use the Deploy command ([+](#)) in the Application Servers , Run or Debug tool window.

## Examples

Examples of the procedures discussed on this page can be found in the following tutorials:

- [Creating, Running and Packaging Your First Java Application](#)
- [Developing a Java EE Application](#)

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Interaction between IntelliJ IDEA and servers](#)

## Basics

Among numerous ways to configure your development and production environments the most frequent ones are as follows:

- The Web server is installed on your computer. The sources are under the server document root (for example, `/htdocs`), and you do your development right on the server.
- The Web server is installed on your computer but the sources are stored in another folder. You do your development, then copy the sources to the server.
- The Web server is on another computer (remote host). Files on the server are available through the FTP/SFTP/FTPS protocol, through a network share, or a mounted drive.

Now let's see how to use IntelliJ IDEA in the above environment configurations. IntelliJ IDEA assumes that all development, debugging, and testing is done on your computer and then the code is deployed to a production environment.

Please note the following:

- The reason to stick to this "local development - deployment" model lies in the way IntelliJ IDEA provides its coding assistance which includes code completion, code inspections & validations, code navigation, etc. All this functionality is based on the **index of the project files** which IntelliJ IDEA builds when the project is loaded and updates on the fly as you edit your code.
- To provide efficient coding assistance, IntelliJ IDEA needs to re-index code fast, which requires fast access to project files. The latter can be ensured only for **local** files, that is, files that are stored on you hard disk and are accessible through the file system. Therefore IntelliJ IDEA does not support the mode when you access your files over a network folder (very often it becomes slow and unresponsive, performs random look-ups for no obvious reason, etc).

## Interaction between IntelliJ IDEA and servers

Interaction between IntelliJ IDEA and servers is controlled through **server access configurations**. Anytime you are going to use a server, you need to define a **server access configurations**, no matter whether your server is on a remote host or on your computer.

Taking into account all the above, let's define the following basic concepts related to synchronization between IntelliJ IDEA and servers.

- An **in-place server** is a server whose **document root** is the parent of the project root, either immediate or not. In other words, the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.
- A **local server** is a server that is running in a local or a mounted folder and whose **document root** is **NOT** the parent of the project root.
- A **remote server** is a server on another computer (remote host).
- The **server configuration root** is the highest folder in the file tree on the **local** or **remote** server accessible through the server configuration. For **in-place** servers, it is the project root.
- A **local file/folder** is any file or folder under the project root.
- A **remote file/folder** is any file or folder on the server, either local or remote.

Suppose you have a project `C:/Projects/My_Project/` with a folder `C:/Projects/My_Project/My_Folder` and a local server with the document root in `C:/xampp/htdocs`. You upload the entire project tree to `C:/xampp/htdocs/My_Project`. In the terms of IntelliJ IDEA, the folder `C:/Projects/My_Project/My_Folder` is referred to as **local** and the folder `C:/xampp/htdocs/My_Project/My_Folder` is referred to as **remote**.

- **Upload** is copying data from the project **TO** the server, either local or remote.
- **Download** is copying data **FROM** the server to the project.

After you have configured synchronization with a server, you can upload, download, and manage files on it directly from IntelliJ IDEA. Moreover, you can suppress uploading or downloading specific files or entire folders. Finally, you can optimize you workflow by configuring content roots so specific folders are not involved in indexing, which significantly saves project indexing time.

Synchronization with servers, uploading, downloading, and managing files on them are provided via the Remote Hosts Access bundled plugin, which is by default enabled. If the plugin is disabled, activate it in the Plugins page of the Settings dialog box. For details, see [Enabling and Disabling Plugins](#). Note that the plugin is available only for the **Ultimate Edition** of IntelliJ IDEA.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Before you start](#)
- [Basics](#)
- [Server access configuration](#)

## Before you start

Synchronization with servers, uploading, downloading, and managing files on them are provided via the Remote Hosts Access bundled plugin, which is by default enabled. If the plugin is disabled, activate it in the Plugins page of the Settings dialog box. For details, see [Enabling and Disabling Plugins](#). Note that the plugin is available only for the **Ultimate Edition** of IntelliJ IDEA.

## Basics

IntelliJ IDEA distinguishes among **in-place**, **local**, and **remote** servers, however the meaning of these terms in the context of IntelliJ IDEA slightly differs from their common meaning:

- An **in-place server** is a server whose **document root** is the parent of the project root, either immediate or not. In other words, the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.
- A **local server** is a server that is running in a local or a mounted folder and whose **document root** is **NOT** the parent of the project root.
- A **remote server** is a server on another computer (remote host).

For more information about possible configuration of the production and development environment and working with servers from IntelliJ IDEA, see [Deploying your application](#).

## Server access configuration

IntelliJ IDEA controls interaction with Web servers through **server access configurations**. Anytime you are going to use a server, you need to define a server access configurations, no matter whether your server is on a remote host or on your machine.

A **server access configuration** defines:

- The server type ( **in-place**, **local**, or **remote** ).
- The computer (host) where the server is running. For **in-place** and **local** servers, IntelliJ IDEA presupposes that it is the current computer where your project is.
- The server access configuration root : the highest folder in the server hierarchy that can be accessed through the server configuration.
- The URL address to access the server configuration root. Both the **HTTP** and the **HTTPS** protocols are supported. To access a server through **HTTPS**, you need to acquire a certificate file `<certificate_name>.cert` signed by a recognized **authority** and import this certificate in the [truststore/keystore](#) of the Oracle JRE (Java Runtime Environment) on which IntelliJ IDEA runs. Note that self-signed certificates are rejected as unsafe.

### To import a certificate in Oracle JRE:

1. Open the embedded Terminal and type the following command:

```
<jre_home>/bin/keytool.exe -importcert -keystore <path to jre truststore/keystore> -file
```

If you are using the **Oracle JRE** bundled with IntelliJ IDEA, the default path to the truststore/keystore is

```
<%product_installation_folder>/jre/jre/lib/security/jssecacerts or  
<%product_installation_folder>/jre/jre/lib/security/cacerts .
```

Otherwise it is `<jre_home>/jre/lib/security/jssecacerts` or `<jre_home>/jre/lib/security/cacerts` .

2. When asked to enter a password for the truststore/keystore, specify the default one `changeit` .
3. Open the `IntelliJ IDEA.exe.vmoptions` file in the `<IntelliJ IDEA installation folder>/bin` and add the following line to it:

```
-Djavax.net.ssl.keyStore=<path to keystore>
```

4. Restart IntelliJ IDEA.

Learn more at [Java6](#) and [Java7](#) .

- The protocol to transfer the data through.
- Correspondence between local (project) folders, destination folders on the server, and URL addresses to access the data on the server. This correspondence is called **mapping** .

You can define as many configurations as necessary, thus enabling flexible switching between upload/download setups.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Creating a server configuration: specifying its name, type, and visibility](#)
- [Configuring access to an in-place server: specifying the URL address of the server document root](#)
- [Specifying the project root folder and the URL address to access it](#)

## Basics

An **in-place server** is a server whose **document root** is the parent of the project root, either immediate or not. In other words, the Web server is running on your computer, your project is under its document root, and you do your development directly on the server.

To configure access to the server in this set-up, you only need to specify the URL address of the sever **document root**, appoint the project root folder, and specify the URL address to access it.

## Creating a server configuration: specifying its name, type, and visibility

1. Open the [Deployment](#) page by doing one of the following:
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment.
  - Choose Tools | Deployment | Configuration on the main menu.
2. In the left-hand pane, that shows a list of all the existing server configurations, click the Add toolbar button **+**. The [Add Server dialog box](#) opens.
3. Specify the server configuration name in the Name text box. From the Type drop-down list, choose the server configuration type In-place. Use the Up and Down keyboard keys to scroll through the list of server configuration types.
4. Use the Visible only for this project checkbox to configure the visibility of the server access configuration (deployment configuration).
  - Select the checkbox to restrict the use of the configuration to the current project. Such configurations cannot be reused outside the current project, they do not appear in the list of available configurations in other projects.
  - When the checkbox is cleared, the configuration is visible in all IntelliJ IDEA projects and the settings from, including SSH credentials, can be reused.
5. Click OK. The Add Server dialog box closes and you return to the [Connection](#) tab of the [Deployment](#) node.

## Configuring access to an in-place server: specifying the URL address of the server document root

In the Web server root URL text box, type the URL address associated with the **document root** of your Web server as defined in the Web server configuration file. This URL address will be the starting point for building the URL address of your application. Both the **HTTP** and the **HTTPS** protocols are supported.

To access a server through **HTTPS**, you need to acquire a certificate file `<certificate_name>.cert` signed by a recognized **authority** and import this certificate in the [truststore/keystore](#) of the **Oracle JRE (Java Runtime Environment)** on which IntelliJ IDEA runs. Note that self-signed certificates are rejected as unsafe.

### To import a certificate in Oracle JRE:

1. Open the embedded Terminal and type the following command:

```
<jre_home>/bin/keytool.exe -importcert -keystore <path to jre truststore/keystore> -file <f
```

If you are using the **Oracle JRE** bundled with IntelliJ IDEA, the default path to the truststore/keystore is

```
<%product_installation_folder>/jre/jre/lib/security/jssecacerts or
```

```
<%product_installation_folder>/jre/jre/lib/security/cacerts .
```

Otherwise it is `<jre_home>/jre/lib/security/jssecacerts` or `<jre_home>/jre/lib/security/cacerts` .

2. When asked to enter a password for the truststore/keystore, specify the default one `changeit` .
3. Open the `IntelliJ IDEA.exe.vmoptions` file in the `<IntelliJ IDEA installation_folder>/bin` and add the following line to it:

```
-Djavax.net.ssl.keyStore=<path to keystore>
```

4. Restart IntelliJ IDEA.

Learn more at [Java6](#) and [Java7](#) .

For example, the [Apache httpd](#) server configuration file is `httpd.conf` . The default document root is the `htdocs` folder and the default URL address to access the data in it is `http://localhost` . If you have changed the default port `80` , you have to specify the port explicitly: `http://localhost:<port>` .

## Specifying the project root folder and the URL address to access it

1. Switch to the [Mappings](#) tab.
2. In the Local path text box, specify the full path to your project root folder. Type the path manually, or click the Browse button  and choose the folder in the dialog box, that opens.
3. In the Web path on server text box, type the path to the project root folder relative to the server document root specified in the server configuration file. As you type, IntelliJ IDEA dynamically builds the URL address through which your project root folder will be accessible and shows it as a link in the Project URL read-only field. To check that the URL address is constructed correctly and ensures access to the project root, click the link.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Creating a server configuration: specifying its name, type, and visibility](#)
- [Specifying the server configuration root and the URL address to access it](#)
- [Example of specifying a server configuration root](#)
- [Mapping project folders with folders on the server and the URL addresses to access them](#)
- [Example of mapping project folders with folders on the server](#)

## Basics

A **local server** is a server that is running in a local or a mounted folder and whose **document root** is **NOT** the parent of the project root.

To configure access to the server in this set-up, you need to specify the following:

1. The **server configuration root** folder and the URL address to access it.
2. Correspondence between the **project root folder**, the folder on the server to copy the data from the **project root folder** to, and the URL address to access the copied data on the server. This correspondence is called **mapping**.

## Creating a server configuration: specifying its name, type, and visibility

1. Open the [Deployment](#) page by doing one of the following:
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment.
  - Choose Tools | Deployment | Configuration on the main menu.
2. In the left-hand pane, that shows a list of all the existing server configurations, click the Add toolbar button . The [Add Server dialog box](#) opens.
3. Specify the server configuration name in the Name text box. From the Type drop-down list, choose the server configuration type Local or mounted folder.  
When editing the server configuration name in the Name text box, use the Up and Down keys on your keyboard to change the preselected server access to type in the Type drop-down list.
4. Use the Visible only for this project checkbox to configure the visibility of the server access configuration (deployment configuration).
  - Select the checkbox to restrict the use of the configuration to the current project. Such configurations cannot be reused outside the current project, they do not appear in the list of available configurations in other projects.
  - When the checkbox is cleared, the configuration is visible in all IntelliJ IDEA projects and the settings from, including SSH credentials, can be reused.
5. Click OK. The Add Server dialog box closes and you return to the [Connection](#) tab of the [Deployment](#) node.  
Click the Use as Default toolbar button  to have IntelliJ IDEA silently apply the current configuration in the following cases:
  - [Automatic upload of changed files](#).
  - [Manual upload of files](#) without choosing the target host.
  - [Comparing local files and folders](#) with their remote versions.

## Specifying the server configuration root and the URL address to access it

1. In the Folder text box of the Upload/download project files area, specify the **server configuration root**.  
The **server configuration root** is the highest folder in the file tree on the server that can be accessed through the server configuration. The easiest way is to use the **document root** of your Web server as defined in the Web server configuration file. However you can appoint any other existing folder under the **document root**.
2. In the Web server root URL text box of the Browse files on server area, specify the URL address of the **server configuration root**. This URL address will be the starting point for building the URL address of your application.  
Depending on your choice of the **server configuration root**, do one of the following:
  - Type the URL address associated with the **document root** of your Web server as defined in the Web server configuration file.
  - Type the URL address in the format `<URL of the server document root>/<path to the relevant folder relative to the server document root>`.

Both the HTTP and the HTTPS protocols are supported.

To access a server through HTTPS, you need to acquire a certificate file `<certificate_name>.cert` signed by a recognized authority and import this certificate in the [truststore/keystore](#) of the Oracle JRE (Java Runtime Environment) on which IntelliJ IDEA runs. Note that self-signed certificates are rejected as unsafe.

### To import a certificate in Oracle JRE:

1. Open the embedded Terminal and type the following command:

```
<jre_home>/bin/keytool.exe -importcert -keystore <path to jre truststore/keystore> -file
```

If you are using the **Oracle JRE** bundled with IntelliJ IDEA, the default path to the truststore/keystore is

```
<%product_installation_folder>/jre/jre/lib/security/jssecacerts or
```

```
<%product_installation_folder>/jre/jre/lib/security/cacerts .
```

Otherwise it is `<jre_home>/jre/lib/security/jssecacerts` or

```
<jre_home>/jre/lib/security/cacerts .
```

2. When asked to enter a password for the truststore/keystore, specify the default one `changeit` .
3. Open the `IntelliJ IDEA.exe.vmoptions` file in the `<IntelliJ IDEA_installation_folder>/bin` and add the following line to it:

```
-Djavax.net.ssl.keyStore=<path to keystore>
```

4. Restart IntelliJ IDEA.

Learn more at [Java6](#) and [Java7](#) .

## Example of specifying a server configuration root

For example, the [Apache httpd](#) server configuration file is `httpd.conf` , according to it, the default **document root** is the `htdocs` folder, and the default URL address to access the data in it is `http://localhost` . For the sake of simplicity, let's suppose that you are using the [XAMPP](#) package and it is installed in the root of the `C:/` drive.

So if you decide to copy your project files directly under the **server document root** , your **server configuration root** will be `C:\xampp\htdocs` and its URL will be `http://localhost:<port>` .

You can establish a more complicated folder structure on the server, for example, to have `MySite1` and `MySite2` folders under the **server document root** . In this case the you will have to decide which of these folders you will use in the current configuration, let it be `MySite2` . Accordingly, the **server configuration root** will be `C:\xampp\htdocs\MySite2` and its URL address will be `http://localhost:<port>\MySite2` .

## Mapping project folders with folders on the server and the URL addresses to access them

Configure **mappings** , that is, set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. The easiest way is to map the entire project root folder to a folder on the server, whereupon the project folder structure will be repeated on the server, provided that you have selected the Create Empty directories checkbox in the [Options dialog box](#) . "For more details, see [Customizing Upload/Download](#) .

1. Switch to the Mappings tab.
2. In the Local Path text box, specify the full path to the desired folder in the project tree. In the simplest case it is the project root.
3. In the Deployment Path text box, specify the folder on the server where IntelliJ IDEA will upload the data from the folder specified in the Local Path text box. Type the path to the folder relative to the **server configuration root** . If the folder with the specified name does not exist yet, IntelliJ IDEA will create it, provided that you have selected the Create Empty directories checkbox in the [Options dialog box](#) . For more details, see [Customizing Upload/Download](#) .
4. In the Web Path text box, type the path to the folder on the server relative to the **server configuration root** . Actually, type the relative path you typed in the Deployment Path text box.

## Example of mapping project folders with folders on the server

For example, if your project is `C:\My_Projects\Mapping_project` , the **server document root** is `C:\xampp\htdocs` , the **server configuration root** is `C:\xampp\htdocs\MySite2` , and its URL address is `http://localhost:<port>\MySite2` , fill in the fields as follows:

1. In the Local Path text box, type `C:\My_Projects\Mapping_project` .
2. In the Deployment Path text box, type `Mapping_project` .
3. In the Web Path text box, type `Mapping_project` .

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Creating a server configuration: specifying its name, type, and visibility](#)
- [Specifying user credentials defined during registration on the host](#)
- [Enabling connection to the server and specifying the server configuration root](#)
- [Mapping local folders to folders on the server and the URL addresses to access them](#)
- [Overloading the deployment destination by configuring nested mappings](#)

## Basics

A **remote server** is a server on another computer (remote host).

To configure access to the server in this set-up, you need to specify the following:

1. Connection settings: server host, port, and user credentials.
2. The **server configuration root** folder and the URL address to access it.
3. Correspondence between the **project root folder**, the folder on the server to copy the data from the **project root folder** to, and the URL address to access the copied data on the server. This correspondence is called **mapping**.

## Creating a server configuration: specifying its name, type, and visibility

1. Open the [Deployment](#) page by doing one of the following:
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment.
  - Choose Tools | Deployment | Configuration on the main menu.
2. In the left-hand pane, that shows a list of all the existing server configurations, click the Add toolbar button . The [Add Server dialog box](#) opens.
3. Specify the server configuration name in the Name text box. From the Type drop-down list, choose the server configuration type depending on the protocol you are going to use to exchange the data with the server.
  - FTP: choose this option to have IntelliJ IDEA access the server via the [FTP file transfer protocol](#).
  - SFTP: choose this option to have IntelliJ IDEA access the server via the [SFTP](#) file transfer protocol.
  - FTPS: choose this option to have IntelliJ IDEA access the server via the FTP file transfer protocol over SSL (the [FTPS](#) extension).

When editing the server configuration name in the Name text box, use the Up and Down keys on your keyboard to change the preselected server access to type in the Type drop-down list.

4. Use the Visible only for this project checkbox to configure the visibility of the server access configuration (deployment configuration).
  - Select the checkbox to restrict the use of the configuration to the current project. Such configurations cannot be reused outside the current project, they do not appear in the list of available configurations in other projects. For example, if this checkbox is selected in an SFTP configuration, you cannot use your SSH credentials from it when you configure a remote interpreter.
  - When the checkbox is cleared, the configuration is visible in all IntelliJ IDEA projects and the settings from, including SSH credentials, can be reused.

See [Configuring Node.js Interpreters](#) and [Configuring Remote PHP Interpreters](#) for details.

5. Click OK. The Add Server dialog box closes and you return to the Connection tab of the Deployment dialog box. Click the Use as Default toolbar button  to have IntelliJ IDEA silently apply the current configuration in the following cases:
  - [Automatic upload of changed files](#).
  - [Manual upload of files](#) without choosing the target host.
  - [Comparing local files and folders](#) with their remote versions.

## Specifying user credentials defined during registration on the host

1. Specify the registration mode:
  - To login in a regular mode, specify the login in the User name text box.
  - To enable [anonymous access](#) to the server with your email address as password, select the Login as anonymous checkbox.
2. Specify the way to authenticate to the server:
  - For **FTP server**, type your password and select the Save password checkbox to have IntelliJ IDEA remember it.
  - For **SFTP server**, choose the way to authenticate to the server. Do one of the following:
    - To access the host through a password, choose Password from the Auth type drop-down list, specify the password, and select the Save password checkbox to have IntelliJ IDEA remember it.
    - To use [SSH authentication](#) via a key pair, choose Key pair (OpenSSH or PuTTY). To apply this authentication method, you need to have your private key on the client machine and your public key on the remote server you connect to. IntelliJ IDEA supports private keys generated using the [OpenSSH](#) utility. Specify the path to the file where your **private key** is stored and type the passphrase (if any) in the corresponding text

boxes. To have IntelliJ IDEA remember the passphrase, select the Save passphrase checkbox.

- If your SSH keys are managed by a credentials helper application (for example, [Pageant](#) on Windows or [ssh-agent](#) on Mac and Linux), choose Authentication agent (ssh-agent or Pageant).
- For **FTPS server**, specify your user name and password and choose the security mechanism to apply.
  - Choose Explicit to have the [explicit \(active\) security](#) applied. Immediately after establishing connection, the FTP client on your machine sends a command to the server to establish secure control connection through the default FTP port.
  - Choose Implicit to have the [implicit \(passive\) security](#) applied. In this case, security is provided automatically upon establishing connection to the server which appoints a separate port for secure connections.

**Tip** See the [Generating a new SSH key and adding it to the ssh-agent](#) tutorial for details on working with SSH keys.

## Enabling connection to the server and specifying the server configuration root

1. Specify the host name of the FTP/SFTP/FTPS server to exchange data with and the port to which this server listens. The default values are:
  - 21 for FTP and FTPS
  - 22 for SFTP
2. In the Root path text box, specify the **server configuration root** relative to your **user home** which was defined when you registered your account. This folder will be the highest one in the folder structure accessible through the current server configuration. Do one of the following:
  - Accept the default value `/`, which points at the **user home** folder on the server.
  - Type the path manually.
  - Click the Browse button  and select the desired folder in the Choose Root Path dialog box that opens.
  - Click the Autodetect button and have IntelliJ IDEA detect the user home folder settings on the FTP/SFTP server and set up the root path according to them. The button is only enabled when you have specified your user name and password.
3. In the Web server root URL text box, type the URL address to access the server configuration root (The **server configuration root** is the highest folder in the file tree on the **local** or **remote** server accessible through the server configuration. For **in-place** servers, it is the project root.). Both the **HTTP** and the **HTTPS** protocols are supported. To access a server through **HTTPS**, you need to acquire a certificate file `<certificate_name>.cert` signed by a recognized **authority** and import this certificate in the [truststore/keystore](#) of the **Oracle JRE (Java Runtime Environment)** on which IntelliJ IDEA runs. Note that self-signed certificates are rejected as unsafe.

### To import a certificate in Oracle JRE:

1. Open the embedded Terminal and type the following command:

```
<jre_home>/bin/keytool.exe -importcert -keystore <path to jre truststore/keystore> -file
```

If you are using the **Oracle JRE** bundled with IntelliJ IDEA, the default path to the truststore/keystore is

```
<%product_installation_folder>/jre/jre/lib/security/jssecacerts or
```

```
<%product_installation_folder>/jre/jre/lib/security/cacerts .
```

Otherwise it is `<jre_home>/jre/lib/security/jssecacerts or`

```
<jre_home>/jre/lib/security/cacerts .
```

2. When asked to enter a password for the truststore/keystore, specify the default one `changeit`.
3. Open the `IntelliJ IDEA.exe.vmoptions` file in the `<IntelliJ IDEA installation folder>/bin` and add the following line to it:

```
-Djavax.net.ssl.keyStore=<path to keystore>
```

4. Restart IntelliJ IDEA.

Learn more at [Java6](#) and [Java7](#).

4. Click the Open button to make sure that the specified URL address is accessible and points at the correct Web page.

## Mapping local folders to folders on the server and the URL addresses to access them

Configure **mappings**, that is, set correspondence between the project folders, the folders on the server to copy project files to, and the URL addresses to access the copied data on the server. The easiest way is to map the entire project root folder to a folder on the server, whereupon the project folder structure will be repeated on the server, provided that you have selected the Create Empty directories checkbox in the **Options dialog box**. "For more details, see [Customizing Upload/Download](#).

1. Switch to the Mappings tab.
2. In the Local Path text box, specify the full path to the desired folder in the project tree. In the simplest case it is the project

root.

3. In the Deployment Path text box, specify the folder on the server where IntelliJ IDEA will upload the data from the folder specified in the Local Path text box. Type the path to the folder relative to the **server configuration root** . If the folder with the specified name does not exist yet, IntelliJ IDEA will create it, provided that you have selected the Create Empty directories checkbox in the [Options dialog box](#) . For more details, see [Customizing Upload/Download](#) .
4. In the Web Path text box, type the path to the folder on the server relative to the **server configuration root** . Actually, type the relative path you typed in the Deployment Path text box.

## Overloading the deployment destination by configuring nested mappings

You can configure separate mappings for a specific folder under the your project root to have the contents of this folder synchronized with another location on the remote host.

Suppose you have configured the mappings as follows:

Local Path	Deployment Path
------------	-----------------

<project_root>	ftp://.../htdocs/my_project
<project_root>/my_folder	ftp://.../htdocs/my_folder

Then the files in your project will be uploaded as follows:

Local Path	Deployment Path
------------	-----------------

<project_root>/file1.js	ftp://.../htdocs/my_project/file1.js
<project_root>/my_folder/file2.js	ftp://.../htdocs/my_folder/file2.js

instead of ftp://.../htdocs/my\_project/my\_folder/file2.js

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Setting common upload/download options](#)
- [Specifying additional protocol-specific customization options for FTP/SFTP/FTPS servers](#)

## Basics

In addition to the mandatory settings that ensure successful upload and download in various project - server set-ups, you can choose additional options to customize interaction with the server. Most of these options apply to all types of **server access configuration**. For FTP/FTPS/SFTP server configurations, you can specify additional protocol-specific options.

### Setting common upload/download options

1. Open the [Options](#) dialog box by doing one of the following:
  - On the main menu, choose Tools | Deployment | Options .
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Build, Execution, Deployment node, and then click Options under Deployment .
2. In the Options dialog box that opens, specify additional settings:
  - To have IntelliJ IDEA skip specific files or entire folders during upload/download, in the Exclude items by name text box, specify the patterns that define the names of these files and folders. Use semicolons as delimiters. Wildcards are welcome.  
The exclusion is applied recursively. This means that if a matching folder has subfolders, the contents of these subfolders are not deployed either.  
  
For more details about excluding files and folders from upload/download, see [Excluding Files and Folders from Upload/Download](#) .
  - Specify the details of the upload/download procedure by selecting or clearing the corresponding checkboxes.

### Specifying additional protocol-specific customization options for FTP/SFTP/FTPS servers

1. Open the [Deployment](#) dialog box by doing one of the following:
  - Choose Tools | Deployment | Configuration on the main menu.
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment .
2. In the [Deployment](#) dialog box, click the Advanced Options button and specify additional uploading settings in the Advanced Options dialog box that opens:
  - To set the client to the [passive mode](#) , select the Passive mode checkbox. In this mode, the client on your machine connects to the server to inform about being in the passive mode, receives the port number to listen to, and established data connection through the port with the received number. This mode is helpful when your machine is behind a firewall.
  - To have the hidden files and directories (those with names that start with a dot `.` ) shown in the [Server Browser Tool Window](#) , select the Show Hidden Files checkbox.
  - Select the Compatibility mode checkbox to ensure [compatibility in child file naming](#) with your FTP server. This option is helpful if the remote FTP server reports the following error:

```
Invalid descendant file name <file name>
```

Selecting this option may slow down synchronization with the server.

- Use the Retrieve accurate files timestamps drop-down list to specify the [MDTM](#) FTP command calling policy to retrieve the last-modified time of a given file on the remote host. The available options are:
  - Always - select this option to have MDTM called for every file shown in the [Remote Host](#) tool window.
  - On copy - select this option to have MDTM called in the following cases:
    - To check whether a file is up to date when the Overwrite up-to-date files checkbox in the [Options](#) dialog box is cleared.
    - To preserve the actual time stamp of a file during download.
  - Never - select this option to suppress calling MDTM.
- Select the Limit concurrent connections checkbox to have IntelliJ IDEA restrict the number of connections to be supported simultaneously and specify the maximum number of allowed connections in the text box.
- In the Control encoding text box, specify the encoding that matches the encoding used by your server. Accept the default value if you are not sure that it supports **UTF-8** encoding.
- Select the Always use LIST command checkbox to use the standard `LIST` command for listing instead of the `MLSD` command. This lets you avoid problems, for example, failure during upload with the **Invalid descendent file name** exception if the FTP server supports `MLSD` and returns `cdir` .
- In the Send keep alive message each text box, specify how often you want IntelliJ IDEA to send commands to the server to reset the timeout and thus preserve the connection.
- From the Use keep alive command drop-down list, choose the commands to be sent to the server to reset the timeout

and thus preserve the connection.

- On some **SFTP** servers, the **SSH banner** may be enabled. Every time a connection is established, a pop-up window with an information message may be shown and to continue you would need to click OK .

To suppress showing the information pop-up window, select the Ignore info messages checkbox.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Excluding a folder on server from upload/download after project creation](#)
- [Excluding a local folder from upload/download](#)
- [Excluding files and folders from upload/download by name](#)
- [Removing the exclusion mark](#)

## Basics

Suppressing uploading, downloading, and synchronization for files or folders with sources ensures that the sources are protected against accidental update. When applied to non-sources, it saves system resources because huge amounts of media, caches, or temporal files are no longer copied hither and thither.

You may need to suppress upload/download in the following cases:

1. You are going to work with externally created and uploaded source code. To process these remote sources in IntelliJ IDEA, you have to download them and arrange them in a project. However, there are some sources that you should not update at all. On the other hand, the folders on the remote host also may contain huge amounts of media, caches, temporal files, that you actually do not need in your work.
2. You have already downloaded the data from the server and arranged them in a IntelliJ IDEA project. However, for this or that reason, you need to have some files or folders on the server protected against upload/download, for example, to prevent accidental overwriting.
3. The local copy of an application contains both source code and other data that you do not need to upload. Besides, you want to protect some sources against overwriting by mistake. In this case, you can suppress upload/download for all files and folders that should not be uploaded.

There are two ways to **exclude folders** from upload/download:

- Explicitly, by marking the corresponding paths as excluded in the [Remote Host](#) tool window or in the [Excluded Paths](#) tab of the [Deployment dialog box](#).
  1. The names of all the not-excluded folders and files are displayed on green background. The names of excluded items are displayed without background.
  2. In the [Remote Host](#) tool window, you can exclude both entire folders and specific files.
- **By name**, that is, by specifying [patterns that determine the names](#) of files and folders to be excluded in the Exclude Items by Name text box of the [Options](#) dialog box.

**Separate files** can be protected against upload/download only through [excluding them by name](#).

**Note** In either case, the exclusion is applied recursively. This means that if the path to a folder is explicitly marked as excluded or the folder name matches the pattern, the contents of all its subfolders, if any, are also protected against upload/download.

## Excluding a folder on server from upload/download after project creation

1. Choose the required folder right in the [Remote Host](#) tool window:
  1. On the main menu, choose Tools | Deployment | Browse Remote Host or View | Tool Windows | Remote Host.
  2. In the [Remote Host](#) tool window that opens, select the relevant [server configuration](#) from the drop-down box.
  3. Select the folder to exclude and choose Exclude Path on the context menu of the selection.
2. Add the required folder to the list of excluded paths:
  1. Open the [Deployment](#) dialog box by doing one of the following:
    - Choose Tools | Deployment | Configuration on the main menu.
    - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment.
  2. In the [Deployment](#) dialog box, switch to the [Excluded Paths](#) tab. The tab shows the list of the previously excluded local and remote folders.
  3. Click the Add deployment path button. An empty line is added to the list.
  4. Click the Browse button `...`. The Select remote excluded path dialog box that opens shows the data on the host accessed through the selected server configuration. Select the required folder.
  5. When you OK, you return to the [Excluded Paths](#) tab, where the selected remote folder is added to the list.

## Excluding a local folder from upload/download

1. Open the [Deployment](#) dialog box by doing one of the following:
  - Choose Tools | Deployment | Configuration on the main menu.
  - Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Deployment under Build, Execution, Deployment.
2. In the [Deployment](#) dialog box, switch to the [Excluded Paths](#) tab. The tab shows the list of the previously excluded local and remote folders.
3. Click the Add local path button. In the empty line that is added to the list, specify the location of the folder to be protected

against upload/download. Type the path manually or click the Browse button  and choose the required folder in the [dialog that opens](#) .

## Excluding files and folders from upload/download by name

1. Open the [Options](#) dialog box by doing one of the following:

- On the main menu, choose Tools | Deployment | Options .
- Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Build, Execution, Deployment node, and then click Options under Deployment .

2. In the [Options](#) dialog box that opens, specify the patterns that define the names of these files and folders in the Exclude items by name text box. Use semicolons as delimiters. Wildcards are welcome.

The exclusion is applied recursively. This means that if a matching folder has subfolders, the contents of these subfolders are not deployed either.

## Removing the exclusion mark

To return a file or folder to upload/download, select it and choose Remove Path from Excluded on the context menu of the selection. Returning a folder to upload/download automatically affects all its subfolders and files.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Accessing a server](#)
- [Handling files and folders on the server](#)

## Basics

Once you have [set up synchronization](#) between your local application sources and the application sources on a server, you can create new folders, move, rename, and delete existing files and folders. You can also [compare](#) files and folders on the server with their local versions.

For the sake of simplicity, any file or folder in your IntelliJ IDEA project is called **local** and any file or folder on the server is called **remote**, even if the server is actually installed on your machine. For details, see [Configuring Synchronization with a Web Server](#).

Although IntelliJ IDEA supports direct editing of individual non-project files on servers, to keep your local and remote sources synchronized, configure automatic upload using the >Upload changed files automatically to the default server drop-down list in the [Options](#) dialog box.

Access to servers is controlled through [server configurations](#) of the type FTP, FTPS, SFTP, or Local or Mounted Folder.

## Accessing a server

1. Open the [Remote Host tool window](#) by choosing *Tools | Deployment | Browse Remote Host or View | Tool Windows | Remote Host* on the main menu.
2. Select the required deployment server from the drop-down list. The tool window shows a tree view of files and folders under the **server root**. If no relevant server is available in the list, click , and in the Deployment dialog box that opens [configure access to the required server](#).

## Handling files and folders on the server

From the Remote Host tool window, you can create, move, rename, and delete files and folders on the server.

### To create a folder

Select the parent directory and choose Create Folder on the context menu.

### To remove a file or folder

Select the required file or folder and choose Delete on the context menu.

### To rename a file or folder

Select the required file or folder in the tree view, choose Rename on the context menu, and specify the new name in the Rename dialog box that opens.

**Tip** Alternatively, select the required file or folder and drag it to the new location.

### To move a file or folder

1. Select the file or folder to move and choose Cut on the context menu.
2. Select the new parent folder and choose Paste on the context menu. Then confirm the changes in the Move remote Items dialog box that opens.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

## Uploading files and folders

IntelliJ IDEA provides the following main ways to upload project files and folders to a deployment server:

- **Manually**, at any time through a menu command.
- **Automatically**, every time a file is updated, or before starting a debugging session, or during commit to your version control system.

### How do I upload a file or folder manually?

In the Project tool window, select this file or folder, choose Upload to on the context menu, and then select the target deployment server from the list.

### How do I upload a file or folder to the default server manually?

In the Project tool window, select this file or folder and then choose Upload to <default deployment server> on the context menu of the selection.

**Tip** If the area is folded, click  to expand it.

### How do I upload checked-in files immediately after commit?

1. [Start checking in your changes](#).
2. In the After Commit area, choose the target server from the Upload file to drop-down list. Choose one of the existing deployment servers or create a new one: click  and [configure access to the relevant server](#) in the [Deployment](#) dialog box that opens.
3. To have IntelliJ IDEA automatically upload checked in files to the chosen server, select the Always use selected server checkbox.

**Tip** IntelliJ IDEA considers a local file changed as soon as it is saved either automatically or manually (File | Save All or ) , see [Saving and Reverting Changes](#). Changed files can be automatically uploaded only to the [default deployment server](#).

### How do I configure automatic upload of changed files to the default server:

1. Open the [Options dialog](#) ( File | Settings | Build, Execution, Deployment | Deployment | Options for Windows and Linux or IntelliJ IDEA | Preferences | Build, Execution, Deployment | Deployment | Options for macOS).
2. From the Upload changed files automatically to the default server list, choose when you want IntelliJ IDEA to upload changed files:
  - To upload any manually or automatically saved file, choose Always .
  - To upload only manually saved files, choose On explicit save action .
  - To suppress automatic upload, choose Never .

## Downloading files and folders

Files and folders can be downloaded only **manually**.

### How do I download a file or folder?

In the Remote Hosts tool window, select the required file or folder and choose Download from here on the context menu of the selection.

### How do I download a file from the default deployment server?

On the main menu, choose Tools | Deployment | Download from <default server configuration> .

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Basics](#)
- [Accessing a server](#)
- [Comparing files and folders on the server with their local versions](#)
- [Comparing local files and folders with their versions on the server](#)
- [Comparing and synchronizing two folders in the Difference Viewer](#)

## Basics

Correspondence between files and folders in your IntelliJ IDEA project and their versions on a server is set through [deployment server mappings](#) . For the sake of simplicity, any file or folder in your IntelliJ IDEA project is called **local** and any file or folder on the server is called **remote** , even if the server is actually installed on your machine. For details, see [Configuring Synchronization with a Web Server](#) .

## Accessing a server

1. Open the [Remote Host tool window](#) by choosing *Tools | Deployment | Browse Remote Host* or *View | Tool Windows | Remote Host* on the main menu.
2. Select the required deployment server from the drop-down list. The tool window shows a tree view of files and folders under the **server root** . If no relevant server is available in the list, click  , and in the Deployment dialog box that opens [configure access to the required server](#) .

## Comparing files and folders on the server with their local versions

Each remote file or folder is [mapped](#) to one and only one local file or folder. Therefore for each remote file or folder, IntelliJ IDEA unambiguously detects its local version so you can compare them at any time.

### To compare a remote file with its local version

1. Open the [Remote Host tool window](#) ( *Tools | Deployment | Browse Remote Host* or *View | Tool Windows | Remote Host* ) and select the required deployment server from the drop-down list.
2. Select the file in question, and then choose Compare with local version on the context menu of the selection.
3. In the [Differences Viewer for Files](#) dialog box, that opens, explore the differences and apply them, if necessary, using the  and  buttons. For details, see [Viewing Differences Between Files](#) .

### To compare a remote folder with its local version

1. Open the [Remote Host tool window](#) ( *Tools | Deployment | Browse Remote Host* or *View | Tool Windows | Remote Host* ) and select the required deployment server from the drop-down list.
2. Select the folder in question and choose Sync with local on the context menu of the selection.
3. In the [Differences Viewer for Folders](#) that opens, explore the differences and synchronize the files, where applicable, as described in [Comparing two folders in the Difference Viewer](#) .

## Comparing local files and folders with their versions on the server

Because local file or folder can be mapped to an unlimited number of remote counterparts, IntelliJ IDEA can uniquely identify remote versions of local files or folders only when they are mapped through the [default deployment server](#) . If no such default deployment server is appointed, you have to choose the relevant configuration manually.

### To compare a local file with its remote version

1. Select the file in question in the [Project](#) tool window.
2. On the context menu of the selection, choose *Deployment | Compare with Deployed Version on <default server access configuration>* .
3. In the [Differences Viewer for Files](#) dialog box, that opens, explore the differences and apply them, if necessary, using the  and  buttons. For details, see [Viewing Differences Between Files](#) .

### To compare a local folder with its remote version

1. Select the folder in question in the [Project](#) tool window.
2. On the context menu of the selection, choose *Sync with Deployed to <default deployment server>* if a default server is appointed. Otherwise, choose *Sync with Deployed to* and then choose the relevant server from the list.
3. In the [Differences Viewer for Folders](#) that opens, explore the differences and synchronize the files, where applicable, as described in [Comparing two folders in the Difference Viewer](#) .

## Comparing and synchronizing two folders in the Difference Viewer

IntelliJ IDEA provides a dedicated [Differences Viewer for Folders](#) for comparing files in remote folders and their local versions against the file size, content, or timestamp. Besides exploring differences, the tool also provides interface for synchronizing the contents of folders.

- The Item List shows the contents of the local and remote folders. Use the [toolbar buttons](#) to narrow down or widen the set of items to show. For example, show or hide files that are present only locally or remotely, equal files, different files, files [excluded from synchronization](#) , etc.

- The contents of the remote folder are always shown in the right-hand pane and the contents of its local version are always shown in the left-hand pane.
- The contents of the selected file are shown in the lower pane, with the differences being color-highlighted.
- The remote files in the Difference Viewer have the status `read-only` . This means that you cannot update them directly in the Difference Viewer . Make all the necessary changes to the local version of the file in question and upload the updated file to the server.

#### To compare two folders

1. Specify the parameter for comparison. In the Compare by drop-down list, select one of the possible options (contents, size, or time stamp).
2. Filter the folders' contents. To do that, type filtering string in the Filter text field, and press `Enter` to apply it. Using the asterisk `*` wildcard to represent any number of characters is welcome.
3. To switch to another pair of folders to compare, update the fully qualified paths to them. Click the Browse button  next to the Paths read-only fields and choose the required folders in the [dialog box that opens](#) .
4. Explore the detected differences between files in the Differences Pane .

#### To synchronize the contents of two folders

1. For each pair of items, in the `*` field specifies the action to apply. Click the icon in the field until the required action is set.
  -  the file will be uploaded, possibly overwriting the remote version.
  -  the file will be downloaded, possibly overwriting the local version.
  -  the files are treated identical with regard to the selected criterion of comparison. No action will be performed by default.
  -  the files differ with regard to the selected criterion of comparison. No action will be performed by default. Explore the differences in the Differences Pane of the Difference Viewer and change the intended action by clicking the icon.

The remote files in the Difference Viewer have the status `read-only` . This means that you cannot update them directly in the Difference Viewer . Make all the necessary changes to the local version of the file in question and upload the updated file to the server.

  -  the file is present only locally or remotely and will be removed.
2. Do one of the following:
  - To synchronize the currently selected item, click the Synchronize Selected button  on the toolbar.
  - To synchronize all the items, click the Synchronize All button  on the toolbar.

The functionality described on this page and in the entire chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

On this page:

- [Introduction](#)
- [Editing files on remote hosts](#)

## Introduction

Once you've set up synchronization with a remote host, you can open individual files directly from the remote host and edit them in IntelliJ IDEA, without adding/downloading them to the local project. Note that for such files not included in a project, some IntelliJ IDEA features are not supported.

To take advantage of debugging, refactorings, and other advanced features, consider including the files into a project; see [Accessing Files on Web Servers](#) for details.

## Editing files on remote hosts

### To edit a file on a remote host

1. Open the [Remote Host tool window](#) by choosing *Tools | Deployment | Browse Remote Host* or *View | Tool Windows | Remote Host* on the main menu.
2. Select the required deployment server from the drop-down list. The tool window shows a tree view of files and folders under the **server root**. If no relevant server is available in the list, click , and in the Deployment dialog box that opens [configure access to the required server](#).
3. To start editing a file, double click its name or select the file name in the [Remote Host Tool Window](#), and choose *Edit Remote File* on the context menu:

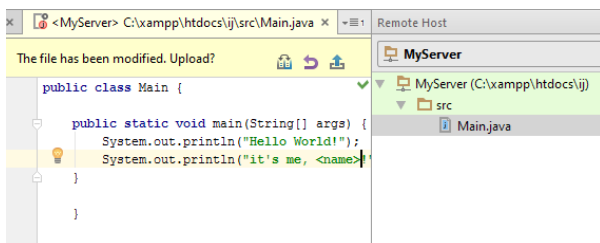

The file opens in the IntelliJ IDEA editor, without being added or downloaded to the local project.

When you work with a remote file, a special toolbar appears at the top of the editor, showing the editing status ("The file is identical to the remote one" or "The file has been changed. Upload?").

Remote files can be easily distinguished from local ones by looking at the annotation, which includes the server name (in our case it is <MyServer>).

4. When you are done editing the file, do one of the following:
  - To upload the file to the remote host, click .
  - To compare the currently opened file with the last uploaded version, click . The files are opened in the standard IntelliJ IDEA [Difference Viewer](#), see [Differences Viewer for Files](#).
  - To discard the changes introduced to the file after the last upload, click .

As it has been mentioned above, an individual file is not added to a project. As a result, all the changes to it are discarded as soon as you close the file or the currently opened project unless these changes have been uploaded. To prevent losing your data accidentally, IntelliJ IDEA displays the following dialog box when you attempt to close the edited file or the entire project:

In this section:

- [Introduction](#)
- [Preparing to work in the SSH Terminal](#)
- [Launching an SSH Terminal](#)

**Warning!** The following is only valid when SSH Remote Run Plugin is installed and enabled!

## Introduction

You can launch an **SSH Session** right from IntelliJ IDEA. By running commands in a dedicated SSH terminal, you can access data on a remote Web server or a Vagrant instance (virtual machine) via an SSH tunnel, mainly upload and download files.

## Preparing to work in the SSH Terminal

1. Make sure the **SSH Remote Run** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).
2. Make sure, an SSH server is available in the **destination environment**: a remote Web server or a Vagrant instance (virtual machine).
3. Register an account on the SSH server in the **destination environment** and generate a pair of SSH keys or a password, depending on the server policy.
4. Appoint the **destination environment** and specify the settings to establish connection with it.
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click SSH Terminal under Tools. The [SSH Terminal](#) page opens.
  2. In the Connection settings area, appoint the **destination environment**:
    - Current Vagrant: select this option to have the commands in the SSH Terminal executed on the currently running Vagrant virtual machine. For details, see [Vagrant](#).
    - Deployment server: select this option to have the commands in the SSH Terminal executed on the local or remote Web server accessible through one of the [server access configurations](#). From the drop-down list, choose the server access configuration that specifies the destination environment and the settings to establish connection to it.
      - Select server on every run: if this option is selected, you will have to choose the desired server access configuration from the pop-up window, every time you choose Tools | Start SSH Session on the main menu.
      - If the desired server access configuration does not appear in the drop-down list, click the link [Configure Servers](#), and define one in the [Deployment](#) page. For details, see the [Configuring Synchronization with a Remote Host](#) section.
  3. From the Default encoding drop-down list, select the desired encoding to be used in the SSH terminal.

## Launching an SSH Terminal

1. On the main menu, choose Tools | Start SSH Session.
2. Depending on the connection settings, defined in the [SSH Terminal](#) page of the Settings/Preferences dialog, the following types of behavior are possible:
  - If the Current Vagrant option has been selected, the SSH Terminal will provide access to the currently running Vagrant virtual machine. For details, see [Vagrant](#).
  - If the option Deployment server has been selected, the SSH Terminal will provide control over the data on the local or remote Web server accessible through the **server access configuration** selected from the list. For details, see [Configuring Synchronization with a Web Server](#).
  - If the option Select server on every run has been selected, IntelliJ IDEA will show a pop-up list to choose the desired **server access configuration** from.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with various third-party [compilers](#) that run in the background and translate Less, Sass, SCSS, and Stylus into CSS, or CoffeeScript into JavaScript, as well as compress JavaScript and CSS.

To use a compiler in IntelliJ IDEA, you need to configure it as a **File Watcher**. For each supported compiler, IntelliJ IDEA provides a predefined File Watcher template.

The output of a File Watcher is stored in a separate file. Each predefined template suggests the type of the output file depending on the compiler type. By default the output file is created in the same folder as the input file when the File Watcher is invoked for the first time, after that this file is only updated. However, in the Project tree view, the output file is shown under the original file which is shown as a node. This is done to improve visibility so you can easier locate necessary files.

File watchers have two dedicated **code inspections** :

- The **File watcher available** inspection is runs in every file where a predefined File Watcher is applicable. If the project has no relevant File Watcher configured, IntelliJ IDEA suggests to add one.
- The **File watcher problems** inspection is invoked by a running File Watcher and highlights errors specific for it.

## Creating a File Watcher

1. In the Settings/Preferences dialog ([Ctrl+Alt+S](#)), choose File Watchers under Tools. The [File Watchers page](#) opens showing a list of File Watchers that are already configured in the project.
2. Click  and choose the predefined template from which you want to create a File Watcher. The choice depends on the compiler you are going to use. To use a compiler that is not on the list, choose Custom. The [New Watcher](#) dialog box opens.
3. In the Name text box, type the name of the File Watcher. By default, IntelliJ IDEA suggests the name of the selected predefined template.

## Configuring the expected type and location of input files

**Tip** By default, the field shows the file type in accordance with the chosen predefined template.

**Tip** See [Scope](#) for details.

**Tip** This option is available only for Babel, Closure Compiler, Compass, Jade, Less, Sass / SCSS, Stylus, UglifyJS, and YUI Compressor JS.

Use the controls in the Files to watch area to define the range of files where you want to apply the File Watcher.

1. From the File type drop-down list, choose the expected type of input files. The File Watcher will consider only files of this type as subject for analyzing and processing. File types are recognised based on [associations between file types and file extensions](#).
2. Choose the Scope in which the File Watcher is applicable. Changes in these files will invoke the File Watcher either immediately or upon save or frame deactivation, depending on the status of the Auto-save edited files to trigger the watcher checkbox.  
Choose one of the predefined scopes from the drop-down list or click  and configure a custom scope in the Scopes dialog that opens.

### Optionally

Specify how you want the File Watcher to deal with dependencies. When the File Watcher is invoked in a file, IntelliJ IDEA detects all the files where it is included. For each of the detected files, in its turn, IntelliJ IDEA again detects the containing files. This operation is repeated recursively until IntelliJ IDEA reaches the files that are not included anywhere [within the specified scope](#). These files are referred to as **root files** (do not confuse with **content roots**).

- To run the File Watcher only against root files, select the Track only root files checkbox.
- Clear the checkbox to run the File Watcher against the file from which it is invoked and against all the files in which this file is recursively included within the specified scope.

Note that the Scope setting overrides the Track only root files checkbox setting: if a dependency is outside the specified scope, the File Watcher is not applied to it.

## Configuring interaction with the compiler

**Tip** `.jar` archives are also acceptable but defining `PATH` variables for them is not supported.

**Tip** When specifying the arguments, follow these rules:

- Use spaces as separators.
- If an argument contains spaces, enclose them or the entire argument in double quotes: `some "arg"` Or `"some arg"`.
- If an argument contains double quotes, use backslashes to escape them: `-Dmy_prop=\"quoted_value\"`.

**Tip** If you leave the field empty, IntelliJ IDEA uses the directory of the file where the File Watcher is invoked.

In the Tool to run on changes area, specify the compiler to use, the arguments to pass to it, the expected output file types, etc.

1. In the Program text box, specify the path to the executable file of the compiler ( `.exe` , `.cmd` , `.bat` , or other depending on the specific tool). Type the path in the text box, or click  and choose the path in the dialog that opens, click Insert Macro button and select the relevant macro from the list in the [Macros](#) dialog.
2. In the Arguments text box, define the arguments to pass to the compiler. Among other cases, use this text box to change the default output location, that is, specify a custom location where you want the compiler to store the files generated during compilation. Note that if you re-define the default output location here you need to clear the Create output file from stdout checkbox in the Advanced Options area because otherwise the content of your generated file will be overwritten by the compiler's output stream.
3. In the Output paths to refresh text box, specify the files where the compiler stores its output: the resulting source code, source maps, and dependencies. Based on these settings, IntelliJ IDEA recognizes the files generated through compilation.

Please note, that changing the value in this text box does not make the compiler store its output in another location. To do that, specify the desired output location in the Arguments text box: type the output paths using colons as separators or click the Insert Macro button to open the [Macros](#) dialog box and select the desired pattern from the list.

#### Optionally

1. Expand the Working Directory and Environment Variables hidden area.
2. Define the environment variables. For example, specify the `PATH` variable for the tool that is required for starting the compiler but is not referenced in the path to it. In most cases it is `Node.js` or `ruby.exe` . Such situation may happen if you installed the compiler in a custom installation folder manually but not through the Node Package Manager (npm) or `gem manager` .
3. In the Working Directory text box, specify the directory to which the compiler will be applied.

Because the tool is always invoked in the context of a file, the default working directory is the directory of the current file. The default working directory is specified in all predefined templates through a `$FileDir$` macros. To specify a custom working directory, type the path to it in the text box, or click  and choose the directory in the Select Path dialog box, or click Insert Macro and select the desired macro from the list in the [Macros](#) dialog box.

## Configuring advanced options

**Tip** Some compilers generate a `standard output stream (stdout)` file, others do not, which may lead to errors. Therefore it is strongly recommended that you preserve the default setting.

In the Advanced Options area, customize the default behaviour of the File Watcher.

1. Specify the events that will invoke the File Watcher:
  - To invoke the File Watcher as soon as any changes are made to the source code, select the Auto-save edited files to trigger the watcher checkbox.
  - When the checkbox is cleared, the File Watcher starts upon save ( `File | Save All` ) or when you move the focus from IntelliJ IDEA (upon frame deactivation).
2. Specify whether you want the File Watcher to interact with the IntelliJ IDEA syntax parser:
  - When the Trigger watcher regardless of syntax errors checkbox is selected, the File Watcher start regardless of the syntactical correctness of a file. The File Watcher will start upon update, save, or frame deactivation, depending on the status of the Auto-save edited files to trigger the watcher checkbox.
  - When the Trigger watcher regardless of syntax errors checkbox is cleared, the File Watcher ignores all triggers in files that are syntactically invalid and starts only in error-free files.
3. Use the Create output file from stdout checkbox to specify how you want to generate the output file.
  - When the checkbox is selected, IntelliJ IDEA reads the native compiler output ( `standard output stream (stdout)` ) and generates the resulting files from it.
  - When the checkbox is cleared, the compiler writes its output directly to the files specified in the Output paths to refresh field.
4. In the Show console drop-down list, choose when you want the File Watcher to open the console.
  - Always: with this option, the console opens when the File Watcher starts.
  - Error: with this option, the File Watcher opens the console only if any errors occur during compilation.
  - Never: choose this option to suppress opening the console at all.

#### Optionally

Configure the output filters to distinguish the output of the File Watcher from other output. These filters make the basis for:

1. Displaying paths to the File Watcher output files as links in error and other messages and logs. When you click such link, the corresponding file is opened in the editor. For example, to get useful error messages displayed, specify the following expression in the Regular expression to match output field of the [Add/Edit Filter Dialog](#) :

```
$FILE_PATH$: $LINE$ $MESSAGE$
```

2. Error highlighting in the output files.

## Enabling and disabling File Watchers

To toggle the enable/disable status of a File Watcher, select/clear the checkbox next to it on the File Watchers page of the Settings dialog box. If an error occurs while a File Watcher is running, the File Watcher is automatically disabled. To restore the status, enable the File Watcher manually.

When a File Watcher is enabled, it starts automatically as soon as a file to which compilation is applicable is changed or saved, see [Configuring advanced options](#).

## Examples of customizing the behaviour of a compiler

Any compiler is an external, third-party tool. Therefore the only way to influence a compiler is pass arguments to it just as if you were working in the command line mode. These arguments are specific for each tool. Below are two examples of customizing the default output location for the **CoffeeScript compiler**.

Suppose, you have a project with the following folder structure:

By default, the generated files will be stored in the folder where the original file is. You can change this default location and have the generated files stored in the `js` folder. Moreover, you can have them stored in a flat list or arranged in the folder structure that repeats the original structure under the `app` node.

- To have all the generated files stored in the output `js` folder without retaining the original folder structure under the `app` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir\js\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir\js\${FileNameWithoutExtension}.js:$ProjectFileDir\js\${FileNameWithoutExtension}.map
```

As a result, the project tree looks as follows:

- To have the original folder structure under the `app` node retained in the output `js` folder:

1. In the Arguments text box, type:

```
--output $ProjectFileDir\js\${FileDirRelativeToProjectRoot}\ --compile --map $FileName$
```

2. In the Output paths to refresh text box, type:

```
$ProjectFileDir$\js\${FileDirRelativeToProjectRoot}\${FileNameWithoutExtension}.js:$ProjectFileDir$\js
```

As a result, the project tree looks as follows:

In this part:

- [Dependencies Analysis](#)
- [Analyzing Dependencies Using DSM](#)
- [Viewing Structure and Hierarchy of the Source Code](#)
- [Analyzing Backward Dependencies](#)
- [Analyzing Cyclic Dependencies](#)
- [Analyzing Dependencies](#)
- [Analyzing Duplicates](#)
- [Analyzing Module Dependencies](#)
- [Analyzing External Stacktraces](#)
- [Analyzing Data Flow](#)
- [Validating Dependencies](#)

IntelliJ IDEA suggests the following means of analyzing dependencies in your projects:

- Analysis of usages, which helps you locate all references to a certain class, variable, method or parameter. This facility includes [search](#) and [view](#) usages across the project and [highlighting usages](#) in a file.
- Possibility to [view file structure](#) .
- Possibility to [explore hierarchy](#) of the types, methods, and method calls.
- Search for [repetitive code fragments](#) .
- Analysis of dependencies ([module](#) , [backward](#) , or [cyclic](#) ).
- Exploring complicated dependencies using [Dependency Structure Matrix Analysis](#) .

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

In this section:

- [Analyzing Dependencies Using DSM](#)
- [DSM Analysis](#)
- [Accessing DSM Analysis](#)
- [Expanding Dependencies](#)
- [Exploring Dependencies](#)
- [Find Usages for Dependencies](#)
- [Limiting DSM Scope](#)

**Tip** IntelliJ IDEA implements the DSM Analysis functionality with a bundled plugin, which can be completely disabled by clearing the DSM Analysis check box on the the Plugins page of IntelliJ IDEA settings ( [Ctrl+Alt+S](#) ).

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

While working on complicated projects that definitely have numerous dependencies, you might experience difficulties trying to understand where to look for the problems. You can perform dependencies analysis, but you have to know exactly which dependencies you would like to analyze. This is where DSM helps.

DSM stands for Dependency Structure Matrix - a method for exploring dependencies between program parts (modules, classes, etc.), and provides a compact matrix representation of a project.

DSM analysis helps you visualize the dependencies between the parts of a project (modules, classes etc.) and highlights the information flow within a project.

DSM analysis can be used to manage how changes will affect the project. For example, if one of the classes needs to be changed, you can identify all dependencies and see how the change will propagate through the project. A dependency structure matrix lists all of the parts of a project and dependencies between them.

Results of the DSM analysis display in the special [DSM view](#) .

**Tip** This functionality is only available when the DSMAnalysis plugin is enabled in your IntelliJ IDEA installation.

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

## To invoke DSM

1. On the main menu, choose Analyze | Analyze Dependency Matrix . Note that this command becomes available on the menu if only the DSM Analysis plugin has been enabled. Refer to the [Plugins settings](#) page of the Settings dialog.
2. In the Specify Analyze Dependency Matrix Scope dialog, click the radio button that corresponds to the desired analysis scope.
3. Check the Include test sources checkbox, if you want to analyze the test sources. Click OK .

**Warning:** If your project class files are out-of-date, the analysis may result in incomplete or incorrect data. To avoid this, IntelliJ IDEA asks you whether you want to compile a project before continuing the DSM analysis.

4. When ready, the DSM View is opened in a new window, enabling you to examine dependencies.

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

You can expand dependencies to examine them in more detail.

### **To expand dependencies**

1. In the DSM view, select the cell to explore.
2. Double-click the cell. This will expand both rows displaying dependencies in more detail.

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

There is a possibility to limit view to selected dependencies only. Note that in contrary to Limit Scope , only classes which produce dependencies selected are left.

### **To explore dependencies**

1. In the DSM view, select the cell to explore.
2. Right-click the dependency and choose Explore Dependencies Between on the context menu. The classes that produce these dependencies will be opened in a new tab within the DSM view.

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

You can open selected dependencies in [Find Usages view](#) for further source-code analysis.

### **To find usages for dependencies**

1. In the DSM view, select the dependency.
2. Right-click the dependency and choose Find Usages for Dependencies on the context menu.

This feature is only supported in the Ultimate edition.

This feature is only supported for Java!

You can limit the scope of your DSM to the selected rows. Only these will remain in the new matrix.

### **To limit DSM scope**

1. In the DSM view, select the rows to remain.
2. Right-click the selected rows and choose Limit Scope To Selection in the menu. The limited scope will be opened in a new tab within the DSM view.

IntelliJ IDEA enables you to examine the hierarchy of classes, methods, and calls in the Hierarchy tool window, and explore the structure of source files in the Structure tool window.

- Both the Hierarchy and the Structure tool windows are available from the View menu.
- the Hierarchy tool window only becomes available, when a hierarchy is built.
- Hierarchies are built in the Navigate menu.

In this part:

- [Building Call Hierarchy](#)
- [Building Class Hierarchy](#)
- [Building Method Hierarchy](#)
- [Retaining Hierarchy Tabs](#)
- [Viewing Hierarchies](#)
- [Viewing Structure of a Source File](#)

You can build and view the hierarchy of callers and callees for a selected method in the [Hierarchy tool window](#) . Before viewing call hierarchy, you need to build at least one.

### **To build a hierarchy of method calls**

1. In the Editor, place the caret at the method declaration or usage. In the Project view, or another tool window, select the desired method.
2. Do one of the following:
  - On the main menu, choose `Navigate | Call Hierarchy` .
  - Press `Ctrl+Alt+H` .

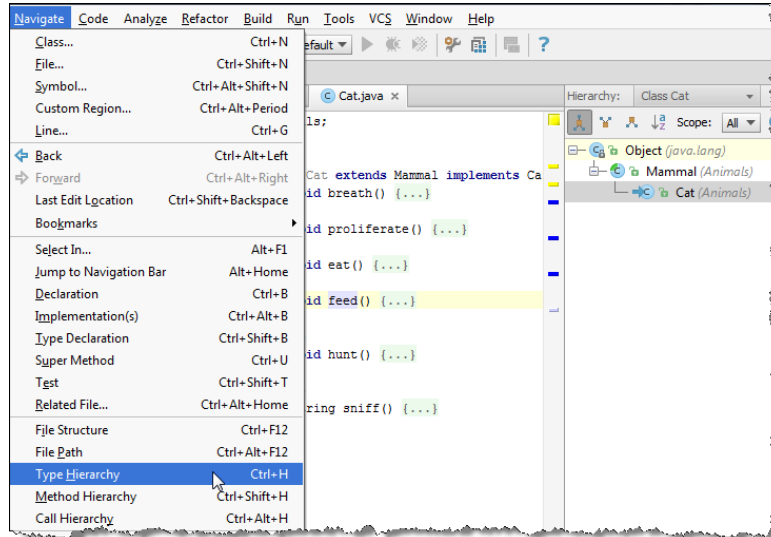

You can explore the hierarchy of parent and children classes of a selected class in the [Hierarchy tool window](#).

Note that the Hierarchy tool window only becomes available, when you build the class hierarchy, as described below.

## To build the hierarchy of classes

1. Select the desired class in the Project tool window, or open it in the editor.
2. On the main menu, choose `Navigate | Type Hierarchy` or press `Ctrl+H`.

The class hierarchy appears in the [Hierarchy tool window](#).

A method hierarchy makes it possible to examine a tree-view of the classes where a given method is:

- defined (+).
- not defined, but defined in the superclass (-).
- to be defined, because the class is not abstract (!).

## To build a method hierarchy

1. Select the desired method in the Project tool window, or place the caret at the method declaration in the editor.
2. Do one of the following:
  - On the main menu, choose Navigate | Method Hierarchy .
  - Press `Ctrl+Shift+H` .

By default, every time you build a new hierarchy, IntelliJ IDEA overwrites the current tab in the [Hierarchy](#) tool window. You can retain the contents of the desired tabs and have next hierarchies built in new tabs.

### **To retain a hierarchy tab**

- In the [Hierarchy](#) tool window, click the Pin Tab button  on the toolbar.

Once **built**, hierarchies can be brought up for close examination in the [Hierarchy tool window](#).

On this page:

## Showing the Hierarchy tool window

The Hierarchy tool window is not shown when there are no hierarchies to display. You have to build hierarchies first.

Refer to [Building Class Hierarchy](#), [Building Call Hierarchy](#), and [Building Method Hierarchy](#) to learn how to build hierarchies.

To open the Hierarchy tool window, do one of the following

- On the main menu, choose View | Tool Windows | Hierarchy.
- Use `Alt+8` keyboard shortcut.

## Navigating between the tabs of the Hierarchy tool window

Do one of the following:

- Right-click the currently displayed tab, and choose Select Next Tab / Select Previous Tab on the context menu.
- Use the `Alt+Right` and `Alt+Left` keyboard shortcuts.
- Click the currently displayed tab, and choose the next tab to display.

## Toggling between views

Toggling between views means showing ascending or descending hierarchy (callee vs. caller methods, parent vs. children classes etc.) To toggle between views, use the toolbar of the Hierarchy tool window:

- Click  to show caller methods, or supertypes.
- Click  to show callee methods, or subtypes.

On this page:

- [Basics](#)
- [Viewing the structure of a file](#)
- [Viewing members](#)

## Basics

You can examine the structure of the file currently opened in the editor using the Structure tool window or the Structure pop-up window.

By default, IntelliJ IDEA shows all the classes, methods, etc. presented in the current file.

To have [other members displayed](#), click the corresponding buttons on the toolbar of the [Structure](#) tool window.

You can also have class members shown in the [Project](#) tool window.

## Viewing the structure of a file

### To view the file structure, do one of the following

- On the main menu, choose View | Tool Windows | Structure to show the [Structure tool window](#).
- Press Structure tool button to show the [Structure tool window](#).
- Press `Alt+7` to show the [Structure tool window](#).
- Press `Ctrl+F12` to show the [Structure popup](#).

## Viewing members

### To have class fields displayed

- Click  on the toolbar of the Structure tool window.

### To have inherited members displayed

- Click  on the toolbar of the Structure tool window.

By default, IntelliJ IDEA shows only methods, constants, and fields defined in the current class. If shown, inherited members are displayed gray.

### To have included files displayed

- Click  on the toolbar.

### To have class members shown in the Project tool window

- Turn on the Show members item on the context menu of the Project tool window title bar. If this option is on, the files in the tree that contain classes turn into nodes. When such node is unfolded, the contained classes with their fields, methods, and other members of the selected item are shown.

With this type of analysis you can find another classes or modules in a certain scope of interest, that depend on the specified scope of analysis (a whole project, a module, a file, unversioned files etc.). Results of the analysis display in a dedicated tab of the [Dependency Viewer](#) .

Backward dependencies analysis might be considerably time-consuming, especially on large projects.

## To analyze a project for backward dependencies

1. On the main menu, choose Analyze | Analyze Backward Dependencies . The [Specify Backward Dependency Analysis Scope](#) dialog box opens.
2. In the Analysis Scope section, specify the part of your project, for which you would like to find the dependencies.
3. In the Scope of Interest section, specify the scope where the dependencies are sought for. You can select one of the pre-defined scopes from the drop-down list, or click the ellipsis button and create your own scope in the [Scopes dialog](#) .
4. Select the Include test sources checkbox, if you wish to analyze the test sources.
5. Click OK to run analysis. Productivity hints are displayed while the analysis is in progress. When ready, the [Dependency Viewer](#) opens a special tab, enabling you to examine dependencies.
6. In the left pane of the Dependency Viewer, select the node to be sought for. In the right pane select the scope to find usages of the selected node. Search results display in the lower pane of the tab.

Cyclic dependencies analysis enables you to detect any circular relationships between the packages in the specified scope. Results of analysis display in a dedicated tab of the [Dependency Viewer](#) .

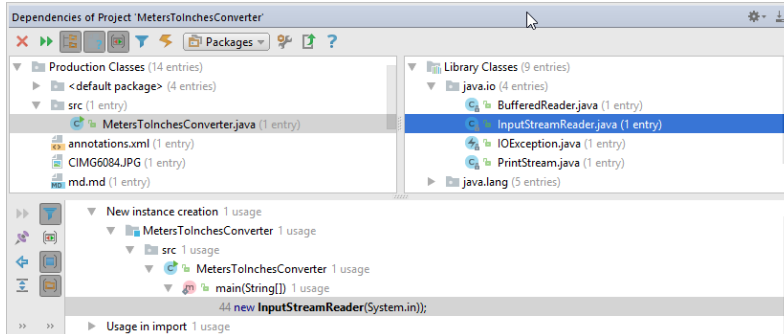

### **To analyze a project for cyclic dependencies**

1. On the main menu, choose Analyze | Analyze Cyclic Dependencies .
2. In the [Specify Cyclic Dependency Analysis Scope dialog](#) , select the desired scope of analysis.
3. Click OK to run the analysis. Productivity hints are displayed while the analysis is in progress. When ready, the [Dependency Viewer](#) opens a special tab, enabling you to examine the dependencies.
4. In the left pane of the Dependency Viewer, select the node to be sought for. In the right pane select the scope to find usages of the selected node. The search results display in the lower pane of the tab.

IntelliJ IDEA enables you to analyze the source code of your project and detect the dependencies, in which your application participates. The results of each dependencies analysis display in a separate tab of the [Dependencies Viewer](#).

## To analyze the dependencies in your project

1. On the main menu, choose Analyze | Analyze Dependencies. Alternatively, right-click the element you want to analyze - a package, a class etc. - and choose the same command on the context menu in the [Project Tool Window](#), or in the editor.
2. In the [Specify Dependency Analysis Scope](#) dialog box, select the desired scope of analysis.
3. Examine dependencies in the [Dependencies Viewer](#).

This feature is only supported in the Ultimate edition.

On this page:

- [Overview](#)
- [Searching for duplicates](#)
- [Detecting duplicates on-the-fly](#)

## Overview

IntelliJ IDEA helps you find repetitive blocks of code in a certain range. This range can be a single file, a project, a module, or a custom scope. Results of analysis display in the dedicated tab of the [Duplicates tool window](#).

## Searching for duplicates

### To search for duplicates

1. Do one of the following:
  - On the main menu, choose Analyze | Locate Duplicates.
  - Choose the Analyze | Locate Duplicates command on the context menu of the editor, or [Project Tool Window](#).
2. In the [Specify Code Duplication Analysis Scope dialog](#), specify the analysis scope (whole project, current file, uncommitted files (for the projects under version control), or some custom scope). In addition, you can include test sources into the analysis too. Click OK, when ready.
3. In the [Code Duplication Analysis Settings dialog](#), do the following:
  1. Select languages to perform analysis in.
  2. For each language, check the options to define your preferences for the analysis. For example, you can opt to request identical match for code fragments to be considered duplicates, or specify a certain limit below which the code constructs are not considered duplicates (to avoid reporting about each `if` construct in the source code).

Click OK.

4. In the [Duplicates tool window](#), explore search results.

- View the list of duplicates in the left pane of the tool window.
- View differences between the found duplicates in the right pane. Use the arrow buttons to place the selected duplicate in one of the sections of the differences viewer and compare fragments of the code.
- Navigate to the duplicates in the editor, using Jump to Source or Show Source commands of the duplicates context menu.
- Eliminate duplicates from the source code by clicking and specifying the method name and parameters in the Extract Method dialog. This procedure is similar to the [Extract method refactoring](#), with the only difference that in case of duplicates analysis the repetitive blocks of code are found automatically.

## Detecting duplicates on-the-fly

IntelliJ IDEA enables spotting duplicates on-the-fly. This is done by the [inspection](#) General | Duplicated Code.

If you stumble upon an existing duplicate, or somehow create one either by writing or pasting code, you will know it instantly:

Inspection is accompanied by quick fixes, which enable you to navigate to the detected duplicates, or view all of them in the [Find tool window](#):

Note that IntelliJ IDEA helps avoid locating duplicates in the generated sources.

To do that, select the checkbox ignore duplicated code in sources marked as generated in the inspection settings page:

Editor > Inspections For current project Reset

Profile: Project Default Manage

Q

- Test method is getter/setter
- Test method is not public
- Test method is static
- Test method should return void
- Test suite has no runner class specified
- Test suite is empty
- FreeMarker inspections
- General
  - Annotator (available for Analyze|Inspect C)
  - Default File Template Usage
  - Duplicated Code**
  - Inconsistent line separators
  - Injected References
  - Line is longer than allowed by code style
  - Problematic whitespace
  - Redundant suppression (available for Ana)
  - Structural Search Inspection
  - Syntax error (available for Analyze|Inspect)

Description

Finds duplicated code

Severity: Weak Warning In All Scopes

Options

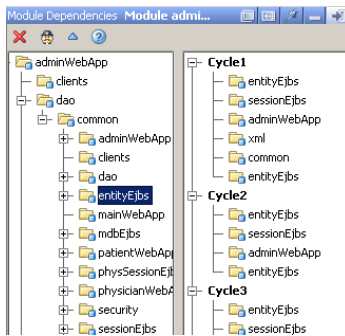

Ignore duplicated code in sources marked as generated

Module dependencies analysis shows all modules that exist in the specified scope, the relationships between these modules, as they are specified in the [Dependencies tab of the Project Structure dialog](#) , and the cyclic dependencies between the modules.

**Tip** You might want to use this type of analysis to make sure that the dependencies you have previously defined, still exist in your project.

## To analyze module dependencies

1. On the main menu, choose Analyze | Analyze Module Dependencies .
2. Specify the scope of analysis. You can opt to select the whole project, or a specific module.
3. Examine dependencies in the [Module Dependencies Tool Window](#)

4. Select a module in the tree view, and use the  toolbar button of the Module Dependencies tool window to [find the modules that depend on the selected one](#) .

On this page:

- [Overview](#)
- [Analyzing external stacktrace](#)

## Overview

You might want to analyze exceptions received by someone else, for example, QA engineers, or investigate a deadlock, or a hang-problem. Unlike the exceptions that you get in the debug mode or when running unit tests, these exceptions do not have links that help you navigate to the corresponding locations in the source code. Moreover, the source code can be scrambled.

With IntelliJ IDEA, you can simply copy an exception or full thread dump, paste it to the Stacktrace Analyzer, explore information, and navigate to the corresponding source code.

## Analyzing external stacktrace

### To analyze an external stack trace or thread dump

1. On the main menu, choose Analyze | Analyze Stacktrace . .
2. In the Analyze Stacktrace dialog box that opens, paste the external stack trace or thread dump into the Put a stacktrace or a complete thread dump here: text area.
3. Specify whether you want to have the stacktrace unscrambled. To do that, select the Unscramble stacktrace checkbox, select the desired unscrambler and log file.
4. If the stacktrace text is corrupted (lines are cut or wrapped, or too long, etc.) after processing with some software (for example, a bug tracker or a mail client), click Normalize .
5. Click OK . The stacktrace is displayed in the [Run](#) tool window.

**Tip** In case of thread dump, IntelliJ IDEA will present all threads in a readable way and sort them to show first those most probably responsible for the deadlock or hang-problem in question.

Analyzing dependencies you might need to exclude some of them from the analysis process. In other words, you can create your own rules for dependencies analysis.

## To validate dependencies

1. In the toolbar of the [Dependency Viewer](#) , click the Edit Rules  button. [Dependency Validation dialog](#) is opened.
2. Define the scopes of prohibited and allowed usages:
  1. Click Add button in the Deny/Allow sections to add the default scope.
  2. Click a scope entry in the Deny/Allow usages of column and select one of the pre-defined scopes from the drop-down list, or click the ellipsis button and define scope in the [Scopes](#) dialog.
  3. Click a scope entry in the in / only in column, and select one of the pre-defined scopes, or click the ellipsis button and define scope in the [Scopes](#) dialog.
  4. Use Add and Remove buttons to make up the complete list.
3. Apply changes. Dependency analysis reruns with the new rules.

In this part you can find descriptions of procedures that are common to all supported version control systems, or specific to certain VCS integrations:

- [Concepts of Version Control](#)
- [Managing Projects under Version Control](#)
- [Accessing VCS Operations](#)
- [Enabling Version Control](#)
- [Configuring Version Control Options](#)
- [Common Version Control Procedures](#)
- [VCS-Specific Procedures](#)
- [Using Local History](#)
- [Comparing Files and Folders](#)

IntelliJ IDEA provides integration with several Version Control Systems (referred to as VCS in documentation). This includes both support of features specific for each VCS as well as unified interface and management for common VCS tasks.

In this part:

- [Supported Version Control Systems](#)
- [Unified Version Control Functionality](#)
- [Directory-Based Versioning Model](#)
- [Changelist](#)
- [Local, Repository, and Incoming Changes](#)
- [Local History](#)
- [Patches](#)
- [Shelved Changes](#)

The list of supported integrations of version control systems is determined by the set of currently enabled [plugins](#) .

The basic principles of getting started with the supported version control systems (VCS) in IntelliJ IDEA are rather similar, though some commands and settings are specific and conform to the version control system conventions. In addition to the common information, you can find VCS-specific procedures in the following sections:

- [Using Git integration](#)
- [Using Subversion Integration](#)
- [Using Mercurial Integration](#)
- [Using CVS Integration](#)
- [Using Perforce Integration](#)
- [Using TFS Integration](#)

In addition to support for general and individual VCS commands, IntelliJ IDEA provides several unique features that simplify and speed up the work with any version control system.

- For the projects with VCS support enabled, the standard VCS actions (commit, update, revert, show differences and show history) are added to the main toolbar.
- Commit and update an entire project.
- Uniform interface for configuring common version control system settings.
- Changelists support for all integrated version control systems.
- Next , Previous , Rollback , Show Difference actions are available from the dedicated gutter bar in changed locations.
- View revision history for file/directory.
- Automatic checkout of all affected files when refactoring.
- Advanced Version Control tool window, with multiple dedicated tabs: History, Status, Update Info, etc.

Mind the difference in terminology in the different version control systems. For example, to denote the check-in functionality, Git uses the term *commit* , Subversion uses *submit* , etc.

IntelliJ IDEA adopts a directory based model for version control association. A version control system is assigned to a project directory and/or additional directories that are part of or related to the project. Directories under version control are not required to be located under the project root. They can reside in any accessible location.

All the settings files in the `.idea` directory should be [put under version control](#) except the `workspace.xml`, which stores your local preferences. The `workspace.xml` file should be [marked as ignored by VCS](#).

A changelist is a set of changes in files that represents a logical change in source code. The changes specified in a changelist are not stored in the repository until committed (pushed).

Any changes made to the source files, are automatically included in the active changelist. Initially, the Default changelist is active, but you can make any other changelist active. The active changelist is displayed on top of the Version Control tool window, with the name being highlighted in bold font.

In addition to the Default changelist, you can create new changelists, delete existing ones (except for the Default changelist), and move files between changelists.

All modified, deleted, unversioned and other files are managed in the [Version Control tool window](#). From this window you can:

- Commit (push) changelists.
- Create new changelists (if you want to keep an eye on certain files and changes).
- Remove existing changelists and set the default changelists.
- Rollback modified files in changelists.
- Add the unversioned files and directories to the version control.
- Move files between changelists.
- Show differences on selected files.
- Refresh the list of VCS changes.
- Jump to the source code from within a changelist.
- Shelve (stash) and unshelve (unstash) changes.

IntelliJ IDEA distinguishes between three categories of changes: Local , Repository , and Incoming .

**Note** Repository and incoming changes are not supported by distributed version control systems, such as Git and Mercurial .

- Local changes : the changes that you have introduced to your local working copy, but have not yet checked in to the repository.
- Repository changes : The changes that you and other team members have checked into the repository
- Incoming changes : the changes that have been checked into the repository, but that you have not checked out locally yet.

All these types of changes are displayed in the respective tabs of the [Version Control](#) tool window. The information on changes is stored in the history cache. Configure the size of this cache and frequency of refreshing information in the [General VCS Settings](#) .

Your source code constantly changes as you edit, test, or compile. Any version control system tracks the differences between the committed versions, but the local changes between commits pass unnoticed. Local History is your personal version control system that tracks changes to your source code on your computer and enables you to compare versions and roll changes back, if necessary. Local History is always at your disposal, no steps are required to enable it.

**Local History** is independent of external version control systems and works with the directories of your project even when they are not under any VCS control. It applies to any structural artifacts: a project, a directory or package, a file, a class, class members, tags, or selected fragment of text.

Unlike usual version control systems, Local History is intended for your personal use, it does not support shared access.

With Local History, IntelliJ IDEA automatically tracks changes you make to the source code, results of refactoring, and state of the source code based on a set of predefined events (testing, deployment, commit or update).

Local History revisions are marked with labels, which are similar to versions in traditional version control systems. Labels based on predefined events are added to the local revisions automatically; besides that, you can put your own labels to the project artifacts to mark your changes. Reverting or viewing differences are performed against these labels.

Local History has certain limitations:

- Tracking local changes is only possible for textual files. Binary files do not have Local History.
- For files larger than 1 Mbyte, Local History tracks only the very fact of changes, but does not preserve the respective contents.
- Local History does not support shared access.

IntelliJ IDEA helps you create and apply patches to the source code. A patch is a file in the standard text format that has the \*.patch extension, and contains a list of differences between two sets of source files.

Patches only contain changes to textual files. Changes to binary files cannot be patched.

This concept is tightly related to the concept of [Shelved Changes](#) .

You can run into a situation when you are short of time to bring your source code to a certain required condition or you need to work on an urgent high priority task. In this case you might want to put some changes aside and continue working on a stable version.

With IntelliJ IDEA, you can use shelves for storing postponed changes temporarily. In due time, the desired changes can be taken back from the shelf (unshelved).

IntelliJ IDEA enables shelving both separate files and entire changelists. Accordingly, you can unshelve entire shelves or specific files.

This section contains information related to sharing IntelliJ IDEA project files with the other developers:

- [Directory based project format](#)
- [Legacy project format](#)
- [Sharing run/debug configurations](#)
- [Sharing inspection profiles](#)
- [Project settings files to share](#)

## Directory based project format

The project settings are stored in the `.idea` directory. This format is used by all the recent IntelliJ IDEA versions by default. Here is what you need to **share** :

- All the files under `.idea` directory in the project root except `workspace.xml` and `tasks.xml` , storing user-specific settings.
- All the `.iml` module files that can be located in different module directories.

## Legacy project format

The project settings are stored in the `.ipr/.iml/.iws` files.

Share the project `.ipr` file and all the `.iml` module files, don't share the `.iws` file as it stores user specific settings.

## Sharing run/debug configurations

You might want to share [run/debug configurations](#) . To do that, just select the checkbox Share in the selected [run/debug configuration dialog box](#) .

The shared run/debug configurations are kept in separate xml files under `.idea\runConfigurations` folder, while the local run/debug configurations are kept in the `.idea\workspace.xml` .

## Sharing inspection profiles

To share inspection profiles, make sure to select the checkbox Share profile on the [Inspections](#) page of the Settings dialog.

The shared inspection profiles are stored in separate xml files under `.idea\inspectionProfiles` folder, while the local profiles are kept in the `.idea\workspace.xml` .

## Project settings files to share

The `config` directory has several subfolders that contain xml files with your personal settings. You can easily share your preferred keymaps, color schemes, etc. by copying these files into the corresponding folders on another IntelliJ IDEA installation. Prior to copying, make sure that IntelliJ IDEA is not running, because it can erase the newly transferred files before shutting down.

The following is the list of some of the subfolders under the `config` folder, and the settings contained therein.

Folder name	User Settings
<code>codestyles</code>	Contains <a href="#">code style schemes</a> .
<code>colors</code>	Contains <a href="#">editor colors and fonts customization schemes</a> .
<code>filetypes</code>	Contains user-defined <a href="#">file types</a> .
<code>inspection</code>	Contains <a href="#">code inspection profiles</a> .
<code>keymaps</code>	Contains IntelliJ IDEA <a href="#">keyboard shortcuts</a> customizations.
<code>options</code>	Contains various options, for example, feature usage statistics and macros.
<code>templates</code>	Contains user-defined <a href="#">live templates</a> .
<code>tools</code>	Contains configuration files for the <a href="#">user-defined external tools</a> .
<code>shelf</code>	Contains <a href="#">shelved changes</a> .

**Warning!** Be careful about sharing the following:

- Android artifacts that produce a signed build, as they contain keystore passwords.
- `dataSources.ids` , `datasources.xml` - these files can contain database passwords.

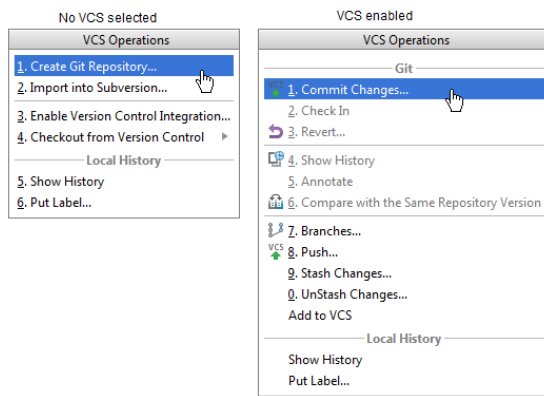

Also, consider not sharing the following:

- The `gradle.xml` file.
- The user dictionaries folder to avoid conflicts if another developer has the same name.

Use the VCS Operations Pop-up to quickly invoke most required commands.

Note that the composition of VCS commands available on the pop-up menu, depends on the specific VCS.

## To quickly invoke a VCS command using VCS Operations Pop-up

1. Open VCS Operations pop-up, in one of the following ways:
  - On the main menu, choose VCS | VCS Operations Pop-up .
  - Press `(Alt+Back Quote)` .
2. Choose command from the VCS Operations list. To do that, perform one of the following actions:
  - Click the desired command in the list.
  - Use up and down arrow keys to select the desired command, and then press `(Enter)` .
  - Press the number key that corresponds to the desired command in the list.

IntelliJ IDEA supports version control integration at two levels:

- At the IDE level, VCS integration is provided through a set of [bundled plugins](#) enabled by default.
- At the project level, VCS integration is enabled by associating project folders with one or several version control systems.

This section describes how to:

- [Associate a project root](#) with version control system.
- [Associate a directory](#) with version control system.
- [Change the associated VCS](#) for the project root or directory.

IntelliJ IDEA allows you to quickly enable your project's integration with a version control system, and associate it with the project root. For instructions on how to associate separate project directories with different version control systems, refer to [Associating a Directory with a Specific Version Control System](#) .

### To assign a version control system to the project root

1. Choose VCS | Enable Version Control Integration on the main menu, or press `Alt+Back Quote` , and select Enable Version Control Integration... .
2. In the [Enable Version Control Integration](#) dialog box that opens, select a version control system from the drop-down list that you want to associate with your [project root](#) .

IntelliJ IDEA supports a [directory-based versioning model](#) , which means that each project directory can be associated with a different version control system.

## Associating a directory with a version control system

To associate a directory with a version control system, follow these steps:

1. Open [version control settings](#) ( File | Settings | Version Control ). This page shows a list of project directories and version control systems associated with them (if no directories have been added, the list only contains the project root).
2. Click the Add button  on the right.
3. In the Add VCS Directory Mapping dialog box that opens, select the Directory option. Type the path to the directory that you want to associate with a version control system, or click the Browse button  and select the directory in the [dialog that opens](#) .
4. From the VCS drop-down list, select the version control system that will be used to control the files in this directory. Note that this list only contains the version control systems for which the corresponding [plugins](#) are currently enabled.
5. Optionally, click the Configure VCS button that allows you to specify the settings for the selected version control system. The same settings are also available under the [Version Control settings](#) node.
6. Click OK to save the mapping and return to the Version Control page.

## Managing unregistered directories

For projects with Git or Mercurial integration enabled, IntelliJ IDEA scans project directories to check if there are Git/Mercurial repositories that are not controlled by the IDE. If such repositories are detected, IntelliJ IDEA displays a notification.

To add an unregistered root, click the Add roots link in the notification. Alternatively, open the [Version Control settings page](#) , select the unregistered root you want to add (they are marked grey) and follow the procedure [Associating a Directory with a Specific Version Control System](#) .

If you do not want to be notified about these roots again, click the Ignore link in the notification. Note that if new unregistered repositories are added to the project, IntelliJ IDEA will notify you about them.

## To change the version control system associated with a directory

1. Open the [Version Control](#) settings page. This settings page displays a table of directories with associated version control systems.
2. In the table, locate the row that corresponds to the directory which you want to put under another version control system.
3. Click the VCS column. From the drop-down list that appears, select a new version control system.

**Tip** Optionally, click the Configure VCS button. The Version Control Configurations dialog box opens where you can configure settings for the selected version control system (see the corresponding configuration settings in the [Version Control](#) settings page reference for details).

4. Click OK to save the new mapping and close the Version Control dialog box.

Configuring version control options involves:

- [Configuring General VCS Settings](#)
- [Configuring VCS-Specific Settings](#)

General version control settings apply to all version control systems integrated with IntelliJ IDEA. General settings are specified on the [Version Control](#) page of the [Settings](#) dialog box, and include defining actions that require confirmation, background operations, ignored files, issue navigation, and depth of history.

### To configure general version control settings, follow these general steps

1. Press [Ctrl+Alt+S](#) or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control .
2. Specify which version control related actions should require [confirmation](#) .
3. Specify which operations should be performed in the [background](#) .
4. Create a list of [files to be ignored](#) by version control systems.
5. Configure [history cache handling](#) .
6. Define [issue navigation](#) rules to switch from check-in comments to corresponding issues in a bug tracking system.

You can define that certain version control related activities should be performed only upon confirmation from your side. The activities for which confirmation is required are specified in the [Confirmation](#) settings page.

## To specify which actions should require confirmation

1. Below the [Version Control](#) node in the settings, select the [Confirmation](#) page.
2. In the Files Creation/Deletion area, define how files created or deleted in IntelliJ IDEA should be added to or removed from a version control system. The available options are:
  - Show options before adding to version control
  - Add silently
  - Do not add
3. In the Display options dialog when these commands are invoked area, specify the commands, for which you want IntelliJ IDEA to display the Options dialog box. The available options are:
  - Check Out
  - Status
  - Get Latest Version
  - Update
  - Undo Check Out
4. Configure additional settings for working with changelists by selecting or clearing the corresponding checkboxes:
  - Specify whether the read-only state of files should require explicit cancellation.
  - Specify whether meaningful comments on committing files to the repository should be required.
  - Specify whether uncommitted changes should be moved to another changelist.
  - Specify whether and how to create a changelist if the commit operation fails.

You can enable background execution of certain version control related activities. These activities are specified in the [Background](#) settings page.

## To specify the operations to run in the background

1. Below the [Version Control](#) node in the settings, select the [Background](#) page.
2. Enable background execution of the necessary actions by selecting the corresponding checkboxes.  
Background execution can be set for the following actions:
  - [Update](#)
  - [Commit](#)
  - [Checkout](#)
  - Edit/Checkout
  - [Add /Remove](#)
  - [Revert](#)
  - [History Cache Handling](#)
  - Detecting "changed on server" conflicts

In this section:

- [Basics](#)
- [Defining a list of ignored files](#)

## Basics

Sometimes you may need to leave files of certain types unversioned. These can be VCS administration files, artifacts of utilities, backup copies, etc. You can create a global ignore list that will be stored in the workspace file and applied to all supported version control systems.

The files you want to ignore can be appointed explicitly by their names or through name patterns with wildcards. To ignore a directory, you need to specify the full path to it relative to the project root.

Use the [Ignored Files](#) settings page to list files that must be excluded from version control operations.

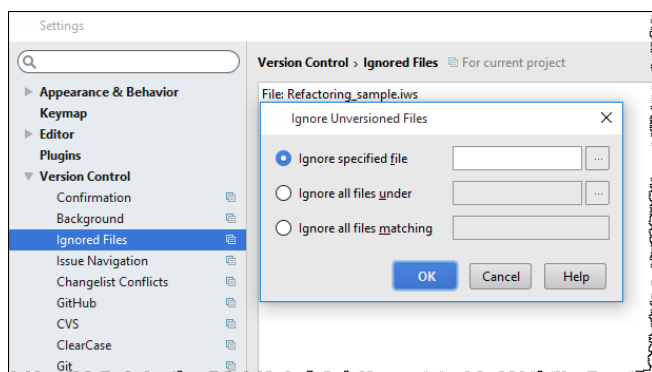

**Tip** If the version control system that you are using has its own ignore facilities, use the corresponding native command provided by the version control integration.

Note that once you've added a file to a version control system, ignoring it will have no effect. You need to remove it from your VCS first.

## Defining a list of ignored files

1. Open the [Ignored Files](#) settings page by doing one of the following:
  - Under the [Version Control](#) node of the [Settings](#) dialog box, click Ignored Files .
  - In the [Local Changes](#) tab of the [Version Control](#) tool window, click the Configure Ignored Files toolbar button  .

The Ignored Files dialog box opens.

2. Click  ( **Alt+Insert** ) to create a new entry, or select an existing entry and click  ( **Enter** ). The Ignore Unversioned Files dialog box opens.
3. Explicitly specify the files/directories to be ignored or define file name patterns. Do one of the following:
  - Choose the Ignore specified file option and specify the file name relative to the project root, for example, `my_folder/my_subfolder1/my_subfolder2/my_file` . Type the name manually or click the Browse button  and select the desired file in the Select File to Ignore dialog box.
  - Choose the Ignore all files under option and specify the directory whose contents should be ignored. Type the directory name relative to the project root, for example, `my_folder/my_subfolder1/` , or click Browse button  and select the desired folder in the Select Directory to Ignore dialog box.  
The rule is applied recursively to all subdirectories of the specified directory. If a directory has several subdirectories and you want only one of them ignored, specify the required directory explicitly, for example, `my_folder/my_subfolder1/my_subfolder2/` .
  - Select the Ignore all files matching option and type the pattern that defines the names of files to be ignored.  
Patterns that define files to ignore, make use of two wildcards.
4. Create as many entries as you need and close the dialog box.

**Tip** You can also add files to the ignore list on-the-fly by using the Ignore command on the context menu of a newly added file under the Unversioned Files node in the [Local Changes](#) tab of the [Version Control](#) tool window .

Two characters can be used as wildcards:

- `*` : to replace any string.
- `?` : to replace a single character.

For example, `*.iml` will ignore all files with the `iml` extension; `*.?ml` will ignore all files whose extension ends with `ml` .

You can configure handling of the history cache in the [Background](#) settings page.

### **To configure history cache handling**

1. Below the [Version Control](#) node in the settings, select the [Background](#) page.
2. Set the cache scope. Depending on the version control system you are using, do one of the following:
  - Specify the maximum number of changelists to be stored in the cache.
  - Specify the maximum number of days for a changelist to be stored in the cache.
3. Specify whether and how often (in minutes) you want your version control system to refresh the cache.

Certain settings are applicable to the version control systems assigned to the [whole project, or its directories](#) . The others are related to the selected version control systems. Use the respective VCS pages under the VCSs node of the [Settings](#) dialog box to define VCS-specific settings.

### **To configure VCS-specific settings, follow these general steps**

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control .
2. Click a page that corresponds to the VCS to be configured.
3. Set up options as required. For detailed information, see VCS-specific pages of the Version Control settings .

IntelliJ IDEA makes it possible to interact with the different version control systems (VCS). Regardless of which VCS you use, certain basic operations are common to all (or almost all) of them. This section covers these basic operations and explains how to perform them from within IntelliJ IDEA:

- [Adding Files to Version Control](#)
- [Browsing Contents of the Repository](#)
- [Getting Local Working Copy of the Repository](#)
- [Changing Read-Only Status of Files](#)
- [Checking In Files](#)
- [Checking Project Files Status](#)
- [Copying, Renaming and Moving Files](#)
- [Deleting Files from the Repository](#)
- [Handling Differences](#)
- [Handling Issues](#)
- [Managing Changelists](#)
- [Refreshing Status](#)
- [Reverting Local Changes](#)
- [Reverting to a Previous Version](#)
- [Shelving and Unshelving Changes](#)
- [Updating Local Information](#)
- [Using Patches](#)
- [Viewing Changes Information](#)
- [Accessing the Authentication to Server Dialog](#)

If a new file is created with IntelliJ IDEA in a directory that is already under version control, it automatically adds to the active changelist with the status Added. All you have to do, is to commit this change.

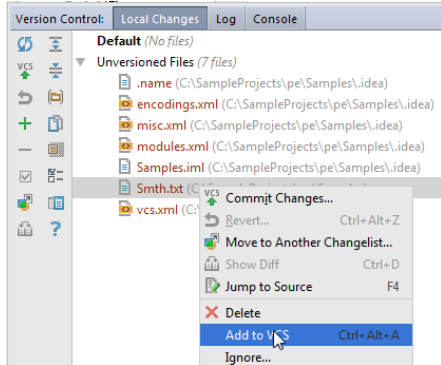

IntelliJ IDEA's behavior on adding files is configurable in the [General Settings tab](#) of the Version Control dialog.

If a new file is created outside of IntelliJ IDEA, or silent adding is disabled, you have to explicitly add it to the version control.

Another approach is VCS-specific. You can import an entire directory to your repository, provided that you have the corresponding access rights. This action is helpful for putting a whole project under version control.

## To explicitly add a file to version control

1. Select file in the Project tool window.
2. On the main Version Control menu or on the context menu of the selected file, choose <VCS> | Add .  
Alternatively, use the Version Control tool window. Select the desired files in the Unversioned files changelist in the Local Changes tab, and choose Add to VCS on the context menu, or just drag it to the target changelist.

3. Select the added file in the changelist and [check in \(commit\) changes](#) .

Prior to checking files out, you can browse the contents of the repository. This action is available for CVS, Git and SVN integrations.

- [Browsing CVS Repository](#)
- [Browsing Subversion Repository](#)

Browsing contents of CVS, Git and SVN repositories is always available, even when the respective VCS is not enabled in project. All you need is a valid user account.

In this section:

- [Basics](#)
- [Checking out](#)

## Basics

As soon as [version control support is enabled](#) in IntelliJ IDEA, you can retrieve the data from the repository. Depending on your purpose and workflow, choose one of the following approaches:

- [Check out](#) the repository sources of an existing project . Then set up version control in the project, if it has not been done before, and put the downloaded sources under control of the VCS used.
- [Check out](#) the repository sources to a location of your choice and have IntelliJ IDEA [create a project around them](#) . This does not require any extra steps from your side. IntelliJ IDEA arranges the downloaded sources in a project itself and suggests to open it as soon as the check-out is completed.

Upon your consent, [IntelliJ IDEA opens the newly created project](#) , where you only need to set up version control.

**Warning!** This approach is not available for Perforce integration.

## Checking out

The check-out procedure depends on the type of VCS you use. Refer to the following sections for details:

- [Retrieving Files from a CVS Repository](#)
- [Retrieving Files from an SVN Repository](#)
- [Cloning a Remote Git Repository](#)
- [Cloning a Remote Mercurial Repository](#)
- [Using Perforce Integration](#)

In this section:

- [Basics](#)
- [Enabling explicit removal of read-only status](#)
- [Changing writable status by icon](#)
- [Example](#)

## Basics

Different version control systems have different semantics for the action of removing read-only status from a file so that you can edit it. Some systems never put read-only status on local files at all unless specifically configured to do so (i.e. the system is configured to support the file locking model).

Different version control systems use different names for this action: check out , edit , Open for Edit , or Get . Regardless of the terminology used by your VCS, if it sets read-only status on your local working files, you can remove read-only status and make files writable from within IntelliJ IDEA, which will also take care of setting a lock on the server, or take whatever other action is required by the VCS, via the respective VCS integration.

This behavior is configurable in the [Confirmation](#) page of the Version Control settings.

## Enabling explicit removal of read-only status

To enable explicit removal of read-only status:

- In the [Confirmation page](#) of the [Version Control settings](#) , check the option Show "Clear Read-Only Status" Dialog .

## Changing writable status by icon

You can make a file writable using the lock icon  in the Status bar. Open the desired file in the editor, and click the lock, as shown below:

## Example

Removing read-only status in Perforce looks as follows:

1. With the Show "Clear Read-Only Status" Dialog option enabled, an attempt to edit a file brings up the respective dialog box.

If you click the radio button Using file system , the file will not be added to the default changelist. If you click radio button Using version control integration , the file is added to the default changelist.

In this section:

- [Basics](#)
- [Checking changed files in](#)

## Basics

Different version control systems have different semantics for the action of uploading changed files to the repository. Two common terms are check in and commit .

In those version control systems, for example, [Git](#) , that distinguish between local and remote repositories, the term commit denotes uploading changes to a local repository. Uploading changes to a remote repository is referred to as push .

Regardless of the terminology, you can perform this operation with the VCS configured for a directory from within IntelliJ IDEA.

## Checking changed files in

### To check in (commit) changed files, perform these general steps

1. In the [Version Control](#) tool window, select one or more files you want to check in (commit) to version control.
2. Open the [Commit Changes](#) dialog box by doing one of the following:
  - On the Version Control tool window toolbar, or on the main toolbar, click  .
  - Press `Ctrl+K` .
  - On the main menu, choose VCS | Commit Changes .
3. Review the changes to be committed in the [Details](#) pane. To do that, unfold the Details pane if it is hidden, and select the file in question in the [Changed Files](#) area.  
The Details pane shows the base version and the local copy of the selected file.

Examine the details of each change:

- To move to the next updated piece of code, click the Next Change button  .
  - To return to the previous updated code fragment, click the Previous Change button  .
  - To expand or narrow the context of an updated code fragment, position the cursor at the change in question, click the More/Less Lines button  , and then specify the number of lines to be shown above and below the current code fragment.
4. Add a commit comment. As you type, IntelliJ IDEA checks the spelling and highlights words in question, provided that the [Spelling code inspection](#) is enabled.
  5. Specify which actions should be performed on the files before and after submitting them to the repository.
  6. Click the Submit / Commit button to launch the [Check-in Changes](#) operations.

**Tip** For Git and Mercurial. To have the changes immediately pushed to your Git or Mercurial repository, do one of the following:

- Hover the mouse pointer over the Submit / Commit button and select Commit and Push on the context menu.
- From the Submit / Commit drop-down list, select Commit and Push .

7. To save the changes as a patch in a text file, hover the mouse pointer over the Submit / Commit button and select Create Patch on the context menu.

**Tip** Alternatively, use the Submit / Commit drop-down list to select the Create Patch item.

In the Create Patch dialog box, that opens, [configure the patch creation](#) .

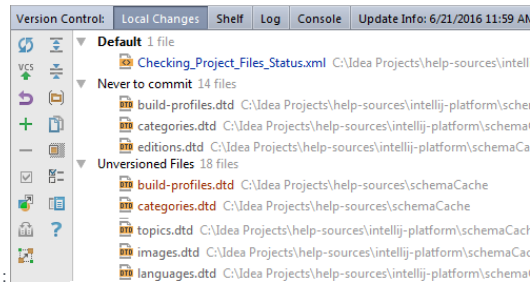

8. If any error occurs when trying to commit, IntelliJ IDEA displays an error message. For example, you might have changed a file that has been already edited by another team member, or you might run into a branch conflict. In these cases, you need to [merge edits](#) , or [update your local copy](#) . The error messages are VCS-specific.

**Tip** Users of [JetBrains TeamCity](#) can obtain the TeamCity plugin for IntelliJ IDEA. Among the features of this plugin is Remote Run, which enables you to create a special *personal* build that does not affect the *real* build. Your changes are built and run through your test suite. If all tests are passed, your changes are automatically committed to version control.

Apart from [indicating the status](#) of the currently opened file relative to the repository, IntelliJ IDEA provides you with an accumulated view of the project files' statuses.

To view the differences between the current state of the project files and the repository, do the following:

1. From the main menu, choose VCS | Refresh File Status .
2. Switch to the [Version Control tool window](#) and open the [Local Changes](#) tab.

The status of each file is indicated by the [color](#) :

There is no automatic renaming or moving files in the version control systems. Working with the clients, you have to manually copy a file to a new location, change its name, add to VCS and remove the old file. IntelliJ IDEA's refactoring features make it possible to easily move and rename files under version control, performing all actions involved in these functions.

In the Version Control tool window, next to the resulting files IntelliJ IDEA explicitly states: `renamed from <file name>` or: `copied from <package name>` .

## To copy, move or rename a file under version control

1. Select the desired file in the Project tool window, and perform refactoring procedures, as described in the sections:
  - [Copy/Clone](#)
  - [Move](#)
  - [Rename](#)

All added and deleted files are placed to a changelist.

2. [Commit changes](#) to the repository.

**Tip** You can revert refactorings, using the Undo command.

If you delete a file under version control, it still exists in the repository until deletion is committed. A deleted file is placed to the active changelist, and is displayed in grey font.

## To delete a file

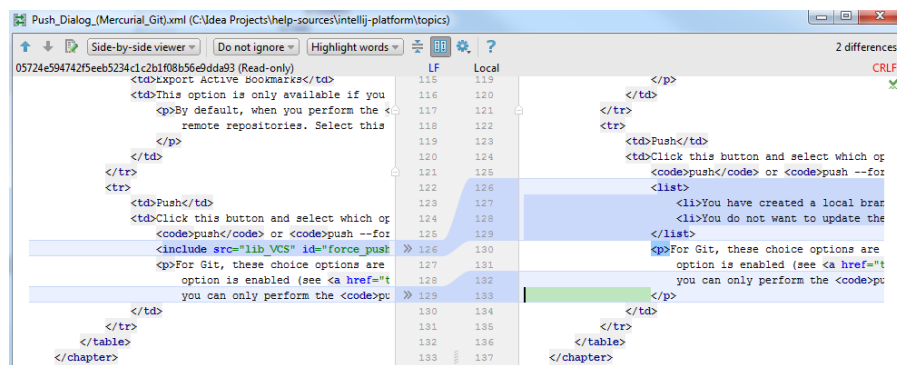

1. Select a file in any navigation view, and press  , or choose Delete on the context menu.
2. In the dialog that opens, you can opt to delete file without search for usages, or perform safe delete, to make sure that you are deleting an unused file, by checking Safe delete option. In this case, specify the refactoring options.

The encountered usages are reported in the Usages Detected dialog box. You can view and correct these usages in the Safe Delete tab of the Find tool window. The deleted files are added to a changelist.

3. [Commit changes](#) to the repository.

IntelliJ IDEA allows you to examine the differences between two revisions of a file, or between its current local copy and the repository version. The differences are displayed in the [Differences viewer](#). This window allows you to compare files and versions, navigate and search through the changes, copy and edit the source code.

This section describes how to:

- [Compare file versions](#)
- [Integrate contents of different versions into a file](#)
- [Resolve conflicts between versions](#)
- [Integrate your local copy of a project into a revision in the repository](#)

## Introduction

IntelliJ IDEA allows you to compare the local copy of a file with its repository versions. The following options are possible:

- [Compare your local copy with the repository version to which you have last synchronized](#)
- If somebody else has committed changes since your last update [compare your local copy with newest repository version](#)
- [Compare your local version with any repository version](#)

For some version control systems, it is possible to compare a file with a branch version. The differences are displayed in the [Differences viewer](#) .

**Note** You can explore changes to binary files in the same way as to textual files. For example, use this feature to check changes to images.

## Comparing with a repository version

### To compare with a repository version to which you last synchronized

1. Select a file in the [Project](#) tool window, or open it in the editor.
2. Do one of the following:
  - From the main VCS menu, or on the context menu of a file, choose <VCS> | Compare with the same repository version .
  - Select a file in the [Local Changes tab](#) of the [Version Control](#) tool window, and choose Show Diff from the context menu.

## Comparing with the latest repository version

### To compare with the latest repository version

1. Select a file in the [Project](#) tool window, or open it in the editor.
2. On the main VCS menu, or on the context menu of a file, choose <VCS> | Compare with the latest repository version .

## Comparing with the specified version of a file

### To compare with the specified version of a file

1. Select a file in the [Project](#) tool window, or open it in the editor.
2. On the main VCS menu, or on the context menu of a file, choose <VCS> | Compare with .
3. In the File Revision pop-up window, click the version to compare with.

**Tip** Alternatively, use the [History](#) view of a file. Select the desired version, and choose Compare with Local on its context menu, or click  on the toolbar.

You may need to integrate the contents of different versions of a file, for example integrate changes from a certain branch into your local copy.

To integrate changes into your working copy, do the following:

1. Select the desired file and [compare it with a version](#).
2. In the [Differences Viewer](#), use the *chevron* buttons »« for any block of lines that existed in the read-only copy and were changed or deleted in your local copy. If you keep the `Ctrl` key pressed, the *chevron* buttons turn into . Click these buttons to apply changes to the current local version of the file.

You may need to integrate your local version of a project into a certain revision of that project in the repository.

Integrating a project is only available for projects that contain directories associated with Perforce or Subversion. If neither of these two VCSs is involved in your project, the Integrate Project command is disabled.

To integrate a project, do the following:

1. On the main menu, choose VCS | Integrate Project . The [Integrate Project](#) dialog appears.
2. Select the [Perforce](#) or [Subversion](#) tab, and configure the merge options as required (see [Integrating SVN Projects or Directories](#) or [Integrating Perforce Files](#) respectively for details .

Depending on your version control system, conflicts may arise in different situations.

When you work in a team, you may come across a situation when somebody commits changes to a file you are currently working on. If these changes do not overlap (i.e. changes were made to different lines of code), the conflicting files are merged automatically. However, if the same lines were affected, your version control system cannot randomly pick one side over the other, and asks you to resolve the conflict.

Conflicts may also arise when merging, rebasing or cherry-picking branches.

## Non-Distributed Version Control Systems

When you try to edit a file that has a newer version on the server, IntelliJ IDEA informs you about that, showing a message pop-up window in the editor:

Outdated version. Modified by user1 on 8/6/2016 10:31 PM: zzz [Show Diff](#) [Update Project](#)

In this case, you should update your local version before changing the file, or merge changes later.

If you attempt to commit a file that has a newer repository version, the commit fails, and an error is displayed in the bottom right corner telling you that the file you are trying to commit is out of date.

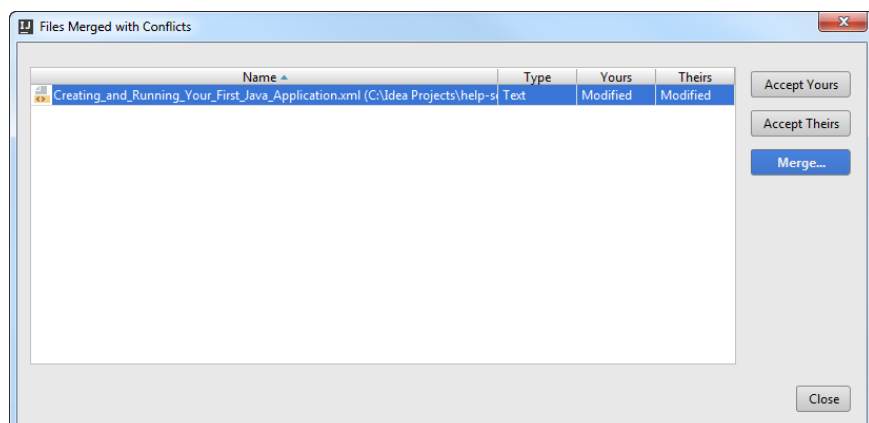

**Tip** The failed commit behavior is regulated by the Create changelist on failed commit drop-down list in the [Version Control | Confirmation](#) page of the [Settings / Preferences](#) dialog.

If you synchronize a file that already has local changes with a newer repository version committed by somebody else, a conflict occurs. The conflicting file gets the **Merged with conflicts** status. The file remains in the same changelist in the [Local Changes](#) tab of the [Version Control](#) tool window, but its name is highlighted in red. If the file is currently opened in the editor, the file name on the tab header is also highlighted in red.

## Distributed Version Control Systems

Under distributed version control systems, such as Git and Mercurial, conflicts arise when a file you have committed locally has changes to the same lines of code as the latest upstream version and when you attempt to perform one of the following operations: [pull](#), [merge](#), [rebase](#), [cherry-pick](#), [unstash](#), or [apply patch](#).

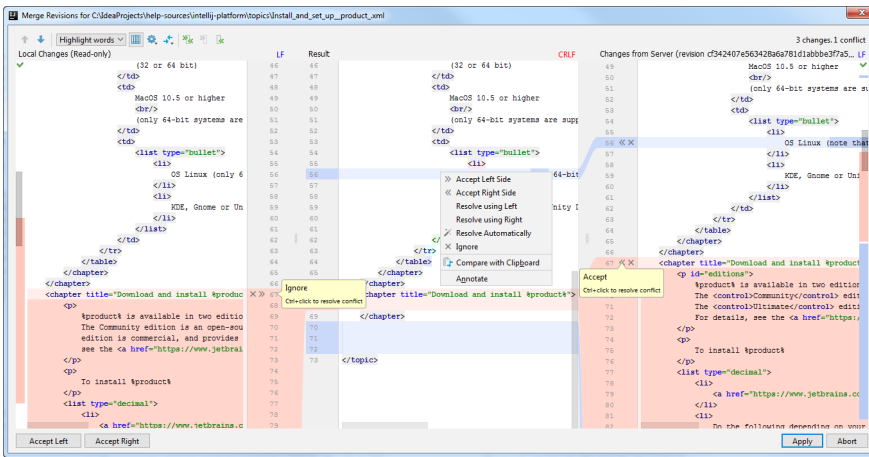

If there are conflicts, these operations will fail and you will be prompted to accept the upstream version, prefer your version, or merge the changes manually:

IntelliJ IDEA provides a tool for resolving conflicts locally. This tool consists of three panes. The left pane shows the read-only local copy; the right pane shows the read-only version checked in to the repository. The central pane shows a fully-functional editor with the results of merging and conflict resolving are displayed. Initially, the contents of this pane is the same as the **base revision** of the file, that is, the revision from which both conflicting versions are derived.

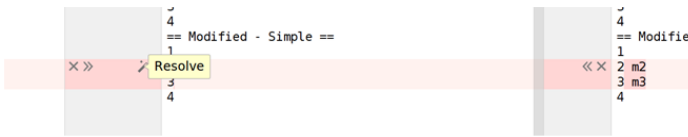

To resolve conflicts, do the following:

1. Click Merge in the Files Merged with Conflicts dialog, or select the conflicting file in the editor and choose VCS | <your\_VCS> | Resolve Conflicts from the main menu.
2. To automatically merge all non-conflicting changes, click  (Apply All Non-Conflicting Changes) on the toolbar. You can also use the  (Apply Non-Conflicting Changes from the Left Side) and  (Apply Non-Conflicting Changes from the Right Side) to merge non-conflicting changes from the left/right parts of the dialog respectively.
3. To resolve a conflict, you need to select which action to apply (accept  or ignore ) to the left (local) and the right (repository) version, and check the resulting code in the central pane:

For simple conflicts (for example, if the beginning and the end of the same line have been modified in different file revisions), the Resolve option is available that allows merging the changes in one click:

Such conflicts are not resolved with the Apply All Non-Conflicting Changes action since you must make sure that they are resolved properly.

4. It may also be useful to compare different versions to resolve a conflict. Use the toolbar button to invoke the list of options. Note that Base refers to the file version that the local and the repository versions originated from (initially displayed in the middle pane), while Middle refers to the resulting version.
5. Review merge results in the central pane and click Apply .

**Tip** You can configure IntelliJ IDEA to always apply non-conflicting changes automatically instead of telling it to do so from the Merge dialog. To do this, in the **Settings/Preferences dialog** , expand the **Tools | Diff Merge** node in the left pane and select the **Automatically apply non-conflicting changes** option.

**Tip** You can also right-click a conflict and use the commands from the popup menu. The **Resolve using Left** and **Resolve using Right** commands provide a shortcut to accepting changes from one side and ignoring them from the other side respectively.

**Tip** You can manage changes in the central pane using a toolbar that appears when you hover the mouse cursor over a change marker in the gutter and then click it. The toolbar is displayed together with a frame showing the previous contents of the modified line:

On this page:

- [Introduction](#)
- [Example](#)
- [Enabling navigation from commit messages to issues](#)
- [Enabling navigation from commit messages to issues related to them](#)
- [Navigating from a commit message to an issues](#)
- [Navigating from a commit message to the related issues](#)

## Introduction

With IntelliJ IDEA, you can connect your check-in comments with the bug tracker or any issues data base and navigate from committed changes to the issues related to these changes.

To enable this navigation, you need to specify a so called **issue navigation pattern** , which means:

1. Figure out an **issue ID pattern** , that is, a format according to which you will reference issues in commit messages, and define this issue pattern using a regular expression.
2. Define the link to the referenced issue by combining the URL address of your tracking system and a regular expression to identify the issue ID.

In other words, an **issue navigation pattern** maps an **issue ID pattern** in commit messages and URL addresses of referenced issues. As soon as IntelliJ IDEA encounters a match to the issue ID pattern in a commit message, the match is displayed as a link in the **Changes** and **Version Control** tool windows. If you mention several issues, all of them will show up as links.

Clicking such link opens the matching issue in the browser according to the defined link.

## Example

**Issue ID pattern** The regular expression that defines the format in which issues are referenced in commit messages.

```
[A-Z]+\-\d+
```

This regular expressions matches all character strings that consist of two substrings separated by an n-dash character:

1. Substring 1: An unlimited number of upper case alphabetic characters.
2. Substring 2: An unlimited number of digital characters.

**Issue link pattern** A combination of the URL address of your issue tracking system and a regular expression that identifies issues in it.

```
http://mytracker/issue/$0
```

Here `$0` indicates a back reference to the entire match. This means that as soon as IntelliJ IDEA detects a match in a commit message, it is added to the URL address of the tracker as is.

**Matching issue ID** IntelliJ IDEA detects the following reference to an issue in the commit message of interest:

```
MYPROJECT-110
```

**Composed issue link** In accordance with the above issue navigation pattern, the detected matching reference is added to the URL of the tracker as is, so the link to the referenced issue is composed as follows:

```
http://mytracker/issue/MYPROJECT-110
```

## Enabling navigation from commit messages to issues

### To enable navigating from commit messages to issues related to them

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | Issue Navigation .
2. On the [Issue Navigation](#) page that opens, configure a list of **issue navigation patterns** by setting correspondence between issue patterns in commit messages and URL addresses of referenced issues.

- If you are using [JIRA](#) or [our bug tracking system YouTrack](#) , click the Add JIRA pattern  or Add YouTrack Pattern  respectively, and type the URL to the installation of bug tracking system in question.

IntelliJ IDEA adds the regular expression that defines such pattern automatically.

- For other issue tracking systems, click the Add button  to create a new entry or select an existing entry and click the Edit button. In the Add Issue Navigation Link dialog box that opens, specify the following:
  1. The **regular expression** that defines the **issue pattern** in a commit message.
  2. The **replacement expression** that defines the URL to access the corresponding referenced issue.
- To remove an **issue navigation pattern** , select it in the list and click Remove  .

## Navigating from a commit message to an issues

### To navigate from a commit message to the related issues

1. Open one of the following views:
  - Local Changes , Incoming , or Log tab of the Version Control tool window.
  - History tab of the Version Control tool window.
  - [Changes Browser](#) .
2. Find the commit of interest and click the hyperlink to the related issue.

This section describes how to:

- [Create](#) , [delete](#) and [rename](#) changelists.
- [Assign active changelists](#) .
- [Group items in a changelist](#) .
- [Move files between changelists](#) .
- [Jump from an item in a changelist to the corresponding source code in the editor](#) .

Active changelist is the one to which the changed files are added automatically. The name of the active changelist is highlighted in bold font.

### **To assign an active changelist**

1. Select a changelist in the Version Control tool window.
2. On the context menu of the selected changelist, click Set Active Changelist .

## To create a new changelist

1. In the toolbar of the Version Control tool window, click **+** button.

**Tip** You can also use one of these alternatives:

- Right-click anywhere in the Local Changes tab of the Version Control tool window and choose New Changelist on the context menu.
- Press **Alt+Insert** .

2. In the New Changelist dialog, specify the name of the new changelist, and optional comment.

3. Click OK .

When a [changelist](#) is deleted, all changes are moved to the active changelist.

## To delete a changelist

1. In the [Version Control tool window](#) , select a changelist to be deleted.
2. In the toolbar of the Version Control tool window, click  . Alternatively, right-click the changelist node and choose Delete Changelist on the context menu, or just press  key.
3. If the changelist is not empty, you are prompted to confirm deletion and move uncommitted items to the active changelist. If you attempt to delete an active changelist, you are prompted to specify another. If Perforce is used for a certain directory, deleting the default changelist is not allowed.

Within each node of the [Version Control tool window](#), you can display the modified files as a flat list, or as a directory tree.

### To toggle grouping items by directories, do one of the following

- On the toolbar of the Version Control tool window, click  .
- Use `Ctrl+P` keyboard shortcut.

## To move items between changelists in the Version Control tool window

1. In the [Version Control](#) tool window, select one or more desired items in a changelist. Use the **Ctrl** and **Shift** keys for multiple selection.
2. Choose Move to Another Changelist on the context menu of the selection.  
You can also use one of these alternatives:
  - Click the Move to Another Changelist button  on the toolbar of the tool window.
  - Press **F6**.
  - Drag the selected items to the target changelist.
3. In the Choose Changelist dialog box, specify the changelist to move the selected items to:
  - If the target changelist exists, click the Existing Changelist option and select the desired changelist from the drop-down list.
  - To create a changelist, click the New Changelist option, type the name of the new changelist, and optionally provide a description.

## To navigate from an entry in the changelist to the source code

1. In the Version Control Tool Window, expand a changelist and select the desired entry.
2. On the context menu of the selection, choose Jump to Source , or press **F4** .

## To rename a changelist

1. Select a changelist in the Version Control Tool Window.
2. On the context menu, choose Edit Changelist .
3. In the Edit Changelist dialog, specify the new name and optional description, and click OK , or use the `Shift+F6` keyboard shortcut.

This feature is helpful if a server, that holds the sources of the project files, is down. The statuses of files and directories become irrelevant, and you are unable to work with the local copy of the project. To avoid such situation, you need to refresh the status of your source files.

When this command is applied, IntelliJ IDEA refreshes the status of each file, no matter whether the file has been changed from IntelliJ IDEA itself or using any other application.

When working under [Perforce](#) control, you can run refresh in two modes:

- **Standard Refresh** takes into consideration only the changes made through the IntelliJ IDEA integration with Perforce. This improves performance because does not require connecting to the server. However, this approach does not let you know about the changes made outside IntelliJ IDEA, for example, right through the `p4v client` application.
- **Force Refresh** considers all the changes made to project, both from IntelliJ IDEA and from any other application, for example, right through `p4v client` .

The status of a file is refreshed only in accordance with the changes in your local workspace. Any changes on the server can be reflected only through [synchronization](#) .

## To refresh the status of files in your project, do one of the following

- On the main menu, choose VCS | Refresh File Status .
- In the Version Control tool window, press `Ctrl+F5` .
- In the Version Control tool window, click the Refresh toolbar button  .
- For [Perforce](#) integration, do one of the following:
  - To run **Standard Refresh** , click the Refresh toolbar button  or press `Ctrl+F5` .
  - To run **Force Refresh** , click the Force Refresh toolbar button  .

When you modify, add, or delete files, which are under version control, you are always able to revert such changes, rolling back the file's contents to what it was before the last successful update, check out, or commit.

The exact name of the command (revert or roll back), and the type of the action performed when you revert changes, depend on the file status and VCS used for a particular directory.

### **To revert local changes, do one of the following**

- In the Local Changes tab of the Version Control tool window, select one or more items in the relevant [changelist](#), then choose Revert on the context menu of the selection or click the Revert button  on the toolbar of the Version Control tool window.
- Select the file to be reverted and choose the relevant VCS-specific revert (roll back) command on the VCS | <VCS> menu.

You can restore any previous version of a file, using the History view of a file. So doing, the current content of the file is replaced with the copy of the older content. After such operation, you have to commit the file to bring the repository up to date.

The exact name of the command (revert or roll back) depends on the specific VCS.

### **To revert a file to its previous version**

1. Select the desired file in the Project tool window, and [open its history](#) .
2. In the History tab, select the desired revision.
3. On the context menu of the selected entry, choose Get , or click the  button on the toolbar.

Shelving is temporarily storing pending changes you have not committed yet. This is useful, for example, if you need to switch to another high priority task and you want to set your changes aside to work on them later.

With IntelliJ IDEA, you can shelve both separate files and entire changelists.

Once shelved, a change can be applied as many times as you need by unshelving and subsequently restoring it on the shelf.

## Put changes to a shelf

1. Open the Version Control tool window (  ) and switch to the Local Changes tab.
2. Select the files or a changelist you want to put to a shelf. On the main Version Control menu or on the context menu of the selection, choose **Shelve changes**.
3. In the **Shelve Changes** dialog, review the list of modified files.
4. In the **Commit Message** field, enter the name of the shelf to be created and click the **Shelve Changes** button.

**Tip** You can switch to a different changelist from the **Shelve Changes** dialog by choosing the **Changelist** drop-down.

You can also shelve changes silently, without displaying the **Shelve Changes** dialog. To do this, select a file or a changelist you want to shelve, and click the **Shelve Silently** icon , on the toolbar, or press . The name of the changelist containing the changes you want to shelve will be used as the shelf name.

**Tip** To avoid ending up with numerous shelves with the same name (such as **Default**, for example), you can simply drag-and-drop a file or a changelist from the **Local Changes** tab to the **Shelf** tab, wait a second until it's activated, and edit the new shelf name on-the-fly when you release the mouse button.

## Unshelve changes

Unshelving is moving postponed changes from a shelf to a pending changelist. Unshelved changes can be filtered out from view or removed from the shelf.

1. In the **Shelf** tab of the Version Control tool window, select a changelist or files you want to unshelve.
2. Press  or choose **Unshelve** from the context menu of the selection.
3. In the **Unshelve Changes** dialog that opens, specify the changelist you want to restore the unshelved changes to in the **Name** field. You can select an existing changelist from the drop-down list or type a name for a new changelist to be created containing the unshelved changes. You can enter the description of the new changelist in the **Comment** field (optional).  
If you want to make the new changelist active, select the **Set active** option. Otherwise, the current active changelist remains active.
4. If you want IntelliJ IDEA to preserve the context of a task associated with the new changelist on its deactivation and restore the context then the changelist becomes active, select the **Track context** option (see [Managing tasks and contexts](#) for details).
5. If you want to remove the changes you are about to unshelve, select the **Remove successfully applied files from the shelf** option. The unshelved files will be removed from this shelf and added to another changelist and marked as applied. They will not be removed completely until deleted explicitly by clicking the  icon on the toolbar, or selecting **Clean Already Unshelved** from the context menu.
6. Click **OK**. If conflicts occur between the patched version and the current version, resolve them as described in [Resolving Conflicts](#).

You can also unshelve changes silently, without displaying the **Unshelve Changes** dialog. To do this, select a file or a changelist you want to unshelve, and click the **Unshelve Silently** icon , on the toolbar, or press . The unshelved files will be moved to the active pending changelist.

**Tip** You can also drag-and-drop a file or a changelist from the **Shelf** tab to the **Local Changes** tab to unshelve it silently.

## Restore unshelved changes

IntelliJ IDEA lets you reapply unshelved changes if necessary. All unshelved changes can be reused until they are removed explicitly by clicking the  icon on the toolbar, or selecting **Clean Already Unshelved** from the context menu.

To restore applied changes on the shelf do the following:

1. Make sure that the **Show Already Unshelved**  toolbar option is enabled.
2. Select the files or the shelf you want to restore.
3. On the context menu of the selection, choose **Restore**.

## Apply external patches

You can import patches created inside or outside IntelliJ IDEA and apply them as shelved changes.

1. In the **Shelf** tab of the Version Control tool window, choose **Import Patches** from the context menu.
2. In the dialog that opens, select the patch file to apply. The selected patch appears in the **Shelf** tab as a shelf.
3. Select the newly added shelf with the patch and choose **Unshelve Changes** from the context menu of the selection.

## Automatically shelve base revision

It may be useful to configure IntelliJ IDEA to always shelve base revisions of files that are under Git version control. To do

this, open the Settings dialog ( `Ctrl+Alt+S` ), select the Version Control | Shelf node on the left and select the Shelf base revisions of files under distributed version control systems option.

If this option is enabled, the base revision of files will be saved to a shelf that will be used during a [3-way merge](#) if applying a shelf leads to conflicts. If it is disabled, IntelliJ IDEA will look for the base revision in the project history, which may take a while; moreover, the revision that the conflicting shelf was based on may be missing (for example, if the history was changed as a result of the [rebase](#) operation).

## Change the default shelf location

By default, the shelf directory is located under your project directory. However, you may want to change the default shelf location. This can be useful, for example, if you want to avoid deleting shelves accidentally when cleaning up your working copy, or if you want to store them in a separate repository allowing shelves to be shared among your team members.

1. Open the Settings dialog ( `Ctrl+Alt+S` ) and select the Version Control | Shelf node on the left.
2. Click the Change Shelves Location button and specify the new location in the dialog that opens.
3. If necessary, select the Move shelves to the new location option to move existing shelves to the new directory.

Watch this video tutorial on how to benefit from shelves to be able to switch to a different task without losing unfinished work:

The Update command enables you to synchronize the contents of your local files with the repository. You can invoke this command on:

- [Single or multiple files and directories](#)
- [An entire project](#)

Depending on the updating options, the update procedure may take place silently. If all files are up-to-date, you will be notified about that. Otherwise, the [Update Info tab](#) opens in the [Version Control tool window](#) where you can [group the information](#) as required.

On this page:

- [Updating files and folders](#)
- [Updating a project](#)
- [Grouping update information by packages or changelists](#)

## Updating files and folders

1. Select one or more files and folders to be updated in any navigation view (for example, in the [Project Tool Window](#) .
2. On the main Version Control menu, or on the context menu of the selection, choose <VCS>| Update .
3. In the Update dialog specify the update options, which are different for the supported version control systems, and click OK .

## Updating a project

1. Do one of the following:
  - On the main menu, choose VCS | Update project
  - Press `Ctrl+T` .
  - On the main menu, click `VCS` .
2. In the Update dialog, click the tab for your version control system.
3. Specify the update options, which are different for the supported version control systems and click OK .

## Grouping update information by packages or changelists

To group the update information by packages or changelists, use the [Group By Package](#)  and [Group By Changelist](#)  buttons on the toolbar of the Update Info tab.

Note the difference in the appearance of the tab:

- Grouped by packages

- Grouped by changelists

Grouping by changelists is not available if the project is under Git or Mercurial control.

In this section:

- [Applying Patches](#)
- [Creating Patches](#)

Postponed changes stored in a patch file can be applied to the target file or directory later. If the source code was edited after creating the patch, conflicts may arise. IntelliJ IDEA suggests a handy way to resolve such conflicts and merge the patch with the changes.

When a patch is opened, IntelliJ IDEA detects files with the same name as the modified files. For each detected file, IntelliJ IDEA compares the path to it relative to the base directory, with the path from the patch, and chooses the closest match. If no matching path is found, the file is considered to be located in the project base directory and is highlighted in red.

You can apply changes to files stored in different locations from those specified in the patch by mapping an arbitrary directory as the base one, or stripping off the leading directories.

## To apply a patch

1. On the main menu, choose **VCS | Apply patch**.
2. In the **Apply Patch** dialog box that opens, specify the fully qualified name of the patch file. Type the name manually or click the **Browse** button  and locate the desired patch file in the **Select Patch File** dialog box.

You can also drag and drop a file or an email attachment to the **Apply Patch** dialog, and it will be selected automatically.

3. Configure the patch presentation layout. To have changes shown in a flat view, press the **Group by Directory** toolbar button .

Release the button to have changes shown in a directory tree view.

4. To have a change applied, select the checkbox next to it.

5. To have a change applied to a modified file that has been moved to another location, specify the new file location.

- To map another base directory, select the desired file, directory, or a group files/directories and click the **Map base directory** toolbar button . In the **dialog that opens** choose the directory relative to which file names will be interpreted.

- To remove leading directories from the path, click the **Strip Directory** toolbar button  as many times as many leading directories you need to strip. The number of removed slashes is indicated in square brackets.

- To revert the last strip directory action, click the **Restore Directory** toolbar button . Click the button as many times as many previously stripped leading directories you need to restore.

- To revert all the strip directory actions in the selection, click the **Reset Directories** toolbar button .

- To have all the leading directories stripped and have the changes applied to the file with the specified name in the base directory, click the **Remove Directories** toolbar button .

6. To view the differences and possible conflicts between your local working copy, the repository version, and the patch in the **Differences Viewer for Files**, select the desired change and click the **Show Differences** button .

7. To **resolve conflicts** between the patched and the current versions, if any, in both versions select the changes to be merged to the resulting file, and then click **Apply**.

Note that you apply a patch that contains a lot of files and causes numerous conflicts, you can cancel applying the patch by clicking **Abort**, and then select whether you want to abort, skip or cancel the remaining conflicts.

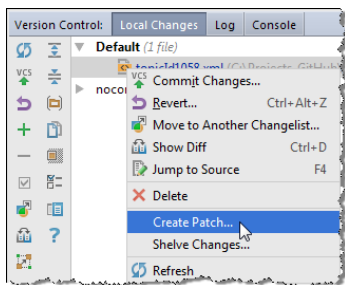

You can also copy a patch file content and apply it by choosing **VCS | Apply Patch from Clipboard** from the main menu. This is convenient when you receive a patch by email, for example, and do not want to save it. For **Git format** patches, IntelliJ IDEA extracts the commit message and the author and automatically fills the corresponding fields in the **Commit Changes** dialog.

IntelliJ IDEA suggests two ways of creating patches:

- On the base of revisions, either local or committed to the repository
- On the base of revisions stored in the local history.

## To create a patch file

1. In the [Local Changes](#) tab or the [Repository](#) tab of the Version Control tool window, select a change or changelist you want to create a [patch](#) for.
2. On the main Version Control menu or on the context menu of the selection, choose Create patch .

3. In the [Create Patch](#) dialog box that opens, review the list of changed files, and make sure that the files to be included in the patch are selected.

**Tip** You can specify the desired changelist immediately in the Create Patch dialog box: click Changelist combo box in the upper right corner, and select the desired changelist.

4. Add a commit comment.

**Tip** As you type, IntelliJ IDEA checks the spelling and highlights erroneous words.

This functionality is available if the ['Spelling' code inspection](#) is enabled.

5. Click Create patch .

You can also create patch on the base of your local history. To do that, open the local history view for the desired directory, file or code fragment, as described in the section [Using Local History](#) , right-click the desired revision, and choose the Create Patch command on the context menu, or click the create patch button  on the toolbar.

This sections explains different ways to keep track of the changes that you and your teammates introduce to the source code.

## Reviewing project history

IntelliJ IDEA allows you to review all changes made to the project sources that match the specified filters.

For distributed version control systems, such as Git and Mercurial, you can view project history in the [Log tab](#) of the [Version Control](#) tool window.

For centralised version control systems, such as Subversion, Perforce, CVS, ClearCase, and TFS, project history is available in the [Repository tab](#) of the [Version Control](#) tool window.

## Tracking changes to a file in the editor

As you modify a file that is under version control, all changes are highlighted in the editor with **change markers** that appear in the left gutter next to the modified lines and show the type of changes introduced since the last synchronization with the repository. When you commit the modified file to the repository, the change markers disappear.

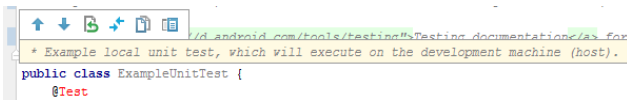

The changes you introduce to the text are color-coded:

-  line added.
-  line changed.

**Tip** You can customize the default colors for line statuses. To do this, open the Settings dialog ([Ctrl+Alt+S](#)) and select Editor | Color Scheme | VCS on the left.

When you delete a line, the following marker appears in the left gutter: .

You can manage changes using the dedicated toolbar. To invoke it, hover the mouse cursor over a change marker and then click it. The toolbar is displayed together with a frame showing the previous contents of the modified line:

You can perform the following operations:

### Item Tooltip and Shortcut

Item	Shortcut	Description
Previous Change / Next Change	<a href="#">Ctrl+Shift+Alt+Down</a> <a href="#">Ctrl+Shift+Alt+Up</a>	Use these buttons to navigate between changes.
Rollback	<a href="#">Ctrl+Alt+Z</a>	Click this icon to rollback the changes. Note that all changes to the file since its last revision will be reverted, not just the current line.
Show Diff	<a href="#">Ctrl+D</a>	Click this icon to explore the differences between the current and the repository version of the current line in the <a href="#">Diff for Range</a> dialog.
Copy	<a href="#">Ctrl+C</a>	Click this icon to copy the previous version of the modified line to the clipboard.
Show Detailed Differences		Toggle this icon to change the way differences to modified lines are presented when you click the <b>line changed</b> change marker. If enabled, the differences are highlighted with the corresponding color:

## Comparing local changes with the repository version

Apart from [navigating](#) through your local changes within a file in the editor, you can review these changes compared to the base revision of the file in question.

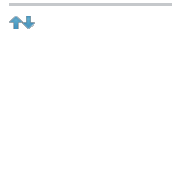

You can review changes in one of the following ways:

- In the Change Details pane in the [Local Changes](#) tab of the [Version Control](#) tool window. Select a file you want to review in the Local Changes tab and click the Preview Diff  button on the toolbar.
- In the [Differences Viewer](#). To invoke the Differences Viewer do one of the following:
  - Select a file you want to review in the Local Changes tab and press [Ctrl+D](#)
  - Click the Show Diff icon  on the toolbar.
  - Right-click a file you want to review and select Show Diff or `<your_VCS> | Compare With Latest Repository Version` from the context menu.

The left pane shows the affected code as it was in the base revision, and the right page shows the affected code after changes have been made.

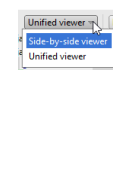

Use the toolbar buttons and controls to navigate between changes and configure the appearance of the Change Details pane or the Differences Viewer :

**Item** **Tooltip** **Description**  
and  
**Shortcut**

	<p>Previous Difference / Next Difference Shift+F7 F7</p>	<p>Use these buttons to jump to the next/previous difference. When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons <b>F7</b> / <b>Shift+F7</b> once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a> .  This behavior is supported only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.</p>
--	--	---

	<p>Compare Previous/Next File Alt+Left Alt+Right</p>	<p>Click these buttons to compare the local copy of the previous/next file with its update from the server.  <b>Note</b> These controls are only available if more than one file has been modified locally.</p>
--	--	---

	<p>Jump to Source F4</p>	<p>Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer .</p>
--	----------------------------------	---

<p>Viewer type</p> 		<p>Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only. Both types of viewers enable you to</p> <ul style="list-style-type: none"> <li>- Edit code. Note that one can change text <i>only</i> in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.</li> <li>- Perform the Apply/Append/Revert actions.</li> </ul>
--	--	---

<p>Whitespace</p> 		<p>Use this drop-down list to define how the differences viewer should treat white spaces in the text.</p> <ul style="list-style-type: none"> <li>- Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.</li> <li>- Trim whitespaces : (<code>"\t"</code>, <code>" "</code>) , if they appear in the end and in the beginning of a line. <ul style="list-style-type: none"> <li>- If two lines differ in trailing whitespaces only, these lines are considered equal.</li> <li>- If two lines are different, such trailing whitespaces are not highlighted in the <a href="#">By word</a> mode.</li> </ul> </li> <li>- Ignore whitespaces : white spaces are not important, regardless of their location in the source code.</li> <li>- Ignore whitespaces and empty lines : the following entities are ignored: <ul style="list-style-type: none"> <li>- all whitespaces (as in the 'ignore whitespaces' option)</li> <li>- all added or removed lines consisting of whitespaces only</li> <li>- all changes consisting of splitting or joining lines without changes to non-whitespace parts.</li> </ul> <p>For example, changing <code>a b c</code> to <code>a \n b c</code> is not highlighted in this mode.</p> </li> <li>- Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).</li> </ul>
--	--	---

<p>Highlighting mode</p> 		<p>Select the way differences granularity is highlighted.</p> <p>The available options are:</p> <ul style="list-style-type: none"> <li>- Highlight words : the modified words are highlighted</li> <li>- Highlight lines : the modified lines are highlighted</li> <li>- Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.</li> </ul> <p>For example, <code>A \n B</code> vs. <code>A X \n B X</code> will be treated as two changes instead of one.</p> <ul style="list-style-type: none"> <li>- Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.</li> </ul>
--	--	--

	<p>Collapse unchanged fragments</p>	<p>Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the <a href="#">Diff &amp; Merge settings</a> page.</p>
--	---	--

	<p>Synchronize scrolling</p>	<p>Click this button to simultaneously scroll both differences panes; if this button is released, each of the panes can be scrolled independently.</p>
--	----------------------------------	--

	<p>Editor settings</p>	<p>Click this button to invoke the list of available settings. Select or clear this options to show or hide whitespaces, line numbers and indent guides, to use or disable the use of soft wraps, and to set the highlighting level.  These commands are also available from the context menu of the differences viewer gutter.</p>
--	------------------------	---

	<p>Show diff in external tool</p>	<p>Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> settings page.</p>
--	---------------------------------------	--

This button only appears on the toolbar when the Use external diff tool option is enabled in the [External Diff Tools](#) settings page.

	Help	Click this button to show the corresponding help page.
		
N/A	Annotate	<p>This option is only available from the context menu of the gutter.</p> <p>Use this option to explore who introduced which changes to the repository version of the file in question, and when. The annotations view lets you see detailed information for each line of code, such as the version from which this line originated, the ID of the user who committed this line, and the commit date.</p> <p>You can <a href="#">configure the amount of information displayed in the annotations pane</a> .</p> <p>For more details on annotations, refer to <a href="#">Viewing Changes Information</a></p>

The most useful shortcuts are the following:

#### ShortcutDescription

	Use this keyboard shortcut to show the popup menu of the most commonly user diff commands.
	Use this keyboard shortcut to switch between the left and the right panes.
	Use this keyboard shortcut to select the position obtained by  in the opposite pane.
	Use this keyboard shortcut to undo/redo a merge operation. Conflicts will be kept in sync with the text.

## Viewing changes history for a file or selection

IntelliJ IDEA allows you to review changes made to files or even fragments of source code. The Show History and the Show History for Selection commands are available from the main VCS menu and from the context menu of files.

The change history for a file is displayed in the dedicated [History tab](#) of the [Version Control](#) tool window.

The change history for a selection of code is displayed in a separate window, in the form of the [differences viewer](#) .

## Viewing the History for a File

Do one of the following:

- Open a file in the editor. Then, on the main VCS menu or on the context menu of the editor tab, choose <VCS> | Show History .
- In the Project tool window, right-click a file and choose <VCS> | Show History from the context menu.

The [History](#) tab for the selected file appears in the Version Control tool window, the name of the file is shown on the title bar of the tab.

You can use the [toolbar](#) buttons to compare the selected revision with the local version, compare classes from the selected revision, checkout the selected revision from your VCS, annotate the selected revision, etc.:

#### ItemTooltip and Shortcut Description

	Compare	Click this button to compare the selected revision of a file with its previous revision in the <a href="#">Differences Viewer for Files</a> . 
	Show Diff with Local	Click this button to compare the selected revision of a file with its local copy in the <a href="#">Differences Viewer for Files</a> .
	Create Patch	Click this button to create a patch from the selected revision.
	Get	Click this button to retrieve the selected revision. If the local copy has already been modified, IntelliJ IDEA prompts to overwrite the local version, or cancel the operation.
	Annotate	Click this button to open the selected revision of a file in the editor with annotations.
	Show All Affected Files	Click this button to open the Paths Affected in Revision dialog where you can view all files that were modified in the selected revision. 
	Copy Revision Number	Click this button to copy the revision number of the commit that the selected file belongs to to the clipboard.
	Compare all classes from revision on UML	Click this button to view all classes of the selected revision as a UML Class diagram. See section <a href="#">Viewing Changes as Diagram</a> . 

	Open in GitHub	Click this button to open the page that corresponds to the selected commit on <a href="#">GitHub</a> .
	Show All Branches	Click this button to display changes from branches other than the current one.
	Show Branches	<div style="background-color: #ffff00; padding: 5px; border: 1px solid #ccc;"> <b>Note</b> This option is only available if you are using Perforce for version control.         </div> Click this button to show branches.
	Show All Revisions Submitted In Selected Changelist	<div style="background-color: #ffff00; padding: 5px; border: 1px solid #ccc;"> <b>Note</b> This option is only available if you are using Perforce for version control.         </div> Click this button to display the list of all revisions committed in the same changelist as the selected revision of a file.
	Refresh	Click this button to refresh the current information.
	Show Details	Click this button to show the commit message for the selected revision.
	Close	Click this button to close the current history tab.

Ctrl+Shift+F4

## Viewing the History for a Selection

1. In the editor, select a fragment of the source code.
2. Choose <VCS> | Show History for Selection from the main VCS menu, or on the context menu of the selection.

The history for the selected fragment will open in a separate window.

## Checking file status

IntelliJ IDEA allows you to check the status of project files relative to the repository. File status shows you which operations have been performed on the file in question since you last synchronized with the repository.

You can check the status of a file in any interface element (e.g. the editor, or various tool windows) by the color used to highlight the file name.

**Tip** You can customize the default colors for file statuses in [Colors and Fonts](#) settings page.

Color	File Status	Description
Black	Up to date	File is unchanged. 
Gray	Deleted	File is scheduled for deletion from the repository. 
Blue	Modified	File has changed since the last synchronization. 
Green	Added	File is scheduled for addition to the repository. 
Violet	Merged	File is merged by your VCS as a result of an update. 
Brown	Unversioned	File exists locally, but is not in the repository, and is not scheduled for adding. 
Olive	Ignored	File will be ignored in any VCS operation. 
Light brown	Hijacked	File is <b>modified without checkout</b> . This status is valid for the files under Perforce, ClearCase and VSS. modified without checkout . 
Red	Merged with conflicts	During the last update, file was merged with conflicts. 
Lilac	Externally deleted	File is deleted locally, but was not scheduled for deletion, and still exists in the CVS repository. 
Dark cyan	Switched	The file is taken from a different branch than the whole project. This status is valid for CVS and SVN.

## Using annotations

### What are VCS annotations?

Annotation is a form of file presentation that shows detailed information for each line of code. In particular, for each line you can see the version from which this line originated, the user ID of the person who committed this line, and the commit date. The annotated view helps you find out who did what and when, and trace back the changes.

Annotating lines of code is available for ClearCase, TFS, Mercurial, Git, CVS, Perforce and Subversion.

The Annotate command is available from VCS-specific nodes of the Version Control menu, the context menu of the Editor left gutter, file context menus, and the [file history](#) view.

When annotations are enabled, the left gutter looks similar to the following example:

```

315 fa821526 10/14/2015 Gasparyan
316 fa821526 10/14/2015 Gasparyan
317 d3c36cc1 5/19/2015 cheptssov
318 d3c36cc1 5/19/2015 cheptssov
319 28824a5c 10/14/2016 RayShade
320 2107bc7f 10/5/2015 Megorskaya
321 2107bc7f 10/5/2015 Megorskaya
322 6c81cac0 4/10/2017 Gasparyan
323 2107bc7f 10/5/2015 Megorskaya
324 6c81cac0 4/10/2017 Gasparyan
325 d3c36cc1 5/19/2015 cheptssov
326 d3c36cc1 5/19/2015 cheptssov
327 d3c36cc1 5/19/2015 cheptssov
328 dcf38ba 1/20/2017 Gasparyan

```

**Tip** Annotations for lines modified in the current revision, are marked with bold type and an asterisk.

### Configuring the amount of information shown in the annotations pane

1. Enable annotations and right-click the annotations gutter.
2. Select View in the context menu and select or deselect the following options:
  - Revision : select this option if you want to see the number of the changelist within which the annotated changes were checked in.
  - Date : select this option if you want to see the date when the annotated changes were checked in.
  - Author : select this option if you want to see the name of the user who checked in the annotated changes.
  - Commit number : select this option if you want to see the revision number of the current file.
  - Colors : use this control to toggle between the following highlighting modes:
    - Author : select this option if you want to highlight changes made by different authors with different colors.
    - Order : select this option if you want annotation colors to indicate how long ago a change was made. The entire file history is divided into several time periods containing an equal number of commits, and each time period is assigned its own color. The most recent changes are highlighted in green, while the oldest changes are highlighted in red:

```

36 2/8/2017 Megorskaya *
37 10/21/2016 Megorskaya
38 2/8/2017 Megorskaya *
39 5/19/2015 cheptssov
40 5/19/2015 cheptssov
41 2/8/2017 Megorskaya *
42 2/8/2017 Megorskaya *
43 2/8/2017 Megorskaya *
44 2/8/2017 Megorskaya *
45 2/8/2017 Megorskaya *

```

- Hide : select this option if you do not want to use color highlighting. In this case, all annotations will be displayed in gray.
- Names : use this control to select how user names will be displayed. The following options are available:
  - Last name
  - First name
  - Full name

3. To view a commit message for an annotated change, hover the mouse cursor over an annotation. A tooltip will appear showing the commit message for the corresponding change:

```

1/25/2016 Megorskaya <1>To view
5/19/2015 commit c0f815fec1a998c55a38eb53fee263f4698709e
10/14/2016 Author: Irina.Megorskaya
1/25/2016 Date: 1/25/2016 12:39 PM
1/25/2016
5/19/2015 https://youtrack.jetbrains.com/issue/IDEA-147758

```

**Note** The amount of information displayed in the tooltip depends on the version control system you are using and is not affected by the [annotation settings](#).

### Annotating previous revisions

IntelliJ IDEA lets you annotate not only the current file revision, but also it's previous revisions. The following options are available from the context menu of the annotations gutter:

- Annotate Revision : this option is useful if you want to check what a file looked like after a particular change was committed. To do this, right-click this change and select Annotate Revision from the context menu.
- Annotate Previous Revision : this option is useful if you find yourself in a situation when the last change in a particular line

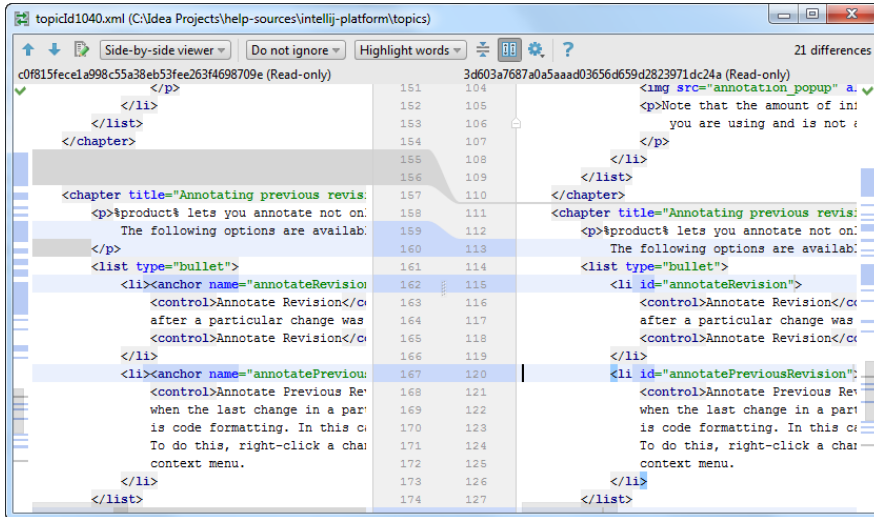

is meaningless, for example if all that was changed is code formatting. In this case, you can check what the previous revision of the file looked like. To do this, right-click a change and select Annotate Previous Revision from the context menu.

You can also annotate a particular file from the [file history](#) view. In the History tab, select the file version you want to review, right-click the corresponding line and select Annotate from the context menu.

## Viewing the differences between revisions

To review the differences between the annotated version of a file and its previous version, position the cursor on an annotation, right-click it and select Show Diff from the context menu. IntelliJ IDEA opens the [Differences Viewer for Files](#) :

To review the differences between the annotated version of a file and its previous version, position the cursor on an annotation, right-click it and select Show Diff from the context menu. IntelliJ IDEA opens the Differences Viewer :

## Navigating to log

If you are using Git for version control, you can also jump from the annotations view to the corresponding commit in the [Log](#) tab of the [Version Control](#) tool window.

To do this, position the cursor on an annotation, right-click it and select Select in Git log from the context menu. You can also use the Copy revision number command to located a revision in the log.

For projects hosted on <https://github.com/>, the Open on GitHub command is also available that takes you to the corresponding commit.

For a number of reasons of various nature you may be not authenticated to the remote server while the authentication dialog box does not appear, as you might expect. Instead, IntelliJ IDEA displays the corresponding message in a pop-up window in the bottom-left corner of the editor.

**Tip** The authentication dialog appears immediately only when you attempt to access a URL address outside your working copies. This feature applies to Perforce, Subversion, and CVS.

## To access the authentication dialog box

1. Click the Notifications Pending button  on the Status bar.
2. In the Notifications pop-up window that opens, click the link Click to fix .

3. In the authentication dialog box that opens, specify your credentials.

In most cases, IntelliJ IDEA provides a unified approach to version control operations, as described in the previous sections. Nevertheless, there are certain VCS-specific features and peculiarities that the user should be aware of. Find helpful tips and notes in the following sections:

- [Using Git integration](#)
- [Using CVS Integration](#)
- [Using Mercurial Integration](#)
- [Using Perforce Integration](#)
- [Using Subversion Integration](#)
- [Using TFS Integration](#)

Before you can [enable Git version control for an existing local project](#) , or [clone a Git project from a remote repository](#) , do the following:

1. [Download](#) and install Git.
2. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), select Version Control | Git in the left pane and specify the path to the Git executable.
3. [Set passwords for remote Git repositories](#)

## Set passwords for Git remotes

Every time you interact with a remote Git repository (for example, during a [pull](#) , [update](#) , or [push](#) operation), it requires authorization. You can [configure IntelliJ IDEA to remember your passwords](#) , so that you do not have to specify your credentials each time authorization is required. The type of authentication depends on which network protocol is used by the remote repository you are trying to access: [HTTP](#) or [SSH](#) .

If you are using HTTP to access a remote, Git requests credentials from a credential helper when you perform an operation that requires authentication. If no credential helper is found, it returns a prompt to the IDE. If you have [configured a password policy](#) , IntelliJ IDEA looks for credentials in the passwords database. If there is no passwords database, it displays a prompt and you have to enter your login and password.

If your remote uses the SSH protocol, in addition to configuring a password policy, you can choose whether you want to use a native or a built-in SSH executable. To do this, in the Settings/Preferences dialog ( `Ctrl+Alt+S` ), select Version Control | Git on the left. From the SSH executable drop-down list, select one of the following options:

- Built-in : all authorization is performed on the IDE side.
  - If login and password are used for authentication, authorization is performed in accordance with the [selected password policy](#) .
  - If an SSH key without a passphrase is used for authentication, IntelliJ IDEA will access the `~/.ssh/config` file and get the key from there.
  - If authentication requires an SSH key with a passphrase, Git looks for it in the credential helper, and, if no credential helper is found, it returns a prompt to the IDE. If you have configured a [password policy](#) , IntelliJ IDEA looks for credentials in the passwords database. If there is no passwords database, it displays a prompt and you have to enter SSH key and a passphrase.
- Native : all authorization is performed on Git side. No prompt will be displayed, so choose this authorization type if you are using SSH without a passphrase, or the passphrase is saved in a credentials helper, or there is an SSH agent.

## Configure a password policy

1. In the Settings dialog ( `Ctrl+Alt+S` ), select Appearance and Behavior | System Settings | Passwords on the left.
  2. Select how you want IntelliJ IDEA to process passwords for Git remote repositories:
    - In native Keychain : select this option to use native Keychain to store your passwords. This setting is only available for MacOS and Linux.
    - In KeePass : select this option to use the [KeePass password manager](#) to store your passwords. When you use the KeePass password manager , a master password will be used to access the file that stores individual passwords. Once IntelliJ IDEA remembers your passwords, it will not ask for them unless you need to access the passwords database. Enter the password that will be used to access the `c.kdbx` file in the MasterPassword field. You can change the default location of the `c.kdbx` file in the Database field.

To import a `c.kdbx` file, click  and select Import from the drop-down menu, or click  and specify the path to a local file containing your passwords.
- If you want to remove the existing passwords from the database, select Clear .
- Do not save, forget passwords after restart : select this option if you want your passwords to be reset after you close IntelliJ IDEA.

## Check out a project from a remote host (clone)

IntelliJ IDEA allows you to check out (in Git terms clone ) an existing repository and create a new project based on the data you've downloaded.

1. From the main menu, choose VCS | Checkout from Version Control | Git , or, if no project is currently opened , choose Checkout from Version Control | Git on the Welcome screen (select the GitHub option for projects hosted on <https://github.com> ).
2. In the Clone Repository dialog, specify the URL of the remote repository you want to clone (you can click Test to make sure that connection to the remote can be established).
3. In the Parent Directory field, specify the path where the folder for your local Git repository will be created.
4. In the Directory Name field, specify the name of the folder into which the repository will be cloned.
5. Click Clone . If you want to create a IntelliJ IDEA project based on the sources you have cloned, click Yes in the confirmation dialog. Git root mapping will be automatically set to the project root directory.

## Put an existing project under Git version control

Apart from [cloning a remote repository](#) , you can create a local repository based on an existing project's sources.

To import an entire project into a single Git repository that will reside in the project root, do the following:

1. Open the project that you want to put under Git.
2. From the main menu, choose VCS | Enable Version Control Integration .
3. In the dialog that opens, select Git from the drop-down list and click OK .

If your project contains several modules that you want to put into different Git repositories, do the following:

1. Open the project that you want to put under Git.
2. From the main menu, choose VCS | Import into Version Control | Create Git Repository .
3. In the dialog that opens, specify the directory where a new Git repository will be created.

**Note** Git does not support external paths, so if you choose a directory that is outside your project root, make sure that the folder where the repository is going to be created also contains the project root.

## Add files to the local repository

After you have [initialized a Git repository](#) for your project, you need to add project data to it.

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Local Changes tab.
2. Put any files in the Unversioned Files changelist under version control by pressing `Ctrl+Alt+A` or selecting Add to VCS from the context menu. You can either add the entire changelist, or select separate files.

If you have enabled Git integration for your project, IntelliJ IDEA suggests to add each newly created file under Git version control (you can change this behavior in the Settings dialog ( `Ctrl+Alt+S` ) under Version Control | Confirmation ). If you want certain files to always remain unversioned, you can [configure Git to ignore them](#) .

**Tip** You can also add files to your local Git repository from the Project tool window. Select the files you want to add, and press `Ctrl+Alt+A` or choose Git | Add from the context menu.

## Exclude files from version control (ignore)

Sometimes you may need to leave files of certain types unversioned. These can be VCS administration files, artifacts of utilities, backup copies, etc.

**Note** Once you've added a file to Git version control, ignoring it will have no effect. You need to remove it from the Git repository first.

You can ignore files through IntelliJ IDEA, and the IDE will not suggest adding them to Git and will highlight them as ignored. However, since this is done on the IDE side, Git treats such files as unversioned, so if you need to perform any operations outside IntelliJ IDEA, or share your project, it is also recommended to add a list of files you want to ignore to the `gitignore` file (for instructions, see <https://git-scm.com/docs/gitignore> ).

To configure a list of files that you don't want to be tracked by Git in IntelliJ IDEA, do the following:

1. Either:
  - Choose File | Settings from the main menu, and select Version Control | Ignored Files in the left pane.
  - Open the Version Control tool window ( `Alt+9` ) and switch to the Local Changes tab. Click the Configure Ignored Files icon  on the toolbar.
2. Click the Add button  on the toolbar.
3. In the Ignore Unversioned Files dialog, specify the files/directories that you want to ignore, or define file name patterns:
  - Ignore specified file : specify the file name relative to the project root.
  - Ignore all files under : specify the directory whose contents should be ignored relative to the project root. The rule is applied recursively to all subdirectories.
  - Ignore all files matching : type the pattern that defines the names of files to be ignored. The rule is applied to all directories under the project root.Two characters can be used as wildcards:
  - `*` : to replace any string.

- `?` : to replace a single character.

For example, `*.iml` will ignore all files with the `iml` extension; `*.?.ml` will ignore all files whose extension ends with `ml`.

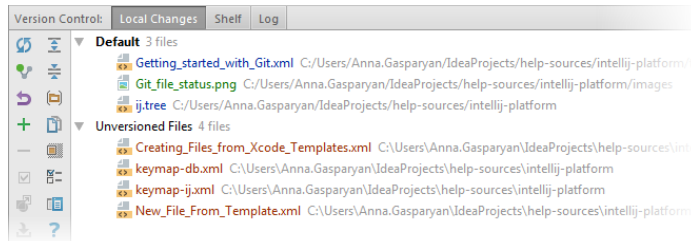

**Note** Using wildcards in combination with slashes (`/`) to restrict the scope to a certain directory is not supported.

**Tip** You can also add files to the ignore list on-the-fly by using the Ignore command on the context menu of a newly added file under the Unversioned Files node in the Local Changes tab of the Version Control tool window.

## Check project status

IntelliJ IDEA allows you to check the status of your local working copy compared to the repository version of the project. It lets you see which files have been modified, which new files have been added to the VCS, and which files are not being tracked by Git.

Open the Version Control tool window (`Alt+9`) and switch to the Local Changes tab:

- The Default changelist shows all files that have been modified since you last synchronized with the remote repository (highlighted in blue), and all new files that have been added to the VCS but have not been committed yet (highlighted in green).
- The Unversioned Files changelist shows all files that have been added to your project, but that are not being tracked by Git.

For more info on changelists, see [Group changes into different changelists](#).

**Tip** If you want **ignored files** to be also displayed in the Local Changes view, click  on the toolbar.

## Track changes to a file in the editor

You can also track changes to a file as you modify it in the editor. All changes are highlighted with change markers that appear in the left gutter next to the modified lines, and show the type of changes introduced since you last **synchronized with the repository**. When you commit changes to the repository, change markers disappear.

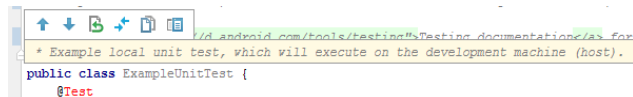

The changes you introduce to the text are color-coded:

-  line added.
-  line changed.

**Tip** You can customize the default colors for line statuses. To do this, open the Settings dialog (`Ctrl+Alt+S`) and select Editor | Color Scheme | VCS on the left.

When you delete a line, the following marker appears in the left gutter: .

You can manage changes using a toolbar that appears when you hover the mouse cursor over a change marker and then click it. The toolbar is displayed together with a frame showing the previous contents of the modified line:

You can rollback changes by clicking  (note that all changes to the file since its last revision will be reverted, not just the current line), and explore the differences between the current and the repository version of the current line by clicking .

## Add a remote repository

To be able to collaborate on your Git project, you need to configure remote repositories that you **fetch** data from and **push** to when you need to share your work.

If you have **cloned a remote Git repository**, for example from [GitHub](#), the remote is configured automatically and you do not have to specify it when you want to synchronize with it (i.e. when you perform a **pull** or a **push** operation).

**Note** The default name Git gives to the remote you've cloned from is `origin`.

However, if you **created a Git repository** based on local sources, you need to add a remote repository for other contributors to be able to push their changes to it, and for you to be able to share the results of your work.

Invoke the Push dialog when you are ready to push your commits by selecting VCS | Git | Push from the main menu, or

1. Invoke the Push dialog when you are ready to push your commits by selecting VCS | Git | Push from the main menu, or press `Ctrl+Shift+K`.
2. If you haven't added any remotes so far, the Define remote link will appear instead of a remote name. Click it to add a remote.
3. In the dialog that opens, specify the remote name and the URL where it will be hosted, and click OK.

**Tip** You can also add a remote from the Push dialog by clicking an existing remote's name.

In some cases, you also need to add a second remote repository. This may be useful, for example, if you have cloned a repository that you do not have write access to, and you are going to push changes to your own [fork](#) of the original project. Another common scenario is that you have cloned your own repository that is somebody else's project fork, and you need to synchronize with the original project and fetch changes from it. In this case:

1. From the main menu, choose VCS | Git | Remotes. The Git Remotes dialog will open.
2. Click the Add button `+` on the toolbar or press `Alt+Insert`.
3. In the dialog that opens, specify the remote name and URL and click OK.

Learn more from this video:

To edit a remote (for example, to change the name of the original project that you have cloned), select it in the Git Remotes dialog and click the Edit button `E` on the toolbar, or press `Enter`.

To remove a repository that is no longer valid, select it in the Git Remotes dialog and click the Remove button `-` on the toolbar, or press `Alt+Delete`.

**Tip** You can also edit a remote from the [Push Dialog](#) by clicking its name.

Before you can share the results of your work by [pushing your changes to the upstream](#) , you need to synchronize with the remote repository to make sure your local copy of the project is up to date. You can do this in one of the following ways: [fetch changes](#) , [pull changes](#) , [update your project](#) .

## Fetch changes

When you fetch changes from the upstream, all new data from commits that were made since you last synced with the remote repository is downloaded into your local copy. This new data is not integrated into your local files, and changes are not applied to your code.

Fetches changes are stored as a remote branch, which gives you a chance to review them before you [merge](#) them with your files. Since fetch does not affect your local development environment, this is a safe way to get an update of all changes to a remote repository.

To fetch changes, from the main menu choose VCS | Git | Fetch .

## Pull changes

Pulling changes from a remote repository is a convenient shortcut for [fetching](#) and subsequently [merging](#) changes. When you pull , you not only download new data, but also integrate it into your local working copy of the project.

To pull changes, do the following:

1. From the main menu, choose VCS | Git | Pull . The Pull Changes dialog opens.
2. If your project has several Git repositories, select the path to the local repository that you want to update from the Git Root drop-down list.
3. If you have several remotes configured for your repository, select the URL of the remote that you want to pull data from in the Remote drop-down list.
4. Select the branches that you want to fetch changes from and merge into the branch that is currently checked out.
5. From the Strategy drop-down list, select the [merge strategy](#) that will be used to resolve conflicts that occur during merge.
6. Select the following if necessary:
  - No commit : select this option if you do not want IntelliJ IDEA to automatically commit merge results. In this case, you can inspect them and adjust if necessary.
  - No fast forward : select this option to generate a merge commit even if the merge was resolved as a fast-forward (i.e. only the branch pointer was updated).
  - Squash commit : select this option to create a single commit on top of the current branch instead of merging one or more branches. It produces the working tree and index state as if a real merge took place, but it does not actually make a commit or move the HEAD.
  - Add log information : select this option if you want IntelliJ IDEA to populate the log message with one-line descriptions from the actual commits that are being merged in addition to branch names.
7. Click Pull to fetch and apply changes from the selected remote repository.

## Update your project

If you have several project roots, or want to fetch changes from all branches each time you sync with the remote repository, you may find updating your project a more convenient option.

When you perform the update operation, IntelliJ IDEA [pulls](#) changes to all project roots and branches, and [merges](#) them into your local working copy (equivalent to pull ).

To update your project, do the following:

1. From the main menu, choose VCS | Update Project or press `Ctrl+T` . The Update Project dialog opens.
2. Select the update type (this strategy will be applied to all roots that are under Git version control):
  - Merge : select this option to perform [merge](#) during the update. This is equivalent to running `git fetch` and then `git merge` , or `git pull --no-rebase` .
  - Rebase : select this option to perform [rebase](#) during the update. This is equivalent to running `git fetch` and then `git rebase` , or `git pull --rebase` (all local commits will be put on top of the updated upstream head).
  - Branch Default : select this option if you want to apply different update strategies for different branches. You can specify the default update type for each branch in the `branch.<name>` section of the `.git/config` configuration file.
3. Specify a method that will be used to save your changes while cleaning your working copy before the update so that your uncommitted changes can be restored after the update is completed:
  - Using Stash : select this option to save local changes in a [git stash](#) . This is useful if you need to apply patches with stashed changes outside IntelliJ IDEA, as they are generated by Git itself.
  - Using Shelve : select this option to put local changes to a [shelf](#) . Shelving is done by IntelliJ IDEA, and patches generated from shelved changes are normally applied inside IntelliJ IDEA.

**TIP** If you choose not to show the Update Project dialog in the future, and then at some point you want to modify the default update strategies, in Setting | Version Control | Confirmation select Update under Display options dialog when these commands are invoked , and modify the update strategy the next time you perform an update.

After you've [added new files to the Git repository](#), or modified files that are already under Git version control and you are happy with their current state, you can share the results of your work. This involves [committing](#) them locally to record the snapshot of your repository to the project history, and then [pushing](#) them to the remote repository so that they become available to others.

## Commit changes locally

1. Invoke the commit dialog in one of the following ways:

- Press `Ctrl+K`.
- In the Local Changes tab of the Version Control tool window, select a changelist or files you want to commit and click the Commit Changes button  on the toolbar or select Commit Changes on the context menu of the selection.
- On the main menu, choose VCS | Commit or VCS | Git | Commit File.

The Commit Changes dialog lists all files that have been modified since the last commit, and all newly added unversioned files.

2. Enter a commit message and select the Before Commit actions you want IntelliJ IDEA to perform before committing the selected files to the local repository.

3. Select the following options in the Git section if necessary:

- Author: if you are committing changes made by another person, you can specify the author of these changes.
- Amend commit: select this option if you want to add the local changes to the latest commit (see [Combine staged changes with the previous commit \(amend commit\)](#) for details).
- Sign-off commit: Select this option if you want to sign off your commit, i.e. to certify that the changes you are about to check in have been made by you, or that you take the responsibility for the code in question.  
When this option is enabled, the following line is automatically added at the end of the commit message: **Signed off by:**  
`<username>`

4. Click the Commit button or hover the mouse over this button to display one of the following available commit options:

- Commit and Push: [push](#) the changes to the remote repository immediately after the commit.
- Create Patch: [generate a patch](#) based on the changes you are about to commit. In the Create Patch dialog that opens, type the name of the patch file and specify whether you need a reverse patch.
- Remote Run: [run your personal build](#). This option is only available when you are logged in to [TeamCity](#). Refer to [TeamCity plugin documentation](#) for details.

**Tip** If you realize you need to edit the commit message, you can do so before you've pushed this commit. See [Edit a commit message](#).

**Tip** You can customize the rules applied to commit messages, such as a blank line between the subject and the body, and the maximum message length. To do this, in the Settings dialog (`Ctrl+Alt+S`), select Version Control | Commit Dialog on the left.

There is also a quick fix and the Reformat action that allow you to wrap a long line or reformat the commit message.

**Note** You can invoke the Commit Changes dialog even if there are only Unversioned files present in the project, for example added from outside IntelliJ IDEA.

## Push changes to a remote repository

Before pushing your changes, [sync with the remote](#) and make sure your local copy of the repository is up-to-date to avoid conflicts.

IntelliJ IDEA allows you to upload changes from the current branch to its [tracked branch](#) or to any other remote branch.

1. Press `Ctrl+Shift+K` or choose VCS | Git | Push from the main menu. The Push Commits dialog opens showing all Git repositories (for multi-repository projects) and listing all commits made in the current branch in each repository since the last push.

If you have a project that uses multiple repositories that are not controlled synchronously, only the current repository is selected by default (for details on how to enable synchronous repositories control, refer to [Version Control Settings: Git](#)).

2. If there are no remotes in the repository, the Define remote link appears. Click this link and specify the remote name and URL in the dialog that opens. It will be saved and you can edit it later via VCS | Git | Remotes (for details, see [Add a remote repository](#)).

3. If you want to modify the target branch where you want to push, you can click the branch name. The label turns into a text field where you can type an existing branch name, or create a new branch. You can also click the Edit all targets link in the bottom-right corner to edit all branch names simultaneously.

Note that you cannot change the local branch: the current branch for each selected repository will be pushed.

4. If you want to preview changes before pushing them, select the required commit. The right-hand pane shows the changes included in the selected commit. You can use the toolbar buttons to examine the commit details.

5. Click the Push button when ready and select which operation you want to perform from the drop-down menu: Push or Force push.

These choice options are only available if the Allow force push option is enabled (see [Version Control Settings: Git](#)), otherwise, you can only perform the `push` operation.

**Note** If the author of a commit is different from the current user, this commit is marked with an asterisk.

**Tip** You can also switch to the editing mode by pressing `Enter` or `F2` for the selected element.

**Tip** You can press `Ctrl+Q` for the selected commit to display extra info, such as the commit author, time, hash and the commit message.

**Tip** If you select an entire repository, all files from all commits will be listed in the right pane.

If the same file was modified within several commits, it will only be listed once if you select these commits or the entire repository, and if you invoke the [Differences Viewer for Files](#) for this file, all changes will be zipped together.

If `push` is rejected because your working copy is outdated, IntelliJ IDEA displays the Push Rejected dialog, provided that the Auto-update if push of the current branch was rejected option in the [Git settings](#) page of the Settings dialog is not selected. Do the following:

1. If your project uses several Git repositories, specify which of them you want to update. If you want to update all repositories, no matter whether `push` was rejected for them or not, select the Update not rejected repositories as well option. If this option is cleared, only the affected repositories will be updated.
2. If you want IntelliJ IDEA to apply the update procedure silently the next time push is rejected using the update method you choose in this dialog, select the Remember the update method choice and silently update in the future option. After you leave this dialog, the Auto-update if push of the current branch was rejected checkbox in the [Git settings](#) page of the Settings dialog will be selected, and the applied update method will become the default one.

To change the update strategy, deselect this option to invoke the Push Rejected dialog the next time push of the current branch is rejected, apply a different update procedure, and select the Remember the update method choice option once again.

3. Select the update method ([rebase](#) or [merge](#)) by clicking the Rebase or Merge button respectively.

## When do I need to use force push?

When you run `push`, Git will refuse to complete the operation if the remote repository has changes that you are missing and that you are going to overwrite with your local copy of the repository. Normally, you need to perform `pull` to synchronize with the remote before you update it with your changes.

The `--force push` command disables this check and lets you overwrite the remote repository, thus erasing its history and causing data loss.

A possible situation when you may still need to perform `--force push` is when you rebase a pushed branch and then want to push it to the remote server. In this case, when you try to push, Git will reject your changes because the remote ref is not an ancestor of the local ref. If you perform `pull` in this situation, you will end up with two copies of the branch which you then need to merge.

**Warning!** Rebasing a pushed branch and modifying its history should be avoided unless absolutely necessary (for example, if you've accidentally pushed some sensitive data).

If you decide to force push the rebased branch and you are working in a team, make sure that:

- Nobody has pulled your branch and done some local changes to it
- All pending changes have been committed and pushed
- You have the latest changes for that branch

IntelliJ IDEA allows you to trace back all changes in your project so that you can locate the author of changes, review the differences between different file versions, and [safely roll back and undo](#) changes if necessary.

## Review project history

IntelliJ IDEA allows you to review all changes made to the project sources that match the specified filters. To view project history, open the Version Control tool window ( `Alt+9` ) and switch to the Log tab. It shows all changes committed to all branches and remote repositories.

**Tip** You can assign a custom shortcut for the Show VCS Log action in Settings | Keymap | Version Control Systems to open the Log tab.

Use the search field to search through the list of commits by entering full commit names or messages or their fragments, revision numbers, or regular expressions. You can also filter the commits by branch, user, date and folder (or root and folder for multi-root projects).

You can also click the Go to Hash/Branch/Tag icon  on the toolbar or press `Ctrl+F` and specify a commit hash, tag or the name of a branch you want to jump to (you will be taken to the latest commit in that branch).

**Tip** You can quickly switch the focus to the search field by pressing `Ctrl+L`.

Note that clicking an arrow takes you to the next commit in a long branch:

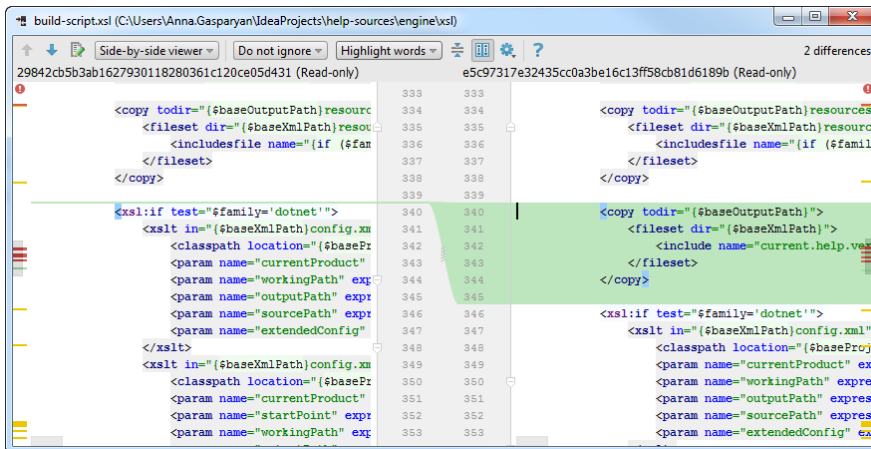

In multi-repository projects, the colored stripe on the left indicates which root the selected commit belongs to (each root is marked with its own color). Hover the mouse cursor over the colored stripe to invoke a tip that shows the root path:

## Review file history

If you need to review all changes made to a specific file, and identify what exactly was modified in each revision, do the following:

1. Select the required file in any view (in the Project tool window, in the editor, in the Local Changes tab of the Version Control tool window, etc.).
2. Select Git | Show History from the main VCS menu or from the context menu of the selection. The History tab is added to the Version Control tool window showing the history for the selected file and allowing you to review and compare its revisions.
3. To identify which changes were introduced in a specific revision, select it in the list and press `Ctrl+D` or click the  button on the toolbar. The Differences Viewer will open showing what has changed in this file revision:

## Review the differences between the local and a committed version

If you need to check how a committed file revision is different from its local version, do the following:

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Log tab.
2. Select the commit you are interested in, and in the right pane select the file in question.
3. Click the  button on the toolbar.

## Review how changes were merged

IntelliJ IDEA allows you to review how changes were [merged from one branch to another](#) , and how exactly conflicts (if any) were [resolved](#) during a merge:

In the Log view, select the merge commit you are interested in:

- If no conflicts were detected and resolved during the merge, IntelliJ IDEA will display the corresponding message in the Changed Files pane, and will suggest you to review changes originating from both parents:

Select the required file from one of the nodes and click the Show Diff icon on the toolbar  or press `Ctrl+D` . The [Differences Viewer](#) will show a two-panel diff allowing you to compare the current version with the selected parent.

- If conflicts occurred during the merge, the Changed Files pane will show you a list of files merged with conflicts. Select the required file and Show Diff icon on the toolbar  or press `Ctrl+D` . The [Differences Viewer](#) will show a three-panel diff allowing you to compare the current version with each of its parents, and see how exactly conflicts were resolved.

## Locate code author (annotate/blame)

IntelliJ IDEA allows you to figure out who introduced which changes to a file by using annotations . Annotation is a form of file presentation that shows detailed information for each line of code, including the revision from which this file originated, the user ID of the person who committed this line, and the commit date. The annotated view helps you find out who did what and when, and trace back the changes.

You can get the annotated view of a file opened in the editor, in the Differences Viewer , or selected in any tool window. The Annotate command is available from the context menu ( Git | Annotate ) or from the left gutter context menu of the editor or the Differences Viewer .

**Tip** If you often use the Annotate command, you can assign a custom shortcut to it. To do this, open the Settings dialog ( `Ctrl+Alt+S` ) and click Keymap on the left. Locate the Annotate command under Version Control | Git , right-click it and select Add Keyboard Shortcut .

When annotations are enabled, the left gutter looks similar to the following example:

Annotations for lines modified in the current revision, are marked with bold type and an asterisk.

You can configure the amount of information displayed in the annotations view by right-clicking the annotations gutter and selecting View from the context menu.

**Tip** To view a commit message for an annotated change, hover the mouse cursor over an annotation. A tooltip will appear showing the commit message for the corresponding change.

**Tip** You can jump from the annotations view to the corresponding commit in the Log tab of the Version Control tool window (use the Select in Git log command from the context menu of an annotation), or, if your project is hosted on GitHub , to the corresponding commit on <https://github.com> (use the Open on GitHub command).

## Annotate a previous revision

IntelliJ IDEA lets you annotate not only the current file revision, but also its previous revisions. The following options are available from the context menu of the annotations gutter:

- Annotate Revision : this option is useful if you want to check what a file looked like after a particular change was committed.
- Annotate Previous Revision : this option is useful if you find yourself in a situation when the last change in a particular line is meaningless, for example if all that was changed is code formatting. In this case, you can check what the previous revision of the file looked like.

You can also annotate a particular file from the History view. In the History tab, select the file version you want to review, right-click the corresponding line and select Annotate from the context menu.

Watch this video to learn more on how you can benefit from using annotations:

Instead of committing your changes, you can put them in a `.patch` file that you can apply to your sources later, or send by email, etc.

## Create a patch

To create a patch based on uncommitted changes, do the following:

1. Open the Version Control tool window (`Alt+9`) and switch to the Local Changes tab.
2. Select a file or a changelist based on which you want to create a patch.
3. Select Create Patch from the context menu or from the main VCS menu.
4. In the dialog that opens, make sure that all changes you want to include in the patch are selected, enter a commit comment (optionally) and click Create Patch.
5. In the Patch File Settings dialog, modify the default patch file location if necessary, and click OK.

If you do not need to save a patch to a file, and want, for example, to send it by email or through a messenger, you can select Copy as Patch to Clipboard from the context menu of the selected file or changelist, and then paste it to a message body.

**Tip** You can also create a patch by invoking the Commit Changes dialog, selecting the changes you want to include in the patch, hovering the mouse cursor over the Commit button and selecting Create Patch.

You can also create a patch based on changes that have already been committed. To create a patch from an entire commit, locate it in the Log view, and select Create Patch from the context menu. If you need to create a patch on a single file, and the corresponding commit contains multiple files, do the following:

1. Select the required file in any view (in the Project tool window, in the editor, in the Local Changes tab of the Version Control tool window, etc.).
2. Select Git | Show History from the main VCS menu or from the context menu of the selection. The History tab is added to the Version Control tool window.
3. Right-click a revision and choose Create Patch from the context menu, or click the Create Patch icon  on the toolbar.

## Apply a patch

To apply changes stored in a file to your sources, do the following:

1. Select VCS | Apply patch from the main menu.
2. In the Apply Patch dialog that opens, specify the path to the `.patch` file you want to apply.
3. If necessary, click the Map base directory icon  to specify a directory relative to which file names in the patch file will be interpreted. You can map a base directory to a single file, directory, or to a selection.
4. If the source code was edited after a patch was created, conflicts may arise. To check if you patch can be applied without conflicts, click the Show Diff icon  or press `Ctrl+D`. If there are conflicts, the corresponding lines will be highlighted in red.
5. If you want to apply changes to files stored in different locations from those specified in the patch, you can strip off the leading directories by using the Strip Directory button .
6. Select an existing changelist where you want to add the patch from the drop-down list, or specify the name of a new changelist in the Name field, and, optionally, enter a comment to this changelist.
7. If you want to make this changelist active, select the Set active option.
8. If you want IntelliJ IDEA to preserve the context of a task associated with the new changelist on its deactivation and restore the context when the changelist becomes active, select the Track context option (see [Managing tasks and contexts](#) for details).

**Tip** You can drag-and-drop a file or an email attachment to any place in the editor.

You can also copy a patch file content and apply it by choosing VCS | Apply Patch from Clipboard from the main menu. This is convenient when you receive a patch by email, for example, and do not want to save it. For [Git format](#) patches, IntelliJ IDEA extracts the commit message and the author and automatically fills the corresponding fields in the Commit Changes dialog.

In Git, branching is a powerful mechanism that allows you to diverge from the main development line, for example, when you need to [work on a feature](#) , or freeze a certain state of a code base for a release, etc.

In IntelliJ IDEA, all operations with branches are performed in the Git Branches popup. To invoke it, do one of the following:

– Click the Git widget in the Status bar:

– Invoke the VCS Operations popup by choosing VCS Operations Popup from the main menu, or press

`Alt+Back Quote` and select Branches there.

– From the main menu, choose VCS | Git | Branches .

– Right-click any file in the editor, and in the context menu choose Git | Repository | Branches .

If you have many branches, you can choose whether you want to display all of them in the Branches popup, or just the favorites. To do this, toggle the Show Only Favorites and the Show x More commands at the bottom of the Branches popup.

To mark a branch as a favorite, hover the mouse cursor over the branch name, and click the star outline that appears on the left:  . The `master` branch is marked as a favorite by default.

The name of the branch that is currently checked out is displayed in the Git widget in the Status bar.

If you have a multi-rooted repository, you can enable synchronous branch control, which means that all branch operations (such as checkout, merge, delete, etc.) will be performed simultaneously as if it were a single repository. If an operation fails at least in one of the repositories, IntelliJ IDEA prevents branches from diverging by suggesting you to roll back this operation in the repositories where it was successful. You can enable synchronous branch control in the Settings/Preferences dialog (`Ctrl+Alt+S`) under Version Control | Git .

## Create a new branch

If you want to create a new branch, for example to [work on a new feature](#) , do the following

1. In the Branches popup, choose New Branch .
2. In the dialog that opens, specify the branch name, and make sure the Checkout branch option is selected if you want to switch to that branch.

The new branch will start from the current HEAD. If you want to start a branch from a previous commit instead of the current branch HEAD, select this commit in the Log and select New Branch from the context menu.

## Checkout a branch as a new local branch

If you want to work in a branch created by someone else, you need to check it out to create a local copy of that branch:

1. In the Branches popup, select a branch that you want to check out locally from Remote Branches , or Common Remote Branches if your project has several roots and [synchronous branch control](#) is enabled, or from Repositories | Remote Branches if it is disabled, and choose Checkout as new local branch from the list of available operations.
2. Enter a new name for this branch if necessary, or leave the default name that corresponds to the remote branch, and click OK .

## Switch between branches

When [multitasking](#) , you often need to jump between branches to commit unrelated changes. To switch to a different branch, in the Branches popup, select the branch that you want to switch to under Local Branches and choose Checkout from the list of available operations. What happens next depends on whether there are conflicts between your local changes that you have not committed yet, and the branch that you are going to check out:

**Tip** IntelliJ IDEA saves your [context](#) (i.e. a set of opened files associated with a branch, as well as the current run configuration and [breakpoints](#) ) provided that the Restore workspace on branch switching option is enabled in the Settings/Preferences dialog (`Ctrl+Alt+S`) under Version Control | Confirmation . When you switch to a different branch, IntelliJ IDEA automatically restores your context associated with that branch.

- If your working tree is clean (i.e. you have no uncommitted changes), or your local changes do not conflict with the specified branch, this branch will be checked out (a notification will pop up in the bottom-right corner of the IntelliJ IDEA window).
- If your local changes will be overwritten by checkout, IntelliJ IDEA displays a list of files that prevent you from checking out the selected branch, and suggests to choose between Force Checkout and Smart Checkout . If you click Force Checkout , your local uncommitted changes will be overwritten and you will lose them.

If you click Smart Checkout , IntelliJ IDEA will [stash](#) uncommitted changes, check out the selected branch, and then unstash the changes. If a conflict occurs during the unstash operation, you will be prompted to merge the changes. For details, see [Resolve conflicts](#) .

## Compare branches

If you want to check how two branches have diverged from each other, you can compare them. To do this, from the Branches popup select the branch that you want to compare with the current branch, and choose Compare from the list of available operations.

In the dialog that opens, the Log tab shows a list of all commits that exist in one branch and do not exist in the other. When

you select a commit, the right pane displays a list of files that were affected by this commit. You can click the Show Diff icon  on the toolbar to see how exactly the selected file was changed in this commit.

The Files tab shows a list of all files that have diverged between the two branches. Clicking  shows the differences between the selected file in the current branch and in the branch you are comparing it with.

**Tip** Click the Swap branches link to toggle which branch is considered as a base against which you are comparing the other branch. The base branch is displayed on the left.

## Delete branches

After you have [integrated the changes](#) from a feature branch into the main line of development, you can delete the branch you do not need anymore:

1. [Invoke the branches popup](#) and select the branch you want to delete.
2. Choose Delete from the submenu.

After you have deleted a branch, a notification will be displayed in the bottom-right corner from which you can restore the deleted branch:

If the branch contained commits that have not yet been merged to its upstream branch or to the current branch, it will still be deleted immediately (equivalent to the `git branch --D` or `git branch --delete --force` command), but the notification will also contain a link allowing you to view the unmerged commits.

If the deleted branch was tracking a remote branch, you will also be able to remove the remote branch from this notification.

In Git, there are several ways to integrate changes from one branch into another: [Merge branches](#) , [Rebase branches](#) , or [Apply separate commits from one branch to another \(cherry-pick\)](#) .

## Merge branches

Suppose you have created a [feature branch](#) to work on a specific task, and want to integrate the results of your work into the

main code base after you have completed and tested your feature:

Merging your branch into master is the most common way to do this.

It is very common that while you are working in your feature branch, your teammates continue to commit their work to master:

When you run `merge` , the changes from your feature branch are integrated into the HEAD of the target branch:

Git creates a new commit (M) that is referred to as a merge commit that results from combining the changes from your feature branch and master from the point where the two branches diverged.

To merge branches, do the following:

1. [Switch to the target branch](#) that you want to integrate the changes to.
2. [Invoke the branches popup](#) , and select the branch that you want to merge into the target branch.
3. Choose Merge from the submenu.

If your working tree is clean (i.e. you have no uncommitted changes), and no conflicts occur between your feature branch and the target branch, Git will merge the two branches, and the merge commit will appear in the Log :

If conflicts occur between your branch and the target branch, you will be prompted to resolve them (see [Resolve conflicts](#) for details).

If you have local changes that will be overwritten by merge, IntelliJ IDEA will suggest performing Smart merge . If you select this option, IntelliJ IDEA will [stash](#) uncommitted changes, perform merge, and then [unstash](#) the changes.

## Rebase branches

When you `rebase` a branch onto another branch, you apply the commits from the first branch on top of the HEAD commit in the second branch instead of [merging](#) them into the target branch.

Suppose you have created a feature branch to work on a specific task and make several commits to that branch:

While you develop in your branch, your teammates continue to commit their work to master:

When you perform the `rebase` operation you integrate changes you have done in your feature branch to the `master` branch by applying your commits on top of the current HEAD commit in `master` :

### To rebase the current branch on top of another branch

To rebase the branch that is currently checked out on top of another branch, do the following:

1. [Invoke the branches popup](#) and select the branch the you want to rebase the current branch onto.

2. Choose Rebase onto from the list of available actions.

**Tip** You can resume an interrupted rebase operation by choosing `VCS | Git | Continue Rebasing` from the main menu, and cancel an unfinished rebase operation by choosing `VCS | Git | Abort Rebasing`.

## To rebase a branch on top of the current branch

To rebase a branch on top of the branch that is currently checked out, do the following:

1. [Invoke the branches popup](#) and select the branch that you want to rebase on top of the current branch.
2. Choose Checkout with Rebase from the list of available actions.

For details on how to skip or squash commit during a rebase, refer to [Edit project history by performing interactive rebase](#).

Watch this video to see how a merge or a rebase operation are reflected in the Log view:

## Apply changes from a specific commit to another branch (cherry-pick)

Sometimes you only need to apply a single commit to a different branch instead of rebasing or merging an entire branch.

This may be useful, for example, if you are working in a feature branch and want to integrate a hotfix from `master` that was committed after the two branches have diverged. Or you may want to backport a fix to a previous release branch, etc.

IntelliJ IDEA allows you to do so by using the Cherry-pick action:

1. [Switch to the target branch](#) that you want to integrate the changes to.

2. Open the Version Control tool window (`Alt+9`) and switch to the Log tab.

3. Locate the commit containing the changes you want to cherry pick.

Note that the log lists all commits. To reduce the number of items in the list, you can filter commits by branch, user or date.

You can also click the Highlight non-picked commits button  to grey out the commits that have already been applied to the current branch. If you know the commit hash, or are looking for a tagged commit, you can also use the Go to Hash / Branch / Tag action (press `Ctrl+F` in the Log view, or click  on the toolbar).

4. Select the required commit. Use the information in the Commit Details area if necessary.

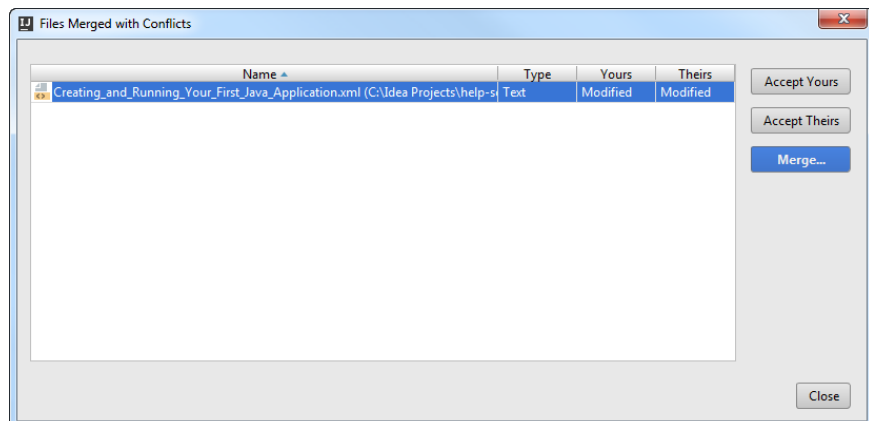

5. Click the Cherry-pick button  on the toolbar. IntelliJ IDEA will display the Commit Changes dialog with the automatically generated commit message. If you want to review the changes or even modify the code before committing it to the target branch, you can do so in the difference viewer available from this dialog.

6. When done, click Commit to cherry-pick the selected changes.

Note that if you click Cancel, a separate changelist will be created with the selected changes that you can see in the Local Changes tab. You can review these changes and commit them later if necessary.

When you work in a team, you may come across a situation when somebody pushes changes to a file you are currently working on. If these changes do not overlap (i.e. changes were made to different lines of code), the conflicting files are merged automatically. However, if the same lines were affected, Git cannot randomly pick one side over the other, and asks you to resolve the conflict.

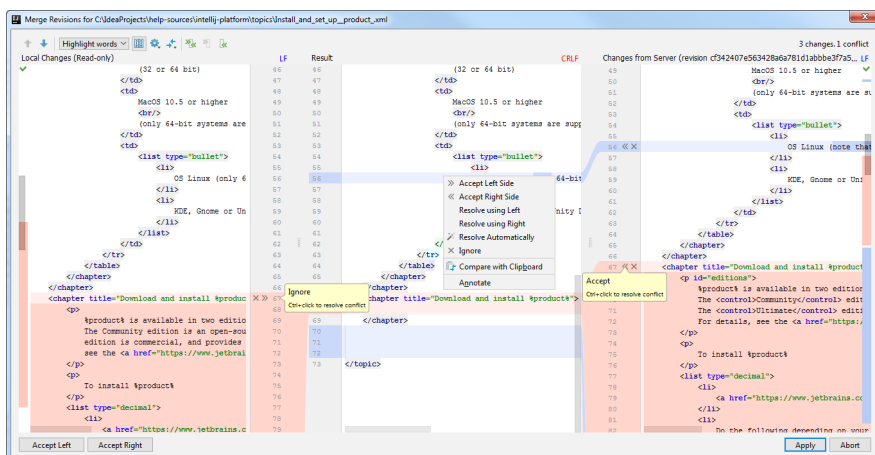

In Git, conflicts may arise when you attempt to perform one of the following operations: [pull](#), [merge](#), [rebase](#), [cherry-pick](#), [unstash changes](#) or [apply a patch](#). If there are conflicts, these operations will fail, and you will be prompted to accept the upstream version, prefer your version, or merge the changes:

IntelliJ IDEA provides a tool for resolving conflicts locally. This tool consists of three panes. The left pane shows the read-only local copy; the right pane shows the read-only version checked in to the repository. The central pane shows a fully-functional editor where the results of merging and resolving conflicts are displayed. Initially, the contents of this pane are the same as the **base revision** of the file, that is, the revision from which both conflicting versions are derived.

To resolve conflicts, do the following:

1. Click Merge in the Files Merged with Conflicts dialog, or select the conflicting file in the editor and choose VCS | <your\_VCS> | Resolve Conflicts from the main menu.
2. To automatically merge all non-conflicting changes, click (Apply All Non-Conflicting Changes) on the toolbar. You can also use the (Apply Non-Conflicting Changes from the Left Side) and (Apply Non-Conflicting Changes from the Right Side) to merge non-conflicting changes from the left/right parts of the dialog respectively.
3. To resolve a conflict, you need to select which action to apply (accept or ignore ) to the left (local) and the right (repository) version, and check the resulting code in the central pane:

For simple conflicts (for example, if the beginning and the end of the same line have been modified in different file revisions), the Resolve option is available that allows merging the changes in one click:

Such conflicts are not resolved with the Apply All Non-Conflicting Changes action since you must make sure that they are resolved properly.

4. It may also be useful to compare different versions to resolve a conflict. Use the toolbar button to invoke the list of options. Note that Base refers to the file version that the local and the repository versions originated from (initially displayed in the middle pane), while Middle refers to the resulting version.
5. Review merge results in the central pane and click Apply.

**Tip** You can configure IntelliJ IDEA to always apply non-conflicting changes automatically instead of telling it to do so from the Merge dialog. To do this, in the [Settings/Preferences dialog](#), expand the Tools | Diff Merge node in the left pane and select the Automatically apply non-conflicting changes option.

**Tip** You can also right-click a conflict and use the commands from the popup menu. The Resolve using Left and Resolve using Right commands provide a shortcut to accepting changes from one side and ignoring them from the other side respectively.

**Tip** You can manage changes in the central pane using a toolbar that appears when you hover the mouse cursor over a change marker in the gutter and then click it. The toolbar is displayed together with a frame showing the previous contents of the modified line:

## Handle conflicts related to LF and CRLF line endings

Quite often, people working in a team and contributing to the same repository use different operating systems. This may result in problems with line ending, because Unix, Linux and MacOS use `LF`, and Windows uses `CRLF` to mark the end of a line.

IntelliJ IDEA displays the discrepancies in line endings in the Differences Viewer, so you can fix them manually. If you want Git to solve such conflicts automatically, you need to set the `core.autocrlf` attribute to `true` on Windows and to `input` on Linux and MacOS (for more details, see [Dealing with line endings](#)). You can change the configuration manually by running `git config --global core.autocrlf true` on Windows or `git config --global core.autocrlf input` on Linux and macOS.

However, IntelliJ IDEA can automatically analyze your configuration, warn you if you are about to commit `CRLF` into a remote repository, and suggest setting the `core.autocrlf` setting to `true` or `input` depending on your operating system.

To enable smart handling of `LF` and `CRLF` line separators, open the Settings dialog (`Ctrl+Alt+S`), and select the Version Control | Git node on the left. Enable the Warn if CRLF line separators are about to be committed option.

After you have enabled this option, IntelliJ IDEA will display the Line Separators Warning Dialog each time you are about to commit a file with `CRLF` separators, unless you have set any related [Git attributes](#) in the affected file (in this case, IntelliJ IDEA supposes that you clearly understand what you are doing and excludes this file from analysis).

In the Line Separators Warning Dialog, click one of the following:

- Commit As Is to ignore the warning and commit a file with `CRLF` separators.
- Fix and Commit to have the `core.autocrlf` attribute set to `true` or `input` depending on your operating system. As a result, `CRLF` line separators will be replaced with `LF` before the commit.

If, at a later time, you need to review how exactly conflicts were resolved during a merge, you can locate the required merge commit in the Log view, select a file with conflicts in the Commit Details pane in the right, and click `+` or press `Ctrl+D` (see [Review how changes were merged](#) for details).

Sometimes you need to switch between different tasks with things left unfinished and then return back to them. IntelliJ IDEA provides you with a few ways to conveniently work on several different features without losing your work:

– You can [stash](#) or [shelve](#) pending changes.

Stashing changes is very similar to shelving. The only difference is in the way patches are generated and applied. Stashes are generated by Git, and can be applied from within IntelliJ IDEA, or outside it. Patches with shelved changes are generated by IntelliJ IDEA and are also applied through the IDE. Also, stashing involves all uncommitted changes, while when you put changes to a shelf, you can select some of the local changes instead of shelving them all.

– You can [keep changes related to different tasks or features in different changelists](#) .

– You can create [branches to work on different unrelated features](#) .

## Shelve changes

Shelving is temporarily storing pending changes you have not committed yet. This is useful, for example, if you need to switch to another high priority task and you want to set your changes aside to work on them later.

With IntelliJ IDEA, you can shelve both separate files and entire changelists.

Once shelved, a change can be applied as many times as you need by unshelving and subsequently restoring it on the shelf.

## Put changes to a shelf

1. Open the Version Control tool window () and switch to the Local Changes tab.
2. Select the files or a changelist you want to put to a shelf. On the main Version Control menu or on the context menu of the selection, choose **Shelve changes** .
3. In the **Shelve Changes** dialog, review the list of modified files.
4. In the **Commit Message** field, enter the name of the shelf to be created and click the **Shelve Changes** button.

**Tip** You can switch to a different changelist from the **Shelve Changes** dialog by choosing the **Changelist** drop-down.

You can also shelve changes silently, without displaying the **Shelve Changes** dialog. To do this, select a file or a changelist you want to shelve, and click the **Shelve Silently** icon , on the toolbar, or press  . The name of the changelist containing the changes you want to shelve will be used as the shelf name.

**Tip** To avoid ending up with numerous shelves with the same name (such as **Default** , for example), you can simply drag-and-drop a file or a changelist from the **Local Changes** tab to the **Shelf** tab, wait a second until it's activated, and edit the new shelf name on-the-fly when you release the mouse button.

## Unshelve changes

Unshelving is moving postponed changes from a shelf to a pending changelist. Unshelved changes can be filtered out from view or removed from the shelf.

1. In the **Shelf** tab of the **Version Control** tool window, select a changelist or files you want to unshelve.
2. Press  or choose **Unshelve** from the context menu of the selection.
3. In the **Unshelve Changes** dialog that opens, specify the changelist you want to restore the unshelved changes to in the **Name** field. You can select an existing changelist from the drop-down list or type a name for a new changelist to be created containing the unshelved changes. You can enter the description of the new changelist in the **Comment** field (optional).  
If you want to make the new changelist active, select the **Set active** option . Otherwise, the current active changelist remains active.
4. If you want IntelliJ IDEA to preserve the context of a task associated with the new changelist on its deactivation and restore the context then the changelist becomes active, select the **Track context** option (see [Managing tasks and contexts](#) for details).
5. If you want to remove the changes you are about to unshelve, select the **Remove successfully applied files from the shelf** option. The unshelved files will be removed from this shelf and added to another changelist and marked as applied. They will not be removed completely until deleted explicitly by clicking the  icon on the toolbar, or selecting **Clean Already Unshelved** from the context menu.
6. Click **OK** . If conflicts occur between the patched version and the current version, resolve them as described in [Resolving Conflicts](#) .

You can also unshelve changes silently, without displaying the **Unshelve Changes** dialog. To do this, select a file or a changelist you want to unshelve, and click the **Unshelve Silently** icon , on the toolbar, or press  . The unshelved files will be moved to the active pending changelist.

**Tip** You can also drag-and-drop a file or a changelist from the **Shelf** tab to the **Local Changes** tab to unshelve it silently.

## Restore unshelved changes

IntelliJ IDEA lets you reapply unshelved changes if necessary. All unshelved changes can be reused until they are removed explicitly by clicking the  icon on the toolbar, or selecting **Clean Already Unshelved** from the context menu.

To restore applied changes on the shelf do the following:

1. Make sure that the **Show Already Unshelved**  toolbar option is enabled.

2. Select the files or the shelf you want to restore.
3. On the context menu of the selection, choose Restore.

## Apply external patches

You can import patches created inside or outside IntelliJ IDEA and apply them as shelved changes.

1. In the Shelf tab of the Version Control tool window, choose Import Patches from the context menu.
2. In the dialog that opens, select the patch file to apply. The selected patch appears in the Shelf tab as a shelf.
3. Select the newly added shelf with the patch and choose Unshelve Changes from the context menu of the selection.

## Automatically shelve base revision

It may be useful to configure IntelliJ IDEA to always shelve base revisions of files that are under Git version control. To do this, open the Settings dialog ( `Ctrl+Alt+S` ), select the Version Control | Shelf node on the left and select the Shelve base revisions of files under distributed version control systems option.

If this option is enabled, the base revision of files will be saved to a shelf that will be used during a [3-way merge](#) if applying a shelf leads to conflicts. If it is disabled, IntelliJ IDEA will look for the base revision in the project history, which may take a while; moreover, the revision that the conflicting shelf was based on may be missing (for example, if the history was changed as a result of the [rebase](#) operation).

## Change the default shelf location

By default, the shelf directory is located under your project directory. However, you may want to change the default shelf location. This can be useful, for example, if you want to avoid deleting shelves accidentally when cleaning up your working copy, or if you want to store them in a separate repository allowing shelves to be shared among your team members.

1. Open the Settings dialog ( `Ctrl+Alt+S` ) and select the Version Control | Shelf node on the left.
2. Click the Change Shelves Location button and specify the new location in the dialog that opens.
3. If necessary, select the Move shelves to the new location option to move existing shelves to the new directory.

Watch this video tutorial on how to benefit from shelves to be able to switch to a different task without losing unfinished work:

## Stash changes

Sometimes it may be necessary to revert your working copy to match the HEAD commit but you do not want to lose the work you have already done. This may happen if you learn that there are upstream changes that are possibly relevant to what you are doing, or if you need to make some urgent fixes.

Stashing involves recording the difference between the HEAD commit and the current state of the working directory (stash). Changes to the index can be stashed as well.

Unstashing involves applying a stored stash to a branch.

You can apply a stash to an existing branch or create a new branch on its basis.

A stash can be applied as many times as you need to any branch you need, just [switch to the required branch](#) . Keep in mind that:

- Applying a stash after a series of commits results in conflicts that need to be resolved.
- You cannot apply a stash to a "dirty" working copy, that is a working copy with uncommitted changes.

## Save changes to a stash

1. From the main menu, choose VCS | Git | Stash Changes .
2. In the Stash dialog that opens, select the appropriate Git root and make sure that the correct branch is checked out.
3. In the Message field describe the changes you are about to stash.
4. To stash local changes and bring the changes staged in the index to your working tree for examination and testing, select the Keep index option.
5. Click Create Stash .

## Apply a stash

To apply a stash, do the following:

1. From the main menu, choose VCS | Git | Unstash Changes.
2. Select the Git root where you want to apply a stash, and make sure that the correct branch is checked out.
3. Select the stash you want to apply from the list.  
If you want to check which files are affected in the selected stash, click View .
4. To remove the selected stash after it is applied, select the Pop stash option.
5. To apply stashed index modifications as well, select the Reinstale Index option.
6. If you want to create a new branch on the basis of the selected stash instead of applying it to the branch that is currently checked out, type the name of that branch in the As new branch field.

**Note** This operation may fail if you have conflicts. This happens because conflicts are stored in the index where you can no longer apply the changes in their original state.

To remove a stash, select it in the list and click Drop . To remove all stashes, click Clear .

## Group changes into different changelists

When you are working on several related features, you may find it convenient to group changes into different changelists. This approach has its pros and cons as opposed to using [feature branches](#) to work on multiple tasks.

Pros :

- You can easily switch between different logical sets of changes and commit them separately from each other.
- Unlike using branches for the same purpose, you have all your changes at hand without having to switch between branches which can take a while if your project is really large.
- It's convenient to test how different features work together.
- You can remote-run a changelist on a build server.

Cons :

- While using changelists may seem a more lightweight option compared to branches, it's not safe as there's no backup for your changes until you have committed and pushed them. If something happens to your local working copy, all your changes will be lost as they are not part of Git project history.
- Using changelists only works if changes do not overlap. If different tasks affect the same file, you cannot separate these changes and put them into separate changelists.
- No atomic testing of features is possible.
- No collaboration on the same feature is possible. Also, you cannot make contributions from different machines unless you send patches with changes through email, which may not be very convenient.

All changelists are displayed in the Local Changes tab of the Version Control tool window. All modified files are automatically placed in the active changelist, which is the Default changelist unless you have created a different one and made it active.

To create a new changelist, click  on the toolbar.

To make a non-default changelist active, right-click it and choose Set Active Changelist from the context menu.

To move changes between changelists, select the file you want to move and click  on the toolbar, or choose Move to Another Changelist from the context menu.

1. Select the Set active option if you want to make the changelist with the changes you are about to discard the active changelist.
2. Select the Track context option if you want IntelliJ IDEA to remember your context and reload currently opened files in the editor when this changelist becomes active.

**Tip** You can also drag-and-drop files between changelists.

## Use feature branches

A branch in Git represents an independent line of development, so if you are working on a separate feature that you want to complete and test before you are ready to share the results of your work and integrate them into `master`, doing it in a feature branch is the best solution. This way you can make sure unstable code is not committed to the main code base of your project, and you can easily switch to other tasks if necessary.

Pros :

- As opposed to using changelists to group changes, using feature branches is safe. After you've committed changes to Git, they become part of Git project history, so you can always restore your commit through [Git reflow](#) even if you corrupt your working tree. After you've pushed your changes, they are backed up.
- You can develop parallel non-related features and test them atomically.
- When you've finished development in your branch, you can [reorder or squash commits](#), so that your history is linear and clean.
- It is easy to collaborate on your feature, or develop it from different machines.

Cons :

- It can take time to switch branches on really large projects.
- It's not very convenient to test related features together.
- You have to learn a [workflow for using feature branches](#) and integrating your changes into the main code base.

There are two major approaches for using feature branches and integrating your changes into the main code base:

- the [merge option](#)
- the [rebase option](#)

## Use merge to integrate changes from a feature branch

The major benefit of the merge option is full traceability, as commits merged into the main code base preserve their original hash and author, and all commits that are part of one feature can be grouped together.

This workflow is good for projects where committing changes to the main code base involves [pull requests](#) or an hierarchical approval procedure, as existing branches are not changed in any way.

The main drawback of this approach is that extraneous merge commits are created each time you need to incorporate changes, which intensely pollutes project history and makes it difficult to read.

The merge option workflow involves the following steps:

1. [Create a branch](#) for your separate line of development.
2. [Commit](#) your changes while you develop.
3. [Push](#) your branch to a remote repository. This should be done for backup, and so that you can collaborate or work from different machines.
4. Switch to a different branch when you need to perform work that is not related to your feature.
5. Have your feature reviewed and tested, and make the necessary fixes.
6. When you are ready to integrate the results of your work into the main branch (e.g. `master` ), do the following:
  - a. [Merge](#) your feature branch into the main code base.
  - b. [Delete the feature branch](#) .
  - c. Push.

## Use rebase to integrate changes from a feature branch

The major benefit of this option is that you get a clean project history that is easy for others to read and understand. Your log does not contain unnecessary merge commits produced by the `merge` operation, and you get linear history that is easy to navigate and search through.

When deciding to adopt this workflow, you should keep in mind, however, that `rebase` rewrites project history as it creates new commits for each commit in the original feature branch, so they will have different hashes, which obstructs traceability.

The rebase option involves the following steps:

1. [Create a branch](#) for your separate line of development.
2. [Commit](#) your changes often while you develop.
3. [Push](#) your branch to a remote repository. This should be done for backup, and so that you can collaborate or work from different machines.
4. [Rebase](#) your feature branch onto `master` from time to time. It only makes sense to do this if your feature branch is a long one. This is useful to:
  - make sure your feature branch and `master` do not fall too far apart.
  - avoid resolving numerous conflicts when you finally integrate your changes into the main code base. When you rebase regularly, you can resolve conflicts iteratively and do not end up struggling with a long diff.
  - speed up checking out branches, as switching between branches gets slower as soon as they diverge sufficiently.

Rebasing involves the following steps:

- a. [Fetch](#) changes from the remote, or [pull](#) changes into the `master` branch.
  - b. [Rebase](#) your branch onto `master` .
  - c. [Force push](#) the results of the `rebase` operation to your feature branch.
5. Switch to `master` when you need to perform work that is not related to your feature. When you turn back to your feature branch, perform Checkout with rebase .
  6. Have your feature reviewed and tested, and make the necessary fixes.
  7. Perform Interactive Rebase when your feature has been completed. This allows you to [reorder and squash](#) commits to make your feature branch history look nice and clean.
  8. When you are ready to integrate the results of your work into the main branch (e.g. `master` ), do the following:
    - a. [Checkout](#) the `master` branch.
    - b. [Merge](#) your branch with `master` . Since `master` has not diverged, Git will just move the pointer forward to the latest commit of the feature branch instead of creating a new merge commit (this is referred to as a fast-forward merge).
    - c. [Delete the feature branch](#) .
    - d. [Push](#) .

**Tip** It makes sense to use your initials or your nickname (if it's short) as a prefix for your feature branches names. This way you can always easily find all your branches using speed search in the Branches menu.

## Revert uncommitted changes

You can always undo the changes you've done locally before you have committed them:

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Local Changes tab.
2. In the active changelist, select one or more files that you want to revert, and select Revert from the context menu, or press `Ctrl+Alt+Z` . All changes done to the selected files since the last commit will be undone, and they will disappear from the Local Changes view.

## Undo the last commit

IntelliJ IDEA allows you to undo the last commit in the current branch (i.e. HEAD):

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Log tab.
2. Select the last commit in the current branch and choose Undo Commit from the context menu.
3. In the dialog that opens, select a changelist where the changes you are going to discard will be moved. You can either select an existing changelist from the Name drop-down list, or specify the name of a new changelist (the commit message is used by default).
4. Select the Set active option if you want to make the changelist with the changes you are about to discard the active changelist.
5. Select the Track context option if you want IntelliJ IDEA to remember your context and reload currently opened files in the editor when this changelist becomes active.

**Note** You cannot undo a commit if it was pushed to a protected branch, i.e. a branch to which `push --force` is not allowed. You can configure the list of protected branches in the Settings dialog ( `Ctrl+Alt+S` ) under Version Control | Git.

## Revert a pushed commit

If you notice an error in a specific commit that has already been pushed, you can revert that commit. This operation results in a new commit that reverses the effect of the commit you want to undo. Thus, project history is preserved, as the original commit remains intact.

1. Locate the commit you want to revert in the Log view, right-click it and select Revert from the context menu. The Commit Changes dialog will open with an automatically generated commit message.
2. If the selected commit contains several files, and you only need to revert some of them, deselect the files you do not want to touch.
3. Click Commit to commit a changeset that reverts changes to the selected files in this particular commit.

## Reset a branch to a specific commit

If you notice an error in a set of recent commits and want to redo that part, you can roll back your repository to a specific state. This is done by resetting the current branch HEAD to a specified commit (and optionally resetting the index and working tree if you prefer not to reflect the undo in the history).

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Log tab.
2. Select the commit that you want to move HEAD onto and select Reset Current Branch to Here from the context menu.
3. In the Git Reset dialog that opens, select how you want your working tree and the index to be updated and click Reset :
  - Soft : all changes from commits that were made after the selected commit will be staged (i.e. they will be moved to the Local Changes view so that you can review them and commit later if necessary).
  - Mixed : changes made after the selected commit will be preserved but will not be staged for commit.
  - Hard : all changes made after the selected commit will be discarded (both staged and committed).
  - Keep : committed changes made after the selected commit will be discarded, but local changes will be kept intact.

## Get a previous revision of a file

If you need to revert a single file instead of discarding a whole commit that includes changes to several files, you can return to a particular version of that file:

1. Select the required file in any view (in the Project tool window, in the editor, in the Local Changes tab of the Version Control tool window, etc.).
2. Select Git | Show History from the main VCS menu or from the context menu of the selection. The History tab is added to the Version Control tool window showing the history for the selected file and allowing you to review and compare its revisions.
3. When you've identified the revision you want to roll back to, select it in the list and choose Get from the context menu.

Git allows you to attach tags to commits to mark some points in the project history as being important, so that you can refer to them in the future. For example, you can tag a commit that corresponds to a release version, instead of [creating a branch](#) to capture a release snapshot.

## Assign a tag to a commit

1. From the main menu, choose VCS | Git | Tag .
2. In the Tag dialog that opens, under Git Root , select the path to the local repository in which you want to tag a commit, and specify the name of the new tag.
3. In the Commit field, specify the commit that you want to tag. You can enter the commit hash, or use an expression, for example: `<branch>~<number of commits backwards between the latest commit (HEAD) and the required commit>` (Refer to Git [commit naming](#) conventions for details).
4. If you enter some comment in the Message field, an annotated tag will be created instead of a regular one. Meta-data for annotated tags contains the name of the user who created them, so they allow you to check who placed them.
5. Click Create Tag . The tag will be shown in the Log view:

**Note** If the Compact References View option is enabled under Quick Settings in the Log toolbar, tag names are hidden behind branch names and are not visible.

**Tip** You can also right-click a commit in the Log view and select New Tag from the context menu if you do not need to specify any additional options.

## Reassign an existing tag

If you've placed a tag on a wrong commit, and want to reassign it (for example, to indicate a commit for a release version), do the following:

1. From the main menu, choose VCS | Git | Tag .
2. In the Tag dialog, in the Tag Name field specify the name of an already existing tag that you want to reassign.
3. Select the Force option.
4. In the Commit field, specify the commit where the tag shall be moved and click Create Tag .

## Jump to a tagged commit

1. Open the Version Control tool window ( `Alt+9` ) and switch to the Log tab.
2. Click the Go To Hash/Branch/Tag icon  on the toolbar, or press `Ctrl+F` .
3. Enter the tag name ( `code completion` suggests tag names as you type) and press `Enter` .

## Check out a tagged commit

Suppose you marked a commit that corresponds to a release version with a tag, and now you want to review the snapshot of your project at that point in time. You can do this by checking out a tagged commit. Do one of the following:

- [Locate](#) the tagged commit that you want to checkout, right-click it and select Checkout Revision from the context menu.
- [Invoke the branches popup](#) , click Checkout Tag or Revision and type in the tag name.

Note that this operation results in a [detached HEAD](#) , which means you are no longer in any branch. You can use this snapshot for inspection and experiments. However, if you want to commit changes on top of this snapshot, you will need to [create a branch](#) .

Git allows you to edit your project history if at some point you need to rewrite your commits as if you made them in a different way.

## Combine staged changes with the previous commit (amend commit)

Sometimes you may find yourself in a situation when you commit too early and forget to add some files or notice an error in the last commit that you want to fix without it being reflected in the project history.

IntelliJ IDEA allows you to do this by using the Amend commit option that combines the previous commit with the current changes, and you end up with a single commit instead of two different commits.

To amend the previous commit, do the following:

1. [Invoke the Commit changes](#) dialog and select the changes that you want to use to fix up the previous commit.
2. Either press `Ctrl+K`, click  on the toolbar, or select Commit from the context menu.
3. In the Commit Changes dialog that opens, select the Amend commit option on the right before committing your changes.

## Edit a commit message

If the only thing you need to change is a commit message, you can edit it without making any other changes:

**Note** This action can only be applied to commits that have not been pushed yet.

1. Locate the commit whose message you want to edit in the Log view, right-click it and select Rework from the context menu, or press `F2`.
2. In the dialog that opens, enter a new commit message and click OK.

## Edit project history by performing interactive rebase

Git allows you to edit project history for the sake of making it linear and meaningful by performing interactive rebase. This allows you to clean up a messy commits history by altering individual commits, changing their order, squashing commits into one, skipping commits that contain extraneous changes, etc. before you integrate changes from your [feature branch](#) to another branch.

**Warning!** Keep in mind that re-writing the commits history may lead to data loss.

## Edit the history of the current branch

IntelliJ IDEA allows you to edit a series of recent commits in the current branch before you [apply the changes to a different branch](#).

1. In the Log tab of the Version Control tool window select the oldest commit in the series of commits you want to edit, right-click it and select Interactively Rebase from Here.  
The Interactive Rebase dialog will be displayed containing the list of all commits in the current branch that were made after the selected commit.
2. Use the Action drop-down list to apply the following actions to commits:
  - Pick : applies the selected commit as is.
  - Edit : select this option to edit the files affected by this commit or the commit message before applying this commit.
  - Skip : ignores the selected commit.
  - Squash : select this option to combine the selected commit with the previous one.
  - Reword : select this option to edit the commit message before applying this commit.
  - Fixup : select this option to combine the selected commit with the previous one and use the message from the previous commit with the "fixup!" prefix.
3. Use the Move Up and Move Down buttons to modify the order in which commits should be applied.

## Edit a branch history and integrate it into another branch

IntelliJ IDEA allows you to [rebase](#) a branch on top of another branch and edit the source branch history before you apply the changes.

1. From the main menu select VCS | Git | Rebase.
2. Select the branch you want to rebase in the Branch field, and the target branch in the Onto field.
3. In the From field, select the commit starting from which you want to apply the selected branch to the new base.
4. Make sure the Interactive option is selected, and click Rebase.  
The Interactive Rebase dialog will be displayed containing the list of all commits in the current branch that were made after the selected commit.
5. Use the Action drop-down list to apply the following actions to commits:
  - Pick : applies the selected commit as is.
  - Edit : select this option to edit the files affected by this commit or the commit message before applying this commit.
  - Skip : ignores the selected commit.
  - Squash : select this option to combine the selected commit with the previous one.
  - Reword : select this option to edit the commit message before applying this commit.
  - Fixup : select this option to combine the selected commit with the previous one and use the message from the previous commit with the "fixup!" prefix.

6. Use the Move Up and Move Down buttons to modify the order in which commits should be applied.

IntelliJ IDEA allows you to manage projects controlled by Git that are hosted on [GitHub](#) without leaving the IDE.

**Note** Commands used to manage GitHub projects from within IntelliJ IDEA are only available if you have a GitHub project specified as your project remote.

## Register a GitHub account in IntelliJ IDEA

To retrieve data from a repository hosted on [GitHub](#), and to be able to share your projects, you need to register your GitHub account in IntelliJ IDEA. You can also create an account on GitHub without leaving the IDE if you do not have one yet.

In either case, IntelliJ IDEA remembers your login and password, so you do not have to specify your credentials each time you [retrieve data](#) from a remote, or [push](#) your commits.

## Register an existing GitHub account

GitHub offers [two-factor authentication](#) to improve the protection of user accounts.

If you enable two-factor authentication and you use SSH to access your repositories, you can choose any authentication type - password or token.

If you use the HTTPs protocol to access your remote repositories on GitHub, you need to configure an [Access token](#) and use it to authenticate, otherwise remote Git operations will fail. When prompted for credentials, either enter the token as your username and leave the password field empty, or specify the token instead of your password.

To register your account, do the following:

1. Invoke the Settings dialog ( `Ctrl+Alt+S` ) and select Version Control | GitHub in the left pane.
2. Select the type of authentication that you want to use from the Auth Type drop-down list:
  - Password . If this option is selected and you have [two-factor authentication](#) enabled in your GitHub account settings, you will be asked to enter an authentication code each time IntelliJ IDEA requires you to log in to your GitHub account.
  - Token (recommended by GitHub for authentication from third-party applications, as it does not require IntelliJ IDEA to remember your password).
3. Specify your credentials depending on the selected authentication type, and click OK .

## Create a new GitHub account

1. Invoke the Settings dialog ( `Ctrl+Alt+S` ) and select Version Control | GitHub in the left pane.
2. Click the Sign up link.
3. On the Sign up for GitHub page that opens in the browser, choose the account plan (free or paid), and specify the requested information. When you are done creating an account, the GitHub Welcome Page is displayed.
4. Return to GitHub settings and specify your credentials for IntelliJ IDEA to register them.

## Checkout a project from GitHub

IntelliJ IDEA allows you to check out (clone) a repository from GitHub and create a new project based on it:

1. From the main menu, choose VCS | Checkout from Version Control | GitHub .
2. In the Clone Repository dialog that opens, specify the URL of the repository that you want to clone, or select a repository from the list that contains all GitHub projects associated with your account and the organization that your account belongs to.
3. In the Parent Directory field, specify the path where the folder for your local Git repository will be created.
4. In the Directory Name field, specify the name of the folder into which the repository will be cloned.
5. Click Clone . If you want to create a IntelliJ IDEA project based on the sources you have cloned, click Yes in the confirmation dialog. Git root mapping will be automatically set to the project root directory.

## Share a project on GitHub

If you want to add a remote repository for your project on [GitHub](#), do the following:

1. Open the project you want to share.
2. From the main menu, choose VCS | Import into Version Control | Share Project on GitHub .  
If you have already [registered your login and password](#) in IntelliJ IDEA, connection to GitHub will be established using these credentials.

If you have not registered your GitHub credentials in IntelliJ IDEA, the Login to GitHub dialog opens. Specify your login and password, or create a new account there.

3. When connection to GitHub has been established, the Share Project on GitHub dialog opens. Specify the new repository name and enter a description of your project's main functionality.  
You can select the Private option if you do not want to allow public access to your repository for other GitHub users (note that this option is unavailable for free accounts).
4. Click Share to initiate a new repository and upload project sources to it.

## Contribute to somebody else's projects

If you want to contribute to a project hosted on GitHub that you do not have rights to push to, follow this workflow:

- a. [Create a fork](#) of the project you want to contribute to, i.e. a copy of the original repository on GitHub.
- b. [Clone](#) this fork to create a local repository.

- c. Make changes to your copy of the original project.
- d. When you are ready to share the results of your work, [rebase](#) your fork on the current HEAD of the master branch in the original project to make sure your changes do not conflict with new commits that were pushed after you created your fork.
- e. [Create a pull request](#) so that you can tell others about the changes you've made, and ask for comments or review. Note that a pull request is merged into the original repository only after approval.

## Fork a project

Open the project that you want to fork on [GitHub](#) and click .

A copy of the original project will be created under your account. To make changes to this project, you need to [clone](#) it to create a local repository.

Watch this video tutorial on how to keep your fork of a project up to date:

## Rebase a fork

From the main menu, choose VCS | Git | Rebase my GitHub fork . Your fork will be rebased onto the HEAD commit in the `master` branch of the original project you created your fork from.

## Create a pull request

By creating a pull request, you tell others about the changes you've pushed to your fork, so that they can be reviewed, discussed, and integrated into the base branch. To create a pull request, do the following:

1. From the main menu, choose VCS | Git | Create Pull Request . The Create Pull Request dialog opens.
2. Under Base Fork , specify the project that you want to send the pull request to. Either select a repository from the list populated by IntelliJ IDEA, or click Select Other Fork .
3. Under Base Branch , specify the branch in the target project that your changes will be applied to. Click Show Diff to review the list of commits that will be included in the pull request. To view a commit details, select it and switch to the Log tab of the Version Control tool window, where you can see a list of files included in the selected commit, view diff, etc.
4. Specify the name for your pull request in the Title field, and, optionally, provide a description of the changes to be applied through your request.

## Share code by using gists

Gists allow you to share your code. You can share code snippets, entire files, or even applications. You can also use gists to save and share console output when running, debugging, or testing your code.

To create a gist, do the following:

1. Select a code fragment in the editor, or files and folders in the Project tool window. To save console output to a gist, right-click anywhere in the tool window or tab that contains that output.
2. On the context menu of the selection, choose Create Gist .
3. In the Create Gist dialog that opens, specify the name for your gist under Filename , and enter a description of the code you are going to publish.
4. Select the Private option to create the so-called secret gist. Secret gists are not searchable and do not show up in [Discover](#) . They can only be used for your own purposes, as you cannot share them.  
If you want to create a public gist, make sure this option is deselected. Public gists are searchable, and they show up in [Discover](#) where people can browse newly appearing gists. Use public gists if you want other people to be able to find and see your code.
5. If you want to create an anonymous gist, select the Anonymous option. Anonymous gists can be both public or private.
6. If you want to open the newly created gist in your default browser, select the Open in browser option and click OK .

**Note** Once you have created a gist, you cannot convert it from secret to public or vice versa.

**Note** You cannot delete an anonymous gist from a web browser. To have it deleted, you will need to contact GitHub support and provide them with the URL of the gist you want to remove.

## Jump to the GitHub version of a file

You can jump from the IntelliJ IDEA to the GitHub version of a file. IntelliJ IDEA detects which branch is currently active, and opens the GitHub copy of the selected file in the corresponding branch.

To view the remote copy of a file, select it in the editor or in the Project view, and choose Open on GitHub from the context menu of the selection. The remote version of the file in the current branch will open in the browser.

With the CVS integration enabled, you can perform basic CVS operations from inside IntelliJ IDEA.

**Note** The information provided in the topics listed below assumes that you are familiar with the basics of CVS version control system.

In this section:

- [Using CVS Integration](#)
  - [Prerequisites](#)
  - [CVS support](#)
- [Browsing CVS Repository](#)
- [Checking Out Files from CVS Repository](#)
- [Configuring CVS Roots](#)
- [Configuring Global CVS Settings](#)
- [Ignoring Files](#)
- [Importing a Local Directory to CVS Repository](#)
- [Resolving Commit Errors](#)
- [Updating Local Information in CVS](#)
- [Using CVS Watches](#)
- [Working Offline](#)
- [Working with Tags and Branches](#)

## Prerequisites

- IntelliJ IDEA comes bundled with the CVS plugin. This plugin is turned on by default. If it is not, make sure that the plugin is enabled.
- IntelliJ IDEA CVS integration does not require a standalone CVS client. All you need is an account in your CVS repository.
- CVS [integration is enabled](#) for the current project root or directory.

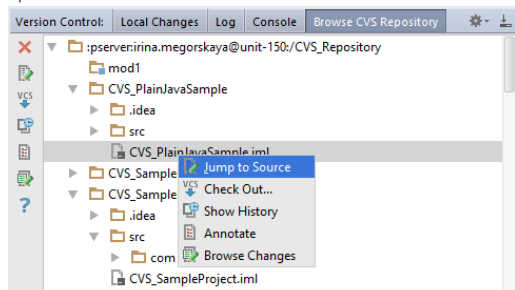

## CVS support

- When CVS integration with IntelliJ IDEA is enabled, the CVS item appears on the VCS menu, and on the context menus of the [Editor](#) and the [Project Tool Window](#) .
- The files in the folders under the CVS control are highlighted according to their status. See [File Status Highlights](#) for file status highlighting conventions.
- Modifications results are shown in the [Version Control tool window](#) .
- When using CVS integration, it is helpful to open the [Version Control](#) tool window. The [Console](#) tab displays the following data:
  - All commands generated based on the settings you specify through the IntelliJ IDEA user interface.
  - Information messages concerning the results of executing generated CVS commands.
  - Error messages.

You can browse any CVS repository and modify the structure of the currently open project, or a different one. Browsing contents of a repository is always available, even when CVS is not enabled in project. All you need is a valid user account.

## To browse the CVS repository and modify its structure

1. Open a project. Then, choose VCS | Browse VCS Repository | Browse CVS Repository... on the main menu. The Select CVS Root Configuration dialog is opened.
2. Select a root from the list of configured CVS roots, or click Configure to specify a new one , and then click OK . The Browse CVS Repository tab opens in the CVS tool window at the bottom of the Editor.
3. Browse the desired CVS repository and perform jump to source, checkout, browse changes and annotate operations for files and folders.

Icons for the tree nodes denote their respective types. For example:

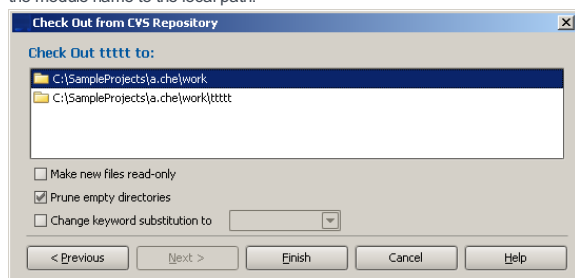

-  means a CVS directory.
-  denotes a CVS module.

Icons appearing next to the files will denote the corresponding file types.

Checking out action helps you obtain a writable copy of the repository, which you can edit as required. After making the necessary changes, you can publish results by committing, or checking in, to the repository. This section describes CVS-specific checkout procedure.

## To check out files from a CVS repository

1. On the main menu, choose VCS | Checkout from Version Control .
2. On the submenu, choose CVS .
3. In the [Checkout From CVS Repository dialog](#) , select the desired CVS configuration, and click Next . If the necessary CVS configuration is not available, click Configure to [create a new one](#) .
4. Select the elements to check out, and click Next .
5. Specify the checkout destination directory where the local copy of the repository files will be created and click Next .  
If you are checking out sources for an existing project, the destination folder should be below a project [content root](#) .
6. If you have selected an element of a CVS module to check out, the last page of the wizard suggests to add the module name to the local path:

7. Set up CVS checkout options, or accept defaults, and click Finish .
8. IntelliJ IDEA suggests to create a project based on the sources, checked out from version control.  
If you accept the suggestion, the [New Project from Existing Code Wizard](#) starts.

CVS roots are global IntelliJ IDEA properties. Once configured, a CVS root is available regardless of which project is currently opened. This is helpful if you need to check out an entire project from CVS.

You can define multiple CVS root configurations for future use and edit them whenever necessary. Alternatively, you can configure CVS roots when [checking out](#) files or directories from or [importing](#) them to a CVS repository.

From this section you will learn how to:

- Configure a [new CVS root](#)
- [Modify](#) a CVS root
- Configure a CVS root [based on an existing](#) configuration
- [Remove](#) a CVS root configuration

### To configure a CVS root, follow these general steps:

1. [Open the CVS Roots](#) dialog box.
2. Click the Add button  on the toolbar.
3. Specify the [CVS root string](#) .
4. Specify the [version to work with](#).
5. Specify [additional connection settings](#) .
6. Click the Test connection button to check that the specified settings ensure establishing successful connection to the CVS server.
7. Click OK to apply the specified settings and close the dialog box.

### To modify an existing CVS root configuration

1. [Open the CVS Roots](#) dialog box.
2. Select the CVS root to modify.
3. Edit the settings as while [configuring a new](#) CVS root.  
Changes made here apply to the current CVS root configuration only.

### To configure a new CVS root based on an existing configuration

1. [Open the CVS Roots](#) dialog box.
2. Select the CVS root to be used as the basis for a new configuration.
3. Click the Copy button  on the toolbar or press  . The selected configuration is copied as a new CVS root.
4. [Edit](#) the newly created CVS root configuration, as required.

### To remove a CVS root configuration

1. [Open the CVS Roots](#) dialog box.
2. Select the CVS root you want to remove and click the Remove button  on the toolbar.

You can access the CVS Roots dialog box in several ways, depending on the general task you are currently performing.

**To open the CVS Roots dialog box, do one of the following:**

- When [checking out](#) files or directories from a CVS repository: on the main menu, choose VCS | Checkout from Version Control | CVS and in the dialog box that opens click the Configure button.
- When [importing](#) files or directories to a CVS repository: on the main menu, choose VCS | Import into CVS and in the dialog box that opens click the Configure button.
- When defining a CVS root to use in the future : open a file which is already under CVS control and choose VCS | CVS | Configure CVS Roots on the main menu.

CVS root strings are specified in the CVS Root text box of the CVS Roots dialog box.

The CVS Root string syntax is:

```
[ :method: ] [ [user] [ :password ] @ ] hostname [ : [port] ] / path / to / repository .
```

You can obtain the valid string from your system administrator, or assemble the CVS root parameters into a correct string manually, or use the Edit by Field functionality, as described below.

### **To assemble the CVS Root parameters**

1. In the CVS Roots dialog box, click the Edit by Field button next to the CVS Root text box. The Configure CVS Root Field by Field dialog box opens.
2. Choose the connection method and specify the user name, port, host, and repository. See the Configure CVS Root Field by Field dialog box reference for details.
3. Click OK . The dialog box closes and you return to the CVS Roots dialog box. The CVS Root text box displays the specified parameters assembled in a valid string.

By default, IntelliJ IDEA suggests to check out the latest (HEAD) revision to work with. However, you can synchronize your local working copy with any previous revision from the repository.

**Tip** Make sure that the CVS root field is filled in with valid data.

## To specify the version to work with

1. In the Use Version section of the CVS Roots dialog box, select the criterion to search for the desired version.

The available options are:

- By tag
- By date

2. Click the Browse button  next to the selected option and do one of the following depending on the selected search criterion:

- If you have selected By tag , select the desired tag from the list of tags that opens. The list displays the tags obtained from the CVS server according to the specified CVS root string.
- If you have selected By date , select the date and time in the calendar that opens.

You can also type the desired revision number, tag, or date in the text box next to the selected option.

You can flexibly configure connection to the CVS server using additional settings. The set of relevant options depends on the [connection method](#) specified in the CVS root string. The available additional options for each of the supported connection methods are displayed in the lower part of the CVS Roots dialog box.

For a module associated with CVS you can specify global CVS settings, which includes character set, location of the password file, connection timeout etc.

### To configure CVS global settings for a directory associated with CVS

1. On the main menu, choose VCS | CVS | Global Settings .
2. In the Global CVS Settings dialog box that opens, specify the global settings and click OK .

**Tip** Alternatively, you can define global CVS settings when [configuring a CVS root](#) . To invoke the [Global CVS Settings](#) dialog box, click the [Global Settings](#) button in the [CVS Roots](#) dialog box.

If you want your CVS integration to ignore certain unversioned files under CVS-associated directories, and skip them when performing update, import etc., add these files to the CVS ignore list, which is stored in the `.cvsignore` file.

The way CVS integration handles unversioned files depends on the [general settings for file creation](#). If the new files, created with IntelliJ IDEA, are not put under version control automatically, you can add them to the ignore list using CVS command.

You can put the `.cvsignore` file under CVS version control, and it will be recognized by all CVS clients.

## To include an unversioned file to the ignore list

1. Select an unversioned file under a CVS-associated directory (by default, such files are brown).
2. On the main VCS menu, or on the context menu of the selection, choose `CVS | Ignore`. If `.cvsignore` file is not under CVS version control, proceed to the next step. If `.cvsignore` already exists and is under version control, IntelliJ IDEA adds the file in question to the ignore list silently.
3. If you want to put the ignore list under version control, in the `Add File .cvsignore to CVS` dialog box, click `Add to CVS` and optionally specify the desired [keyword substitution](#).

**Tip** If you want to remove a file from the ignore list, you can only do it manually. Open the `.cvsignore` file for editing by pressing `F4`, and remove the lines for the files that should not be ignored by CVS.

You can import an entire directory to your CVS repository, provided that you have the corresponding access rights. This action is helpful for putting a whole project under version control.

Import to the repository is always available, even when CVS is not enabled in project.

## To import a directory into CVS repository

1. On the main menu, choose VCS | Import into CVS .
2. On the first page of the [Import into CVS](#) wizard, select the target CVS root. If the desired target repository does not exist, you can create a new one. To do that, click [Configure](#) , and [define the desired CVS root](#) . Click [Next](#) .
3. On the second page of the wizard, select the target directory in the repository, and click [Next](#) .
4. On the third page of the wizard, select the local directory that will be imported into the CVS repository. Click [Next](#) .
5. In the [Customize Keyword Substitution](#) page, specify the [keyword substitution rule](#) for the files imported into the repository, and click [Next](#) .
6. Specify the required [import settings](#) . The fields of this page correspond to CVS command-line arguments for `import` , and additional options that define the checkout status of the imported directory.
7. Click [Finish](#) .

In the section [Checking In Files](#) , you have learnt how to check in (commit) your changes to the repository. In this section you can find examples of CVS-specific error messages and suggestions on resolving conflicts.

If any error occurs when trying to commit, IntelliJ IDEA displays an error message. For example:

- If you have a modified file, which has been already changed on the server by someone else, since your last synchronization, you will get the following error:

```
Error: cvs server: Up-to-date check failed for 'source/com/...'
```

In this case you would need to [merge](#) your local copy with the current revision in the repository. When the copies are merged, and all possible conflicts are [resolved](#) , so that the file is assigned the merged status, you can safely commit it to the repository.

- If you try to commit a file marked with a sticky tag, or sticky date, the CVS server will detect an attempt to *change the past* , and the error looks as follows:

```
Error: cvs server: sticky tag '1.1' for file 'source/com/impl/ManagerImpl.java& is not a branch
```

To solve the problem, you need to update with resetting sticky data; in this case your changes will be merged with the most recent revision of the file. After resolving possible conflicts (by calling the Merge command) you will be able to commit the files.

From the [Updating Local Information](#) topic, you have learnt the general procedure. CVS integration provides a special [Update File / Directory](#) dialog box with the options that map directly to the corresponding CVS command-line options of the `update` command. Refer to the [CVS documentation](#) for details.

This section will consider the CVS-specific procedure and several of the options in terms of their presentation in IntelliJ IDEA.

## To update local information

1. Select one or more files and/or directories in any navigation view (for example, [Project Tool Window](#)).
2. On the main menu, select VCS | Update Project or on the context menu of the selection choose CVS | Update File (Directory). The Update dialog for a project or file opens. In case of project update, select CVS tab.
3. Specify the following options:  
Branch Merging

You can choose to merge your local file(s) with the counterpart(s) in one or two CVS branches. In the CVS command-line interface, this is the `-j` option.

The option *Don't Merge* is selected by default, as merging across branches is not commonly needed. If you choose one of the other options, one or both of the text fields are enabled (depending on the choice of options). Clicking the Browse button  next to each field opens the Select Tag dialog box which lists all the branch tags maintained by the repository on the CVS server. Locate the branch you want to merge with, select it in the list, and click OK.

### Use Version

You can optionally update your local system from some different revision. You can choose a revision by its tag or by its date. The Default option synchronizes with your file's current revision, as this is the most common synchronization. The other options for Use Version are:

- By tag (-r): When updating a single file, you can choose the revision either by Revision or Tag. When you choose this option, the text field and corresponding ellipsis button are enabled. Enter a revision number or tag in the text field, or click the ellipsis button and select either a revision or a tag in the resulting dialog.

When updating multiple files (selected individually, or when invoking update on a directory), you can only select the revision by Tag.

- By date (-d): You can update from the revision of a specific date. This is possible whether you are invoking update on one file or multiple files or directories. When you choose this option, the date defaults to the current date. To specify a different date, click the ellipsis button and specify the desired date in the Choose Date dialog which appears.

### Reset sticky data (-A)

If the last checkout or update of the selected file(s) was from some revision that was specified by tag or date, the tag/date information is *sticky* for the file(s). If you now want to update these sticky-tagged files from the *HEAD* revision, select this option in combination with selecting the Default option in *Use Version* so that the sticky information is removed.

### Change keyword substitution to

If checked, this is converted to the `-k` CVS parameter. Refer to [CVS Options: Default keyword substitution for text files](#) for details.

### Do not show this dialog in the future

Select this option if you want the update operation take place silently. For details see CVS Options.

To have IntelliJ IDEA show this dialog box before update again:

1. Open the [Version Control - Confirmation](#) page of the [Settings](#) dialog box.
2. In the Display Option dialogs when these commands are invoked area, select the Update checkbox.

CVS integration of IntelliJ IDEA helps coordinate the activities of team members, who concurrently work on the same files or directories.

CVS watches enable you to notify the users of a CVS repository whenever a file has been opened for editing, or committed. If you watch a file or directory for changes and commits, you are added to the list of watchers.

Usage the commands related to watches depends on configuration of the `CVSROOT/notify` file.

Edit and Unedit commands change read-only status of the files or directories under CVS. If the sources were checked out with the option `-c`, you can apply Edit command to make them writable. In this case you are added to the list of editors. When you are done with editing, use Unedit command to restore read-only status. So doing, you are removed from the list of editors. If watching is configured, the watchers will receive email notification about these events.

In fact, the option Use read-only flag for not edited files in the CVS provides the same functionality automatically. If this option is checked, Unedit always applies to the source files after commit.

Edit and Watch commands apply to all the files you have selected in the current view (including all the files in any selected directory), or to the current file in the editor if you invoked the command there.

This section describes how to:

- [Access Edit and Watch commands](#)
- [Change read-only status of a file or directory](#)
- [View the other persons who edit the same file or directory](#)
- [Set watch on a certain event for a file or directory and thus add yourself to the list of watchers](#)
- [Enable or disable watching](#)
- [View the other persons who watch the same file or directory](#)

## To access Edit and Watch commands

1. In one of the tool windows, select the desired files or directories, or open a file in the editor.
2. Do one of the following:
  - On the main menu, choose VCS | CVS | Edit and Watch
  - On the context menu, choose CVS | Edit and Watch

## To get write access to a file or directory

1. [Open Edit and Watch menu](#).
2. Choose Edit on the submenu. Edit Options dialog box is displayed.
3. If you want to gain exclusive write access, check the option Reserved edit (-c). Click OK.

## To restore read-only status of a file or directory

1. [Open Edit and Watch menu](#).
2. Choose Unedit on the submenu.

## To view the other persons who edit the same file or directory

1. [Open Edit and Watch menu](#).
2. Choose Show Editors on the submenu. This will display the list of all users who have run the Edit command on the same file or directory.

## To set watch on a file or directory

1. [Open Edit and Watch menu](#).
2. Choose Add Watch on the submenu.
3. In the dialog box that opens, select the type of action you would like to be notified about:
  - Edit: you will notified whenever Edit is applied to a watched file or directory.
  - Unedit: you will notified whenever Unedit is applied to a watched file or directory.
  - Commit: you will notified whenever Commit is applied to a watched file or directory.
  - All: you will notified whenever any of the above commands is applied to a watched file or directory.

## To remove watch from a file or directory

1. [Open Edit and Watch menu](#).
2. Choose Remove Watch on the submenu.

3. In the dialog box that opens, select the type of action for which you would like to skip notification (Edit, Unedit, Commit or All).

### **To suspend or resume watching**

1. [Open Edit and Watch menu](#) .
2. Choose Watch Off or Watch On on the submenu.

### **To view the list of users who are watching the same files or directories**

1. [Open Edit and Watch menu](#) .
2. Choose Show Watchers on the submenu.

Offline mode in CVS makes it possible to ignore network errors. When this mode is enabled, you will not receive any notifications about connection problems.

### **You can go to offline mode in two ways**

- When a connection error occurs, IntelliJ IDEA informs you about that. With the first successful transaction, offline modes automatically turns off.
- Using the CVS menu command on the main Version Control menu, or a context menu: VCS | CVS | Work Offline .

From within IntelliJ IDEA, you can create and delete CVS tags and branches. The names of the tags and branches must start with a letter, and contain only alphanumeric characters.

Branch and tag commands apply to all the files you have selected in the current view (including all the files in any selected directory), or to the current file in the editor if you invoked the command there.

This section describes how to:

- [Access the tags and branches commands](#) .
- [Create a branch](#) in the repository on the base of the current revision.
- [Tag a revision in you local working directory](#) .
- [Delete a tag](#) .

## To access tags and branches commands

1. In one of the tool windows, select the desired files or directories, or open a file in the editor.
2. Do one of the following:
  - On the main menu, choose VCS | CVS
  - On the context menu, choose CVS
3. On the submenu, choose the appropriate command ( Create Branch , Create Tag , or Delete Tag )

## To create a branch

1. [Invoke](#) the Create Branch command.
2. In the Create Branch dialog box, specify the name of the new branch. To do that, type the name in the Branch name field, or click the Browse button  and select the desired name from the list of existing CVS tags.
3. Optionally, specify the following:
  - Select the Override existing checkbox, if you want to move an existing tag to a new branch, as defined by the option `-F` of `rtag` CVS command.
  - Select the Switch to this branch checkbox to switch your local working copy to the branch specified in the Branch name field.

## To create a new tag

1. [Invoke](#) the Create Tag command.
2. In the Create Tag dialog box, specify the new tag name. To do that, type the name in the Tag name field, or click the Browse button  and select the desired name from the list of CVS tags.
3. Optionally, specify the following:
  - Select the Override existing checkbox, if you want an existing tag to point to the current revision, as defined by the option `-F` of `rtag` CVS command.
  - Select the Switch to this tag checkbox to switch your local working copy to the tag specified in the Tag name field.

## To delete a tag

1. [Invoke](#) the Delete Tag command.
2. In the Delete Tag dialog box, specify the name of the tag you want to delete. To do that, type the name in the Tag name field, or click the Browse button  , and select tag name from the list of the current tags in the repository.

With the Mercurial integration enabled, you can perform basic Mercurial operations from inside IntelliJ IDEA.

**Note** The information provided in the topics listed below assumes that you are familiar with the basics of Mercurial version control system.

In this section:

- Using Mercurial Integration
  - [Prerequisites](#)
  - [Mercurial support](#)
- [Adding Files To a Local Mercurial Repository](#)
- [Setting Up a Local Mercurial Repository](#)
- [Managing Mercurial Branches and Bookmarks](#)
- [Switching Between Working Directories](#)
- [Pulling Changes from the Upstream \(Pull\)](#)
- [Pushing Changes to the Upstream \(Push\)](#)
- [Tagging Changesets](#)

## Prerequisites

- [Mercurial](#) is installed on your computer.
- The location of the Mercurial executable file `hg.exe` is correctly specified on the Mercurial page of the Settings/Preferences dialog box.  
If you followed the standard installation procedure, the default location is `/opt/local/bin` or `/usr/local/bin` for Linux and macOS and `/Program Files/TortoiseHG` for Windows.

It is recommended that you add the path to the Mercurial executable file to the `PATH` variable. In this case, you can specify only the executable name, the full path to the executable location is not required.

- Mercurial [integration is enabled](#) for the current project root or directory.

If you want to use a remote repository, create a Mercurial hosting account first. You can access the remote repository through a pair of `ssh keys` or apply the username/password and keyboard interactive authentication methods supported by the Mercurial integration.

## Mercurial support

- When Mercurial integration with IntelliJ IDEA is enabled, the Mercurial item appears on the VCS menu, and on the context menus of the [Editor](#) and the [Project Tool Window](#).
- The files in the folders under the Mercurial control are highlighted according to their status. See [File Status Highlights](#) for file status highlighting conventions.
- Modifications results are shown in the [Version Control tool window](#).
- When using Mercurial integration, it is helpful to open the [Version Control](#) tool window. The [Console](#) tab displays the following data:
  - All commands generated based on the settings you specify through the IntelliJ IDEA user interface.
  - Information messages concerning the results of executing generated Mercurial commands.
  - Error messages.

After a Mercurial repository for a project is [initialized](#) , you need to add the project data to it:

- If you have specified Mercurial as the version control system for your project in the Settings dialog box, IntelliJ IDEA suggests to put each new file under Mercurial control during the file creation.  
To have Mercurial ignore some types of files, [configure files to ignore](#) .
- You can [add all unversioned](#) files to Mercurial control or [select files to add](#) .

### **To add all currently unversioned files to Mercurial control**

1. Switch to the [Version Control](#) tool window.
2. In the [Local Changes](#) tab, navigate to the Unversioned Files node and choose Add to VCS from the context menu.

### **To add specific file(s) to a local Mercurial repository, do one of the following:**

- Switch to the [Version Control](#) tool window, expand the Unversioned Files node, and select the files to be added. From the context menu, choose Add to VCS .
- Switch to the [Project](#) tool window and select the files to be added. From the context menu, choose Mercurial | Add to VCS .

Although Mercurial provides high flexibility in arranging data and your work with repositories, the following scenarios are most commonly used for setting up a local Mercurial repository:

- [Clone](#) an existing remote repository and create a new project with the downloaded data.
- [Create a local repository](#) which you can push to a remote location later, if necessary.

## To clone a remote Mercurial repository

1. On the main menu, choose VCS | Checkout from Version Control | Mercurial . The Clone Mercurial Repository dialog box opens.
2. In the Mercurial Repository URL text box, type the URL of the remote repository which you want to clone.
3. Click the Test Repository button next to the Mercurial Repository URL text box to check that connection to the remote repository can be established successfully.
4. In the Parent Directory text box, specify the directory where you want IntelliJ IDEA to create a folder for your local Mercurial repository. Use the Browse button  button, if necessary.
5. In the Directory Name text box, specify the name of the new folder into which the repository will be cloned. Click Clone .
6. Create a new project based on the cloned data by accepting the corresponding suggestion displayed by IntelliJ IDEA.

## To create a local Mercurial repository

1. Open the project you want to store in a repository.
2. On the main menu, choose VCS | Import into Version Control | Create Mercurial Repository . The [Create Mercurial Repository](#) dialog box opens.
3. Specify the location of the new repository.
  - To have the repository created in the project root, choose the Create repository for the whole project option. IntelliJ IDEA will create the `.hg` directory in the project root folder. This option is selected by default.
  - To have a new repository created in another location, choose the Select where to create repository option and specify the path to the repository location in the text box below. Type the path manually or click the Browse button  and choose the relevant folder in the Select directory for hg init dialog box that opens.

**Warning** Mercurial does not support external paths. So if you choose another directory, note that it must contain the tree where the project root resides.

If you choose a directory which is already under Mercurial control, IntelliJ IDEA opens the Directory Is Under hg dialog box, where you can choose to create a repository in the specified location or to stay in the parent repository.

4. Put the required files under Mercurial version control. The files appear in the [Version Control](#) tool window under the Default node.  
Note that if you specify Mercurial as the version control system for a directory in the [Version Control](#) dialog box, IntelliJ IDEA will suggest to put each new file in this directory under Mercurial control.

With IntelliJ IDEA, you can use both [named branches](#) and [light-weight branches \(bookmarks\)](#) . IntelliJ IDEA provides interface for creating, merging, and switching between branches and bookmarks, see [Switching Between Working Directories](#) . You can also run commands in the embedded Terminal , see [Working with Embedded Local Terminal](#) .

On this page:

- [Opening the Branches pop-up list](#)
- [Creating a named branch](#)
- [Creating a bookmark](#)
- [Closing a branch](#)
- [Merging named branches and bookmarks](#)
- [Merging a named branch or bookmark with another named branch or bookmark](#)
- [Merging a named branch or bookmark with a changeset](#)

For information about switching between branches and bookmarks, see [Switching Between Working Directories](#) .

## Opening the Branches pop-up list

Most of the operations with branches and bookmarks are invoked from the Branches pop-up list.

The list shows all the Mercurial repositories under the project root, all the named branches, and all the bookmarks in them. The current repository and the current bookmark are marked with a tick. The name of the current named branch is shown in the dedicated hg area on the Status bar:

To open the Branches pop-up list, do one of the following:

- On the Status bar, click the name of the current named branch in the dedicated hg area.

- On the main menu, choose VCS | Mercurial | Branches .
- On the context menu of the Editor or Version Control tool window, choose Mercurial | Branches .

## Creating a named branch

1. In the Branches pop-up list, click New Branch .
2. In the Create New Branch dialog box that opens, specify the name of the new branch.

The new branch immediately becomes active and its name is shown on the Status bar in the hg area.

## Creating a bookmark

1. In the Branches pop-up list, click New Bookmark .
2. In the [New Bookmark dialog box](#) that opens, specify the name of the bookmark to be created.
3. Specify, whether you want to switch to the new bookmark immediately or not.
  - To activate the new bookmark and thus enable tracking and updating the light-weight branch the bookmarks identifies, leave the Inactive checkbox cleared. The new bookmark immediately becomes active and its name is marked with a tick in the Branches pop-up list.
  - To have an inactive bookmark created, that is, to remain in the current light-weight branch (bookmark) or named branch and switch to the new bookmark later, select the Inactive checkbox.

## Closing a branch

According to [Mercurial workflows](#) , when you are done with a feature development and do not expect any further changes, you close the corresponding branch. A closed branch is not displayed among active branches, in the [Log view](#) , etc. To close a branch, do the following:

1. In the Branches popup, click Close branch . The [Commit changes dialog](#) will be displayed.
2. Click Commit and Close . All changes will be committed and the current branch will be closed.

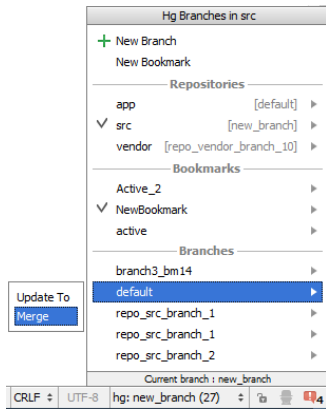

Note that if you have several repositories listed in the Repositories section, the corresponding menu option will toggle to Close branches and the `close` operation will be applied to all of them.

## Merging named branches and bookmarks

You can merge a named branch or a bookmark with another named branch, another bookmark, or a specific changeset identified by a tag or a revision number.

– Merging a named branch or a bookmark with another named branch or bookmark means merging with its **head**.

Merging with named branches and bookmarks can be invoked through the menu item `VCS | Mercurial | Merge`, which opens the Mercurial-specific Merge dialog box of from the Branches pop-up list.

– Merging a named branch or a bookmark with a changeset means merging the branch **head** with the specified changeset.

A changeset can be identified either by a revision number or a tag, see <https://www.mercurial-scm.org/wiki/Tag>.

Merging a named branch or a bookmark with a specific changeset can be invoked **only** through `VCS | Mercurial | Merge`.

For definitions and Mercurial-specific details regarding the merge operation itself, see <https://www.mercurial-scm.org/wiki/Merge>.

By default, **Mercurial** requires that before merge the current working directory should be **clean**, that is, it should not contain any uncommitted changes. Otherwise the merge operation fails and IntelliJ IDEA shows the corresponding error message. The message also recommends that you clean the current working directory by running the `hg merge <target branch, bookmark, or changeset> -C` to discard the uncommitted changes.

If your current working copy is not clean, you can either commit the changes or shelve them as described in [Shelving and Unshelving Changes](#).

## Merging a named branch or bookmark with another named branch or bookmark

Merging a named branch or a bookmark with another named branch or bookmark means merging with its **head**.

1. Make sure, your current working directory is **clean**, that is, it does not contain any uncommitted changes. Commit or shelve the changes, if any.
2. Invoke merge by doing one of the following:
  - In the Branches pop-up list, click the name of the branch or bookmark to merge with, then choose Merge on the pop-up menu:
  - Choose `VCS | Mercurial | Merge` on the main menu or `Mercurial | Merge` on the context menu of the Editor. In the Merge dialog box that opens:
    1. Choose the target repository from the Repository drop-down list which shows all the Mercurial repositories available under the current project root.
    2. Choose the Branch or Bookmark option and choose the named branch or bookmark to merge the current working directory with.
3. Resolve conflicts. As soon as a conflict takes place, the Files Merged with Conflicts dialog box opens with a list of conflicting files. Use the controls of the dialog box to resolve the problems:
  - To have the version of the current working directory preserved, click Accept Yours.
  - To have the version of the branch you are merging with preserved, click Accept Theirs.
  - To resolve the conflicts manually, click Merge and use the Conflict Resolution Tool, as described in [Resolving Conflicts](#).

If no conflicts arise during merge, the operation passes silently and the merge log is shown in the Version Control tool window.

## Merging a named branch or bookmark with a changeset

Merging a named branch or a bookmark with a changeset means merging the branch **head** with the specified changeset. A changeset can be identified either by a revision number or a tag, see <https://www.mercurial-scm.org/wiki/Tag>.

[scm.org/wiki/Tag](http://scm.org/wiki/Tag) .

1. Make sure, your current working directory is **clean** , that is, it does not contain any uncommitted changes.  
Commit or shelve the changes, if any.
2. Choose VCS | Mercurial | Merge on the main menu or Mercurial | Merge on the context menu of the Editor .
3. In the Merge dialog box that opens:
  1. Choose the target repository from the Repository drop-down list which shows all the Mercurial repositories available under the current project root.
  2. Choose the Tag or Revision option and choose the tag or specify the hash or revision number to merge the current working directory with. To copy a hash, open the Log tab of the Version Control tool window, select the relevant branch and revision, and then choose Copy Hash on the context menu of the selection.
4. Resolve conflicts. As soon as a conflict takes place, the Files Merged with Conflicts dialog box opens with a list of conflicting files. Use the controls of the dialog box to resolve the problems:
  - To have the version of the current working directory preserved, click Accept Yours .
  - To have the version of the branch you are merging with preserved, click Accept Theirs .
  - To resolve the conflicts manually, click Merge and use the Conflict Resolution Tool , as described in [Resolving Conflicts](#) .

If no conflicts arise during merge, the operation passes silently and the merge log is shown in the Version Control tool window.

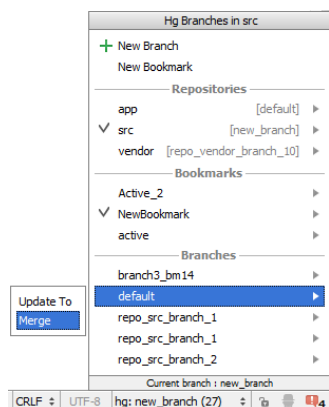

The Mercurial integration with IntelliJ IDEA provides the possibility to switch update the repository's [working directory](#) to the specified [changeset](#) or a specific [line of development](#) . Changesets can be identified by their hashes or by previously assigned [tag identifiers](#) .

On this page:

- [Opening the Branches pop-up list](#)
- [Switching to another named branch or bookmark](#)
- [Switching to another changeset](#)

You can update a named branch or a bookmark to another named branch, another bookmark, or a specific changeset identified by a tag or a revision number.

- Updating a named branch or a bookmark to another named branch or bookmark means updating to its **head** .  
Updating to named branches and bookmarks can be invoked through the menu item VCS | Mercurial | Update to , which opens the Mercurial-specific Switch Working Directory dialog box of from the Branches pop-up list.

- Updating a named branch or a bookmark to a changeset means updating the branch **head** to the specified changeset. A changeset can be identified either by a revision number or a tag, see <https://www.mercurial-scm.org/wiki/Tag> .  
Updating a named branch or a bookmark to a specific changeset can be invoked **only** through VCS | Mercurial | Update to .

By default, **Mercurial** requires that before update the current working directory should be **clean** , that is, it should not contain any uncommitted changes. Otherwise the update operation fails and IntelliJ IDEA shows the corresponding error message. The message also recommends that you clean the current working directory by running the `hg update <target branch, bookmark, or changeset> -C` to discard the uncommitted changes.

If your current working copy is not clean, you can either commit the changes or shelve them as described in [Shelving and Unshelving Changes](#) . IntelliJ IDEA provides the possibility to discard any uncommitted changes when the update operation is already invoked. This option is available only in the Mercurial-specific Switch Working Directory dialog box.

## Opening the Branches pop-up list

To open the Branches pop-up list, do one of the following:

- On the Status bar, click the name of the current named branch in the dedicated hg area.

- On the main menu, choose VCS | Mercurial | Branches .
- On the context menu of the Editor or Version Control tool window, choose Mercurial | Branches .

## Switching to another named branch or bookmark

Updating a named branch or a bookmark to another named branch or bookmark means updating to its **head** .

1. Make sure, your current working directory is **clean** , that is, it does not contain any uncommitted changes.  
Commit or shelve the changes, if any.  
If you invoke update through the Switch Working Directory dialog box, you can also prevent conflicts by having any uncommitted changes discarded.
2. Invoke update by doing one of the following:
  - In the Branches pop-up list, click the name of the branch or bookmark to update to, then choose Update to on the pop-up menu:
  - Choose VCS | Mercurial | Update to on the main menu or Mercurial | Update to on the context menu of the Editor .  
In the Switch Working Directory dialog box that opens:
    1. Choose the target repository from the Repository drop-down list which shows all the Mercurial repositories available under the current project root.
    2. Choose the Branch or Bookmark option and choose the named branch or bookmark to update the current working directory to.
    3. To prevent failures during update if the current working directory is not clean, select the Overwrite locally

modified files (no backup) check box. The uncommitted changes will be discarded.

## Switching to another changeset

1. Make sure, your current working directory is **clean**, that is, it does not contain any uncommitted changes. Commit or shelve the changes, if any.  
If you invoke update through the Switch Working Directory dialog box, you can also prevent conflicts by having any uncommitted changes discarded.
2. Invoke update by doing one of the following:
  - In the Branches pop-up list, click the name of the branch or bookmark to update to, then choose Update to on the pop-up menu:
  - Choose VCS | Mercurial | Update to on the main menu or Mercurial | Update to on the context menu of the Editor .In the Switch Working Directory dialog box that opens:
  1. Choose the target repository from the Repository drop-down list which shows all the Mercurial repositories available under the current project root.
  2. Choose the Branch or Bookmark option and choose the named branch or bookmark to update the current working directory to.
  3. To prevent failures during update if the current working directory is not clean, select the Overwrite locally modified files (no backup) check box. The uncommitted changes will be discarded.
3. Resolve conflicts. As soon as a conflict takes place, the Files Merged with Conflicts dialog box opens with a list of conflicting files. Use the controls of the dialog box to resolve the problems:
  - To have the version of the current working directory preserved, click Accept Yours .
  - To have the version of the branch you are merging with preserved, click Accept Theirs .
  - To resolve the conflicts manually, click Merge and use the Conflict Resolution Tool , as described in [Resolving Conflicts](#) .If no conflicts arise during update, the operation passes silently and the update log is shown in the Version Control tool window.

Refreshing a local Mercurial repository with the changes from the remote repository ( Pull ) involves retrieving changes and applying them to the local data . The Mercurial integration with IntelliJ IDEA provides interface for specifying the mandatory Pull settings and for customizing the Pull procedure.

### **To pull changes from a remote repository**

1. On the main menu, choose VCS | Mercurial | Pull Changesets . The [Pull](#) dialog box opens.
2. Specify the required URL address of the source remote repository.

Do the following:

1. From the main menu, choose VCS | Mercurial | Push . The [Push Commits dialog](#) opens showing all Mercurial repositories (for multi-repository projects) and listing all commits made in the current branch in each repository since the last push. If you have a project that uses multiple repositories that are not controlled synchronously, only the current repository is selected by default. For details on how to enable synchronous repositories control refer to [Version Control Settings: Mercurial](#) .
  2. If necessary, you can modify the path to the remote repository by clicking it. The label turns into a text field where you can type the new path or invoke completion by pressing `Ctrl+Space` . If there are no remotes in the repository, the Define remote link appears. Click this link and specify the remote name and URL in the dialog that opens.
  3. If you want to preview changes before pushing them, select the required commit. The right-hand pane shows the changes included in the selected commit. You can use the toolbar buttons to [examine the commit details](#) .
- Note** If the author of a commit is different from the current user, this commit is marked with an asterisk.
5. If you want to push active bookmarks with your commits (they are not sent to the remote repositories by default), select the Export Active Bookmarks option.
  6. Click the Push button when ready and select which operation you want to perform from the drop-down menu: `push` or `push --force` .

**Tip** You can also switch to the editing mode by pressing `Enter` or `F2` for the selected element.

**Tip** You can press `Ctrl+Q` for the selected commit to display extra info, such as the commit author, time, hash and the commit message.

**Tip** If you select an entire repository, all files from all commits will be listed in the right pane.

If the same file was modified within several commits, it will only be listed once if you select these commits or the entire repository, and if you invoke the [Differences Viewer for Files](#) for this file, all changes will be zipped together.

## Using force push

When you run `push` , Mercurial will refuse to complete the operation if the remote repository has changes that you are missing and that you are going to overwrite with your local copy of the repository. Normally, you need to perform `pull` to synchronize with the remote before you update it with your changes.

The `--force push` command disables this check and lets you overwrite the remote repository, thus erasing its history and causing data loss.

A possible situation when you may still need to perform `--force push` is when you rebase a pushed branch and then want to push it to the remote server. In this case, when you try to push, Mercurial will reject your changes because the remote ref is not an ancestor of the local ref. If you perform `pull` in this situation, you will end up with two copies of the branch which you then need to merge.

**Warning!** Rebasing a pushed branch and modifying its history should be avoided unless absolutely necessary (for example, if you've accidentally pushed some sensitive data).

**Warning!** Using the `--force` will lead to all new heads being pushed on all branches, which is likely to cause confusion for your team.

If you decide to force push the rebased branch and you are working in a team, make sure that:

- Nobody has pulled your branch and done some local changes to it
- All pending changes have been committed and pushed
- You have the latest changes for that branch

IntelliJ IDEA supports both **local** and **global** tags. **Local** tags are stored in the file `.hg/localtags` in the repository, **global** tags are stored in the file `.hgtags` .

Currently tagging specific changesets is supported only in the command line mode in the embedded Terminal . To launch the Terminal , hover your mouse pointer over  in the lower left corner of the IDE, then choose Terminal from the menu (see [Working with Embedded Local Terminal](#) for details) . After commit, tags appear in the Log tab of the Version Control tool window.

For more information about Mercurial tags, see [Mercurial Documentation: Tag](#) .

## Tagging a repository

IntelliJ IDEA provides UI for tagging the current repository which means assigning a tag to its **tip** . The created tag is **global** , is stored in the file `.hgtags` . After commit, the tag appears in the Log tab of the Version Control tool window.

1. Open the Tag dialog box by doing one of the following:
  - On the main menu, choose VCS | Mercurial | Tag Repository .
  - On the context menu of the Editor , choose Mercurial | Tag Repository .
2. In the Tag dialog box that opens, specify the tag name. The name must be unique.

This feature is only supported in the Ultimate edition.

With the Perforce integration enabled, you can perform basic Perforce operations from inside IntelliJ IDEA.

**Note** The information provided in the topics listed below assumes that you are familiar with the basics of Perforce version control system.

In this section:

- Using Perforce Integration
  - [Prerequisites](#)
  - [Preliminary steps](#)
  - [Perforce support](#)
- [Enabling and Configuring Perforce Integration](#)
- [Handling Modified Without Checkout Files](#)
- [Integrating Perforce Files](#)
- [Resolving Conflicts with Perforce Integration](#)
- [Showing Revision Graph and Time-Lapse View](#)
- [Using Multiple Perforce Depots with P4CONFIG](#)
- [Working Offline](#)
- [Checking Perforce Project Status](#)
- [Attaching and Detaching Perforce Jobs to Changelists](#)

## Prerequisites

- A Perforce client is installed on your computer.
- You have an account with the Perforce depot.

### To start using Perforce integration, perform the following preliminary steps

1. Create a client spec using your Perforce client.
2. Get source files from the Perforce depot using your Perforce client.
3. As soon as the local working copy is on your computer, [associate your local directory with Perforce](#) .  
After that you will be able to open source files for edit, and perform the usual Perforce-related tasks using IntelliJ IDEA.

## Perforce support

- When Perforce integration with IntelliJ IDEA is enabled, the Perforce item appears on the VCS menu, and on the context menus of the [Editor](#) and the [Project Tool Window](#) .
- The files in the folders under the Perforce control are highlighted according to their status. See [File Status Highlights](#) for file status highlighting conventions.
- Modifications results are shown in the [Version Control tool window](#) .
- When using Perforce integration, it is helpful to open the [Version Control](#) tool window. The [Console](#) tab displays the following data:
  - All commands generated based on the settings you specify through the IntelliJ IDEA user interface.
  - Information messages concerning the results of executing generated Perforce commands.
  - Error messages.

The Perforce Integration is disabled by default. If you want to perform Perforce-related operations right from IntelliJ IDEA, enable the integration at the IDE level and associate the project root or specific directories with Perforce. The general procedure is described in the section [Enabling Version Control](#).

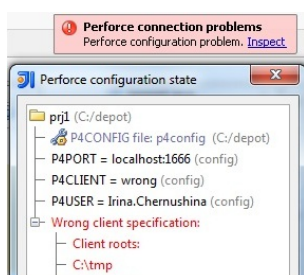

In this section:

- [Enabling Perforce integration for a project or directory](#)
- [Configuring Perforce integration settings](#)

## To enable Perforce integration for a project or directory

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control.
2. In the [Version Control](#) page, that opens, point to the desired root.
3. From the VCS drop-down list, choose Perforce.

If you specify a wrong client workspace, and your project roots do not match with the workspace roots, IntelliJ IDEA displays a pop-up window with a warning.

Click [Inspect](#) to view and fix the discrepancies.

## To configure Perforce integration

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | Perforce.
2. To establish live connection to the Perforce server, select the Perforce is online checkbox.
3. Specify which credentials you want to use for connecting to the Perforce server.
  - To use the connection settings from your `P4CONFIG` files, choose the Use `P4CONFIG` or default connection option.  
If you are using `P4CONFIG` files for configuration, IntelliJ IDEA shows what config files it has found and what other default settings are used. This way you can be sure that your `P4CONFIG` files are detected and taken into account.
  - To configure connection manually, choose the Use connection parameters option and specify the following settings in the corresponding text boxes:
    1. The **Port** the Perforce client will listen to.
    2. The **Client name**.
    3. Your **User name** and **Password** to authenticate to the server.
4. To use ticket-based authentication, select the Login authentication checkbox. Otherwise, password-based authentication will be used. In either cases IntelliJ IDEA uses the login name and password specified in the dialog box or stored in the `P4CONFIG` files.
5. To attempt to log on the Perforce server without authentication, select the Try to login silently checkbox.
6. To have IntelliJ IDEA create a `P4.output` file and store the output of Perforce commands in it, select the Dump Perforce Commands to: checkbox.
7. Specify the path to the Perforce executable file. Click Test Connection to make sure your settings ensure successful connection.
8. In the Timeout field, specify the lapse of time in seconds during which IntelliJ IDEA waits for response from the server. If the server does not respond in due time, the user is prompted to disable integration.
9. To enable displaying the branch history of a specified file, including all file branch points, edits, and merges, select the Show branching history checkbox.
10. To have IntelliJ IDEA point at committed changes that are also integrated to other changelists and provide information on the target changelists that received the content in question, select the Show integrated changelists in committed changes checkbox.
11. To get the user interface for attaching and detaching Perforce jobs to changelists, select the Enable Perforce Jobs Support checkbox.

If you are going to modify or delete a file under Perforce version control, the read-only status of such file should be removed. IntelliJ IDEA takes care of automatically making files writable. However, you can change read-only status manually, which may happen in a number of ways; for example:

- [With the Clear Read-Only Status dialog enabled](#) , you make a file writable using file system.
- When a read-only file is opened in the editor, you double-click lock icon  in the status bar.
- You remove read-only attribute externally, using file properties.

In these cases, the file gets status Modified without checkout and appears in the [Local Changes tab of the Version Control tool window](#) .

### **To resolve 'modified without checkout' files**

1. In the [Local Changes tab of the Version Control tool window](#) , expand Modified without Checkout node, and select the desired file.
2. On the context menu of the file, choose Check Out . The file becomes writable, and moves to the active changelist.

You can merge changes between the branches into your local working copy, using the branch specification, or a changelist.

The Integrate Project command is available for both Perforce and Subversion integrations.

Integration results display in the Integrate Info tab of the Version Control tool window. Context menu of a file enables you to compare versions, view history and annotations, browse changes and more.

## To integrate a Perforce branch into a project

1. On the main menu, choose VCS | Integrate Project .
2. In the Integrate dialog box, select the Perforce tab (if both Perforce and Subversion integrations are used in this project).
3. Select the sources to be merged, and the desired revision.
4. Define VCS-specific merge options.
5. Click OK .

As described in the section [Resolving Conflicts](#) , the conflicts might occur in course of team work. Perforce integration makes use of the following commands:

- Resolve enables you to resolve a conflict to a specific file.
- Resolve All applies to all files in a changelist that have merge status.

### **To resolve conflicts for the files under Perforce version control**

1. In the [Local Changes tab of the Version Control tool window](#) , select a conflicting file, or a whole conflict node.
2. On the context menu of the selection, choose Resolve or Resolve All . Files Merged with Conflicts dialog box appears.
3. If you want to accept server version and overwrite your local changes, click Accept Theirs . If you want to force your changes to the repository, click Accept Yours . Clicking Merge opens the merge tool, where you can [accept or discard](#) each change individually.
4. Once the conflicts are successfully resolved, [commit](#) your local version to the repository.

Using Perforce integration, you can view the Revision Graph or Time-lapse View for a file without leaving the IDE, provided that `p4v.exe` is installed on your computer.

### **To show Revision Graph or Time-lapse View for a file**

1. Select the desired file in any navigation tool window, or open it in the editor.
2. On the main Version Control menu, or on the context menu of the selection, choose Perforce , and then select Revision Graph , or Time-Lapse View on the submenu.
3. With the first invocation, enter password in the login dialog box.

If your project contains directories that are stored in the different Perforce depots, you might need to switch between them. IntelliJ IDEA uses P4CONFIG to automatically switch to the respective depot as you use a Perforce-versioned directory.

P4CONFIG is an environment variable that contains the name of P4CONFIG file without a path. If a certain directory is associated with Perforce, IntelliJ IDEA seeks for P4CONFIG file in this directory and its parents; if the file is not found, it is sought in the bin directory of IntelliJ IDEA installation. When a P4CONFIG file is found, IntelliJ IDEA uses the settings contained therein, to connect to the respective Perforce depot.

A sample P4CONFIG file might consist of such lines:

```
P4CLIENT=MyClient  
P4USER=MySelf  
P4PORT=ida:3456
```

### **To use multiple Perforce depots in a project, follow these general steps**

1. Create a P4CONFIG file in each directory associated with Perforce.
2. Create environment variable P4CONFIG that contains file name without a path.

In this section:

- [Offline mode basics](#)
- [Going offline](#)
- [Going online](#)

## Offline mode basics

The Perforce plugin keeps a log of VCS operations performed while offline, and replays the log when the user comes back online. The log of operations is stored in the `.iws` file and persists between IntelliJ IDEA restarts.

While offline, you can perform the following operations, which will be automatically replayed in online mode:

- Edit
- Add/Copy
- Delete
- Move/Rename
- Revert
- Move to another changelist
- View Committed/Incoming changes (displaying cached information only).

The following operations are not supported in offline mode: update, commit, integrate, tracking of the unversioned, locally deleted and *modified without checkout* files (unversioned files are shown as *unchanged*), and any other operations that require server connection.

**Tip** The performance of IntelliJ IDEA Perforce integration in offline mode is considerably better than in online mode (because no server calls are required), so you might want to use offline mode even though connection to the Perforce server is successful.

## To go to offline mode, do one of the following

- **Automatically**, when the Perforce server becomes unavailable. IntelliJ IDEA switches to the offline mode automatically, and displays an offline notification in a pop-up window. To enable this behaviour, select the Switch to offline mode automatically if Perforce is unavailable checkbox in the **Perforce** page of the **Settings** dialog box.
- Manually at anytime, by choosing **VCS | Perforce** and select **Work Offline** on the main menu.

When offline mode is activated, the following notification balloon appears:

This balloon fades after a while; **Perforce is offline** message appears at the bottom of the **Local Changes** tab of the Version Control tool window.

## To return to online mode, do one of the following

- Choose **VCS | Perforce** and clear **Work Offline**.
- In the offline notification balloon, click the **Go online** link.
- In the **Local Changes** tab of the Version Control tool window, click the **Go online** link:

Besides indicating the [current file status](#) relative to the repository, IntelliJ IDEA integration with Perforce provides you with the accumulated view of the project files' statuses.

In this section:

- [Viewing the statuses of project files](#)
- [Refreshing file status](#)

## To view differences between the current state of the project files and the repository

1. Open the required project.
2. On the main menu, choose VCS | Refresh File Status .
3. Switch to the Version Control tool window, tab [Local](#) .

The status of each file is indicated by the [color](#) in which the path to the file is displayed.

## To refresh the statuses of project files

IntelliJ IDEA provides two refresh modes for statuses of files under Perforce control.

- **Standard Refresh** takes into consideration only the changes made through the IntelliJ IDEA integration with Perforce. This improves performance because does not require connecting to the server. However, this approach does not let you know about the changes made outside IntelliJ IDEA, for example, right through the `p4v client` application.
- **Force Refresh** considers all the changes made to project, both from IntelliJ IDEA and from any other application, for example, right through `p4v client` .

1. Switch to the Version Control tool window, tab [Local](#) .
2. Do one of the following:
  - To run **Standard Refresh** , click the Refresh toolbar button  or press `Ctrl+F5` .
  - To run **Force Refresh** , click the Force Refresh toolbar button  .

The Perforce integration with IntelliJ IDEA provides you with a user interface for attaching and detaching Perforce [jobs](#) to changelists.

Note that the integration does not support creation of Perforce jobs.

To get access to working with Perforce jobs, select the Enable Perforce Jobs Support checkbox on the [Perforce](#) page of the [Settings](#) dialog box.

From this topic you will learn how to:

- Attach jobs to changelists:
  - [At any stage](#) of your work from the [Local](#) tab.
  - [During commit](#) from the [Commit Changes](#) dialog box.
- Find the desired job to attach to a changelist using:
  - The [standard search](#) functionality, which enables you to specify numerous search criteria and thus to flexibly configure the search procedure.
  - The [quick search](#) functionality, which enables you to have the found job linked to the changelist automatically.

**Tip** This functionality is helpful when you need to attach only one job to a changelist and you either know the exact name of the desired job or at least can specify a search pattern for the name.

- [Detach](#) jobs from changelists.

## To find and link a job at any stage of your work

1. Open the [Local](#) tab of the [Version Control](#) tool window.
2. Select the changelist you want to link a job to.
3. From the context menu of the changelist, choose Edit Associated Jobs .
4. Find the desired job. Do one of the following:
  - To use the [standard search](#) functionality, click the  button.
  - To use the [quick search](#) functionality, click the  button.
5. View the details of the found job and click OK .

## To find and link a job during commit

1. In the [Local Changes](#) tab of the [Version Control](#) tool window, select the changelist you want to link a job to and open the [Commit Changes](#) dialog box.
2. Find the desired job using the controls in the Jobs area. Do one of the following:
  - To use the [standard search](#) functionality, click the  button.
  - To use the [quick search](#) functionality, click the  button.
3. View the details of the found job and continue the [commit](#) procedure.

## To find a job using the standard search functionality

1. In the dialog box that opens or in the Jobs area of the [Commit Changes](#) dialog box, click the  button. Which dialog box you are currently in depends on whether you are linking jobs [during commit](#) or at any [other stage](#) of work.
2. In the dialog box that opens, specify the desired search parameters.

**Tip** At least one of the fields should be filled in.
3. Click the Search button. The jobs that match the specified criteria are shown in the Search Results list. To view the details of a job, select it in the list.
4. Select the desired job and click OK . The dialog box closes and you return to the dialog box where you started the search:
  - The [Commit Changes](#) dialog box, if you are linking jobs [during commit](#) .
  - The Edit Jobs Linked to Changelist dialog box, if you are linking jobs at any [other stage](#) stage of work.

## To quickly find and link one job

1. Open the Edit Jobs Linked to Changelist dialog box or switch to the Jobs area of the [Commit Changes](#) dialog box.

The dialog box to be used depends on whether you are linking jobs [during commit](#) or at any [other stage](#) of work.
2. In the text box, type the desired job name search pattern and click the  button. The job is found and automatically linked to the current changelist.

If no job matching the specified pattern is found, the corresponding information message is displayed.

**Warning** The details of jobs that are found and linked through the quick search functionality are available only in the Edit Jobs Linked to Changelist dialog box.

## To detach a job from a changelist

- In the Edit Jobs Linked to Changelist dialog box or in the Jobs area of the Commit Changes dialog box, select the desired job and click the  button.

The dialog box to be used depends on whether you are detaching jobs [during commit](#) or at any [other stage](#) of work.

With the Subversion integration enabled, you can perform basic Subversion operations from inside IntelliJ IDEA.

IntelliJ IDEA currently supports integration with Subversion 1.9 and below.

IntelliJ IDEA comes bundled with the Subversion plugin. If you are using SVN 1.7 or below, this plugin is enough for Subversion integration. If you are using SVN 1.8 or higher, you also need to [download](#) and install the command line client on your machine. In this case, make sure the Use command line client option is selected in the [Subversion settings page](#) .

## Subversion support

- When Subversion integration with IntelliJ IDEA is enabled, the Subversion item appears on the VCS menu, and on the context menus of the [Editor](#) and the [Project Tool Window](#) .
- The files in the folders under the Subversion control are highlighted according to their status. See [File Status Highlights](#) for file status highlighting conventions.
- Modifications results are shown in the [Version Control tool window](#) .
- When using Subversion integration, it is helpful to open the [Version Control](#) tool window. The [Console](#) tab displays the following data:
  - All commands generated based on the settings you specify through the IntelliJ IDEA user interface.
  - Information messages concerning the results of executing generated Subversion commands.
  - Error messages.

The Subversion server does not require user authentication on every request. When you use Subversion integration in IntelliJ IDEA, you only need to answer the authentication challenge of the server if it is required by the authentication and authorization policies. Upon successful authentication, your credentials are saved on disk, in `~/.subversion/auth/` on Unix systems or `<USER> \HOME> \.subversion_IDEA` on Windows and macOS.

When an authentication challenge comes from the server, the credentials are sought for in the disk cache; if the appropriate credentials are not found, or fail to authenticate, you are prompted to specify your login and password.

If necessary, you can opt to delete all credentials stored in the cache for the http, svn and ssh+svn protocols.

### To delete credentials from disk

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Version Control .
2. Open the [Subversion settings page](#) and click the Clear Auth Cache button.

Prior to checking files out, you can browse the contents of a Subversion repository. The Subversion Repository browser enables you to add or discard repository locations, view the history of files and folders, check out files and folders, navigate to the source code, browse changes, create branches or tags, etc.

Browsing the contents of a Subversion repository is always available, even when Subversion is not enabled in your project. All you need is a valid user account.

### To browse the contents of a Subversion repository

1. On the main menu, choose VCS | Browse VCS Repository | Browse Subversion Repository .
2. The SVN Repositories tool window will open.
3. If no repositories have been specified so far, click  in the toolbar and specify the repository URL in the New Repository Location dialog that opens.
4. Browse the repository. If authentication is required, enter your credentials in the Authentication Required dialog that opens when you first try to expand the top node.

By checking out files from a Subversion repository, you obtain a [local working copy of the repository](#) , which you can edit. After making the necessary changes, you can publish the results by [committing, or checking in](#) your changes to the repository.

To check out files from a Subversion repository, do the following:

1. On the main menu, choose [VCS | Checkout from Version Control | Subversion](#) .
2. In the [Check Out From Subversion](#) dialog box, expand the desired repository location and select the element you want to check out.
3. Click the Checkout button.
4. In the [dialog that opens](#) , specify the destination directory where the local copy of the repository files will be created, and click OK .  
If you are checking out sources for an existing project, the destination folder should be below the project [content root](#) .
5. In the SVN Checkout Options dialog box, specify the following settings:
  - Revision to be checked out (HEAD or a selected revision).
  - Whether you need to check out the nested directories.
  - Whether you need to include the external locations.

Click OK .

**Tip** This action is also available from the [SVN Repositories tool window](#) . Right-click a directory and choose the required command from the context menu.

IntelliJ IDEA suggests to create a project based on the sources checked out from version control.

The Cleanup command in Subversion can be helpful in the following situations:

- Your local working copy is in an inconsistent state because a Subversion command was interrupted.
- The timestamp of a file has changed while its content remains intact.

To clean up the local working copy, do one of the following:

- Select the desired file or directory in the [Project](#) tool window and choose Subversion | Cleanup from the context menu of the selection.
- Open the desired file in the editor and choose VCS | Subversion | Cleanup from the main menu.
- Select the desired file or directory in the [Local Changes](#) tab of the [Version Control](#) tool window and choose Subversion | Cleanup from the context menu of the selection.

In addition to the common file versions comparison options, the Subversion integration with IntelliJ IDEA provides a special command that enables you to compare a file from your local working copy with its version in the selected branch.

To compare a file with its version in a specified branch, do the following:

1. Select the desired file in the [Project Tool Window](#), or open it in the editor.
2. From the main VCS menu, or on the context menu of the selection, choose Subversion | Compare with Branch .
3. In the Compare with Branch pop-up, select the desired branch. The Compare with Branch dialog in the form of the [Differences Viewer for Files](#) appears.

**Tip** This action is also available in the SVN Repositories browser. Right-click the desired directory and choose the corresponding command from the context menu.

A working copy is a directory that contains a collection of files which you can use as your private work area, as well as some extra files, created and maintained by Subversion. For example, each directory in your working copy contains an administrative directory named `.svn`.

You can have local working copies created with Subversion 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, or 1.9. IntelliJ IDEA handles all these formats, giving you a choice to upgrade to the new format or preserve the legacy one.

Switching to another Subversion format is always associated with a specific working copy (directory) under the Subversion control. In other words, one cannot upgrade to a newer Subversion format at the IDE level, but only to a directory under Subversion control.

**Tip** To check VCS association, go to [File | Settings | Version Control](#) where all mappings between the project directories (or the entire project) and VCSs are listed.

To change the format of the local working copy, do the following:

1. Open the [Version Control](#) tool window by doing one of the following:
  - On the main menu, choose [View | Tool Windows | Version Control](#).
  - Press `Alt+9`.

2. Switch to the [Subversion Working Copies Information](#) tab.

This tab is only available, when the current project sources are entirely or partially under Subversion control.

3. Scroll to the information on the required directory and click the [Change](#) link.

**Note** Note that Subversion 1.9 can be used with the local working copy version 1.8, so in this case the [Change](#) link will not appear.

4. In the [Convert Working Copy Format](#) dialog box, that opens, select the desired format option.

Subversion stores the http proxy settings in the `servers` file in the user's runtime configuration area (`~/ .subversion/auth/` on Unix systems or `<USER HOME>/Application Data/Subversion/auth/` on Windows).

You can configure the Subversion proxy settings in two ways:

- [Edit the servers file](#) manually.
- Configure proxy settings directly from IntelliJ IDEA. Do the following:
  1. Open the Version Control | Subversion page of IntelliJ IDEA settings (`Ctrl+Alt+S`), and then open the Network tab.
  2. Click the Edit Network Options button and specify the proxy settings in the [Edit Subversion Options Related to Network Layers](#) dialog box that opens.

Subversion repository locations are global IntelliJ IDEA properties. It means that the configured repository locations will be available no matter if a project is open or not, which is useful if you need to check out an entire project from Subversion. You can define multiple Subversion repository locations for future use.

To configure a Subversion repository location, do the following:

1. Open the [SVN Repositories tool window](#) by choosing `VCS | Browse VCS Repository | Browse Subversion Repository` from the main menu.
2. In the SVN Repositories tool window choose `New | Repository Location` from the context menu, or click the `+` button on the toolbar.
3. In the New Repository Location dialog, specify the repository URL.

IntelliJ IDEA allows you to compose a list of parent folders of the branches you work with. This list will be displayed every time you perform any operation with branches, for example, when you synchronize your local working copy, compare branches, etc.

Branches are configured in the [Configure Subversion Branches](#) dialog box.

To configure Subversion branches, do the following:

1. Access the [Configure Subversion Branches dialog](#) in the [Version Control](#) tool window, switch to the [Subversion Working Copies Information](#) tab, and then click the [Configure Branches](#) link.
2. In the Trunk location field, specify the URL of your repository trunk. Type the address or click the [Browse](#) button  and select the trunk location in the [Select Repository Location](#) dialog that opens. This dialog shows a tree of all branches and tags under the [repository root](#).
3. In the Branch locations area, make up a list of folders where the branches you need in your work are stored. Use the [+](#) and [-](#) buttons to add/remove branches to/from the list.

IntelliJ IDEA allows you to create branches or tags on the basis of your local working copies, or their repository versions.

To create a branch or a tag in a Subversion repository, do the following:

1. From the main menu, choose **VCS | Subversion | Branch or Tag** . Alternatively, select the source folder in the [SVN Repositories tool window](#) and choose the Branch or Tag command from the context menu.
2. In the [Create Branch or Tag dialog](#) that opens, in the Copy From section, specify the source folder that will be copied to a branch or a tag. You can use your local working copy, or a repository location.  
If a repository location is selected as the source:
  - Click  to fill the Repository Location field with the path to the project location.
  - Specify the revision to base the new branch on. This can be the HEAD revision, or a revision with the specified number.  
If the Specified option is selected, type the revision number, or click  and find the desired revision in the Subversion Changes Browser .
3. In the Copy To section, specify the destination where the branch or the tag will be created. If you use the base URL, specify the name of the new branch or tag. If you opt to create a branch or tag in another repository location, type its URL, or click  and select the destination from the [Select Repository Location](#) dialog.
4. Optionally, enter a comment a click OK .

You might need to obtain a *clean* local copy of the Subversion working tree without the `.svn` catalogs. Instead of checking files out and then manually deleting the administrative directories, you can use the Export command available in the Subversion repository browser.

To export a directory from a Subversion repository, do the following:

1. In the main menu, select VCS | Browse VCS Repository | Browse Subversion Repository to open the [SVN Repositories](#) tool window.
2. Right-click a directory you want to export and choose Export from the context menu.
3. In the Select Path dialog that opens, specify the destination directory and click OK .
4. In the SVN Export Options dialog that opens, check the Export and Destination paths and specify the following options:
  - Depth : use this drop-down list to specify the range of recursion into Subversion subdirectories. The available options are:
    - working copy : select this option to get files/directories from the repository subtrees that have not been checked out yet.
    - empty : select this option to involve only the current file.
    - files : select this option to involve files from the current folder.
    - immediates : select this option to involve direct children of the current file.
    - infinity : select this option to enable full recursion.
  - Replace existing files : select this option to replace files in the destination directory with the exported sources.
  - Include external locations : select this option to include external references into the export.
  - Override 'native' EOLs with: : use this drop-down list if you want to override the `svn:eol-style=native` property. This is useful if team members sharing the same repository use different operating systems, which may result in problems with line endings. The following options for line separators are available:
    - None : this option is selected by default, and keeps the `svn:eol-style=native` property unchanged.
    - LF : select this option if you are using unix
    - CRLF : select this option if you are using Windows
    - CR : select this option if you are using macOS

You can import an entire directory to your Subversion repository provided that you have access rights. This is helpful for putting a whole project under version control.

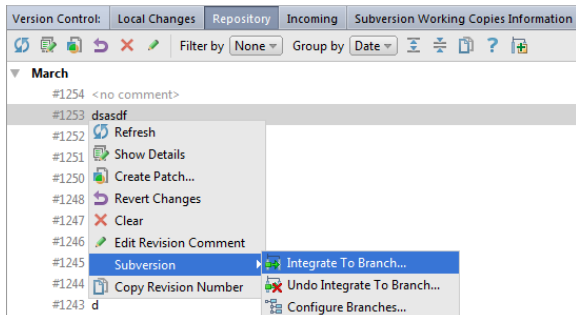

Import to the repository is always available, even if Subversion integration is not enabled for your project.

To import a directory to a Subversion repository, do the following:

1. From the main menu, choose **VCS | Import into Version Control | Import into Subversion**.
2. In the **Import into Subversion** dialog that opens, select the target Subversion repository. If the desired target repository location is not in the list, click the **+** button to add it (for more details, see [Configuring Subversion Repository Location](#)). Click **Import**.
3. In the **Select Path** dialog that opens, specify the directory you want to import and click **OK**.
4. In the **SVN Import Options** dialog that opens, check the **Import to** and **Import from paths** and specify the following options:
  - **Depth** : use this drop-down list to specify the range of recursion into Subversion subdirectories. The available options are:
    - **working copy** : select this option to get files/directories from the repository subtrees that have not been checked out yet.
    - **empty** : select this option to involve only the current file.
    - **files** : select this option to involve files from the current folder.
    - **immediates** : select this option to involve direct children of the current file.
    - **infinity** : select this option to enable full recursion.
  - **Include ignored resources** : select this option to include files that have been added to the Subversion ignore list and are not subject to version control into the import.
5. Optionally, enter a commit message, or select one from the **Recent Messages** drop-down list and click **OK**.

IntelliJ IDEA allows you to integrate changes into a selected branch, and commit the results of such integration to the repository. Do the following:

1. In the **Version Control** tool window, switch to the **Repository** tab .
2. Right-click the changelist you want to integrate, and select **Subversion | Integrate to Branch** from the context menu:

If you want to integrate separate files instead of the whole changelist, select them in the **Changed Files** pane and choose **Subversion | Integrate To Branch** from the context menu.

If you are using SVN 1.5 or higher both on the server and in your local working copy, select the relevant changelist/file(s) in the **Changelists** or **Changed Files** pane and click  on the toolbar.

The **Integrate to Branch** dialog opens displaying the URL addresses of the source and target branches and a list of available local working copies.

3. From the **Integrate into working copy** list, select the path to the local working copy into which the selected changelist will be integrated.

To add a path to the list, click the **+** button.

To remove a path from the list, click the **-** button.

**Note** Make sure the specified working copy directory is under Subversion version control!

4. To preview the merge result by enabling the `--dry-run` switch of the `svn` command, select the **Try merge**, but make no changes checkbox.

If this checkbox is not selected, sources are merged silently.

5. Click **OK** . The **Commit Changes** dialog opens.

6. Review the summary, specify the necessary options, and **run commit** .

Integrating projects or directories in Subversion means merging the differences between the two specified revisions into your working copy.

The Integrate Project command is available for both Subversion and Perforce.

Integration results are displayed in the Update Info tab of the [Version Control tool window](#) . The context menu of a file allows you to compare versions, view file history and annotations, browse changes, etc.

To integrate different sources into one Subversion project, do the following:

1. From the main menu, choose VCS | Integrate Project . The [Integrate Project](#) dialog opens.
2. If both Subversion and Perforce are used as version control systems in your project, select the Subversion tab.
3. In the Source 1 and Source 2 fields, specify the sources to be merged and select the revision. If you check the Specified option, you can click the Browse button  and select a revision from the Changes Browser .
4. If necessary, select the following merge options and click OK :
  - Use ancestry : if this option is selected, **ancestry** of files will be noticed (this corresponds to the `svn merge` command). If unchecked, any relations between files and directories will be ignored (corresponds to `svn diff` ).
  - Try merge but make no changes : select this option to preview merge results by enabling the `--dry--run` option of the SVN command. If unchecked, sources will be merged silently.
  - Depth : use this drop-down list to specify the range of recursion into Subversion subdirectories. The available options are:
    - working copy : select this option to get files/directories from the repository subtrees that have not been checked out yet.
    - empty : select this option to involve only the current file.
    - files : select this option to involve files from the current folder.
    - immediates : select this option to involve direct children of the current file.
    - infinity : select this option to enable full recursion.

A [Feature Branch](#) is intended for working on a particular feature. It is normally constituted of data downloaded from the trunk, and is integrated back into the trunk when work on the feature is completed. You can apply all changes or select a subset of changes. IntelliJ IDEA creates a changelist with the merged changes and offers it for commit.

To integrate changes from a branch, do the following:

1. Open the [Version Control tool window](#) and switch to the [Subversion Working Copies Information tab](#) .
2. Click the Merge from link and select the source of changes from the popup menu. The available options are:
  - trunk : select this option to merge changes from the trunk to the current branch.
  - branches : select this option to apply changes from a specific branch to the current branch. Select the source branch from the Branches popup.
  - tags : select this option to apply changes from a specific branch to the current branch. Select the source branch from the Tags popup.

**Tip** To edit the list of branches, choose the Configure branches option and update the list of branches in the [Configure Subversion Branches](#) dialog box that opens.

3. In the Merge from <branch\_name> dialog box that opens, specify the scope of changes to apply.
  - To have all changes applied, click the Merge all button.
  - To have a subset of changes applied, click the Select revisions to merge button. In the list of revisions that is displayed, appoint the revisions to apply changes from by selecting checkboxes next to the desired revisions. To have the selected changes applied, click the Merge selected button.

**Tip** To have all changes applied regardless of the selection, click the Merge all button.

4. In the Files merged with conflicts , view the list of files where problems occurred during the merge procedure and [resolve the problems](#) using the following buttons:

- Accept Yours - click this button to have IntelliJ IDEA force your changes.
- Accept Theirs - click this button to have IntelliJ IDEA overwrite your changes.
- Merge - click this button to open the merge tool and [resolve the conflicts](#) there.

Though Subversion integration allows you to successfully modify and merge files changed by different team members, sometimes it makes sense to lock files (for example, images) to avoid overwriting changes.

To lock a file:

1. Select the file you want to lock in the [Project Tool Window](#) or open it in the editor.
2. From the main menu, select VCS | Subversion | Lock from the main menu, or Subversion | Lock from the context menu of the selection.
3. Enter a lock comment in the [Lock File](#) dialog that opens.

To unlock a file, select the file you want to unlock, or open it in the editor, and choose VCS | Subversion | Unlock from the main menu, or Subversion | Unlock from the context menu of the selection.

**Tip** To forcibly break a lock set by somebody else, select the Steal Existing Lock checkbox.

If a conflict occurs in a file under the Subversion version control, conflict markers are added to the conflicting file, and three auxiliary unversioned files are created in your local working copy:

- filename.mine : the copy of your local file without conflict markers.
- filename.rOld : the base revision you have last synchronized to.
- filename.rNew : the latest version on the server.

Conflicting files are marked with red in the [Local Changes](#) tab of the [Version Control](#) tool window. In the [Update Info](#) tab, they are grouped in the Merged with conflicts list and are also marked with red.

With IntelliJ IDEA, you can resolve conflicts in two ways:

- Semi-automatically, using a merge tool.
- Manually in the editor. After that, you need to manually mark the processed files as conflicts-free.

On this page:

- [To resolve a text conflict using the merge tool](#)
- [To resolve a text conflict manually](#)
- [To mark a file as resolved](#)

## To resolve a text conflict using the merge tool

1. In the [Local Changes](#) tab of the [Version Control](#) tool window, select the conflicting file:

2. On the main VCS menu, or on the context menu of the selection, choose [Subversion | Resolve Text Conflict](#) . The [Files Merged with Conflicts](#) dialog appears.

3. If you want to accept the server version and overwrite your local changes, click [Accept Theirs](#) . If you want to force your changes to the repository, click [Accept Yours](#) . Clicking [Merge](#) opens the merge tool, where you can [accept or discard](#) each change individually. As a result, the file is automatically marked as resolved, and auxiliary files are deleted.

**Tip** You can click the column header to sort the conflicting files by name.

4. Once the conflicts have been successfully resolved, commit your local version to the repository.

## To resolve a text conflict manually

Open the conflicting file in the editor, and do one of the following:

- Edit the contents within the conflict markers as required.
- Copy one of the auxiliary files on top of your working file.

## To mark a file as resolved

1. Do one of the following:

- Select the file in the [Project](#) tree or in the [Local Changes](#) tab of the [Version Control](#) tool window, and choose [Subversion](#) , and then choose [Mark Resolved](#) on the context menu of the selection.
- With the conflicting file opened in the editor, right-click the mouse anywhere in the editor tab. On the context menu choose [Subversion](#) , and then choose [Mark Resolved](#) .
- On the main menu, choose [VCS | Subversion | Mark Resolved](#) .

2. In the [Mark Resolved](#) dialog box that opens select the file in question.

3. Click the [Mark Resolved](#) button.

IntelliJ IDEA supports the Subversion sharing directories feature. The **Share Directory** command is applied to the content roots. When such content root is shared, a new directory is created in the specified location of the Subversion repository, checked out to the local directory you want to share, and the contents of the local directory is added to the repository. As a result, the local directory contains a valid working copy of the repository.

To share a directory via the Subversion repository, do the following:

1. In the [Project Tool Window](#) , select an unversioned directory that is the content root of a module associated with Subversion.
2. From the main menu, select Subversion | Share Directory .
3. Specify the target repository location where the directory shall be shared.

If you are using Subversion 1.5 or higher on the server and in your local working copy, you can take advantage of the extended Merge Info functionality implemented through the [Merge Info](#) pane of the [Version Control tool window](#), the [Repository tab](#).

With this functionality, instead of browsing all changelists within a certain period, you can define a set of changelists to display. This is done by specifying a pair of branches in the repository (source and target), whereupon IntelliJ IDEA shows only the changelists from the source branch that have been integrated into the target branch.

Additionally, you can specify various filtering options to minimize the number of extraneous changelists.

Finally, integration and managing integration status are also available directly from the Merge Info pane.

The extended browsing functionality includes:

- [Defining the Set of Changelists to Display](#)
- [Filtering Out Extraneous Changelists](#)
- [Integrating Files and Changelists from the Version Control Tool Window](#)
- [Viewing and Managing Integration Status](#)

**Tip** Before enabling the extended Merge Info functionality, make sure you are using SVN Server 1.5 or higher.

If you are using SVN 1.4 or lower, to enable the Merge Info functionality, you need to [change the format of your local working copy](#) first.

With the extended [Merge Info](#) functionality, you can limit the set of changelists to be displayed in the [Changelists](#) pane to changelists that have been integrated from one specific branch to another. These branches are referred to as "source" and "target" respectively.

To define the set of branches you want to display, do the following:

1. Open the [Version Control tool window](#) and switch to the [Repository tab](#).
2. To open the Merge Info pane, click the Highlight Integrated button  on the toolbar.
3. In the From field, specify the URL address of the source branch.
4. In the To field, specify the path to the target branch. If necessary, use the Browse button  to open the [Select Branch](#) dialog.
5. Specify the path to the local [working copy](#) to which you are going to apply patches created based on the selected changelists. If necessary, use the Browse button  to open the Configure Working Copy Paths dialog box.

With the extended [Merge Info](#) functionality, you can limit the number of changelists displayed in the Changelists pane by applying the following filters:

**Tip** Filtering out integrated/not integrated changelists is available only when integration status is highlighted.

Otherwise the Filter out integrated button  and Filter out not integrated button  are disabled. To enable integration status highlighting, click the Highlight Integrated button  on the toolbar.

- To display only the changelists that have not been integrated into the working copy, click the Filter out integrated button  on the toolbar.
- To display only the changelists that have been integrated into the working copy, click the Filter out not integrated button  on the toolbar.
- To hide the changelists that are [managed in another VCS](#) or are located under another root, click the Filter out others button  on the toolbar.
- To display only the changelists that were committed by a specific user, select User in the Filter by drop-down list. Then select the required user name.
- To display only the changelists applied to a specific module or folder, select Structure in the Filter by drop-down list. Then select the required location.
- To group changelists by users who committed them, or by commit dates, select the corresponding option in the Group by drop-down list.

You can integrate changelists or files into your local working copy directly from the Version Control tool window.

Do the following:

1. In the Changelists pane, select the required changelist. If necessary, you can select several changelists at a time.
2. Do one of the following:
  - To integrate an entire changelist, click the Integrate to Branch button  on the Merge Info pane toolbar.
  - To integrate a particular file from the selected changelist, select the file in the Changed Files pane and click the Integrate to Branch button  on the Merge Info pane toolbar.
  - To revert the last integration of the selected changelist into the working copy, click the Undo Integrate to Branch button  on the toolbar.

With the extended [Merge Info](#) functionality, you can view and update changelists' integration status.

Subversion stores the information on whether a changelist has been integrated into the local working copy or not. Based on this data, IntelliJ IDEA informs you on the integration status of a specific changelist by displaying one of the following icons next to it:

-  integrated
-  not integrated
-  integration status unknown
-  common history

To have the integration status displayed, click the Highlight Integrated button  on the Merge Info pane toolbar.

You can change the integration status of a changelist without actually integrating it into the working copy or reverting the previous integration. This will affect only the administrative data.

To toggle the integration status of a changelist, do one of the following:

- To mark a changelist as Integrated, select it and click the Mark As Merged button  on the Merge Info pane toolbar.
- To mark a changelist as Not integrated, select it and click the Mark As Not Merged button  on the Merge Info pane toolbar.

Subversion integration enables you to work with Subversion-specific properties without leaving IntelliJ IDEA.

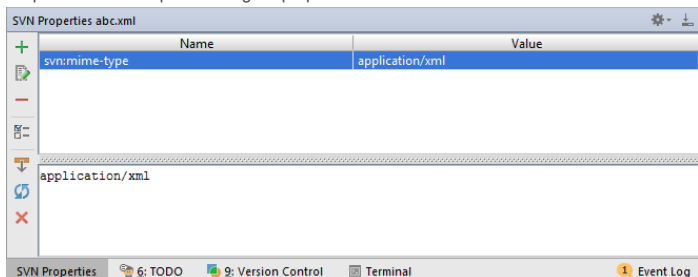

Once defined, the properties of a file or a directory are displayed in the SVN Properties view. In this view you can explore and change the existing properties and their values, or create new ones using the toolbar buttons or context menu commands.

This section describes how to:

- [View properties of a file or directory from within IntelliJ IDEA](#)
- [Create a new property, or change the value of an existing property](#)
- [Set up a keyword property](#)
- [Delete a property](#)
- [Resolve property conflicts](#)

## To view the properties of a file or directory

1. In the [Project Tool Window](#), select the desired file or directory under the SVN version control.
2. From the main VCS menu, or from the context menu of the selection, choose Subversion | Edit Properties. The SVN Properties view will open showing the properties of the selected file:

3. Use the toolbar buttons or the context menu commands to create, edit or delete properties, as described in the procedures below.

**Tip** If you want the SVN Properties view to preserve its contents as you navigate through your project or edit files, make sure that the Follow Selection button  is not pressed; otherwise the view will show the properties for the currently selected or edited file.

## To create a new property, or set the value for an existing property

1. Open the [SVN Properties view](#).

**Tip** Use the Set property command on the Subversion menu to define a single property.

2. Click the add button  on the toolbar of the SVN Properties view, or choose the Add property command on the context menu. The [Set Property](#) dialog box appears.
3. In the Property name field, type the name of the new property, or select one from the drop-down list.
4. Choose the Set property value option, and specify the desired value in the text area below.
5. To apply the changes to all subdirectories of the selected directory, select the Update properties recursively checkbox.
6. Click OK.

## To set up the svn: keywords property

- In the SVN Properties view for a file, click .
- In the SVN Keywords dialog box, check the keywords to be included in the property.
- Click OK.

## To delete a property

1. Select the property you want to delete.
2. Click  on the toolbar.

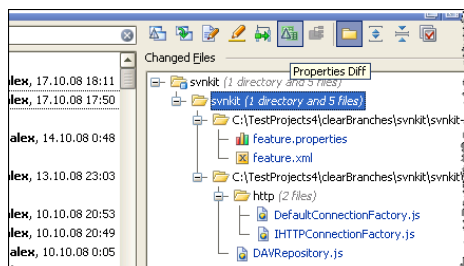

You can also delete a property from the Set Property dialog. To do this:

1. In the Property name field, select the property to be deleted.
2. Select the Delete property radio-button.
3. If you want this property to be deleted from all files and subdirectories of the selected directory, select the Update properties recursively option.

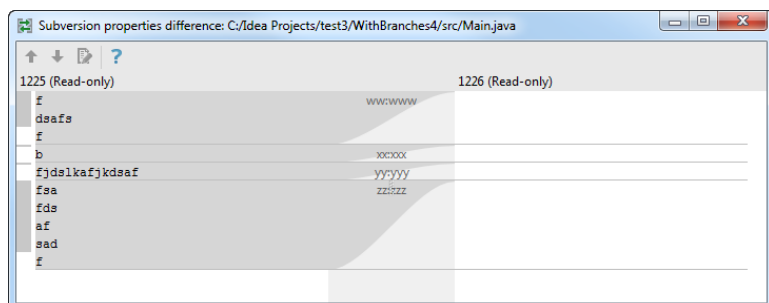

With IntelliJ IDEA, you can view differences in properties between a file in the [local copy](#) and in the [repository](#) or between [two revisions](#) of a file in the local copy.

## To view property difference between the local copy and the repository version

1. Open the Version Control tool window and switch to the [Repository](#) tab.
2. In the [Changed Files](#) pane, select the file for which you want to view property differences.
3. Choose Properties Diff on the context menu of the selection or click  on the toolbar.

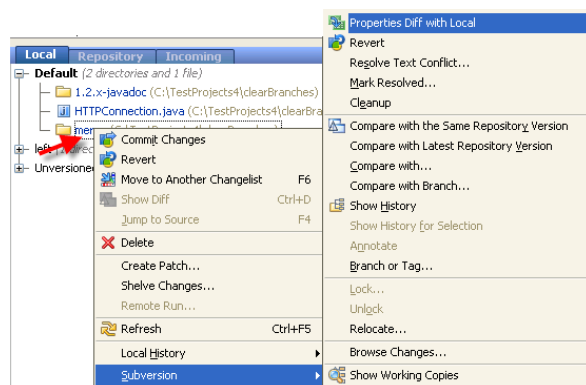

4. In the Subversion properties difference viewer, explore the differences:

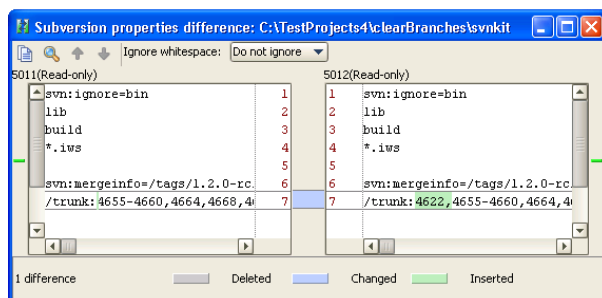

## To view property difference between two revisions in the local copy

1. Open the Version Control tool window and switch to the [Local](#) tab.
2. Select the file for which you want to view property differences between revisions and choose Subversion | Properties Diff with Local in the context menu.

3. In the Subversion properties difference viewer explore the differences:

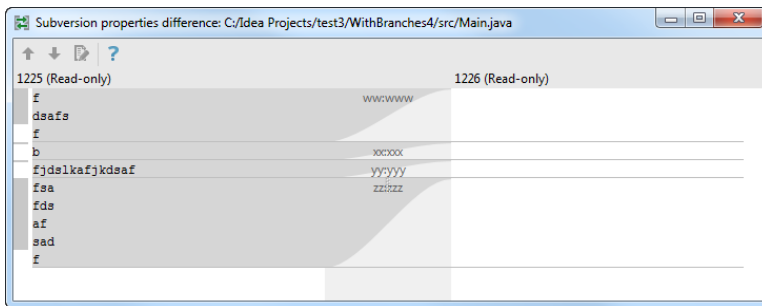

A **property conflict** is reported during synchronization with the server when IntelliJ IDEA detects differences between the properties of a local file or folder and their server version. IntelliJ IDEA does not attempt to resolve property conflicts automatically, and displays the conflicting files and folders under the Merged with property conflicts node in the [Update Info](#) tab of the [Version Control](#) tool window. You have to resolve property conflicts manually and then tell IntelliJ IDEA to treat the corresponding files and folders as conflict-free.

On this page:

- [To resolve a property conflict](#)
- [To mark a file as resolved](#)

## To resolve a property conflict

1. Open the [Version Control](#) tool window and switch to the [Repository](#) tab.
2. In the [Changed Files](#) pane, select the conflicting file.
3. Choose Properties Diff from the context menu of the selection, or click  on the toolbar.
4. Explore the differences in the Subversion properties difference viewer:

5. [Update the properties](#) so the conflict is resolved.

## To mark a file as resolved

- In the [Update Info](#) tab of the [Version Control](#) tool window, select the fixed file under the Merged with property conflicts node. As you can see, the file is still displayed in red as conflicting.
- On the context menu of the selection, choose Subversion, and then choose Mark Resolved.
- When the dialog box is closed, the Local Changes tab of the Version Control tool window shows the affected files as updated and available for checking in to the server.
- [Check in](#) the resolved files.

If any problem occurs with Subversion integration, feel free to [contact our support](#) . To facilitate detecting, locating, and resolving your issue, provide detailed information regarding your Subversion integration with IntelliJ IDEA. This topic lists the necessary information and explains how you can retrieve it.

The following data is usually required to diagnose Subversion problems:

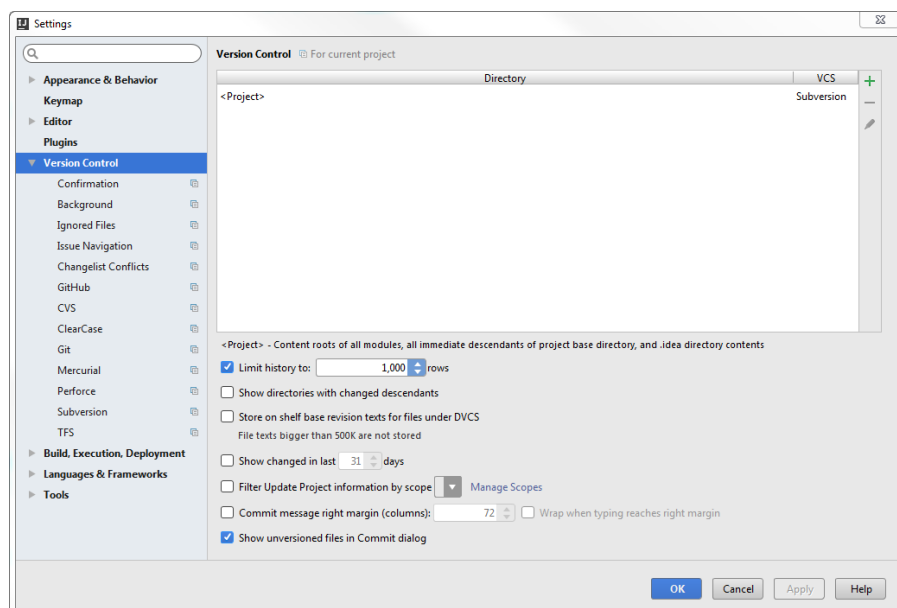

- The IntelliJ IDEA version and the build number.
- The operating system used.

On this page:

- [General VCS settings](#)
- [Subversion settings](#)
- [Local working copy format](#)
- [Parent folders of the branches used](#)
- [Enabling svnkit logging](#)

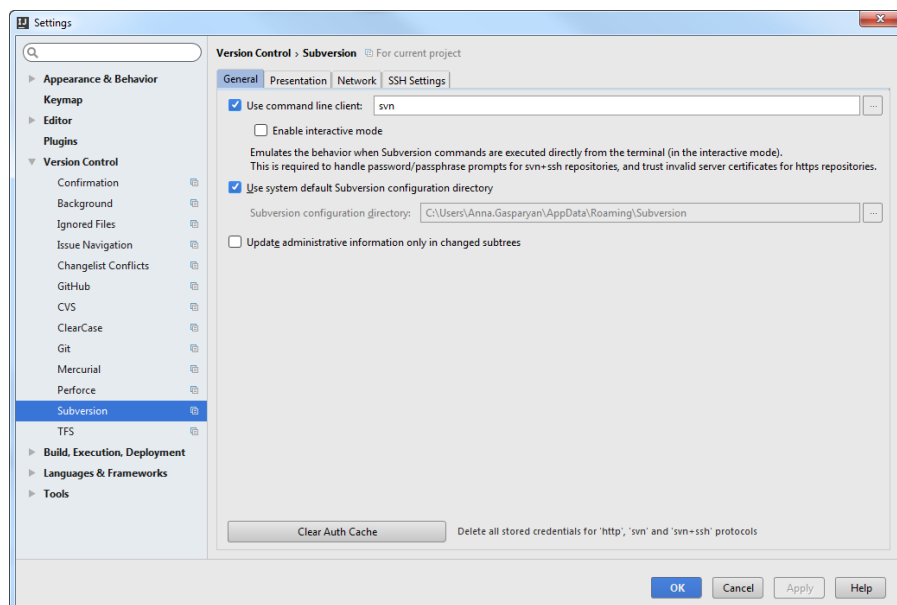

## General VCS settings

The general version control settings applied to your project are specified on the [Version Control](#) page of the [Settings/Preferences dialog](#) . Open the [Settings / Preferences Dialog](#) by pressing `(Ctrl+Alt+S)` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`, and click `Version Control` .

## Subversion settings

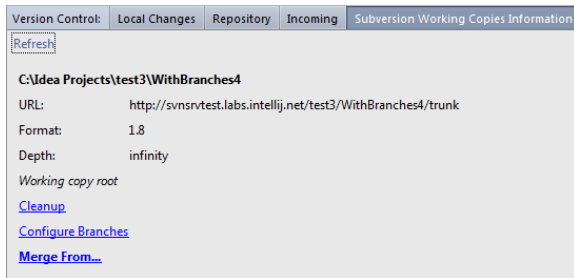

Subversion-specific settings are configured on the [Subversion](#) page, under the [Version Control](#) node of the [Settings/Preferences dialog](#) . Open the [Settings / Preferences Dialog](#) by pressing `(Ctrl+Alt+S)` or by choosing `File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS`, and click `Subversion` under `Version Control` .

## Local working copy format

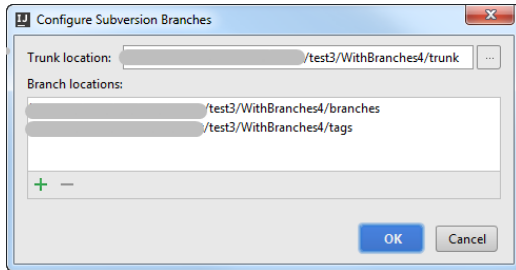

The working copy format is the Subversion format in compliance with which the working copy was created. To view the

working copy format, choose View | Tool Windows | Version Control on the main menu. In the Version Control tool window that opens, switch to the Subversion Working Copies Information tab.

## Parent folders of the branches used

To view the configuration of branches, in the Subversion Working Copies Information tab of the Version Control tool window, click the Configure Branches link.

## Enabling svnkit logging

If data saved in the IntelliJ IDEA logs is not sufficient to solve the problem and the problem is related to the communication protocol or authentication, enable **svnkit logging**, reproduce the problem, and attach the `idea.log`.

To enable svnkit logging, add `-Djavasvn.log=true` to one of the following files depending on the operating system used:

- Windows: `IntelliJ IDEA.exe.vmoptions`
- Linux: `IntelliJ IDEA.vmoptions`
- macOS: <http://stackoverflow.com/a/13581526/72788>

Refer to [Tuning IntelliJ IDEA](#) to learn about IntelliJ IDEA `idea.properties` and `vmoptions` files locations.

This feature is only supported in the Ultimate edition.

With the TFS integration enabled, you can perform basic TFS operations from inside IntelliJ IDEA.

IntelliJ IDEA supports TFS up to TFS 2015.

The information provided in this section assumes that you are familiar with the basics of the TFS version control system.

## Before you start

- The TFS integration does not require a standalone TFS client. All you need is an account in your Team Foundation Server.
- Make sure that the **TFS Integration** plugin is enabled.  
This plugin is bundled with IntelliJ IDEA and enabled by default. If not, [enable the plugin](#).
- Make sure that TFS integration is enabled for the entire project root or a specific directory. For more details, see [Enabling Version Control](#).

## TFS support

- When TFS integration with IntelliJ IDEA is enabled, the TFS item appears on the VCS menu, and on the context menus of the [Editor](#) and the [Project Tool Window](#).
- The files in the folders under the TFS control are highlighted according to their status. See [File Status Highlights](#) for file status highlighting conventions.
- Modifications results are shown in the [Version Control tool window](#).
- When using TFS integration, it is helpful to open the [Version Control](#) tool window. The [Console](#) tab displays the following data:
  - All commands generated based on the settings you specify through the IntelliJ IDEA user interface.
  - Information messages concerning the results of executing generated TFS commands.
  - Error messages.
- TFS integration with IntelliJ IDEA allows you to resolve/associate work items with the new changeset when committing your changes. To achieve this, you can access saved queries and browse work item trees.

In this section:

- [Creating and Managing TFS Workspaces](#)
- [Checking Out from TFS Repository](#)
- [TFS Check-in Policies](#)

The interaction between your TFS server and local projects is configured through [workspaces](#) . A workspace mainly maps the folders in the repository with their copies on your machine.

In IntelliJ IDEA, you can configure access to several TFS servers and have as many workspaces under them as you need. The list of available TFS server access configurations and workspaces is handled through the [Manage TFS Servers and Workspaces](#) dialog box.

In this topic:

- [Opening the Manage TFS Servers and Workspaces dialog box](#)
- [Configuring access to a TFS server](#)
- [Creating a workspace](#)

## To open the Manage TFS Servers and Workspaces dialog box

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | TFS .
2. On the [TFS](#) page that opens, click the Manage button in the Servers and Workspaces area. The [Manage TFS Servers and Workspaces](#) dialog box shows the list of all available servers and workspaces in them.

## To configure access to a TFS server

1. [Open the Manage TFS Servers and Workspaces](#) dialog box with the list of all available servers and workspaces in them.
2. Click the Add button in the Team Servers area.
3. In the [Add Team Foundation Server](#) dialog box, that opens, specify the URL address of the target server in the Address text box.  
In the Auth field, specify the authentication protocol to access the server. TFS uses [NTLM authentication](#) , so native **Windows** applications (that is, **Microsoft Team Explorer** ) authenticate silently with system credentials. IntelliJ IDEA users must always specify their username and password because of limitations posed by Java Runtime.

To authenticate through OAuth (**Windows Live ID** ), choose Alternate from the Auth drop-down list.

4. For the NTLM and Alternate authentication types, specify your credentials:
  - For NTLM : the network domain where the TFS server is located, your TFS user name, and your TFS password.
  - For Alternate : your TFS user name and password.
5. Click OK . IntelliJ IDEA returns to the Manage TFS Servers and Workspaces dialog box, where the new server is added to the list.

To discard a server access configuration, select the server in the list and click the Remove button in the Team Servers area.

## To create a server workspace

A workspace is identified by its name and the name of its owner, contains the name of your machine, the URL address of the server the workspace belongs to, and a set of mappings between remote and local working folders that are accessible through the workspace.

1. [Open the Manage TFS Servers and Workspaces](#) dialog box, and select the server in question. To refresh the list of the available server workspaces, click the Reload workspaces button.
2. Click the Create button in the Workspaces area.
3. In the [Create Workspace](#) dialog box, that opens, specify the workspace name. Optionally, provide a brief description of the workspace in the Comment text box.
4. In the Working folders area, define the mappings.
  1. Click the Add button `+` . A new line is added to the list of mappings.
  2. In the Server path text box, specify the folder on the server you need to work with.
  3. In the Local path text box, specify the local folder to store the downloaded data in.
  4. Specify the status of the mapping in the Status drop-down list.
    - To enable retrieving data from the server according to the mapping, choose Active .
    - To prevent downloading data from the server according to the mapping, choose Cloaked .
5. To discard a mapping, select it in the list and click the Remove button `-` .

Checkout helps you obtain a local working copy of the repository folders, which you can edit as required. After making the necessary changes, you can publish results by [committing](#), or [checking in](#) changes to the repository.

Interaction between your TFS server and the local projects is configured through [workspaces](#) that map the folders in the repository with their copies on your machine. You can have remote folders downloaded either according to the mappings from an [existing workspace](#) or define the required mappings during download and have the corresponding workspace generated automatically. In either case, the Checkout from TFS wizard is used. Upon checkout, a IntelliJ IDEA project is created around the downloaded sources.

On this page:

- [Downloading data to a new workspace generated automatically](#)
- [Downloading data to an existing workspace](#)

## To have a new workspace generated

1. On the main menu, choose VCS | Checkout from Version Control | TFS . The Checkout from TFS wizard starts.
2. On the Checkout Mode page, choose the Create workspace automatically option, specify the name to identify the workspace, and click Next .
3. On the Source Server page, specify the server to download the data from. Do one of the following:
  - Choose one of the existing server access configurations.
  - Click Add and [define a new server access configuration](#) in the [Add Team Foundation Server](#) dialog box, that opens.

Click Next , when ready.

4. On the [Choose Source and Destination Paths](#) page, define the working folder mapping to generate a workspace around:
  1. In the Source path area, select the remote folder to download.
  2. In the Destination path text box, specify the location to store the downloaded data in. Type the path manually or click the Browse button  and select the folder in the dialog box, that opens.

Click Next .

5. On the [Summary](#) page, check the details of the workspace to be generated and click Finish to launch the checkout procedure. When the checkout is completed, IntelliJ IDEA creates a project around the downloaded sources and suggests to open it.

## To download data to an existing workspace

1. On the main menu, choose VCS | Checkout from Version Control | TFS . The Checkout from TFS wizard starts.
2. On the Checkout Mode page, choose the Choose workspace manually option and click Next .
3. On the [Source Workspace](#) page, choose the server to download the data from and the workspace of this server to add the working folders to. If necessary, create new [server access configurations](#) and [workspaces](#) . Click Next , when ready.
4. On the [Choose Source Path](#) page, specify the remote folder to download. Such folders are available only if the selected workspace contains a mapping either for the folder itself or for its parent. If such mapping is missing, return to the [Source Workspace](#) page and [add the required mapping](#) . Click Next , when ready.
5. On the [Summary](#) page, check the details of the workspace to be generated and click Finish to launch the checkout procedure. When the checkout is completed, IntelliJ IDEA creates a project around the downloaded sources and suggests to open it.

A check-in policy is a rule that is executed before every check-in to ensure that the selected changeset is OK to commit.

**Standard policies** are stored on the server and are executed on the client machines.

**Custom policies** are implemented as custom plugins to IntelliJ IDEA. The IDs of these plugins are stored on the server, while the policies themselves are applied locally. Therefore, to enable the use of a policy in a team, all the team members should install the corresponding plugin.

On this page:

- [Defining the default policy settings](#)
- [Suppressing the default IntelliJ IDEA-wide check-in policy settings in a current project](#)
- [Managing the list of available policies](#)
- [Introducing a custom check-in policy](#)

## To define the default policy settings to be applied at the IntelliJ IDEA level

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | TFS .
2. On the [TFS](#) page, that opens, select the applicable checkboxes in the Checkin policies compatibility area.
  - Evaluate Team Explorer policies: select this checkbox to have the Microsoft Team Explorer policy definitions installed and executed on the client machine.
  - Evaluate Teamprise policies: select this checkbox to have the Teamprise policy definitions installed and executed on the client machine.
  - Warn about not installed policies: select this checkbox to have warnings displayed in case the specified policy definition is not installed.

## To suppress applying the default check-in policy settings to a project

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | TFS .
2. On the [TFS](#) page, that opens, click the Manage button in the Servers and Workspaces area.
3. In the [Manage TFS Servers and Workspaces](#) dialog box, that opens, select the project in question from the Team project drop-down list.
4. In the Compatibility area, select the Override default settings for team project <project name> checkbox.
5. Re-define the default settings by selecting or clearing the corresponding checkboxes below.
  - Evaluate Team Explorer policies: select this checkbox to have the Microsoft Team Explorer policy definitions installed and executed on the client machine.
  - Evaluate Teamprise policies: select this checkbox to have the Teamprise policy definitions installed and executed on the client machine.
  - Warn about not installed policies: select this checkbox to have warnings displayed in case the specified policy definition is not installed.

## To manage the list of available policies

The list of available policies consists of standard third-party policies and custom, user-defined policies.

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Version Control | TFS .
2. On the [TFS](#) page, that opens, click the Manage button in the Servers and Workspaces area.
3. In the [Manage TFS Servers and Workspaces](#) dialog box, that opens, select the required workspace and click the Checkin Policies button.
4. In the [Edit Checkin Policies](#) dialog box, that opens, configure the list of policies:
  - To activate a policy, select the Enabled checkbox next to it.
  - To suppress a policy, clear the Enabled checkbox next to it.
  - To discard a policy permanently, select it in the list and click the Remove button.

## To introduce a custom check-in policy

1. Implement the required policy as a custom plugin.
2. Download, install, and enable the plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

This section describes how to use [Local History](#), which is your personal real-time version control system. Local History is independent of external version control systems and works with the directories of your project even when they are not under any VCS control.

Local history is cleared when you install a new version of IntelliJ IDEA or when you invalidate caches. Therefore, check in the changes to your version control system before performing these operations.

This section describes how to:

- [View local history of a file or folder](#)
- [View local history of a class, method, field or selection](#)
- [View local history of a selection](#)
- [View recent changes](#)
- [Restore files from local history](#)
- [Mark local versions with labels](#)

On this page:

- [Introduction](#)
- [Adding a label to a local version](#)

## Introduction

Before embarking on a risky change to your source code, it is a good idea to mark the stable version with some meaningful label. This will help you quickly roll back to a safe version.

Labels apply to a whole project.

## Adding a label to a local version

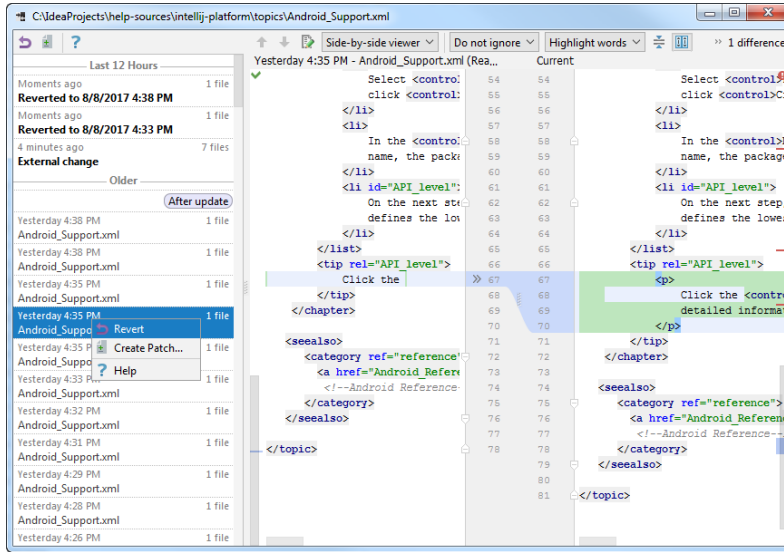

### To add a label to a local version

1. Select a file or folder in the Project tool window, or open a file in the editor.
2. Do one of the following:
  - On the main VCS menu, or on the context menu of the selection, choose Local History | Put Label .
  - Press `Alt+Back Quote` and choose Put Label command from the VCS Operations quick list.
3. In the Put Label dialog box, type the label name.

Rolling back changes from the local history works same way as in the regular version control.

## To roll back changes in the local history

1. Open the Local History view .
2. Select the version you want to roll back to.
3. On the toolbar, click  .

On this page:

- [Basics](#)
- [Viewing local history of a class](#)
- [Viewing local history of a source code block](#)

## Basics

Besides [file history](#) , you can track local changes for a [class](#) , [its elements](#) , or selected block of source code. This history shows only those changes that affect the selected element or code fragment.

### Viewing local history of a class

#### To view local history of a class

1. Select a class file in the project tool window, or right-click class name in the editor.
2. On the main VCS menu, or on the context menu of the selection, choose Local History | Show History for Class .

#### To view local history of a method or field

1. In the editor, place the caret at the name of the desired method or field.
2. On the main VCS menu, or on the context menu of the selection, choose Local History | Show History for Method (Field) .

### Viewing local history of a source code block

#### To view local history of a source code block

1. In the editor, select a fragment of source code.
2. Do one of the following:
  - On the main VCS menu, or on the context menu of the selection, choose Local History | Show History for Selection .
  - Press `Alt+Back Quote` , and choose the desired command from the VCS Operations quick list.

On this page:

- [Basics](#)
- [Viewing local history](#)

## Basics

Local History makes it possible to view changes made to a certain file or a whole directory. Each entry in the Local History dialog box is displayed with its time stamp, action and optional label. So doing, the local history for a file includes all changes that affect both the selected file and the whole project; local history for a folder shows changes to the source code tree in general. You can explore changes, selecting the respective row in the Local History dialog box.

## Viewing local history

### To view local history

1. Select a folder or file in the Project tool window, or open a file in the editor.
2. Do one of the following:
  - On the main VCS menu, or on the context menu of the selection, choose Local History | Show History .
  - Press `(Alt+Back Quote)` , and choose the desired command from the VCS Operations quick list.
  - Use [View Recent Changes](#) that shows a summary of recent changes in a single pop-up list. Clicking an entry in this list shows the respective Local History.
3. Use the Local History view to compare local versions and revert changes.

On this page:

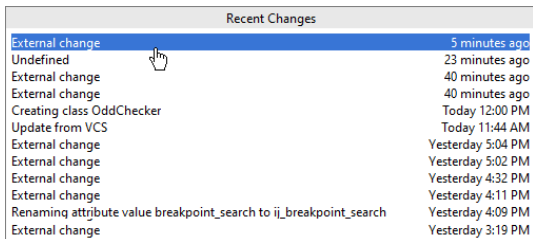

- [Basics](#)
- [Viewing recent changes](#)

## Basics

IntelliJ IDEA allows you to view the summary of recent changes to all recent projects, the IntelliJ IDEA configuration directory, etc. From the Recent Changes pop-up, you can browse through the history of changes, navigate to a particular change, compare versions, and revert changes if necessary

## Viewing recent changes

1. From the main menu, choose View | Recent Changes , or press `Shift+Alt+C` .
2. In the Recent Changes pop-up, select the change you are interested in:

Recent Changes	
External change	5 minutes ago
Undefined	23 minutes ago
External change	40 minutes ago
External change	40 minutes ago
Creating class OddChecker	Today 12:00 PM
Update from VCS	Today 11:44 AM
External change	Yesterday 5:04 PM
External change	Yesterday 5:02 PM
External change	Yesterday 4:32 PM
External change	Yesterday 4:11 PM
Renaming attribute value breakpoint_search to ij_breakpoint_search	Yesterday 4:09 PM
External change	Yesterday 3:19 PM

3. In the dialog that opens, review the differences and discard changes if necessary.

IntelliJ IDEA helps explore differences in the various situations: differences between files, directories, revisions of the same file under version control or in the local history, database objects, local and remote files.

All these operations are performed in a similar way. In this section we'll consider the most basic operations:

- [Comparing Files](#)
- [Comparing Folders](#)

On this page:

- [Introduction](#)
- [Comparing two files](#)
- [Comparing a file in the editor with the Clipboard contents](#)
- [Comparing a file with the editor contents](#)

## Introduction

IntelliJ IDEA enables you to compare arbitrary files in project (including image files), selected file with the editor, or compare a file in the editor with the Clipboard contents. All comparisons are performed in the [Differences viewer](#).

## Comparing two files

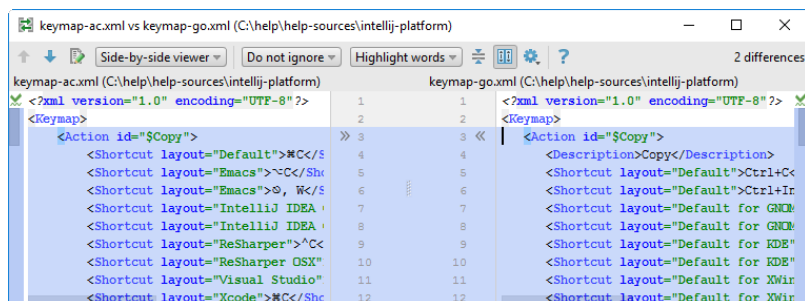

1. Press and keep holding **Ctrl** for Windows and Linux or **⌘** for macOS and click the two files to compare in the Project tool window.
2. On the context menu of the selection, choose Compare Files, or press **Ctrl+D**. The [Differences Viewer for Files](#) opens, with the differences being color-highlighted.

**Tip** It is enough to select a single file in the Project tool window. In this case the context menu command is Compare File with Editor, and the Differences Viewer shows the contents of the selected file on the left pane, and the contents of the active editor tab on the right pane.

3. View the differences and apply them, if necessary, using the **chevron** buttons **»»**.

Note that keeping **Ctrl** (for Windows and Linux) or **⌘** (for macOS) pressed turns the chevron buttons **»»** to **»**. Click these buttons to append changes.

Keeping **Shift** pressed turns the chevron buttons **»»** to **×**. Click this button to revert changes.

## Comparing a file in the editor with the Clipboard contents

1. Open the desired file in the editor.
2. Right-click the editor pane and choose Compare with Clipboard on the context menu.
3. View and manage differences in the [Differences Viewer for Files](#).

## Comparing a file with the editor contents

1. Right-click the desired file in the Project tool window.
2. Choose Compare File with Editor on the context menu.
3. View and manage differences in the [Differences Viewer for Files](#).

On this page:

- [Basics](#)
- [Opening the Difference Viewer](#)
- [Comparing two folders in the Difference Viewer](#)
- [Synchronizing contents of folders](#)

## Basics

IntelliJ IDEA provides a dedicated [Differences Viewer for Folders](#) for comparing files in two folders against the file size, content, or timestamp. The Differences Viewer shows the contents of the selected directories in the left and right panes of the Item List. The contents of the selected file are shown in the lower pane, with the differences being color-highlighted.

Besides exploring differences, the tool also provides interface for synchronizing the contents of folders.

## Opening the Difference Viewer

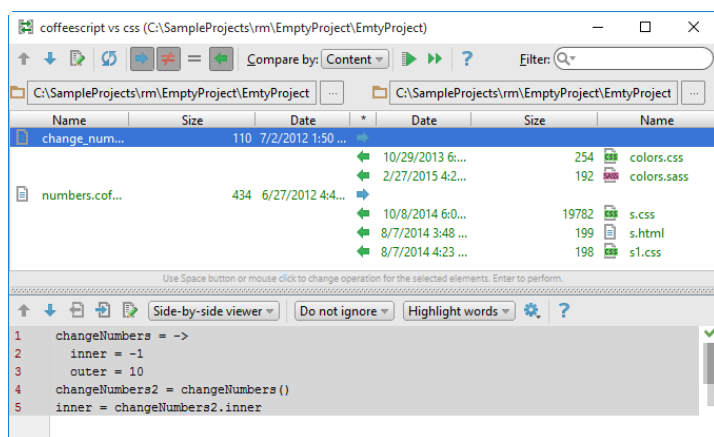

Do one of the following:

- Keeping the **Ctrl** key pressed, click two directories in the Project tool window, and choose Compare Directories on the context menu of the selection, or press **Ctrl+D**.
- Select a directory in the Project tool window, choose Compare with on the context menu of the selection, or press **Ctrl+D**, and then select the second directory in the [dialog that opens](#).

**Tip** You can also open the difference viewer without running IntelliJ IDEA. This is done through the following command: `<path to IntelliJ IDEA executable file> diff <path_1> <path_2>` where `path_1` and `path_2` are paths to the folders in question.

## Comparing two folders in the Difference Viewer

1. Configure the layout of the Items List. Use the toolbar buttons to narrow down or widen the set of items to show. For example, show or hide files that exist in just one of the directories, equal files, or different files, etc.
2. Specify the parameter for comparison. In the Compare by drop-down list, select one of the possible options (contents, size, or time stamp).
3. Filter the folders' contents. To do that, type filtering string in the Filter text field, and press **Enter** to apply it. Using the asterisk `*` wildcard to represent any number of characters is welcome.
4. To switch to another pair of folders to compare, update the fully qualified paths to them. Click the Browse button  next to the Paths read-only fields and choose the required folders in the [dialog box that opens](#).
5. Explore the detected differences between files in the Differences Pane.

## Synchronizing contents of folders

1. For each pair of items, in the `*` field specify the action to apply. Click the icon in the field until the required action is set.

### IconAction

-  Copy the item in the left side to the right side, possibly overwriting the contents of the corresponding target item, if it already exists.
-  Copy the item in the right side to the left side, possibly overwriting the contents of the corresponding target item, if it already exists.
-  The items are treated identical with regard to the selected criterion of comparison. No action will be performed by default.
-  The items differ with regard to the selected criterion of comparison. No action will be performed by default. Explore the differences in the [Differences Pane](#) and change the intended action by clicking the icon.
-  The item is present only in one of the folders and will be removed.

2. Do one of the following:

- To synchronize the currently selected item, click the Synchronize Selected button  on the toolbar.
- To synchronize all the items, click the Synchronize All button  on the toolbar.

**Warning!** Before you start working with tasks, make sure that the Task Management plugin is enabled in the Settings/Preferences | Plugins window.

When you work on a project, you can organize your work in smaller tasks that you need to complete.

These can be tasks that you set yourself. In IntelliJ IDEA, you can divide a large task into smaller tasks associated with dedicated changelists.

Or these can be tasks coming from your issue tracker. For example, you can work with tasks and bugs assigned to you directly from IntelliJ IDEA. To be able to do so, configure a connection between the IDE and your tracker account first.

## Configuring integration with issue trackers

**Note** IntelliJ IDEA supports integration with:

- [Jira](#)
- [YouTrack](#)
- [Lighthouse](#)
- [PivotalTracker](#)
- [Redmine](#)
- [Trac](#)
- [FogBugz](#)
- [Mantis](#)
- Generic server
- [Asana](#)
- [Assembla](#)
- [Sprintly](#)
- [Trello](#)
- [Gitlab](#)
- [Bugzilla](#)
- [GitHub](#)

**Note** If a server is not trusted, IntelliJ IDEA shows a box suggesting you to accept the server, or reject it. If you accept the server as trusted, IntelliJ IDEA writes its certificate to the trust store. This dialog will not be displayed the next time you connect to the server.

To enable integration with an issue tracker:

1. Access the Servers box. To do so, navigate to File | Settings | Tools | Tasks | Servers (if you work on MacOS, use the use the IntelliJ IDEA | Preferences menu options) or press `Ctrl+Alt+S`.
2. Click `+`, or press `Alt+Insert`, and select the necessary issue tracker form the list.
3. In the Servers window, enter connection details. Note that settings may differ depending on your issue tracker.
  - General tab: normally, you will have to specify the server URL and connection credentials.

Select the Share URL option to allow access to the server for other members of your team.

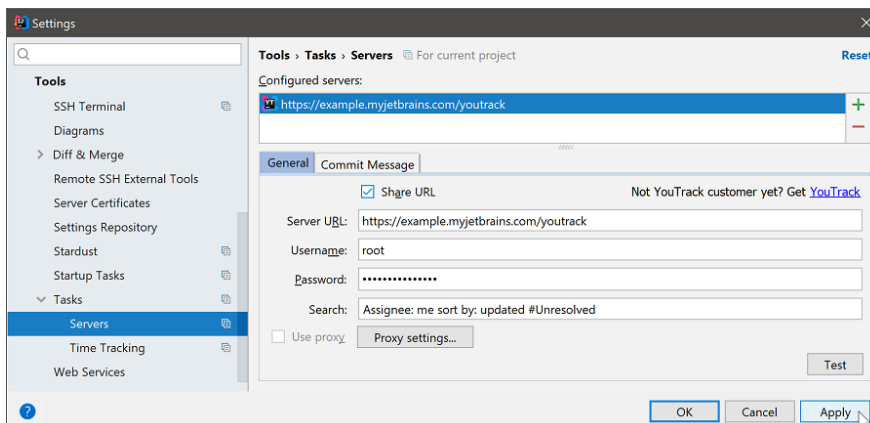

Click Proxy settings if you want to access the server via a proxy server. You can find more information on proxy settings in the [HTTP Proxy](#) section.

- Commit Message tab: ( *optional* ) enable adding a commit message for a changelist and configure a message template.
- Server Configuration tab: for some trackers (for example, for trackers not supported out of the box), you will have to configure server parameters as well.

Specify the URLs and the request type for accessing tasks, select a format for a tracker server response – XML for XPath, JSON for [JSONPath](#), or text for regular expressions. You can also use the table of selectors to specify details about tasks you want to get from the server. For example, this can be a date when a task was created or its URL.

Note that you can use code completion in this window. For more information on how to configure connection to a custom (or generic) tracker, refer to [Configuring Generic Task Server](#).

The screenshot below shows a configuration example for YouTrack.

4. ( *Optionally* ) Optimize synchronization between IntelliJ IDEA and your issue tracker.

IntelliJ IDEA caches the list of issues loaded from the tracker and updates them repeatedly. You can specify how many issues should be cached and how often IntelliJ IDEA should update information about them. To do so, return to the Tasks window. In the Cache settings section, enter the necessary values.

**Tip** Synchronization is especially recommended if you work with "slow" issue tracking systems.

## Working with tasks

In IntelliJ IDEA, there two types of tasks:

**Tip** IntelliJ IDEA allows you to configure additional settings to work with tasks in the Settings/Preferences | Tools | Tasks window.

– Tasks that were loaded to IntelliJ IDEA from your issue tracker. These are tracker tasks .

Tracker tasks are linked with the corresponding issues in your issue tracker. This allows you to monitor and update them directly from IntelliJ IDEA.

– Tasks that were originally created in IntelliJ IDEA. These are local tasks .

As you work on a project, it may be essential for you to organize the entire scope of your work in smaller tasks. You will be able to focus on more important pieces of work and postpone less important. Local tasks are not related to an issue tracker.

If you have created at least one task of either type, a drop-down list called task combo becomes available on the toolbar. Use the task combo to navigate your tasks, switch between them, or remove them.

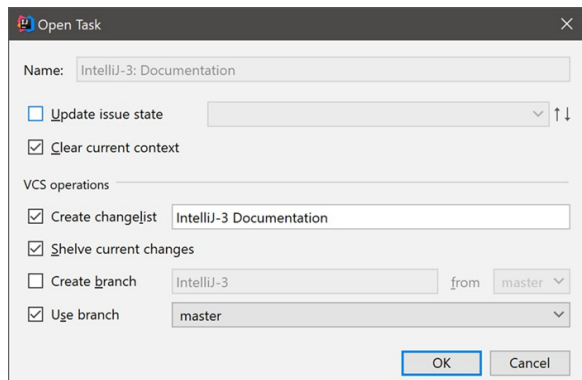

## Opening tracker tasks

Tracker tasks are loaded to your IntelliJ IDEA once you connect it to your issue tracker. To open a tracker task:

1. Open the list of tasks. To do so, navigate to Tools | Tasks&Contexts | Open Task , click the task combo on the toolbar, or press `Shift+Alt+N` .
2. Select the necessary task from the list.
3. In the Open Task dialog, you can update issue state, choose whether to clear the current context.
4. In the VCS operations section, you can create a new changelist, select an existing branch to which you want to contribute, or create a new branch.

You can also shelve the current changes to return to them later. Shelving means putting aside changes that you have not committed yet. For more information, refer to [Shelving and Unshelving Changes](#) .

Tracker tasks have the light-colored background until they are opened in IntelliJ IDEA. After that, their background color changes to white.

## Creating local tasks

In IntelliJ IDEA, you can create local tasks that do not originate from your issue tracker. To create local tasks:

1. Launch the Open Task dialog by navigating to Tools | Tasks&Contexts | Open Task . You can also use the task combo or just press `Shift+Alt+N` .
2. In the Enter task name pop-up window, select Create New Task .
3. Enter a name for the new task, and select whether you want to clear the current context.
4. In the VCS operations section, you can create a new changelist, select an existing branch to which you want to contribute,

or create a new branch.

You can also shelve the current changes to return to them later. Shelving means putting aside changes that you have not committed yet. For more information, refer to [Shelving and Unshelving Changes](#) .

## Viewing task description

When you are choosing a task to switch to, the list of tasks shows only task IDs. This information is not always sufficient, because it reflects neither the steps that lead to the problem nor the related discussion. To open a task description:

1. Launch the Open Task dialog.
2. Select the necessary task and press **CTRL+Q** .
3. To open the description in a browser, click  or press **Shift+F1** (for tracker tasks only).

Alternatively, navigate to Tools | Tasks&Contexts and click Show ' *task ID* ' Description or Open ' *task ID* ' in Browser .

## Viewing closed tasks

A closed local task is a task that is not associated with a changelist if the [entire project](#) or the [affected directory](#) is under a version control.

A closed tracker task is a task that has the closed status in your the issue tracker.

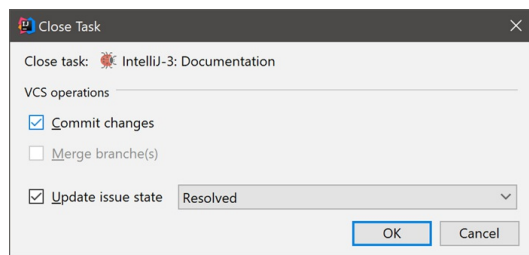

To display closed tasks:

1. Click the task combo and then click Open Task .
2. Select the Include closed tasks checkbox, or press **Shift+Alt+N** .

## Closing and deleting tasks

To close a task, navigate to Tools | Tasks&Contexts and click Close Active Task .

This will close the current context in the IntelliJ IDEA. Select the necessary checkboxes to commit changes and, optionally, merge the branch that was created. For tracker tasks, you can also change their state. The new state will be propagated to your issue tracker.

If you do not need a task to appear in IntelliJ IDEA, you can remove it from the list of tasks. To delete a task:

1. Click the task combo on the main toolbar.
2. Select one or more tasks you want to delete.

Use **Shift** (for adjacent items) or **Ctrl** (for non-adjacent items) keys for multiple selection.

3. Click the right-arrow button, and select Remove .

When you are deleting tracker tasks, you remove them from the IDE. They will remain in your issue tracker. Local tasks in this case will be completely removed, since they are not connected to your issue tracker.

## Time tracking

With IntelliJ IDEA, you can track the amount of time you spend on a task working within the editor.

For local tasks, this information might be helpful if you want to know how much time exactly you need to compete a task as you work on a project.

For tracker tasks, this option is useful if your issue tracker configuration requires that you log the time you spend on tasks. In this case, you can send your time log from IntelliJ IDEA to the tracker.

To enable the time tracking option:

**Warning!** Note that the time tracking feature is available in the Ultimate edition only.

**Tip** Make sure that the Time Tracking plugin is enabled in the Settings/Preferences | Plugins window.

1. Navigate to Settings/Preferences | Tools | Tasks | Time Tracking and select the Enable Time Tracking checkbox.
2. (Optionally) Change the Suspend delay value. Here you can specify how much time you have to stay inactive before the task will be considered suspended.

In the Time Tracking tool window, use the Auto mode  for automatic time logging, or the Start timer for the active task .

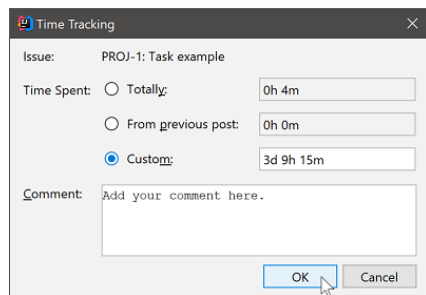

and Stop timer for the active task  options for manual time recording.

## Sending time log to tracker

To send the recorded time log to your issue tracker:

1. Click Post work item to bug tracker  in the Time Tracking tool window.
2. Specify time interval you want to log. Optionally add a comment.
3. Click OK to push the log to the tracker.

## Working with contexts

### Saving context

A context is a set of files that are connected with a task. With IntelliJ IDEA, you can save and clear contexts without associating them with specific tasks.

To save the current context:

1. From the main menu, select Tools | Tasks&Contexts | Save Context on the main menu, or press `Shift+Alt+S`.
2. (Optionally) In the Save Context dialog, specify a comment, if necessary.

### Switching between contexts

With IntelliJ IDEA, you can switch between contexts that are not associated with specific tasks. This will let you work with tasks and switch between them without mixing the changes that were made between both tasks.

To switch to another context:

1. From the main menu, select Tools | Tasks&Contexts | Load Context, or press `Shift+Alt+L`.
2. In the Load Context pop-up window, select the necessary context from the list.

Alternatively, click the right arrow and select Load.

### Clearing and deleting contexts

To clear the current context without loading another one, choose Tools | Tasks&Contexts | Clear Context on the main menu, or press `Shift+Alt+X`.

When a task is finished, or if you do not need a context anymore, you can remove it. To delete a context:

1. From the main menu, select Tools | Tasks&Contexts | Load Context, or press `Shift+Alt+L`.
2. In the Load Context pop-up window, click the right arrow and select Remove.

## Overview

Switching from **Eclipse** to **IntelliJ IDEA**, especially if you've been using **Eclipse** for a long time, requires understanding some fundamental differences between the two IDEs, including their [user interfaces](#), [compilation methods](#), [shortcuts](#), project configuration and other aspects.

## User Interface

### No workspace

The first thing you'll notice when launching **IntelliJ IDEA** is that it has no **workspace** concept. This means that you can work with only one project at a time. While in **Eclipse** you normally have a set of projects that may depend on each other, in **IntelliJ IDEA** you have a single project that consists of a set of modules.

If you have several unrelated projects, you can open them in separate windows.

If you still want to have several unrelated projects opened in one window, as a workaround you can configure them all in **IntelliJ IDEA** as modules.

### IntelliJ IDEA vs Eclipse terminology

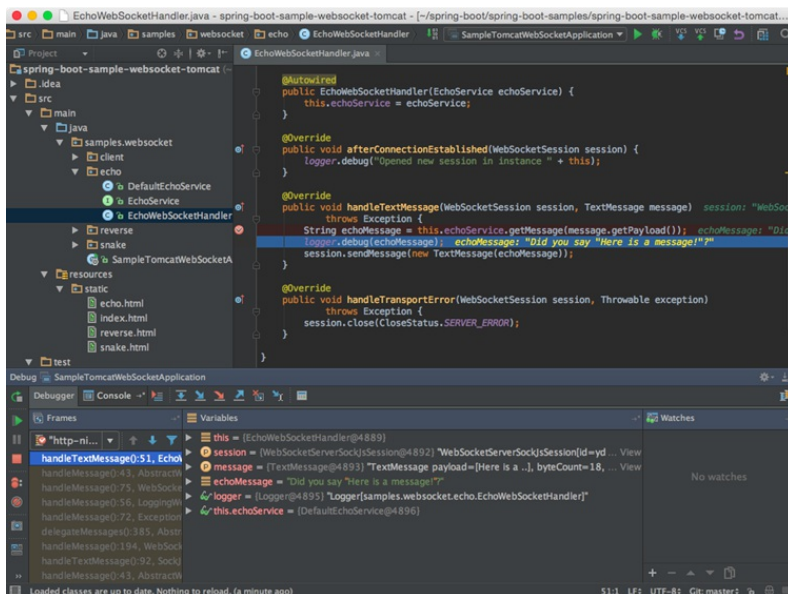

The table below compares the terms in **Eclipse** and **IntelliJ IDEA**:

Eclipse	IntelliJ IDEA
Workspace	Project
Project	Module
Facet	Facet
Library	Library
JRE	SDK
Classpath variable	Path variable

### No perspectives

The second big surprise when you switch to **IntelliJ IDEA** is that it has no **perspectives**.

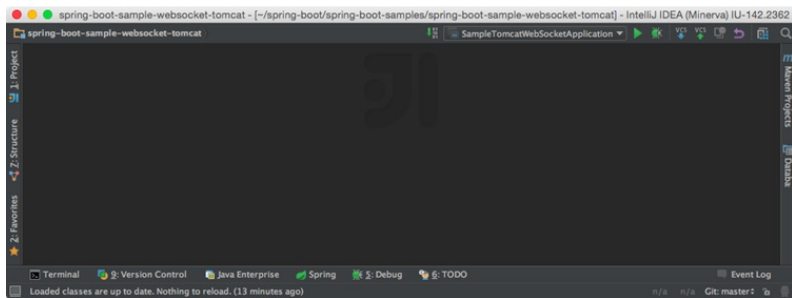

It means that you don't need to switch between different workspace layouts manually to perform different tasks. The IDE follows your context and brings up the relevant tools automatically.

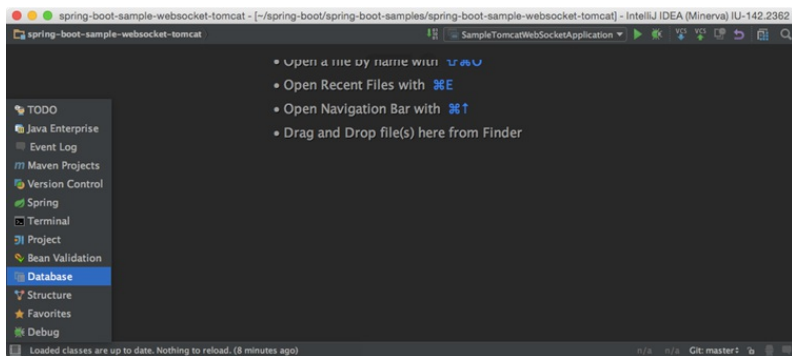

## Tool windows

Just like in Eclipse, in IntelliJ IDEA you also have tool windows. To open a tool window, simply click it in the tool window bar:

If the tool window bar is hidden, you can open any tool window by hovering over the corresponding icon in the bottom left corner:

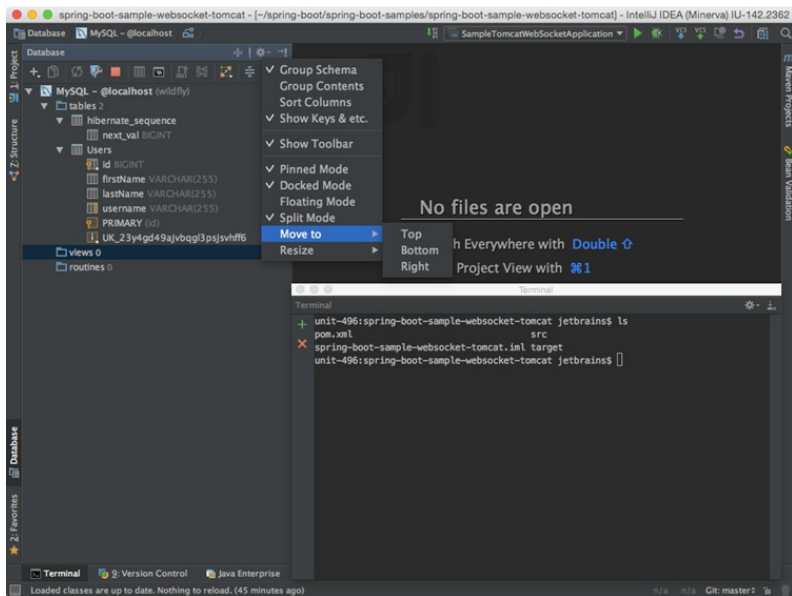

If you want to make the tool window bar visible for a moment, you can press **Alt** (**Cmd** for macOS) twice and hold it.

If you don't want to use the mouse, you can always switch to any toolbar by pressing the shortcut assigned to it. The most important shortcuts to remember are:

- Project : **Alt+1**
- Version Control : **Alt+9**
- Terminal : **Alt+F12**

Another thing about tool windows is that you can drag, pin, unpin, attach and detach them:

To help store/restore the tool windows layout, there are two useful commands:

- Window | Store Current Layout as Default
- Window | Restore Default Layout (also available via **Ctrl+F12**)

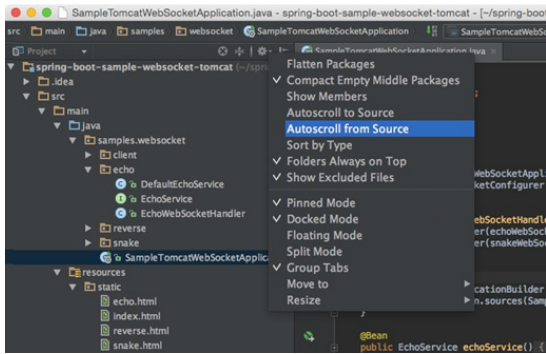

## Multiple windows

Windows management in IntelliJ IDEA is slightly different from Eclipse. You can't open several windows with one project, but you can detach any number of editor tabs into separate windows.

## Auto-scrolling to/from sources

By default, IntelliJ IDEA doesn't change the selection in the Project Tool Window when you switch between editor tabs.

However, you can enable it in the tool window settings:

## Enabling line numbers

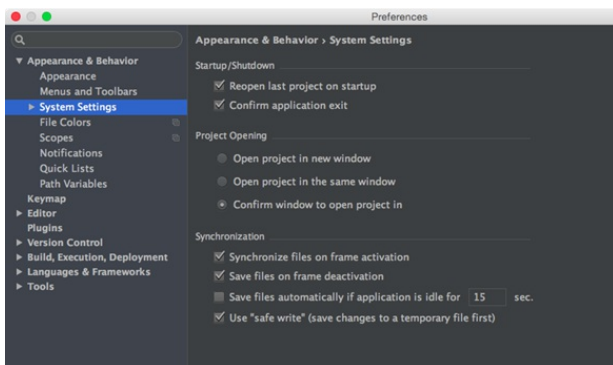

Line numbers are not shown in the editor by default. To enable them, go to Settings/Preferences | Editor | General | Appearance | Show line numbers . There you will also find other useful settings.

## General workflows

### No 'save' button

Time for some really shocking news: **IntelliJ IDEA** has no Save button. Since in **IntelliJ IDEA** you can undo refactorings and revert changes from [Local History](#) , it makes no sense to ask you to save your changes every time.

Still, it's worth knowing that physical saving to disk is triggered by certain events, including compilation, closing a file, switching focus out of the IDE, etc. You can change this behavior via Settings | Appearance & Behavior | System Settings :

### No save actions

One of the features you may miss in **IntelliJ IDEA** as an Eclipse user is save actions , i.e. the actions triggered automatically on save, such as reformatting code, organizing imports, adding missing annotations and the final modifier, etc. Instead, **IntelliJ IDEA** offers you to run the corresponding actions automatically on commit:

Or manually:

- Code | Reformat Code ( `Ctrl+Alt+L` )
- Code | Optimize Imports ( `Ctrl+Alt+O` )
- Analyze | Code Cleanup

If, for some reason, you can't live without an Eclipse save action, you can install a [plugin that imitates Eclipse save actions](#) .

## Compilation

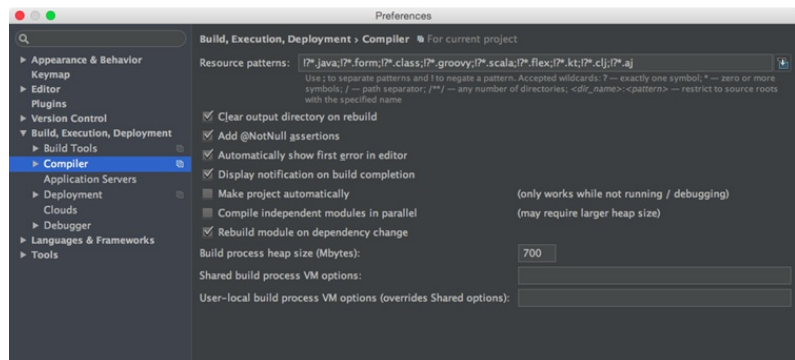

The way **IntelliJ IDEA** compiles projects is different from Eclipse in a number of ways.

### Auto-compilation

By default, **IntelliJ IDEA** doesn't automatically compile projects on saving because normally we don't invoke the **save** action explicitly in **IntelliJ IDEA** .

If you want to mimic the Eclipse behavior, you can invoke the Make Project action (`Ctrl+F9`) - it will save the changed files and compile them. For your convenience, you can even reassign the `Ctrl+S` shortcut to the Make Project action.

To enable automatic compilation, navigate to Settings/Preferences | Build, Execution, Deployment | Compiler and select the Make project automatically option:

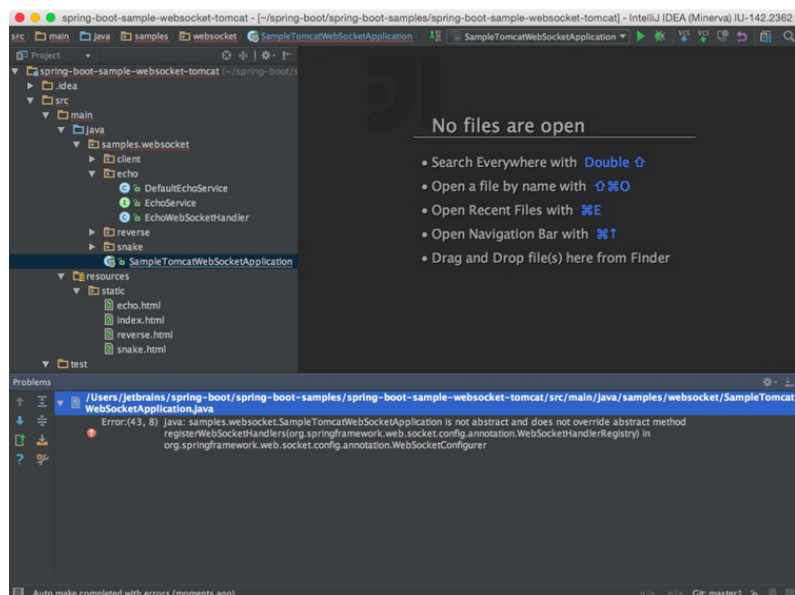

Note that automatic compilation in IntelliJ IDEA differs from that in Eclipse. In Eclipse it's not fully automatic, as it is triggered by the save action invoked by the user explicitly, whereas in IntelliJ IDEA it is invoked implicitly when you type in the editor.

This is why, even if the Make project automatically option is enabled, IntelliJ IDEA doesn't perform automatic compilation if at least one application is running: it will reload classes in the application implicitly. In this case you can call Build | Make Project (`Ctrl+F9`).

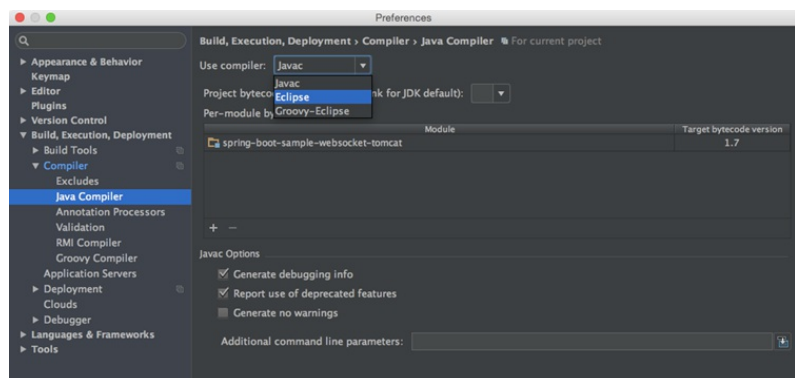

## Problems tool window

The Problems tool window appears if the Make project automatically option is enabled in the Compiler settings. It shows a list of problems that were detected on project compilation:

## Eclipse compiler

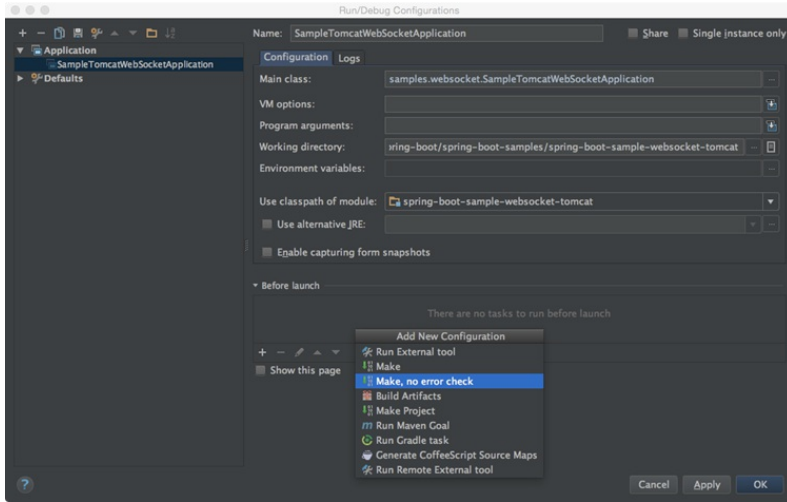

While Eclipse uses its own compiler, IntelliJ IDEA uses the javac compiler bundled with the project JDK. If you must use the Eclipse compiler, navigate to Settings/Preferences | Build, Execution, Deployment | Compiler | Java Compiler and select it as shown below:

The biggest difference between the Eclipse and javac compilers is that the Eclipse compiler is more tolerant to errors, and sometimes lets you run code that doesn't compile.

In situations when you need to run code with compilation errors in IntelliJ IDEA, replace the Make option in your run

configuration with Make, no error check :

## Shortcuts

IntelliJ IDEA shortcuts are completely different from those in Eclipse .

The table below shows how the top Eclipse actions (and their shortcuts) are mapped to IntelliJ IDEA (you may want to print it out to always have it handy).

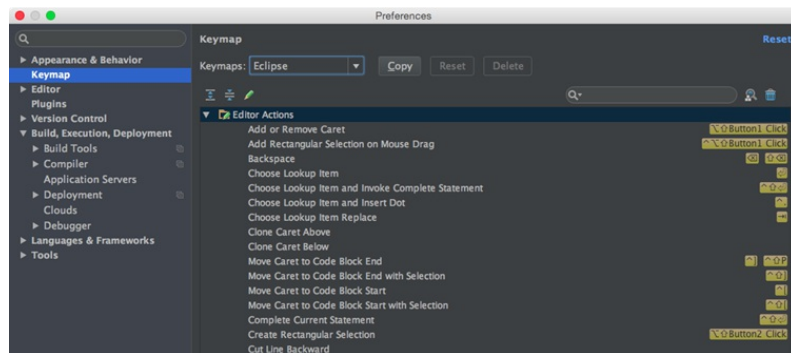

**Note** If you choose a keymap specific to your operating system ( Default for Windows/Linux or macOS 10.5+ for macOS), there may be conflicts between shortcuts used in IntelliJ IDEA and your OS. To avoid such conflicts, we recommend tweaking your OS shortcut settings (refer to [Keymap](#) for more details).

Eclipse	IntelliJ IDEA		
Action	Shortcut	Action	Shortcut
Code completion	Ctrl+Space	Basic completion	Ctrl+Space
-	-	Smart completion	Ctrl+Shift+Space
-	-	Statement completion	Ctrl+Shift+Enter
Quick access	Ctrl+3	Search everywhere	Shift x 2
Maximize active view or editor	Ctrl+M	Hide all tool windows	Ctrl+Shift+F12
Open type	Ctrl+Shift+T	Navigate to class	Ctrl+N
Open resource	Ctrl+Shift+R	Navigate to file	Ctrl+Shift+N
-	-	Navigate to symbol	Ctrl+Shift+Alt+N
Next view	Ctrl+F7	-	-
-	-	Recent files	Ctrl+E
-	-	Switcher	Ctrl+Tab
Quick outline	Ctrl+O	File structure	Ctrl+F12
Move lines	Alt+Up/Down	Move lines	Shift+Alt+Up / Shift+Alt+Down
Delete lines	Ctrl+D	Delete lines	Ctrl+Y
Quick fix	Ctrl+I	Show intention action	Alt+Enter
Quick switch editor	Ctrl+E	Switcher	Ctrl+Tab
-	-	Recent files	Ctrl+E
Quick hierarchy	Ctrl+T	Navigate to type hierarchy	Ctrl+H
-	-	Navigate to method hierarchy	Ctrl+Shift+H
-	-	Show UML popup	Ctrl+Alt+U
Last edit location	Ctrl+Q	Last edit location	Ctrl+Shift+Backspace
Next editor	Ctrl+F6	Select next tab	Alt+Right
Run	Ctrl+Shift+F11	Run	Shift+F10
Debug	Ctrl+F11	Debug	Shift+F9
Correct indentation	Ctrl+I	Auto-indent lines	Ctrl+Alt+I
Format	Ctrl+Shift+F	Reformat code	Ctrl+Alt+L

Surround with	Ctrl+Alt+Z	Surround with	Ctrl+Alt+T
-	-	Surround with live template	Ctrl+Alt+J
Open declaration	F3	Navigate to declaration	Ctrl+B
-	-	Quick definition	Ctrl+Shift+I
Open type hierarchy	F4	Navigate to type hierarchy	Ctrl+H
-	-	Show UML popup	Ctrl+Alt+U
References in workspace	Ctrl+Shift+G	Find usages	Alt+F7
-	-	Show usages	Ctrl+Alt+F7
-	-	Find usages settings	Ctrl+Shift+Alt+F7
Open search dialog	Ctrl+H	Find in path	Ctrl+Shift+F
Occurrences in file	Ctrl+Alt+U	Highlight usages in file	Ctrl+Shift+F7
Copy lines	Ctrl+Alt+Down	Duplicate lines	Ctrl+D
Extract local variable	Ctrl+Alt+L	Extract variable	Ctrl+Alt+V
Assign to field	Ctrl+2 / Ctrl+F	Extract field	Ctrl+Alt+F
Show refactor quick menu	Ctrl+Alt+T	Refactor this	Ctrl+Shift+Alt+T
Rename	Ctrl+Alt+R	Rename	Shift+F6
Go to line	Ctrl+L	Navigate to line	Ctrl+G
Structured selection	Shift+Alt+Up / Shift+Alt+Down	Select word at caret	Ctrl+W / Ctrl+Shift+W
Find next	Ctrl+J	Find next	F3
Show in	Ctrl+Alt+W	Select in	Alt+F1
Back	Ctrl+[	Back	Ctrl+Alt+Left
Forward	Ctrl+]	Forward	Ctrl+Alt+Right

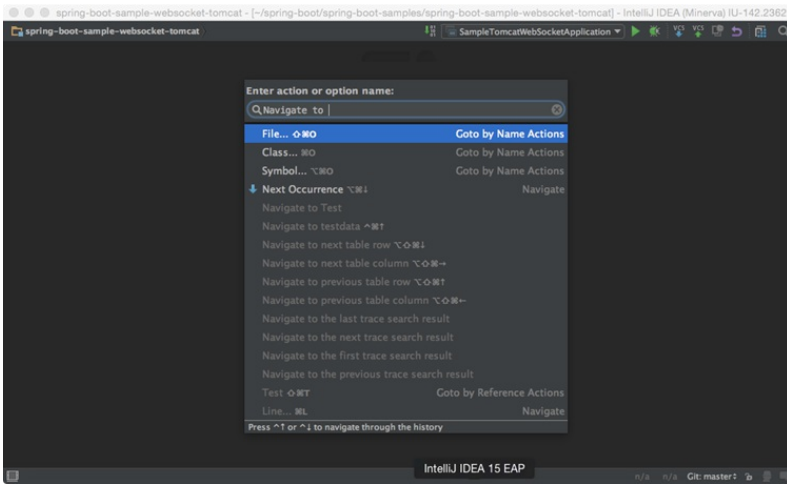

## Eclipse keymap

For **Eclipse** users who prefer not to learn new shortcuts, **IntelliJ IDEA** provides the **Eclipse** keymap which closely mimics its shortcuts:

## Find action

When you don't know the shortcut for some action, try using the Find action feature available via **Ctrl+Shift+A**. Start typing to find an action by its name, see its shortcut, or call it:

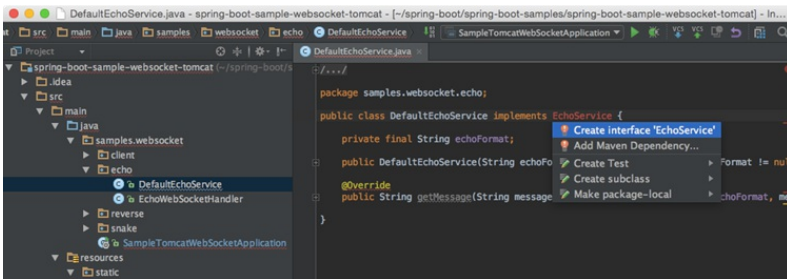

## Coding assistance

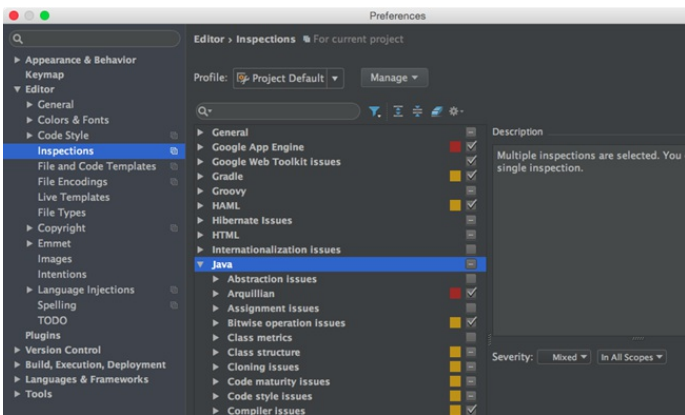

Both **Eclipse** and **IntelliJ IDEA** provide coding assistance features, such as code completion, code generation, quick-fixes, live templates, etc.

## Quick-fixes

To apply a quick-fix in **IntelliJ IDEA**, press `Alt+Enter`:

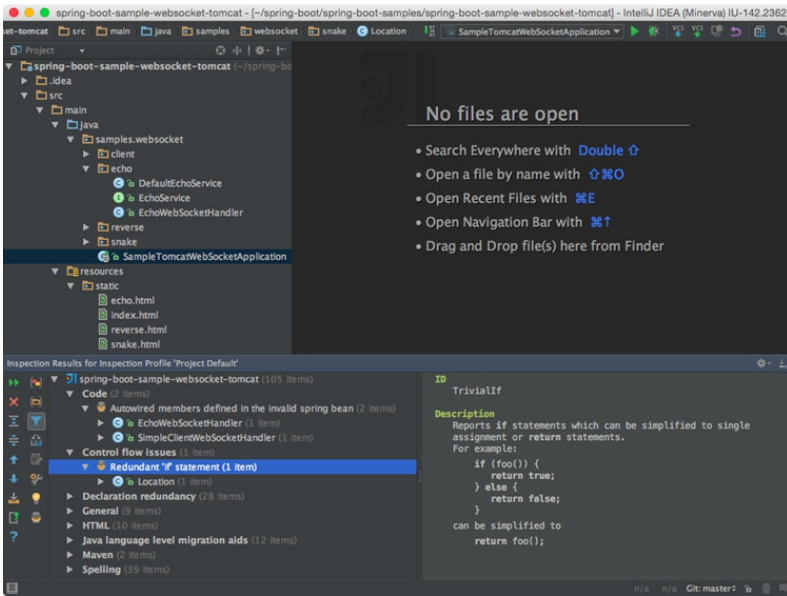

All quick-fixes are based on inspections configured in **Settings | Inspections**:

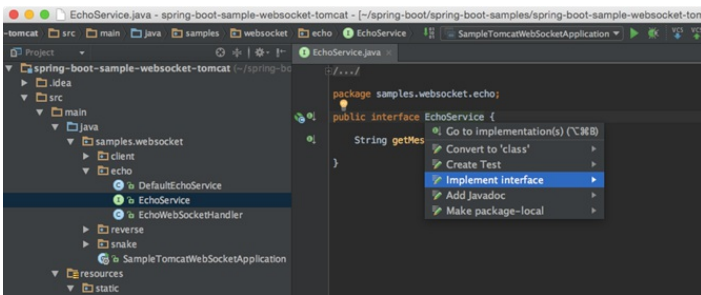

If you want to apply a quick-fix to several places at once (i.e. to a whole folder, module or even a project), you can do it by running the corresponding inspection via **Analyze | Run Inspection By Name** or by running the whole batch of inspections via **Analyze | Inspect Code**:

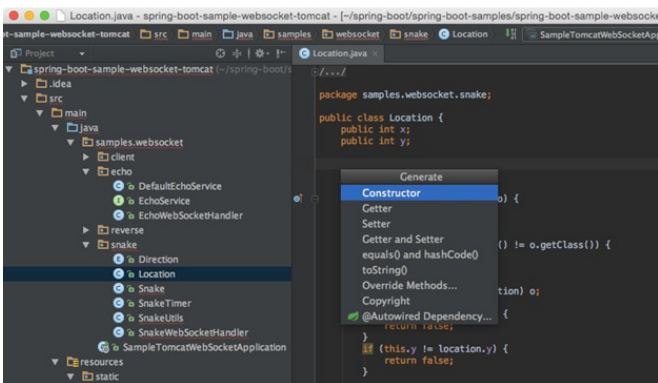

Apart from outright problems, IntelliJ IDEA also recognizes code constructs that can be improved or optimized via the so-called intentions (also available with **Alt+Enter**):

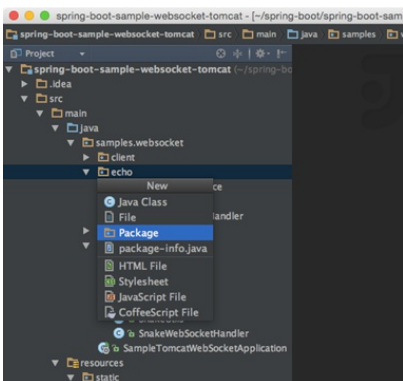

Eclipse	IntelliJ IDEA
Action	Shortcut      Action      Shortcut
Quick fix	<b>Ctrl+1</b> Show intention action <b>Alt+Enter</b>

## Generating code

The key action for generating code is Code | Generate, available via **Alt+Insert**:

This action is context-sensitive and is available not only within the editor, but also in the [Project Tool Window](#) and the [Navigation bar](#):

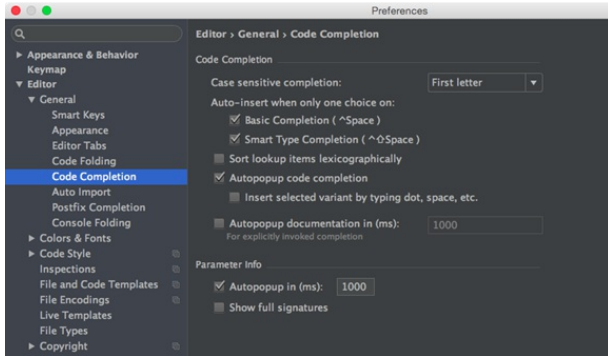

## Code completion

IntelliJ IDEA provides several different types of code completion, which include:

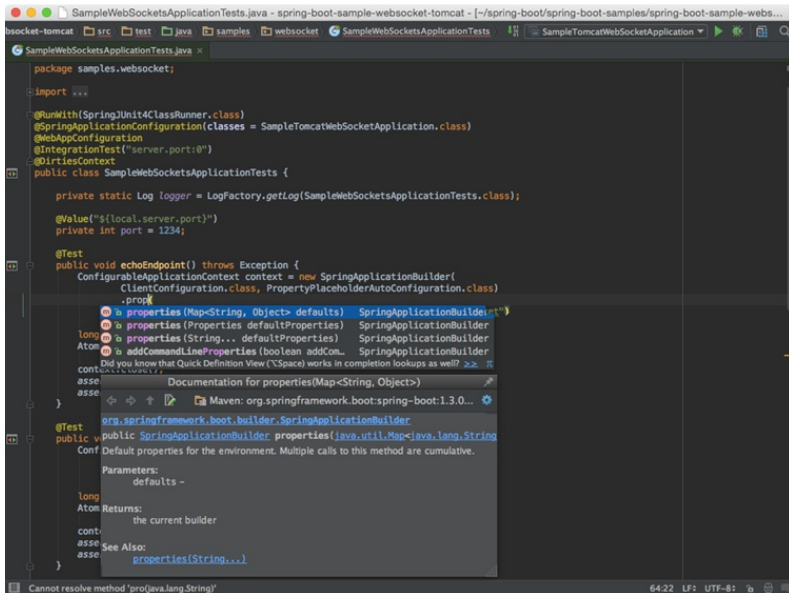

- Basic completion
- Second basic completion
- Smart completion
- Second smart completion
- Statement completion

To learn more about the differences between these completion types, refer to [Top 20 Features of Code Completion in IntelliJ IDEA](#).

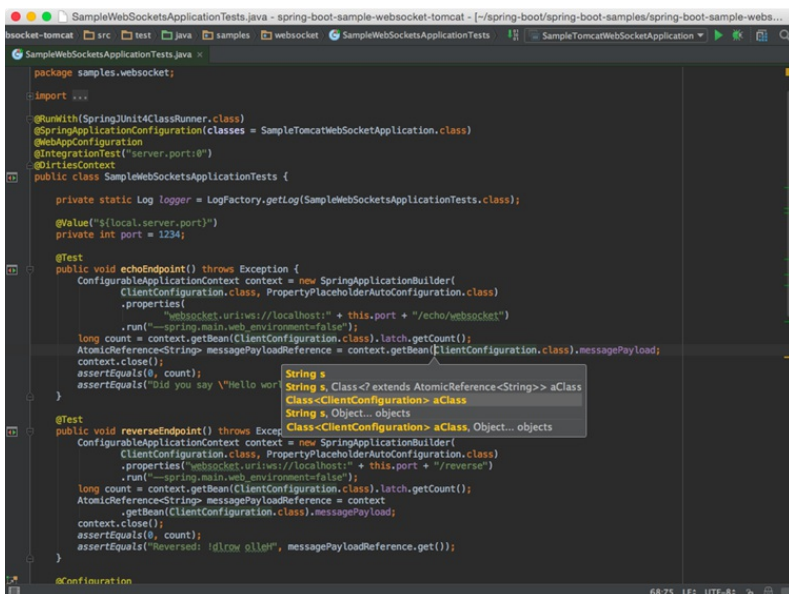

By default, IntelliJ IDEA doesn't show the Documentation popup for the selected item, but you can enable it in Settings/Preferences | Editor | Code Completion | Autopopup documentain in (ms) :

If you don't want to enable this option, you can manually invoke this popup by pressing **Ctrl+Q** when you need it:

When the caret is within the brackets of a method or a constructor, you can get the info about the parameters by calling Parameter Info with **Ctrl+P** :

Action	Shortcut	Action	Shortcut
Code completion	Ctrl+Space	Basic completion	Ctrl+Space
-	-	Smart completion	Ctrl+Shift+Space
-	-	Statement completion	Ctrl+Shift+Enter

## Templates

You may be used to typing `main` in the editor and then calling code completion to have it transformed into a main method definition. However, **IntelliJ IDEA** templates are a little different:

Template	Eclipse	IntelliJ IDEA
Define a main method		<code>main</code> <code>psvm</code>
Iterate over an array		<code>for</code> <code>itar</code>
Iterate over a collection		<code>for</code> <code>itco</code>
Iterate over a list		<code>for</code> <code>itli</code>
Iterate over an iterable using foreach syntax		<code>foreach</code> <code>iter</code>
Print to System.out		<code>sysout</code> <code>sout</code>
Print to System.err		<code>syserr</code> <code>serr</code>
Define a static field		<code>static_final</code> <code>psf</code>

The list of available templates can be found in Settings/Preferences | Editor | Live Templates . There you can also add your own templates or modify any existing ones.

While **IntelliJ IDEA** suggests templates in code completion results, you can quickly expand any template without using code completion simply by pressing `Tab` .

## Postfix templates

In addition to 'regular' templates, **IntelliJ IDEA** offers the so-called **postfix** templates. They are useful when you want to apply a template to an expression you've already typed. For instance, type a variable name, add `.ifn` and press `Tab` . **IntelliJ IDEA** will turn your expression into a `if (...!=null){...}` statement.

To see a complete list of available postfix templates, go to Settings/Preferences | Editor | General | Postfix Completion .

## Surround with live template

The **surround with** templates is another addition that works similarly to **live templates** but can be applied to the selected code with `Ctrl+Alt+J` .

To define your own **surround with** template, go to Settings/Preferences | Editor | General | Live Templates and use `$$SELECTION$` within the template text:

```

$LOCK$.readLock().lock();
try {
    $$SELECTION$
} finally {
    $LOCK$.readLock().unlock();
}

```

## Navigation

The table below roughly maps the navigation actions available in **Eclipse** with those in **IntelliJ IDEA** :

Eclipse	IntelliJ IDEA		
Action	Shortcut	Action	Shortcut
Quick access	Ctrl+3	Search everywhere	Shift x 2
Open type	Ctrl+Shift+T	Navigate to class	Ctrl+N
Open resource	Ctrl+Shift+R	Navigate to file	Ctrl+Shift+N
-	-	Navigate to symbol	Ctrl+Shift+Alt+N
Quick switch editor	Ctrl+E	Switcher	Ctrl+Tab
-	-	Recent files	Ctrl+E
Open declaration	F3	Navigate to declaration	Ctrl+B
Open type hierarchy	F4	Navigate to type hierarchy	Ctrl+H
-	-	Show UML popup	Ctrl+Alt+U
Quick outline	Ctrl+O	File structure	Ctrl+F12
Back	Ctrl+[	Back	Ctrl+Alt+Left

Forward Ctrl+]  Forward Ctrl+Alt+Right

Later, when you get used to these navigation options and need more, refer to [Top 20 Navigation Features in IntelliJ IDEA](#) .

## Refactorings

The following table maps the shortcuts for the most common refactorings in **Eclipse** with those in **IntelliJ IDEA** :

Eclipse		IntelliJ IDEA	
Action	Shortcut	Action	Shortcut
Extract local variable	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+L </span>	Extract variable	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+V </span>
Assign to field	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+2 </span>	Extract field	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+F </span>
Show refactor quick menu	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+T </span>	Rafactor this	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Shift+Alt+T </span>
Rename	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+R </span>	Rename	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Shift+F6 </span>

To learn more about many additional refactorings that **IntelliJ IDEA** offers, refer to [Top 20 Refactoring Features in IntelliJ IDEA](#)

## Undo

Sometimes, refactorings may affect a lot of files in a project. **IntelliJ IDEA** not only takes care of applying changes safely, but also lets you revert them. To undo the last refactoring, switch the focus to the [Project Tool Window](#) and press Ctrl+Z  .

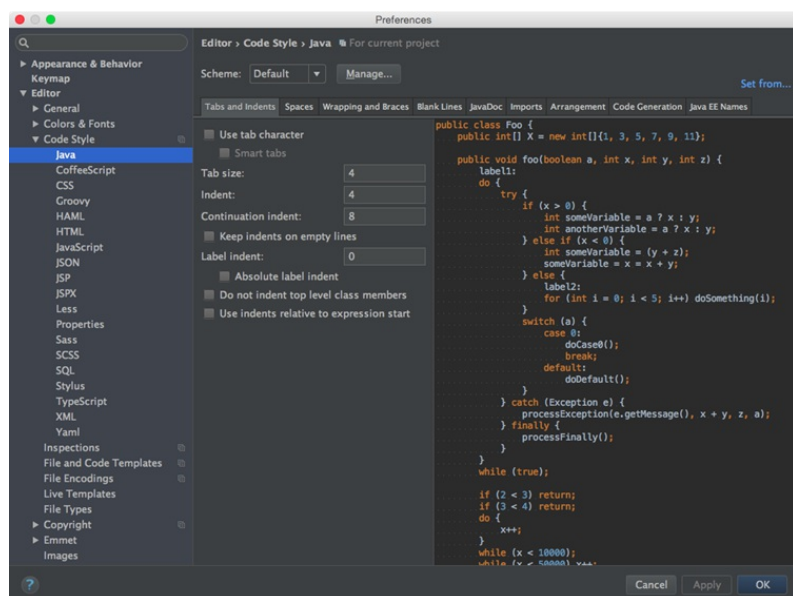

## Search

Below is a map of the most common search actions and shortcuts:

Eclipse		IntelliJ IDEA	
Action	Shortcut	Action	Shortcut
Open search dialog	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+H </span>	Find in path	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Shift+F </span>
References in workspace	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Shift+G </span>	Find usages	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Alt+F7 </span>
-	-	Show usages	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+F7 </span>
-	-	Find usages settings	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Shift+Alt+F7 </span>
Occurrences in file	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+Alt+U </span>	Highlight usages in file	<span style="border: 1px solid gray; border-radius: 10px; padding: 2px 5px;">Ctrl+F7 </span>

## Code formatting

**IntelliJ IDEA** code formatting rules (available via Settings/Preferences | Editor | Code Style ) are similar to those in **Eclipse** , with some minor differences. You may want to take note of the fact that the Using the Tab char option is disabled by default, the Indent size may be different, etc.

If you would like to import your **Eclipse** formatter settings, go to Settings/Preferences | Editor | Code Style | Java , click **Manage** , click **Import** and select the exported **Eclipse** formatter settings (an XML file).

**Tip** Note that if the Eclipse formatter settings cannot be imported, the following error message shows up:

The input file is not a valid Eclipse XML profile.

Note that there may be some discrepancies between the code style settings in **IntelliJ IDEA** and **Eclipse** . For example, you cannot tell **IntelliJ IDEA** to put space after (but not before). If you want **IntelliJ IDEA** to use the **Eclipse** formatter, consider installing the [Eclipse code formatter plugin](#) .

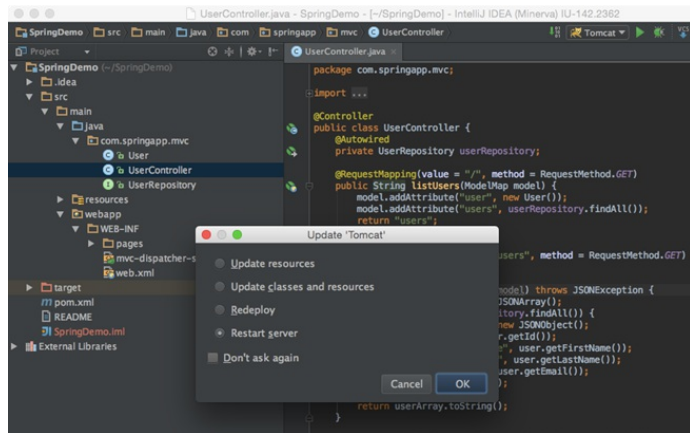

Eclipse	IntelliJ IDEA		
Action	Shortcut	Action	Shortcut
Format	<b>Ctrl+Shift+F</b>	Reformat code	<b>Ctrl+Alt+L</b>

## Running and reloading changes

Similarly to **Eclipse** , **IntelliJ IDEA** also has **Run/Debug Configurations Dialog** that you can access either from the main toolbar, or the main menu. Compare the related shortcuts:

Eclipse	IntelliJ IDEA		
Action	Shortcut	Action	Shortcut
Run	<b>Ctrl+Shift+F11</b>	Run	<b>Shift+F10</b>
Debug	<b>Ctrl+F11</b>	Debug	<b>Shift+F9</b>
-	-	Make	<b>Ctrl+F9</b>
-	-	Update application	<b>Ctrl+F10</b>

As mentioned before, by default **IntelliJ IDEA** doesn't compile changed files automatically (unless you configure it to do so). That means the IDE doesn't reload changes automatically. To reload changed classes, call the **Make** action explicitly via **Ctrl+F9** . If your application is running on a server, in addition to reloading you can use the **Update application** action via **Ctrl+F10** :

## Debugging

The debuggers in **Eclipse** and **IntelliJ IDEA** are similar but use different shortcuts:

Eclipse	IntelliJ IDEA		
Action	Shortcut	Action	Shortcut
Step into	<b>F5</b>	Step into	<b>F7</b>
-	-	Smart step into	<b>Shift+F7</b>
Step over	<b>F6</b>	Step over	<b>F8</b>
Step out	<b>F7</b>	Step out	<b>Shift+F8</b>
Resume	<b>F8</b>	Resume	<b>F9</b>
Toggle breakpoint	<b>Ctrl+Shift+B</b>	Toggle breakpoint	<b>Ctrl+F8</b>
-	-	Evaluate expression	<b>Alt+F8</b>

## Working with Application Servers (Tomcat/TomEE, JBoss EAP, Glassfish, WebLogic, WebSphere)

This feature is only supported in the Ultimate edition.

Deploying to application servers in **IntelliJ IDEA** is more or less similar to what you are probably used to in **Eclipse** . To deploy your application to a server:

Configure your **artifacts** via **Project Structure | Artifacts** (done automatically for **Maven** and **Gradle** projects)

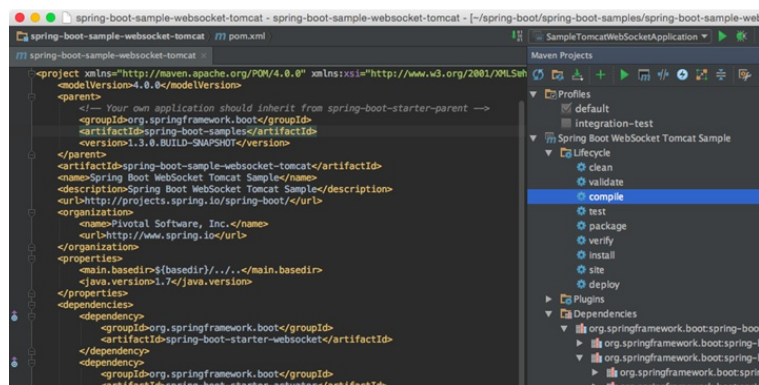

1. Configure your **artifacts** via Project Structure | Artifacts (done automatically for **Maven** and **Gradle** projects).
2. Configure an application server via Settings | Application Servers .
3. Create a **run configuration** , and then specify the artifacts to deploy and the server to deploy to.

You can always tell the IDE to build/rebuild your artifacts once they have been configured via Build | Build Artifacts .

## Working with Build Tools (Maven/Gradle)

IntelliJ IDEA doesn't provide visual forms for editing **Maven/Gradle** configuration files. Once you've imported/created your **Maven/Gradle** project, you are free to edit its `pom.xml/build.gradle` files directly in the editor. Later, you can tell IntelliJ IDEA to **synchronize the project model** with the changed files on demand, or **automatically import changes** to the new build files. Any changes to the underlying build configuration will eventually need to be synced with the project model in IntelliJ IDEA .

For operations specific to **Maven/Gradle** , IntelliJ IDEA provides the **Maven Project tool window** and the **Gradle tool window** . Apart from your project structure, these tool windows provide a list of **goals/tasks** plus a toolbar with the relevant actions.

If you want the IDE to synchronize your changes immediately:

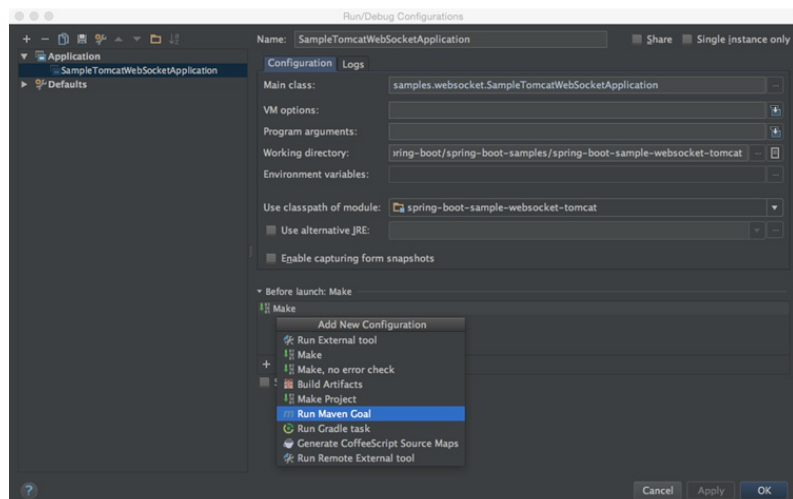

- For `pom.xml` , enable the corresponding options in Settings | Build, Execution, Deployment | Build Tools | Maven | Importing | Import Maven projects automatically
- For `build.gradle` , enable the corresponding option in Settings | Build, Execution, Deployment | Build Tools | Gradle | Use auto-import .

For manual synchronization, use the corresponding action on the **Maven/Gradle** tool window toolbar:  .

## Running goals/tasks

Use the Maven/Gradle tool window to run any project **goal/task** . When you do, IntelliJ IDEA creates the corresponding run configuration which you can reuse later to run the **goal/task** quickly.

It's worth mentioning that any **goal/task** can be attached to be run before a **Run Configuration** . This may be useful when your **goal/task** generates specific files needed by the application.

Both the **Maven** and **Gradle** tool windows provide the **Run Task** action. It runs a **Maven/Gradle** command similarly to how you'd run it using the console.

## Configuring artifacts

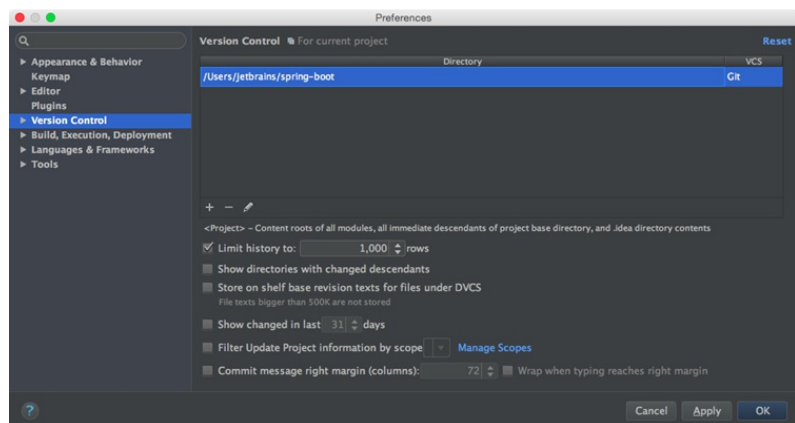

If you have **WAR** artifacts configured in your `pom.xml/build.gradle` file, IntelliJ IDEA automatically configures the corresponding artifacts in Project Structure | Artifacts .

Note that when you compile your project or build an artifact, IntelliJ IDEA uses its own build process which may be faster, but is not guaranteed to be 100% accurate. If you notice inconsistent results when compiling your project with **Make** in IntelliJ IDEA , try using a **Maven goal** or a **Gradle task** instead.

## Working with VCS (Git, Mercurial, Subversion, Perforce)

### Configuring VCS roots

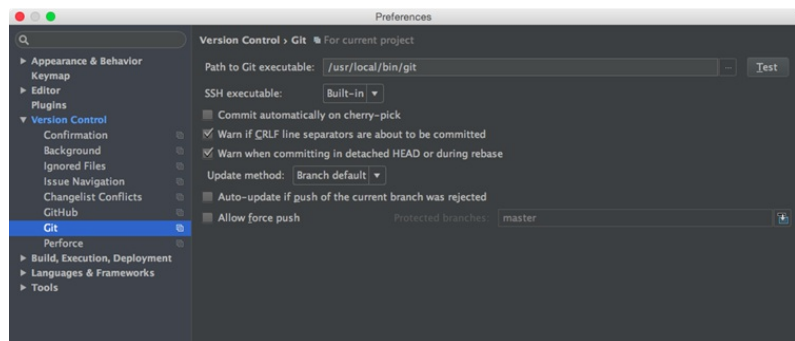

When you open a project located under a VCS root, **IntelliJ IDEA** automatically detects it and suggests adding this root to the project settings. To change version control-related project settings (or manually add a VCS root), go to Settings | Version Control :

**IntelliJ IDEA** works perfectly with multi-repository projects. Just map your project directories to VCS, and the IDE will take care of the rest. For **Git** and **Mercurial**, the IDE will even offer you synchronized branch control, so that you can perform branch operations on multiple repositories simultaneously (for more details, see [Using Git integration](#)).

### Editing VCS settings

Every VCS may require specific settings, for example, Path to Git executable, GitHub/Perforce credentials, etc.:

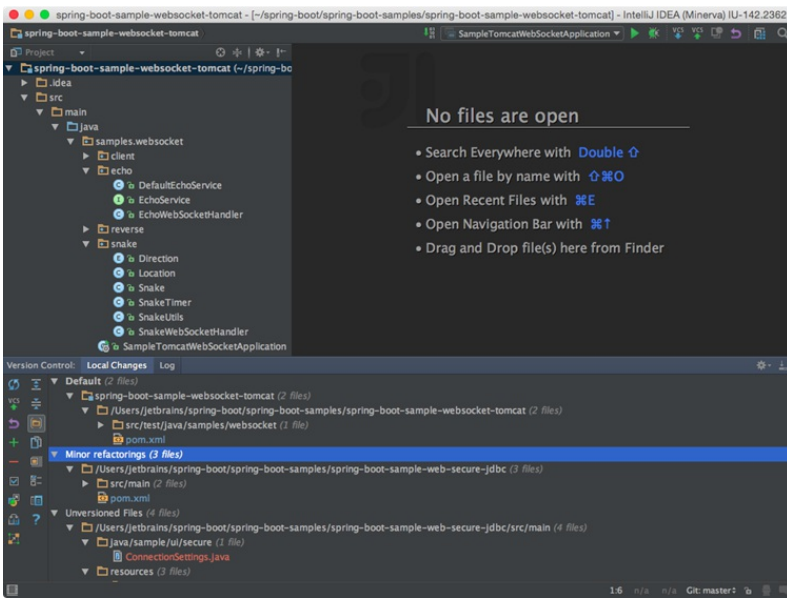

Once you've configured the VCS settings, you'll see the **Version Control tool window**. You can invoke it any time by pressing **Alt+9**.

### Checking projects out

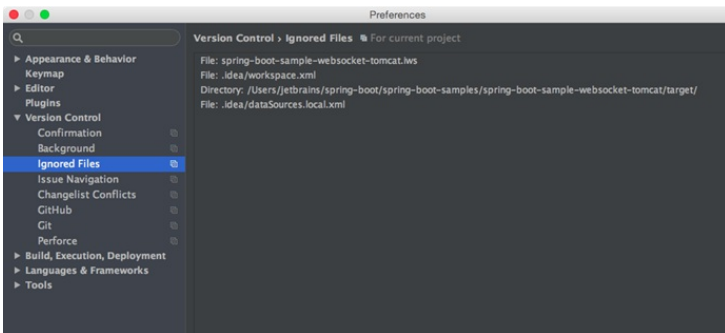

To check out a project from a VCS, click Checkout from Version Control on the **Welcome Screen**, or in the main VCS menu.

### Working with local changes

The **Local Changes** tab of the **Version Control tool window** shows your local changes: both **staged** and **unstaged**. To simplify managing changes, all changes are organized into **changelists**. Any changes made to source files are automatically included into the active changelist. You can create new changelists, delete the existing ones (except for the Default changelist), and move files between changelists.

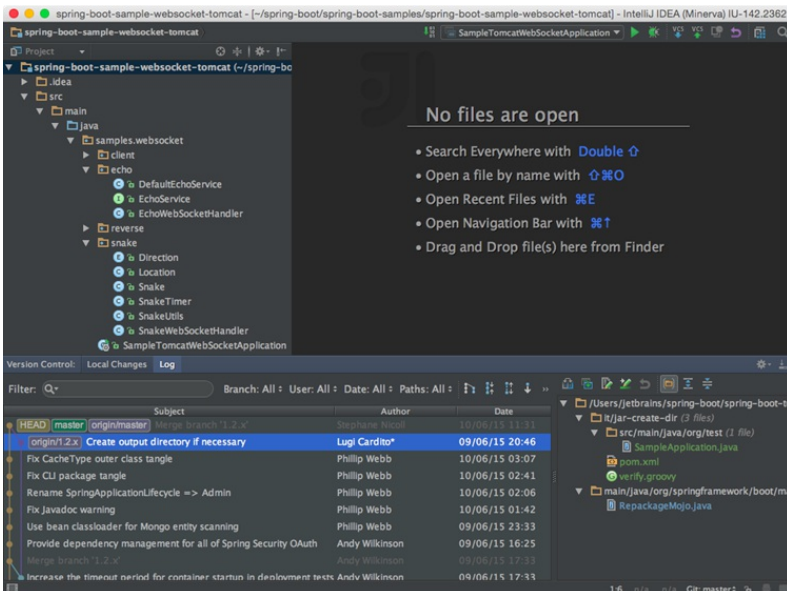

To configure ignored files , go to Settings | Version Control , or use the corresponding button in the Version Control tool window.

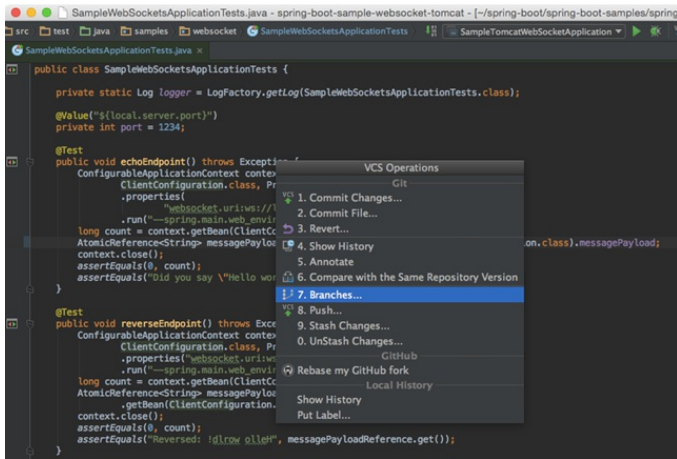

## Working with history

The **Log** tab of the **Version Control tool window** lets you see and search through the history of commits. You can sort and filter commits by the repository, branch, user, date, folder, or even a phrase in the description. You can find a particular commit, or just browse through the history and the branch tree:

## Working with branches

IntelliJ IDEA lets you create, switch, merge, compare and delete branches. For these operations, either use Branches from the main or context VCS menu, or the VCS operations popup (you can invoke it by pressing `Alt+Back Quote`), or the widget on the right of the status bar:

All VCS operations are available from the VCS main menu:

Action	Shortcut
Version Control tool window	Alt+9
VCS operations popup	Alt+Back Quote
Commit changes	Ctrl+K
Update project	Ctrl+T
Push commits	Ctrl+Shift+K

## Importing an Eclipse project to IntelliJ IDEA

Despite these differences in terms and the UI, you can import either an **Eclipse** workspace or a single **Eclipse** project. To do this, click **Import Project** on the Welcome Screen, or select **File | New | Project from Existing Sources** in the main menu.

If your project uses a build tool such as [Maven](#) or [Gradle](#), we recommend choosing the corresponding option when prompted in the **Import Project** wizard, and selecting the associated build file (`pom.xml` or `build.gradle`):

If you'd like to import your existing run configurations from **Eclipse**, consider using this [third-party plugin](#).

On this page:

- [Overview](#)
- [Exporting to Eclipse](#)
- [Converting an IntelliJ IDEA module to the Eclipse-compatible format](#)

## Overview

You can export an IntelliJ IDEA project to Eclipse. Such export results in creating Eclipse project files ( `.project` and `.classpath` ) for each module file ( `*.iml` ) in the module directory that contains the content root. Another way to export an IntelliJ IDEA module to an Eclipse project is converting such module to an Eclipse-compatible format.

Before you start exporting a project, make sure that the Eclipse Integration plugin is [enabled](#) .

## Exporting to Eclipse

### To export the currently open project to Eclipse, follow these steps:

1. On the main menu, choose File | Export to Eclipse . The Export to Eclipse dialog displays the list of modules that have not been converted and switched to use the Eclipse format yet (the modules that have the IntelliJ IDEA module format `.iml` ).
2. Select the modules you want to export.
3. Select the suggested [options](#) if necessary.
4. Click OK .

**Note** At present, migration from IntelliJ IDEA to Eclipse is subject to certain limitations:

- IntelliJ IDEAModules with multiple content roots cannot not be migrated.
- External sources in Eclipse are not migrated.
- Only Java modules are created automatically during the export. However, any module can be converted to the Eclipse compatible format manually.
- The default workspace JRE is not converted to/from the project SDK.

## Converting an IntelliJ IDEA module to the Eclipse-compatible format

### To convert an IntelliJ IDEA module to the Eclipse-compatible format, follow these steps:

1. On the main menu, choose File | Project Structure , or press `Ctrl+Shift+Alt+S` .
2. In the [Project Structure Dialog](#) dialog, select the module you want to convert.
3. Switch to the [Dependencies Tab](#) tab.
4. From the Dependencies storage format drop-down list, select Eclipse (`.classpath`) .

NetBeans users ask the following question about IntelliJ IDEA most frequently:

#### – ABOUT PROJECTS

- [How do I open a NetBeans project in IntelliJ IDEA?](#)

- [Is it possible to build NetBeans RCP applications with IntelliJ IDEA?](#)

## ABOUT PROJECTS

### How do I open a NetBeans project in IntelliJ IDEA?

Use File | New | Project from Existing Sources and select your NetBeans project directory.

When the Import Project wizard opens, select the Create project from existing sources option and then follow the instructions of the wizard.

IntelliJ IDEA will add the necessary definition files (the `.idea` directory) to your project directory. The NetBeans `.nbproject` directory and `build.xml` will remain untouched, and you'll be able to use IntelliJ IDEA along with NetBeans.

During the import IntelliJ IDEA will fix missing libraries, add facets for different Web frameworks and create a run configuration.

If you are using Maven with NetBeans and you want to import a Maven project into IntelliJ IDEA, select File | Open and then select your project's `pom.xml`. You'll still need to configure a run configuration, however, all project dependencies will get resolved.

### What's the difference between projects and modules?

IntelliJ IDEA creates a project for an entire code base and a module for each of its individual components. So, IntelliJ IDEA module is more like a NetBeans project.

The following table maps the most important NetBeans concepts to IntelliJ IDEA ones.

#### NetBeansIntelliJ IDEA

Project	Module
Global library	Global library
Project library	Module library
Project dependency	Module dependency

### Is there a directory-based project format in IntelliJ IDEA?

Yes, there is a `.idea` directory where project definition XML files are stored. For more information, see [Configuring projects](#).

### How do I change the JDK for my project?

1. Open the Project Structure dialog ( File | Project Structure or `Ctrl+Shift+Alt+S` ).
2. Under Platform Settings , select SDKs .
3. Click `+` , select JDK and specify the JDK installation directory.
4. Click Apply .

5. Under Project Settings , select Project .
6. Under Project SDK , select the JDK from the list.
7. Click OK .

For more information, see [Configuring projects](#) .

## How do I add a library to my project?

1. Open the Project Structure dialog ( File | Project Structure or `Ctrl+Shift+Alt+S` ).
2. Under Project Settings , select Libraries .
3. Click `+` , select Java and specify the library location.
4. Select the modules in which this library will be used.
5. Click OK .

For more information, see [Working with libraries](#) .

## How do I configure a Web framework for my project?

In IntelliJ IDEA Ultimate (there's no corresponding functionality in the Community Edition):

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the necessary module and select Add Framework Support . (Framework support is enabled at a module level.)
3. In the Add Frameworks Support dialog that opens, select the frameworks to be supported, specify the associated settings and click OK .

For more information, see [Add Frameworks Support dialog](#) and e.g. [Enabling JSF support for an existing module](#) .

## The Run button is disabled. How do I run my application?

The Run button is disabled because there are no [run configurations](#) in your project.

If you have a Java class with a `main()` method, open the corresponding file in the editor, right-click the editing area and select Run ^<FileName>.main() . As a result, the necessary run configuration will be created automatically and then executed.

You can also create run configurations yourself: e.g. Run | Edit Configurations | `+` , etc.

## How do I generate an Ant build script for my project?

Select Build | Generate Ant Build . For more information, see [Generating Ant Build File](#) .

## Where is the Options dialog?

In IntelliJ IDEA, the Settings dialog is used for similar purposes. To open this dialog, press `Ctrl+Alt+S` .

There is also the Project Structure dialog ( `Ctrl+Shift+Alt+S` ) which lets you manage JDKs, libraries, module dependencies, etc.

For more information, see [Settings / Preferences Dialog](#) and [Project Structure Dialog](#) .

## How do I close a project?

Select File | Close Project . You can also use File | Exit to close all open projects and quit IntelliJ IDEA.

## ABOUT THE EDITOR

### Can I use the NetBeans key bindings in IntelliJ IDEA?

Yes, you can.

1. Open the Settings dialog (e.g. `Ctrl+Alt+S` ).
2. In the Appearance and Behavior category, select Keymap .
3. In the right-hand part of the dialog, next to Keymaps , select NetBeans 6.5 from the list.
4. Click OK .

### How does code completion in IntelliJ IDEA work?

The code completion suggestion list appears automatically after you type one or two letters. To narrow down this list, use:

- `Ctrl+Space` . The list is reduced to keywords and also the names of classes, methods and fields available in the current context. Note that the list changes when you press `Ctrl+Space` for the second or third time.
- `Ctrl+Shift+Space` . Only the types appropriate for the current context are shown.

For more information, see [Auto-Completing Code](#) .

### Is local history in IntelliJ IDEA any different from that in NetBeans?

Local history in IntelliJ IDEA, generally, is more detailed. Whatever you do with a directory, file, class, method or field, or a code block is reflected in your local history. The local history also includes VCS operations.

For more information, see [Using Local History](#) .

## Are there any special code analysis features in IntelliJ IDEA?

IntelliJ IDEA can analyze dependencies, data flows and stacktraces, find duplicates and evaluate code quality. Just have a look at the options in the Analyze menu.

For more information, see [Analyzing applications](#) and [Code Inspection](#).

## Can I enable 'mark occurrences' in IntelliJ IDEA?

You can. The corresponding option in IntelliJ IDEA is called Highlight usages of element at caret . This option is enabled by default.

Just in case:

1. Open the Settings dialog (e.g. `Ctrl+Alt+S` ).
2. In the Editor category, select General .
3. In the right-hand part of the dialog, under Highlight on Caret Movement , select the Highlight usages of element at caret checkbox.
4. Click OK .

See also, [Highlighting Usages](#) .

## Can I enable 'compile on save' in IntelliJ IDEA?

You can.

To enable automatic compilation on every save (or autosave), turn on the Make project automatically option in the Settings dialog:

1. Open the Settings dialog (e.g. `Ctrl+Alt+S` ).
2. In the Build, Execution, Deployment category, select Compiler .
3. In the right-hand part of the dialog, select the Make project automatically checkbox.
4. Click OK .

Also note that by default, IntelliJ IDEA saves changed files automatically, so you don't need to use `Ctrl+S` as frequently as in other IDEs.

## Can I enable 'deploy on save' in IntelliJ IDEA?

There is no such option in IntelliJ IDEA settings, however, you can get similar result by choosing an appropriate application update option in the corresponding run configuration.

For more information, see [Updating Applications on Application Servers](#) .

(The corresponding functionality is available only in IntelliJ IDEA Ultimate. The Community Edition doesn't provide integration with application servers.)

## ABOUT PLUGINS

### Can I use NetBeans plugins in IntelliJ IDEA?

Unfortunately not. However, a lot of functionality implemented as plugins for NetBeans is available in IntelliJ IDEA "out of the box". Besides, there's a lot of plugins for IntelliJ IDEA, so you can always find an IntelliJ IDEA plugin with the functionality similar to that of your favorite NetBeans plugin.

### How do I find the plugin that I need?

All the functions related to working with plugins are on the Plugins page of the Settings dialog (`Ctrl+Alt+S` | Plugins ).

You can look for, download, install and update the plugins as well as enable and disable them.

For more information, see [Plugins settings](#) and [Managing Plugins](#) .

### How do I install the plugin that I have available on my computer?

1. Open the Settings dialog (e.g. `Ctrl+Alt+S` ).
2. In the left-hand pane, select Plugins .
3. In the lower part of the Plugins page, click Install plugin from disk .
4. In the dialog that opens, select the plugin file (normally, a JAR or ZIP).
5. Click OK .
6. If asked, restart IntelliJ IDEA.

### I'd like to write a plugin for IntelliJ IDEA. Are there any instructions?

Yes, have a look at:

- [Plugin Development Guidelines](#)
- Information for Plugin Developers on the [IntelliJ IDEA Plugins page](#)
- [Open API and Plugin Development](#)

### Is it possible to build NetBeans RCP applications with IntelliJ IDEA?

It is possible, however you won't get the same kind of support you would in the case of NetBeans (wizards, menu actions, etc.). Have a look at [Using IntelliJ IDEA for NetBeans Platform Development](#) .

NetBeans and IntelliJ IDEA use different names for similar entities. It is important to understand the difference between the terminologies of both IDEs. In this section you can find a table of mappings between the NetBeans and IntelliJ IDEA terms.

**NetBeans**   **IntelliJ IDEA**

Project	Module
Project-specific JDK	Module SDK
Global library	Global library
Project library	Module library
Project dependency	Module dependency

This part provides descriptions of the actions required to fulfil certain tasks using the frameworks integrated into IntelliJ

- [Running and Debugging ActionScript and Flex Applications](#)
- [Packaging AIR Applications](#)
- [Importing Adobe Flash Builder Projects](#)
- [Testing ActionScript and Flex Applications](#)
- [ActionScript-Specific Refactorings](#)

## Basics

To support [ActionScript](#) and [Flex](#), IntelliJ IDEA provides:

- The Flash/Flex Support [plugin](#). This plugin is bundled with the IDE and must be enabled.
- A dedicated [module](#) type (Flash).
- [Build configurations](#) for the various target platforms (Web, Desktop and Mobile) and output types (SWF and SWC).
- Dedicated [run/debug configuration](#) types (Flash App, FlexUnit and Flash Remote Debug).
- The ActionScript Profiler and Flash UI Designer plugins. These plugins are available for download from the JetBrains repository. For more information, see [Profiling CPU in Flash and Flex Applications](#). See also, [Installing, Updating and Uninstalling Repository Plugins](#).

## ActionScript and Flex support

ActionScript and Flex support includes:

- [Code completion](#), including [completion of statements](#) ([Ctrl+Shift+Enter](#)) and [Smart Type completion](#) ([Ctrl+Shift+Space](#)).
- Error and syntax highlighting.
- ActionScript and Flex code [refactorings](#):
  - [Change Method Signature](#).
  - [Delegate Methods](#).
  - [Extract Interface](#).
  - [Extract Method](#).
  - [Extract Superclass](#).
  - [Inline](#).
  - [Introduce Constant](#).
  - [Introduce Field](#).
  - [Extract Parameter](#).
  - [Introduce Variable](#).
  - [Move a class or an interface to a package](#).
  - [Move Inner to Upper Level](#) for moving classes, functions, variables, constants and namespaces declared outside of packages into a package.
  - [Move/Copy](#) a file.
  - [Move Static Members](#).
  - [Pull Members Up](#), [Push Members Down](#).
  - [Rename](#) a file, function, variable, parameter, property or label (both directly and via references).
  - [Safe Delete](#) a file.
- ActionScript and Flex code [inspections](#) and [quick-fixes](#).
- [Intention Actions](#) for creating various application elements.
- Code [formatting](#) and [folding](#).
- Advanced [Search](#) and [Navigation](#), plus [Structure View](#).
- Enhanced [navigation](#) with gutter icons.
- Navigation from CSS properties and selectors to their declarations in ActionScript ([Ctrl+B](#)).
- Possibility to build ActionScript and Flex applications using various compiler shells and [compilation options](#).
- Support for breakpoints and specific [run/debug configurations](#) for debugging ActionScript and Flex applications directly from IntelliJ IDEA.
- ActionScript and Flex-aware [debugger](#) that lets you execute applications step by step, evaluate expressions, examine related information and find runtime bugs.

- [Quick Javadoc](#) ([Ctrl+Q](#)) for AsDoc.
- BlazeDS support.
- AIR application development support at all stages of application development cycle. Development of AIR applications for mobile devices is also supported. For basic how-to information, see [New in IntelliJ IDEA 10.5: Develop Mobile AIR Applications for Android](#).
- Possibility to create pure ActionScript applications.
- ActionScript [live templates](#): File | Settings | Live Templates | ActionScript and JavaScript groups.
- Ability to wrap and unwrap code constructs in ActionScript and MXML ([Ctrl+Alt+T](#)) and ([Ctrl+Shift+Delete](#)).
- Type Hierarchy ([Ctrl+H](#)), Method Hierarchy ([Ctrl+Shift+H](#)) and Call Hierarchy ([Ctrl+Alt+H](#)) for Flex sources ([\\*.mxml](#) and [\\*.as](#) files).
- Easy [import of Flex projects created in Adobe Flash Builder](#).
- Import of [Flexmojos](#) projects. See the description of [related import setting](#).
- ActionScript and Flex [UML class diagrams](#). Among the features is the ability to [view changes](#) in ActionScript source files in a structured visual form.

## FlexUnit support

IntelliJ IDEA supports the versions 0.9 and 4 of [FlexUnit](#), a unit testing framework for Flex and ActionScript applications and libraries.

FlexUnit support includes:

- Dedicated [FlexUnit run/debug configurations](#) to run a single test method, test suite, all methods in a certain test class, or all test classes in a given package.
- Ability to perform the tests both in the run and the debug modes.
- Support for FlexUnit tests via FlexUnit 4 test runner.
- FlexUnit-aware code inspections (turned off by default).

This feature is only supported in the Ultimate edition.

In this section:

- [Preliminary steps](#)
- [Registering a Flex or AIR SDK in IntelliJ IDEA](#)
- [Configuring general Flex compiler settings](#)
- [Creating a Flash module](#)
- [Configuring module contents](#)

## Preliminary steps

To prepare for ActionScript or Flex application development:

1. Make sure that the **Flash/Flex Support** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .
2. Download and install a Flex or AIR SDK on your computer. IntelliJ IDEA provides integration with [Apache Flex](#) , [Adobe Flex](#) , [Adobe AIR](#) and [Adobe Gaming SDKs](#) .
3. [Register the Flex or AIR SDK](#) in IntelliJ IDEA. (You can postpone this step until a later time. You will be able to specify the SDK when [creating a Flash module](#) .)
4. [Check general Flex compiler settings](#) and, if necessary, adjust them to your needs.
5. Create a new project with a Flash module, or add a Flash module to an existing project. See [Creating a Flash module](#) . Note that you can create a project or a module by [importing Adobe Flash Builder projects](#) .
6. Check the initial module configuration and make the necessary adjustments. These may include [configuring the module contents](#) , [adding libraries](#) , modifying the existing [build configuration](#) and creating additional ones, etc. All these tasks, however, may be performed at a later time, when needed, in parallel with [developing your source code](#) .

## Registering a Flex or AIR SDK in IntelliJ IDEA

### To register a Flex or AIR SDK in IntelliJ IDEA

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Under Platform Settings , click SDKs .
3. Click Add New SDK  on the toolbar, and then click  Flex/AIR SDK in the Add New SDK list.
4. In the [dialog that opens](#) , select the directory in which the Flex or AIR SDK is installed and click OK . As a result, the SDK configuration is shown on the [SDK page](#) in the right-hand part of the Project Structure dialog.
5. Generally, you don't need to make any changes on the Classpath and Sourcepath tabs because all the necessary libraries and sources are already there. However, you may want to add external online documentation to be able to access additional reference information when writing your code. To do that: On the Documentation Paths tab, click  . In the dialog that opens, just click OK . (The URL suggested by IntelliJ IDEA is the one you want.)
6. Click OK in the Project Structure dialog.

## Configuring general Flex compiler settings

### To configure general Flex compiler settings

1. Open the Settings/Preferences dialog (for example, `Ctrl+Alt+S` ), or  on the toolbar).
2. In the left-hand part of the dialog, under Build, Execution, Deployment node, open the Compiler node and click ActionScript and Flex Compiler .
3. On the Compiler > ActionScript and Flex Compiler page, configure the settings as required.

## Creating a Flash module

### To create a Flash module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project . As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module . As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Flash .
3. In the right-hand part of the page, select the necessary options. For more information, see [Flash](#) .

Click Next .

4. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

As a result, the module structure looking similar to this is generated (the contents may be different depending on the module options that you have selected):

In this structure:

- `html-template` is a folder with files that constitute an [HTML wrapper](#) template.
- `src` is a folder for your application source files ( `.as` and, possibly, `.mxml` ).

In addition to the module itself, IntelliJ IDEA creates the following:

- One [build configuration](#) .
- One [run/debug configuration](#) . If when creating the module you have selected to create a sample application, you can use this configuration to run the application straight away. To do that, click  on the toolbar ( `Shift+F10` ).

## Configuring module contents

### To configure module contents

The module contents are configured by adding and removing the module [content roots](#) as well as by assigning individual folders (within the content roots) to source folders, test source folders and also by excluding the folders.

For a Flash module, generally, these task are performed on the [Module page](#) of the Project Structure dialog.

To access this page:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Under Project Settings , select Modules .
3. In the area under  , select the necessary Flash module.

This feature is only supported in the Ultimate edition.

When working on ActionScript and Flex applications, you create and edit application elements such as [packages](#) , ActionScript [classes](#) and [interfaces](#) , and [MXML components](#) .

For ActionScript classes, interfaces and MXML components, IntelliJ IDEA provides a number of predefined [file templates](#) .

- [Creating a package](#)
- [Creating an ActionScript class or interface](#)
- [Creating an MXML component](#)
- [Initiating ActionScript class creation in the editor](#)
- [Template-based ActionScript classes, interfaces and MXML components](#)
- [Predefined file template variables for ActionScript and Flex](#)
- [An example of creating a custom file template for an MXML component](#)
- [Using the SWF metadata tag to control HTML wrapper properties](#)
- [Editing ActionScript and Flex sources](#)

## Creating a package

1. In the Project tool window, select your source root folder (e.g. `src` ) or the package in which you want to create a new package. Choose File | New | Package , or press `(Alt+Insert)` and select Package . Alternatively, right-click the corresponding folder or package and select New | Package from the context menu.
2. In the New Package dialog that opens, specify the package name and click OK . Note that you can create more than one package at once if you use dots ( `.` ) to separate the package names. For example, if you type `myPackage.mySubpackage` and none of these packages currently exists, both these packages ( `myPackage` and `mySubpackage` ) will be created.

Also note that you can create a new package when creating a new ActionScript class or interface, or an MXML component. See [Creating an ActionScript class or interface](#) and [Creating an MXML component](#) .

## Creating an ActionScript class or interface

1. In the Project tool window, select your source root folder (e.g. `src` ) or the package in which you want to create a new ActionScript class or interface. Choose File | New | ActionScript Class , or press `(Alt+Insert)` and select ActionScript Class . Alternatively, right-click the corresponding folder or package and select New | ActionScript Class from the context menu.
2. In the [New ActionScript Class dialog](#) that opens, specify the name of the class, the package, the [file template](#) to be used, and click Create . If the [Class with Supers template](#) is used, you can also specify a superclass and/or one or more interfaces that the class should implement. Note that if you specify a package that doesn't yet exist, the corresponding package will be created.

See also, [Initiating ActionScript class creation in the editor](#) .

## Creating an MXML component

1. In the Project tool window, select your source root folder (e.g. `src` ) or the package in which you want to create a new MXML component. Choose File | New | MXML Component , or press `(Alt+Insert)` and select MXML Component . Alternatively, right-click the corresponding folder or package and select New | ActionScript Class from the context menu.
2. In the [New MXML Component dialog](#) that opens, specify the name of the component, the package, the [file template](#) to be used, the parent component, and click Create . Note that if you specify a package that doesn't yet exist, the corresponding package will be created.

## Initiating ActionScript class creation in the editor

When working with the source code of a class, you can start creating its subclass right in the editor. Similarly, you can initiate creating a class implementing an interface. For these purposes, IntelliJ IDEA provides [intention actions](#) called Create Subclass and Implement Interface respectively.

Here is an example of using the Create Subclass intention action. (The Implement Interface action is accessed in a similar way.)

1. In the editor, place the cursor within the line containing the class declaration.
2. Press `(Alt+Enter)` and select Create Subclass .
3. In the [New ActionScript Class dialog](#) that opens, specify the settings for your new class and click Create .

## Template-based ActionScript classes, interfaces and MXML components

ActionScript classes, interfaces and MXML components are created according to [file templates](#) . The following [predefined templates](#) are available:

- ActionScript Class. This template generates the file contents shown below (the destination package and the name of the class are specified when creating a class):

```
package myPackage {
    public class MyClass {
        public function MyClass() {
        }
    }
}
```

- ActionScript Class with Supers. This template generates the file contents shown below (the destination package, the class name, the superclass and/or the interfaces that the class implements are specified when creating a class):

```
package myPackage {
    MyClass1 extends MyClass implements IMyInterface1, IMyInterface2 {
    unction MyClass1() {
        r();
    }
}
```

- ActionScript Interface. This template generates the file contents shown below (the destination package and the interface name are specified when creating an interface):

```
package myPackage {
    face IMyInterface {
    }
}
```

- Flex 3 Component. This template generates the file contents shown below (the root tag is defined by the parent component specified when creating the component; when generating the following example, `mx.core.Application` was specified as the parent component):

```
<?xml version=
    "1.0"?>
<mx:Application
    xmlns:mx=
        "http://www.adobe.com/2006/mxml">
</mx:Application>
```

- Flex 4 Component. This template generates the file contents shown below (the root tag is defined by the parent component specified when creating the component; when generating the following example, `spark.components.Application` was specified as the parent component):

```
<?xml version=
    "1.0"?>
<s:Application
    xmlns:fx=
        "http://ns.adobe.com/mxml/2009"
    xmlns:s=
        "library://ns.adobe.com/flex/spark">
</s:Application>
```

If necessary, you can modify the predefined templates or create your own, custom file templates. See [Creating and Editing File Templates](#) and [An example of creating a custom file template for an MXML component](#) .

See also, [Predefined file template variables for ActionScript and Flex](#) .

## Predefined file template variables for ActionScript and Flex

For ActionScript and Flex file templates, the list of [predefined template variables](#) is broader. The following predefined variables are available in addition:

- `${SuperClass}` - a superclass for an ActionScript class or a parent component for an MXML component.
- `${SuperInterfaces}` - a list of the interfaces that an ActionScript class implements.

### An example of creating a custom file template for an MXML component

As already mentioned, the predefined [MXML 4 Component file template](#) just generates the root tag for an MXML component. Let's assume that you want the `<fx:Declarations>` and `<fx:Script>` tags to be generated in addition.

If for some reason you want to keep the predefined template unchanged, you can create the corresponding custom file template.

1. Press `Ctrl+Alt+S` or choose File | Settings (for Windows and Linux) or IntelliJ IDEA | Preferences (for macOS) on the main menu, and then go to Editor | File and Code Templates .
2. On the [File Templates](#) page that opens in the right-hand part of the dialog, select the Templates tab.
3. Select Flex 4 Component.

- Now, to create a copy of this template, click .
- Change the name of the template, for example, to **Flex 4 Component with Declarations and Script**.
- In the template body (shown in the area under the Reformat according to style checkbox), after the line `<${Superclass} xmlns:fx="http://ns.adobe.com/mxml/2009">`

add

```
<fx:Declarations>
</fx:Declarations>
<fx:Script><![CDATA[
]]></fx:Script>
```

- Click OK in the Settings dialog.

Now, to check the result:

- Select your source root folder (e.g. `src`) and press `Alt+Insert`. Note that the Flex 4 Component with Declarations and Script option (which corresponds to the name of your new template) is now available in the New menu.
- Select MXML Component. In the New MXML Component dialog that opens, check the contents of the Template list. Note that Flex 4 Component with Declarations and Script has also been added to this list.

## Using the SWF metadata tag to control HTML wrapper properties

You can use the SWF metadata tag in your main application class to set the title, the background color, and the `width` and `height` properties in your [HTML wrapper](#).

For example, if the ActionScript class contains

```
package myPackage {
port flash.display.Sprite;
WF(pageTitle="hello", backgroundColor="#ccdde", width="400", height="200")
public class MyClass extends Sprite {
...
}
```

the corresponding properties will be set in the HTML wrapper.

In a similar way the SWF metadata tag will work for an MXML component if the corresponding file contains:

```
<?xml version="1.0"?>
<s:Application xmlns:fx="http://ns.adobe.com/mxml/2009"
xmlns:s="library://ns.adobe.com/flex/spark">
<fx:Metadata>
[SWF(pageTitle="hello", backgroundColor="#ccdde", width="400", height="200")]
</fx:Metadata>
...
</s:Application>
```

By default, the title is the same as the name of the embedded `.swf` file, the background color is white (`#ffffff`), and the `width` and `height` are both `100%`.

## Editing ActionScript and Flex sources

When editing your ActionScript and Flex sources, you can use the following IntelliJ IDEA features:

- Syntax and error highlighting. Note that the way your code is highlighted is defined by an [active build configuration](#).

- Code completion.

- Surrounding with tags or code constructs (`Ctrl+Alt+T` and `Ctrl+Alt+J`), and removing enclosing tags (`Ctrl+Alt+K`).

Ctrl+Shift+Delete ).

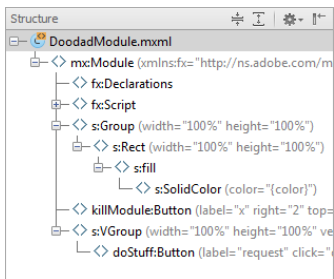

- Intention actions and quick fixes ( Alt+Enter ).

- Code inspections.

- Structure view for MXML components and ActionScript classes.

- Jumping to declarations ( Ctrl+B ).

- Code refactoring.

- Automatic code generation ( Alt+Insert ): generating getters and setters, bindable getters and setters, event handlers, etc.

This feature is only supported in the Ultimate edition.

In this section:

- [Introduction](#)
- [Build configuration types](#)
- [Main options for build configurations](#)
- [Build configuration dependencies \(build path\)](#)
- [Compiler options](#)
- [Active build configuration](#)
  - [Managing build configurations and their settings](#)
  - [Selecting an active build configuration](#)
  - [Using shortcuts to open build configuration settings](#)
- [Possible changes when changing the build configuration type](#)

## Introduction

Every Flash module in IntelliJ IDEA includes one or more build configurations. A build configuration defines how the module source files are transformed into the target output type (SWF or SWC) and then packaged.

One build configuration is created when creating a module. You can add more build configurations if and when needed.

## Build configuration types

The build configuration type is defined by the following:

- Target platform (i.e. the environment in which the developed content is going to be used): Web (for Flash player / Web browser-targeted content), Desktop (for [Adobe AIR](#) -targeted content), or Mobile (AIR Mobile, for the content intended for Android and iOS mobile devices).
- Whether the build configuration uses the Flex framework or is pure ActionScript.
- Output type: Application (a runnable application, an SWF file), Library (an SWC file), or a Runtime-loaded module (a dynamically-loadable [module](#) , an SWF file).

## Main options for build configurations

Once the build configuration type is defined, the following main options can be specified:

- For the Applications and Runtime-loaded modules: the [main class](#) .
- The output file name.
- The output folder.
- For Web Applications: the folder with the [HTML wrapper](#) template.
- For Web and Desktop Applications: the [modules](#) and [runtime style sheets](#) .

## Build configuration dependencies (build path)

Generally, the build path for each build configuration may be defined by the following:

- Flex SDK. The necessary SDK SWCs are selected automatically depending on the build configuration type. Additionally, you can manage the set of the SWCs by selecting the following:
  - For the Web target platform: the Flash player version. If the SDK includes more than one player version, you can choose which of the corresponding SWCs should be used.
  - For Flex framework-based build configurations: the Flex 4 component sets. You can specify that only the Spark or MX or both component sets should be used.
    - For Flex components you can specify their [framework linkage type](#) (Merged Into Code, RLS or External).
- Other build configurations that generate libraries and runtime-loaded modules.
- 3rd-party libraries, both SWC and raw ActionScript.

## Compiler options

Each build configuration is associated with a set of compiler options.

IntelliJ IDEA provides the default sets of compiler options at the level of the IDE, project and module.

The defaults at a lower level may be inherited from the upper level or redefined. At the level of individual build configurations, similarly, the compiler options may be inherited from the module level defaults. Alternatively, build configuration-specific values may be specified.

IntelliJ IDEA provides a convenient interface for editing the defaults at various levels. There is also an ability to restore the defaults for the values that were changed.

## Active build configuration

One of the build configurations is set active for the corresponding module.

The active build configuration provides the basis for source code highlighting in the editor. So when you change the active configuration, the code highlighting in the module changes as well.

### To manage build configurations and their settings, follow these steps

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Under Project Settings , select Modules .
3. In the area under `+ -` , expand the necessary Flash module node and select any of the build configurations. Now you can:
  - View and edit the settings for the selected build configuration on the [Build Configuration page](#) shown in the right-hand part of the dialog.
  - Create a copy of the selected build configuration. To do that, click `+` or select Copy in the context menu. Specify the settings for the copy the build configuration in the dialog that opens. Note that depending on the settings, the copy of the build configuration may have the `type` different from that of the original. See [Possible changes when changing the build configuration type](#) .
  - Find the usages of the selected build configuration in the project. To do that, click `🔍` , press `Alt+F7` or select Find usages in the context menu.
  - Delete the selected build configuration. To do that, click `-` , press `Delete` or select Delete in the context menu.
  - Create a new build configuration. To do that:
    1. Click `+` , press `Alt+Insert` or select New in the context menu.
    2. Select Flash build configuration .
    3. In the Add Build Configuration dialog that opens, specify the name and select the main options for the new build configuration, and click OK .
    4. If necessary edit the build configuration settings on the [Build Configuration page](#) .
  - Change the build configuration `type` . To do that, click Change on the General tab (to the right of the area where the build configuration type is shown) and specify the build configuration properties in the dialog that opens. See [Possible changes when changing the build configuration type](#) .
4. Click OK in the Project Structure dialog.

See also, [To use shortcuts to open build configuration settings, follow these steps](#) .

### Selecting an active build configuration

#### To select an active build configuration, follow these steps

The name of the build configuration which is currently `active` is shown in the right-hand part of the status bar.

To make a different build configuration active, click this name.

As a result, the Active Flash build configuration menu is shown in which you can select a different build configuration which will become active.

The Active Flash build configuration menu can also be accessed from the editor when working with a `.as` or `.mxm1` file. The Active Flash Build Configuration command is available for this purpose.

### Using shortcuts to open build configuration settings

#### To use shortcuts to open build configuration settings, follow these steps

As already mentioned, the Active Flash build configuration menu is used to select an active build configuration (see [To select an active build configuration, follow these steps](#) ).

In addition, this menu provides a shortcut for accessing build configuration settings (the Project Structure option).

When you select Project Structure in the Active Flash build configuration menu, the Project Structure dialog opens showing the settings for the active build configuration.

See also, [To manage build configurations and their settings, follow these steps](#) .

### Possible changes when changing the build configuration type

When changing the build configuration [type](#) (by using the Change type command or when creating a copy of a build configuration), the following changes may occur if the build configuration output type has changed (e.g., from Application to Library):

- The output file name extension may change (from `.swf` to `.swc` and vice versa).
- If the output type has changed to Library, dependencies on runtime-loaded modules (if existed) are removed.
- If dependencies on the build configuration with the changed type have become inappropriate, such dependencies are removed.

When creating a copy of a build configuration, the following changes occur in addition:

- The output file name changes.
- If applicable, the package file name or names change.

This feature is only supported in the Ultimate edition.

There are two ways of configuring dependencies for modular applications. (Modular applications are ones that include dynamically loadable modules, see [Modular applications overview](#) in Flex documentation.)

One way is to list the main classes for runtime-loaded modules (RLMs) in the [build configuration](#) for the main application (a.k.a. shell). This way doesn't require creating build configurations for the modules.

The other way is to create build configurations for each of the RLMs and then, in the build configuration for the main application, specify the dependencies on these build configurations.

These two approaches along with their advantages and drawbacks are discussed below.

- [Specifying the dependencies by listing the main RLM classes](#)
- [Specifying the dependencies by listing the RLM build configurations](#)

## Specifying the dependencies by listing the main RLM classes

If the source code of the main application and its runtime-loaded modules are in the same IntelliJ IDEA module, you can just list the main RLM classes in the build configuration for the main application. In addition, if you want to optimize a module against the main application (this considerably reduces the size of compiled module file), you can do that by turning the corresponding option on in the UI.

Note that this way of specifying the dependencies is available for Web and desktop applications but unavailable for mobile applications.

Advantages:

- You don't need to create build configurations for your modules (RLMs).
- To use the `load-externs` and `link-report` compiler options, you don't need to specify them manually, a checkbox is provided in the UI to turn module optimization on or off.

Drawbacks:

- The same set of compiler options is used for the application and the modules.
- The source code of the main application and the modules must be in the same IntelliJ IDEA module.

Here are the main steps of the procedure to be used:

1. Open the build configuration settings for the main application. For instructions, see [To manage build configurations and their settings, follow these steps](#) and [To use shortcuts to open build configuration settings, follow these steps](#).
2. On the General tab, to the right of the Runtime-loaded modules field, click . (Alternatively, click the field and press `Shift+Enter`.)
3. In the [Runtime-Loaded Modules dialog](#) that opens, click  (`Alt+Insert`).
4. In the Choose Main Class of Runtime-Loaded Module dialog that opens, select the main class of the corresponding RLM and click OK.
5. If you want the module SWF file size to be optimized, select the Optimize checkbox.
6. In a similar way, add dependencies on other RLMs.
7. Click OK in the Runtime-Loaded Modules dialog.
8. Click OK in the Project Structure dialog.

## Specifying the dependencies by listing the RLM build configurations

When using this way of specifying the dependencies, you should have build configurations for each of the RLMs. Besides, to optimize the file size of the RLMs, you should specify the `load-externs` and `link-report` compiler options manually (in the corresponding build configurations).

Advantages:

- The main application and the modules can be compiled using different sets of compilation options. (Every build configuration has its own set of compiler options.)
- The source code of the main application and the RLMs may be in the same IntelliJ IDEA module or in different modules (within the same project).

Drawbacks:

- You have to create a build configuration for each of the RLMs.
- To use the `load-externs` and `link-report` compiler options, you should specify them manually.

Here are the main steps of the procedure to be used:

1. Open the build configuration settings for the main application. For instructions, see [To manage build configurations and their settings, follow these steps](#) and [To use shortcuts to open build configuration settings, follow these steps](#).
2. On the Dependencies tab, click  (`Alt+Insert`), and select Build Configuration.
3. In the Add Dependency dialog that opens, select all the necessary build configurations for the RLMs and click OK.
4. If you need module optimization:
  1. On the Compiler Options tab, in the Additional compiler options field, add `-link-report=<path_to_report_file>`,

for example, `-link-report=c:/temp/link-report.xml` .

2. Add `-load-externs=<path_to_report_file>` (e.g. `-load-externs=c:/temp/link-report.xml` ) to the Additional compiler options field in all the corresponding RLM build configurations.
5. Click OK in the Project Structure dialog.

This feature is only supported in the Ultimate edition.

Your ActionScript and Flex sources are compiled according to corresponding [build configurations](#), in particular:

- When you compile a Flash module or its part ( Build | Make Module '<name>' or Build | Compile '<target\_name>' ( `Ctrl+Shift+F9` )), the compilation output, generally, is produced for all the build configurations associated with the module.  
To disable compilation for certain build configurations, turn on the [Skip compilation option](#) in the corresponding build configurations.
- When you compile a whole project ( Build | Make Project ( `Ctrl+F9` ), Build | Rebuild Project ), similarly, the compilation output is generated for all the build configurations for which the compilation is not explicitly disabled.
- When the sources are compiled using a [run/debug configuration](#), the compilation output is generated only for the associated build configuration.

## Compilation process

During the compilation, for each individual [build configuration](#), the following files are processed, and the results of processing are placed into the output folder:

- Resource files (e.g., image files).  
For applications, you can explicitly specify whether you want the resource files within the module source roots to be copied to the output folder (the [Copy resource files to output folder option](#) on the [Build Configuration page](#)). You can also select individual files and folders that should not be copied (the [Compiler | Excludes page](#) of the [Settings dialog](#)).

For libraries and RLMS, the resource files are never copied to the output folder.

- Source files ( `.as` and `.mxm1` ).  
The source files are compiled and, depending on the build configuration output type, the corresponding `.swf` or `.swc` file is produced.
- `.css` files to be compiled into runtime style sheets (for Web and desktop applications).  
The specified `.css` files (the [Runtime style sheets field](#) on the [Build Configuration page](#)), obviously, are compiled. Their file names don't change; the extension changes to `.swf`.
- [HTML wrapper](#) template files (for Web applications).  
If so specified (the [Use HTML wrapper option](#) on the [Build Configuration page](#)), the files that constitute the HTML wrapper template are processed. (These files are stored in a separate folder called `html-template` or something similar.)

The `index.template.html` file is renamed: the resulting `.html` wrapper file will have the same name as the application `.swf` file. The tokens contained in this file such as `${title}`, `${swf}` are replaced with the appropriate values. For example, `${swf}` is replaced with the `.swf` file name. See also, [Using the SWF metadata tag to control HTML wrapper properties](#).

Other files that constitute the HTML wrapper are copied to the output folder without any changes.

- An [application descriptor](#) template (for desktop and mobile applications).  
Depending on the build configuration settings, either an auto-generated descriptor is created in the output folder, or a specified template file is used. In the latter case, the text in the `<content>` element of the template is replaced with the name and extension ( `.swf` ) of the application file.

This feature is only supported in the Ultimate edition.

In this section:

- [Run/debug configuration types](#)
- [Running or debugging an application from within the editor](#)
- [How IntelliJ IDEA selects or creates a class-specific run/debug configuration](#)
- [Using Flash Remote Debug configurations](#)
- [Hiding or showing \[SWF\] and \[UnloadSWF\] debugger messages](#)

For general guidelines, see [Running](#) and [Debugging](#) .

## Run/debug configuration types

The following [run/debug configuration](#) types are available for Flash modules:

-  Flash App configurations let you compile and then run or debug your Flash (ActionScript and Flex) applications. You can create the necessary configurations prior to running or debugging. You can also start running or debugging an application right in the editor, when working with your source code (see [Running or debugging an application from within the editor](#) ).
-  FlexUnit configurations let you compile and then run or debug your [FlexUnit](#) tests. See [Testing ActionScript and Flex Applications](#) .
-  Flash Remote Debug configurations let you debug applications that have already been compiled and, if necessary, packaged, and are ready to be run on a local or remote computer, or a mobile device. See [Using Flash Remote Debug configurations](#) .

To be able to debug your applications:

- The applications must be debug-ready, that is, contain the necessary debug information.
- For Web-targeted applications, you must install the debugger version of Flash player or the debugger version of the Flash player plugin for your Web browser. Normally, this software is included in Flex SDKs. You can also download the corresponding software separately from the [Adobe Flash Player Downloads page](#) .

## Running or debugging an application from within the editor

When working with the class source code in the editor, if appropriate, you can run or start debugging your application with the current class as the [main application class](#) . To do that, right-click somewhere in the editor area to open the context menu and select:

-  Run "<class\_name>" ([\(Ctrl+Shift+F10\)](#) ) to run the application.
-  Debug "<class\_name>" to start debugging the application.

If a [Flash App run/debug configuration](#) appropriate for the task already exists, this configuration is selected and used. Otherwise, a new run/debug configuration is created and saved as a [temporary run/debug configuration](#) . For details, see [How IntelliJ IDEA selects or creates a class-specific run/debug configuration](#) .

In addition to Run and Debug , the following related commands may be available depending on the situation:

-  Create "<class\_name>". If an appropriate run/debug configuration is not found, you can use this command to create a new run/debug configuration and make it current. (The Create Run/Debug Configuration dialog will open.)
-  Save "<class\_name>". If the corresponding run/debug configuration is available as a temporary configuration, you can use this command to save the configuration and thus make it [permanent](#) .
-  Select "<class\_name>". Use this command if you want to make the corresponding temporary or permanent run/debug configuration current.

All the functions described above may alternatively be accessed as the context menu commands in the Project or Favorites tool window.

## How IntelliJ IDEA selects or creates a class-specific run/debug configuration

As already mentioned, when you [run or debug your application from within the editor](#) , IntelliJ IDEA first tries to find an existing run/debug configuration with the class you are currently working with as the main class.

If no such configuration is found, a new run/debug configuration is created.

If more than one configuration with the suitable main class is found, IntelliJ IDEA prioritizes the configurations according to the following conditions and select the one with the highest priority:

1. The run/debug configuration is based on the active build configuration, the build configuration output type is Application, the main class is not overridden in the run/debug configuration.
2. The run/debug configuration is based on a build configuration with the output type Application, the main class is not overridden in the run/debug configuration.
3. The run/debug configuration is based on the active build configuration, the main class is overridden in the run/debug configuration.
4. Any run/debug configuration with the suitable (overridden) main class.

When creating a new run/debug configuration, IntelliJ IDEA tries to find a build configuration with a suitable main class. If found, the new run/debug configuration will be based on such a build configuration. Otherwise, the active build configuration

will be used, and the main class will be overridden in the new run/debug configuration.

## Using Flash Remote Debug configurations

1. Select and start the necessary Flash Remote Debug configuration (🔍 or `Shift+F9`).

As a result, the **Debug tool window** opens; the debugger is waiting for the application to connect.

2. Now, to connect to the debugger, do one of the following:

- Start the Flash or AIR application on your local computer; the application will connect to the debugger automatically.
- If the application is already running in a Web browser or a Flash player on the local or remote computer, right-click the corresponding page in the browser or the application in the player, and select Debugger from the context menu.
- Start the application on the mobile device. If the device is capable of communicating with your computer, the application will connect to the debugger automatically.

## Hiding or showing [SWF] and [UnloadSWF] debugger messages

Your Flash Player Debugger output may contain many `[SWF]` and `[UnloadSWF]` messages (the Console tab of the Debug tool window). There are situations when you don't want to see them.

You can hide or show the `[SWF]` and `[UnloadSWF]` messages by using  on the toolbar.

Note that changing the state of this toggle doesn't change the current console content. That is, if you turn the filter on, the messages already present in the output won't be hidden. Only new messages won't be shown.

This feature is only supported in the Ultimate edition.

When ready, you can package your AIR (Desktop and Mobile) applications for all the appropriate [build configurations](#) existing in the project.

## To package AIR applications

1. Choose Build | Package AIR Application
2. In the [Package AIR Application dialog](#) that opens, select the necessary build configurations, specify packaging options and click Package .

This feature is only supported in the Ultimate edition.

You can import [Adobe Flash Builder](#) projects and then continue working with them in IntelliJ IDEA.

Each individual Flash Builder project imported into IntelliJ IDEA is represented by a Flash [module](#) .

By importing Flash Builder projects, you can create a new IntelliJ IDEA [project](#) . You can as well import Flash Builder projects into an existing IntelliJ IDEA project.

For creating a new project, two options are available. You can use the Import Project or the Open command. Importing is more precise but longer, opening is quicker but less precise.

- [Supported Flash Builder formats](#)
- [Creating an IntelliJ IDEA project by using the Import Project command](#)
- [Creating an IntelliJ IDEA project by using the Open command](#)
- [Importing Flash Builder projects into an existing project](#)

## Supported Flash Builder formats

When importing Flash Builder projects into IntelliJ IDEA, you can specify the following as a source of import:

- A Flash Builder workspace or project directory
- A `.project` file
- A `.fxp` or `.fxp1` file
- A `.zip` file that contains an ActionScript project or projects.

### Creating an IntelliJ IDEA project by using the Import Project command

1. If no project is currently open in IntelliJ IDEA, click Import Project on the [Welcome screen](#) . Otherwise, select File | New | Project from Existing Sources .
2. In the [dialog that opens](#) , select the directory or file which you want to use as a [source of import](#) . Click OK . As a result, the [Import Project wizard](#) opens.
3. On the [first page of the wizard](#) , select Import project from external model , then select Flash Builder and click Next . (This page is not shown if IntelliJ IDEA has guessed that you are importing a Flash Builder project.)
4. On the [next page](#) of the wizard:
  1. Specify the location of the [file or directory to be imported](#) . Use  to select the necessary file or folder in the [corresponding dialog](#) .
  2. If necessary, change the name and location of the IntelliJ IDEA project that is going to be created.
  3. Optionally, select the Create subfolder option (if present).
  4. If necessary, change the suggested [project format](#) .
  5. Click Next or Finish .
5. If you are importing a workspace, select the projects that you want to import on the [next page](#) of the wizard and click Finish .
6. If undefined [path variables](#) are found in the project or projects that you are importing, the [Configure Path Variables dialog](#) is shown. Specify the values of the undefined variables or include them in the list of ignored variables.
7. In the Flash Builder Project Import dialog, specify the Flex SDK to be associated with the imported project or projects in IntelliJ IDEA.

### Creating an IntelliJ IDEA project by using the Open command

1. If no project is currently open in IntelliJ IDEA, click Open on the [Welcome screen](#) . Otherwise, select File | Open .
2. In the [dialog that opens](#) , select a file or directory that you want to use as a [source of import](#) , and click OK .
3. If suggested, specify the location of the IntelliJ IDEA project that is going to be created (shown under Extract project to in the corresponding dialog).
4. If undefined [path variables](#) are found in the project or projects that you are importing, the [Configure Path Variables dialog](#) is shown. Specify the values of the undefined variables or include them in the list of ignored variables.
5. In the Flash Builder Project Import dialog, specify the Flex SDK to be associated with the imported project or projects in IntelliJ IDEA.

### Importing Flash Builder projects into an existing project

1. Open the project into which you want to import Flash Builder projects, and select File | New | Module from Existing Sources .

2. In the [dialog that opens](#) , select the directory or file which you want to use as a [source of import](#) . Click OK .  
As a result, the [Import Module wizard](#) opens.
3. On the [first page of the wizard](#) , select Import module from external model , then select Flash Builder and click Next . (This page is not shown if IntelliJ IDEA has guessed that you are importing a Flash Builder project.)
4. On the [next page](#) of the wizard:
  1. Specify the location of the [file or directory to be imported](#) . Use [...](#) to select the necessary file or folder in the [corresponding dialog](#) .
  2. If necessary, change the location of the module that is going to be created. (Shown under Extract project to ; the corresponding option may be missing.)
  3. Click Next or Finish .
5. If you are importing a workspace, select the projects that you want to import on the [next page](#) of the wizard and click Finish .
6. If undefined [path variables](#) are found in the project or projects that you are importing, the [Configure Path Variables dialog](#) is shown. Specify the values of the undefined variables or include them in the list of ignored variables.
7. In the Flash Builder Project Import dialog, specify the Flex SDK to be associated with the imported project or projects in IntelliJ IDEA.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports the versions 0.9 and 4 of [FlexUnit](#), a unit testing framework for Flex and ActionScript applications and libraries.

For running FlexUnit tests, there is a dedicated run/debug configuration type ( FlexUnit).

The FlexUnit-specific tasks are briefly outlined below. For general instructions, see [Testing](#).

– [Preparing for writing FlexUnit tests](#)

– [Running or debugging FlexUnit tests](#)

## Preparing for writing FlexUnit tests

To prepare for writing FlexUnit tests, you should add the core FlexUnit library to dependencies of the corresponding [build configuration](#), and make this build configuration [active](#).

1. Download and decompress the archive containing FlexUnit libraries. (The corresponding archives ( `.zip` ) are available, for example, on the [FlexUnit Downloads page](#). The archive name, normally, starts with `flexunit.`)

The only file that you'll need is the core FlexUnit library ( `.swc` ). Depending on the FlexUnit version, this file may be called `FlexUnit.swc`, `flexunit-4.0.0.swc`, `flexunit-4.1.0-8-as3_4.1.0.16076.swc`, `flexunit-core-flex-4.1.0-beta1.64-sdk4.0.0.14159.swc` or something similar.

2. Though this isn't really necessary, it might be useful to define the core FlexUnit library as a global or project [library](#). This will let you use this library in many projects or modules.
3. Add the core FlexUnit library to dependencies of one or more of the build configurations. See [To manage build configurations and their settings, follow these steps](#) and [Build Configuration Page for a Flash Module](#).
4. Make one of these build configurations active. This will ensure that the code in your tests is highlighted properly. See [To select an active build configuration, follow these steps](#).

Now you are ready to start developing your test sources.

## Running or debugging FlexUnit tests

To run or debug your FlexUnit tests, you can create the necessary FlexUnit run/debug configurations and then use those. Note that the corresponding run/debug configurations should be based on the build configurations that have the core FlexUnit library among their dependencies. See [Creating and Editing Run/Debug Configurations](#) and [Run/Debug Configuration: FlexUnit](#).

The other alternative is to run or debug you test package, class or method from within the editor, or the Project or Favorites tool window. (The Run and Debug commands, if appropriate, are available in the context menus.) In such cases you don't even need to create the run/debug configuration prior to running the tests.

This feature is only supported in the Ultimate edition.

In this section:

- [Change Method Signature in ActionScript](#)
- [Extract Parameter in ActionScript](#)

For the complete list of the refactorings available for ActionScript, see [ActionScript and Flex](#).

This feature is only supported in the Ultimate edition.

In ActionScript, you can use the [Change Method Signature](#) refactoring to:

- Change the method name and return type.
- Add new parameters and remove the existing ones. Note that you can also add a parameter using a dedicated [Extract Parameter](#) refactoring.
- Reorder parameters.
- Change parameter names and types.
- Propagate new parameters through the method call hierarchy.

On this page:

- [Example](#)
- [Initializer, default value, and propagation of new parameters](#)
- [More refactoring examples](#)
- [Changing a method signature](#)

## Example

Before/After

```
// The function paint() is declared in
// the IShape interface.

public interface IShape {
    function paint(g: Graphics): void;
}

// This function is then called within the
// paint() function of the Canvas class.

public class Canvas {
    private var shapes: Vector.<IShape>;

    public function paint(g: Graphics): void {
        for each (var shape: IShape in shapes) {
            shape.paint(g);
        }
    }
}

// Now we are going to show an example of the
// Change Signature refactoring for the function
// paint() of the IShape interface.
```

```
// In this refactoring example we have changed the name of the existing parameter
// and introduced two new parameters. Note that the first of the new parameters is
// a required parameter while the second is optional because the default value
// for it is specified in the function definition.

public interface IShape {
    function paint(graphics:Graphics, wireframe:Boolean, offset:Point = null):void;
}

// When performing this refactoring, the new parameters were propagated to
// the paint() function of the Canvas class. As a result, the signature of
// Canvas.paint() has changed. Also note how IShape.paint() within
// Canvas.paint() is called now.

public class Canvas {
    private var shapes: Vector.<IShape>;

    public function paint(g:Graphics, wireframe:Boolean): void {
        for each (var shape: IShape in shapes) {
            shape.paint(g, wireframe);
        }
    }
}

// Other results for this refactoring are possible.
// For more information, see the discussion that follows.
```

## Initializer, default value, and propagation of new parameters

For each new parameter added to a function, you can specify:

- A value (or an expression) to be used for initializing the parameter (the **Initializer** field in IntelliJ IDEA).
- A default value (or an expression) (the **Default value** field).

You can also propagate the parameters you have introduced to the functions that call the function whose signature you are changing.

The refactoring result depends on whether or not you specify those values and use the propagation.

**Propagation.** New parameters can be propagated to any function that call the function whose signature you are changing. In such a case, generally, the signatures of the calling functions change accordingly. These changes, however, also depend on the combination of the initializer and the default value set for the new parameters.

**Initializer.** The value specified in the **Initializer** field is added to the function definition as the default parameter value. This makes the corresponding parameter an optional parameter. (See the discussion of required and optional parameters in [Flex/ActionScript documentation](#).)

If the default value for the new parameter is not specified (in the **Default value** field), irrespective of whether or not the propagation is used, the function calls and the signatures of the calling functions don't change.

If both, the initializer and the default value are specified, the refactoring result depends on whether or not the propagation is used:

- If the propagation is not used, the initializer value don't affect the function calls and the signatures of the calling functions.
- If the propagation is used, the initializer value is added to the definition of the calling function as the default value for the corresponding parameter (in the same way as in the function whose signature you are changing).

Default value. Generally, this is the value to be added to the function calls.

If the new parameter is not propagated to a calling function, the function calls within such a function will also use this value.

If the propagation is used, this value won't matter for the function calls within the calling functions.

## More refactoring examples

To see how different refactoring settings discussed above affect the refactoring result, let us consider the following examples.

All the examples are a simplified version of the refactoring [shown earlier](#). In all cases, a new parameter `wireframe` of the type `Boolean` is added to the function `paint()` defined in the `IShape` interface.

In different examples, different combinations of the initializer and the default value are used, and the new parameter is either propagated to `Canvas.paint()` (which calls `IShape.paint()`) or not.

InitializerDefault value	Propagation used	Result
<code>false</code>	Yes	<pre>public interface IShape {     int(g:Graphics, wireframe:Boolean):void;      paint() in the Canvas class:      tion paint(g:Graphics,         wireframe:Boolean): void {     h (var shape: IShape in shapes) {         pe.paint(g, wireframe);     } }</pre>
<code>false</code>	No	<pre>public interface IShape {     int(g:Graphics,         wireframe:Boolean):void;      paint() in the Canvas class:      tion paint(g:Graphics): void {     h (var shape: IShape in shapes) {         pe.paint(g, false);     } }</pre>
<code>true</code>	Yes	<pre>public interface IShape {     int(g:Graphics,         wireframe:Boolean = true):void;      paint() in the Canvas class:      tion paint(g:Graphics): void {     h (var shape: IShape in shapes) {         pe.paint(g);     } }</pre>
<code>true</code>	No	<pre>public interface IShape {     int(g:Graphics,         wireframe:Boolean = true):void;      paint() in the Canvas class:      tion paint(g:Graphics): void {     h (var shape: IShape in shapes) {         pe.paint(g);     } }</pre>
<code>true</code>	<code>false</code> Yes	<pre>public interface IShape {     int(g:Graphics,         wireframe:Boolean = true):void;      paint() in the Canvas class:      tion paint(g:Graphics,         wireframe:Boolean = true): void {     h (var shape: IShape in shapes) {         pe.paint(g, wireframe);     } }</pre>
<code>true</code>	<code>false</code> No	

```

public interface IShape {
    int(g:Graphics,
        wireframe:Boolean = true):void;

    paint() in the Canvas class:

    tion paint(g:Graphics): void {
    h (var shape: IShape in shapes) {
    pe.paint(g, false);

```

## Changing a method signature

1. In the editor, place the cursor within the name of the method whose signature you want to change.

2. Do one of the following:

- Press `Ctrl+F6`.
- Choose Refactor | Change Signature in the main menu.
- Select Refactor | Change Signature from the context menu.

3. In the [Change Signature dialog](#), make the necessary changes to the method signature and specify which other, related changes are required.

You can:

- Change the method return type by editing the contents of the Return type field.

**Note** Code completion is available in this field and also in certain fields of the table that contains the function parameters.

- Change the method name. To do that, edit the text in the Name field.
- Manage the method parameters using the table of parameters and the buttons to the right of it:
  - To add a new parameter, click `+` (`Alt+Insert`) and specify the properties of the new parameter in the corresponding fields.  
When adding parameters, you may want to [propagate these parameters](#) to the methods that call the current method.
  - To remove a parameter, click any of the cells in the corresponding row and click `-` (`Alt+Delete`).
  - To reorder the parameters, use `↑` (`Alt+Up`) and `↓` (`Alt+Down`). For example, if you wanted to make a certain parameter the first in the list, you would click any of the cells in the row corresponding to that parameter, and then click `↑` the required number of times.
  - To change the name or type for a parameter, make the necessary edits in the corresponding table cells.
- Propagate new method parameters (if any) along the hierarchy of the methods that call the current method. (There may be the methods that call the method whose signature you are changing. These methods, in their turn, may be called by other methods, and so on. You can propagate the changes you are making to the parameters of the current method through the hierarchy of the calling methods and also specify which calling methods should be affected and which shouldn't.)

To propagate the new parameters:

1. Click `+` (`Alt+G`).
2. In the left-hand pane of the Select Methods to Propagate New Parameters dialog, expand the necessary nodes and select the checkboxes next to the methods you want the new parameters to be propagated to.  
To help you select the necessary methods, the code for the calling method and the method being called is shown in the right-hand part of the dialog (in the Caller Method and Callee Method panes respectively).

As you switch between the methods in the left-hand pane, the code in the right-hand part changes accordingly.

3. Click OK.

4. To perform the refactoring right away, click Refactor.

To [see the expected changes](#) and make the necessary adjustments prior to actually performing the refactoring, click Preview.

This feature is only supported in the Ultimate edition.

This section discusses the [Extract Parameter](#) refactoring in ActionScript.

- [Example](#)
- [Extracting parameter in ActionScript](#)

## Example

BeforeAfter

```
// Two ways of extracting a parameter for the function
// formatPrice() will be shown.

public function foo():void {
    formatPrice(0);
}

// The new parameter will be optional in the first
// of the examples and required in the second example.

public function formatPrice(value:int):String {
    trace("currency: " + "$");
    return "$" + value;
}

// The function formatPrice() may be called as before because
// the new parameter is introduced as an optional parameter.

public function foo():void {
    formatPrice(0);
}

// The default value for the new parameter is specified
// in the function definition.

public function formatPrice(value:int, s:String = "$"):String {
    trace("currency: " + s);
    return s + value;
}

// The new parameter in this example is a required parameter.
// So two values must be passed to formatPrice() now.

public function foo():void {
    formatPrice(0, "$");
}

// The new parameter is a required parameter because the default
// value for it is not specified in the function definition.

public function formatPrice(value:int, s:String):String {
    trace("currency: " + s);
    return s + value;
}
```

## Extracting parameter in ActionScript

### To extract a parameter in ActionScript

1. In the editor, place the cursor within the expression to be replaced by a parameter.
2. Do one of the following:
  - Press **Ctrl+Alt+P**.
  - Choose Refactor | Extract | Parameter on the main menu.
  - Choose Refactor | Extract | Parameter from the context menu.
3. If more than one expression is detected for the current cursor position, the Expressions list appears. If this is the case, select the required expression. To do that, click the expression. Alternatively, use the **Up** and **Down** arrow keys to navigate to the expression of interest, and then press **Enter** to select it.

4. In the [Extract Parameter dialog](#) :
    1. Usually, IntelliJ IDEA sets a proper parameter type itself. If necessary, you can select another appropriate type from the Type list.
    2. Specify the parameter name in the Name field.
    3. The Value field, initially, contains the expression that you have selected. Normally, you don't need to change this.
      - If the new parameter is going to be an optional parameter, the specified value will be used as the default parameter value in the function definition.
      - If the new parameter is introduced as a required parameter, the specified value will be added to the function calls.
- For information about required and optional parameters, see the discussion of function parameters in [Flex/ActionScript documentation](#).
4. If you want the new parameter to be an optional parameter, select the Optional parameter checkbox.
  5. If more than one occurrence of the expression is found within the function body, you can choose to replace only the selected occurrence or all the found occurrences with the references to the new parameter. Use the Replace all occurrences check box to specify your intention.

6. Click OK.

```
public function formatPrice(value:int, g:String = "$"):String {  
    trace("currency: " + g);  
    return g + value;  
}
```

In this part:

- [Android Support Overview](#)
- [Getting Started with Android Development](#)
- [Creating Android Application Components](#)
- [Managing Resources](#)
- [Designing Layout of Android Application](#)
- [Running and Debugging Android Applications](#)
- [Testing Android Applications](#)
- [Sharing Android Source Code and Resources Using Library Projects](#)
- [Renaming an Application Package \(Application ID\)](#)
- [Generating Signed and Unsigned Android Application Packages](#)
- [Accessing Android SQLite Databases from IntelliJ IDEA](#)
- [Android Tutorials](#)

To support Android development, IntelliJ IDEA provides a dedicated Android Support plugin. This plugin is bundled with the IDE and is enabled by default.

Android support in IntelliJ IDEA includes:

- [Gradle-based build system](#) for Android applications.
- [Smart XML editor](#) that facilitates working with layout, manifest, resources and other XML files.
- A [graphical editor](#) for layout files: build the design of your application without having to edit the XML files manually.
- [Enhanced navigation](#) between related files: navigate between layout files and the associated activities, or a service and the manifest file, etc. via gutter icons.
- [Automatic generation of basic layout files](#) .
- [Android-specific code inspections](#) , including integrated [Android Lint](#) inspections.
- Possibility to [preview your application UI](#) on different devices at the same time.
- [Access to SQLite Databases](#) right from the IDE.
- Built-in [9-patch editor](#) .
- [Detection of mismatched resource types](#) in Android APIs and your own libraries and APIs with the help of [resource type annotations](#) .
- [Possibility to automatically rearrange XML attributes](#) according to predefined rules.
- Dedicated [Android run/debug configurations](#) .
- Dedicated [Android artifacts](#) .

In this topic:

- [Before you start](#)
- [Choosing the module type you need](#)
- [Creating an Android project](#)
- [Adding an Android module to a project](#)
- [Attaching an Android facet to an existing Java module](#)
- [Configuring the code style of Android-specific XML definition files](#)

## Before you start

- Download and extract the [Android SDK](#) . We strongly recommend that the path to the Android SDK home directory does not contain spaces.

**Note** The Android SDK is not a substitute for a Java SDK (JDK). You need to download and [configure a Java SDK for your project](#) anyway.

- Add SDK packages. For detailed instructions and download links, refer to [Adding SDK Packages](#) .
- Configure the Android SDK in IntelliJ IDEA, see [Configuring projects](#) .
- Make sure that the bundled Android Support plugin is activated. This plugin provides Android support at the IntelliJ IDEA level and is enabled by default. If not, enable it as described in [Enabling and Disabling Plugins](#) .
- Depending on your task, [choose the module type](#) you need for your Android development.
- [Create a project with an Android module](#) from scratch, [add an Android module](#) to a project, or [attach an Android facet](#) to an existing Java module.

Depending on the chosen module type, IntelliJ IDEA automatically sets up the correct module structure with the `res` and `gen` folders, downloads the necessary libraries, and generates various Android-specific descriptors.

**Note** Starting with the IntelliJ IDEA version 2016.1, non-Gradle Android projects are not supported.

## Choosing the module type you need

IntelliJ IDEA lets you choose Application modules (form factors) when you create your project, add different Android modules to an existing project, or add Android facets to your modules.

## Creating an Android project

1. In the menu, choose File | New | Project to open the [New Project Wizard](#) . In the left-hand pane select Android .
2. In the right-hand pane configure your [new project](#) and click Next .
3. On the next page of the wizard, select the [application module type](#) and its minimum SDK. Click Next .
4. On the next page of the wizard, select the [Android activity](#) and click Next .
5. On the next page of the wizard, specify the [Activity settings](#) and click Finish .

## Adding an Android module to a project

1. Choose File | New | Module from the main menu or New | Module from the context menu of the Project tool window. The [New Module wizard](#) opens.
2. In the left-hand pane, select Android . In the right-hand pane, select a module you want to add and click Next .
3. On the next page of the wizard, specify the application or library name, module name, package name and a minimum SDK that is required for this type of application. Click Next .
4. On the next page of the wizard, select an activity for your module and click Next .
5. On the next page of the wizard, specify the settings to [customize the selected activity](#) and click Finish .

## Attaching an Android facet to an existing Java module

You need to perform this procedure if you want to attach an Android facet to an existing Java module. Android modules have this facet applied by default.

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Under Project Settings , select Modules .
3. Select the module you want to add an Android facet to, click `+` , and choose Android .
4. On the [Facet 'Android'](#) page that opens, specify the location of the key application components in the Structure tab: the [AndroidManifest.xml](#) file, the [application resources](#) , the [application assets](#) , and the [Android native libraries](#) . If necessary, you can edit the default paths. To return to the default Android facet settings, click Reset paths to defaults .
5. To make the [module source code and resources available from other projects](#) , select the Library module checkbox on top of this page.

## Configuring the code style of Android-specific XML definition files

Android development involves working with dedicated XML files, such as layout and resource definition files, manifest files, etc. You can have IntelliJ IDEA apply the standard XML code style to such files, or configure custom code style settings for them.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click XML under Code Style .
2. On the [Code Style:XML](#) page that opens, switch to the Android tab.
3. Do one of the following:

- To define a custom code style for Android-specific XML files, select the Use custom formatting settings for Android XML files checkbox and configure the settings to be applied to various types of Android XML files using the controls of the tab as described in [Code Style:XML - Android](#).
- To have IntelliJ IDEA format Android-specific XML files according to the standard XML code style settings defined in the other tabs of the page, clear the Use custom formatting settings for Android XML files checkbox.

An Android application may contain the following components:

- [AIDL](#) : an Android Interface Definition Language (AIDL) interface used for interprocess communication.
- [Activity](#) : implements a window where you place your UI to interact with the user.
- [Android Auto](#) : lets you extend your application for use in vehicles. You can add either Media Service or Messaging Service activity.
- [Folder](#) : creates a source root based on the activity you have selected for this component.
- [Fragment](#) : represents a behavior or a part of user interface in an activity.
- [Google](#) : lets you create an activity for Google maps and [AdMob Ads](#) activities.
- [Application](#) : an Android package, i.e. an `.apk` archive that contains the contents of an Android app and the installer.
- [Service](#) : represents an application's desire either to perform an operation without interacting with the user, or to supply functionality for other applications.
- [Other](#) : lets you add the following components to your application:
  - [Android Manifest File](#)
  - [Broadcast Receiver](#)
  - [Content Provider](#)
  - [Daydream](#)
- [UIComponent](#) : lets you add custom views to you application.
- [Wear](#) : lets you extend your application for use in Android wear.
- [Widget](#) : lets you add different types of widgets for your application.
- [XML](#) : lets you add different types `.xml` files for Android layouts and values.

All Android application components are created in the same way. When you create a new component, a class that implements this component is generated and the component is automatically declared in the [AndroidManifest.xml](#) file.

On this page:

- [Creating an Android component](#)
- [Navigating between an activity or a fragment and its related layout definition file](#)
- [Navigating from a component to its declaration in the AndroidManifest.xml file](#)

## Creating an Android component

1. In the Project view, right-click the destination package where the application classes are stored and from the context menu, select New | 'component name' and the specific service, file or an activity .
2. In the [dialog box that opens](#) , specify the necessary information and click Finish .

Note that when you create an activity, a service or a broadcast receiver, they are automatically registered in the `androidmanifest.xml` file.

## Navigating between an activity or a fragment and its related layout definition file

You can jump from the source code of an activity or a fragment to the layout definition file which represents its content view and vice versa, from the layout definition to the source code.

- To jump from a component to its related layout definition, open the source code of the component, and do one of the following:
  - Click the icon in the gutter area and choose the layout definition file in the Go To Related Symbol pop-up list.
  - On the main menu, choose Navigate | Related Symbol .
- To jump from a layout definition to the source code of the corresponding component, open the layout definition file in the text mode and do one of the following:
  - Click the  icon in the gutter area.
  - On the main menu, choose Navigate | Related Symbol .

## Navigating from a component to its declaration in the AndroidManifest.xml file

As soon as a component is created, it is immediately declared in the `AndroidManifest.xml` file. For components of the `activity` , `fragment` , `service` , and `broadcast receiver` type, you can jump to this declaration right from the component source code.

1. Open the source code of the component, and click the icon in the gutter area.
2. If the component also has a related layout definition file, choose `AndroidManifest.xml` in the Go To Related Symbol pop-up list.

IntelliJ IDEA provides a number of facilities for managing [resources](#) used in Android applications. In the project view, resource definition files are shown grouped into folders under the `res` directory.

The following coding assistance is provided:

- Basic [code completion](#)
- Code completion for various resource types, including alternate resources
- Syntax and error highlighting
- [Find](#) usages
- Navigation from resource usages to resource definition
- Quick fixes including resource creation upon reference failure
- Code completion for referencing Android SDK resources
- Extract style refactoring (see [Refactoring Android XML Layout Files](#) for details)
- Extract layout refactoring (see [Refactoring Android XML Layout Files](#) for details)
- Extract string resource intention (see [Refactoring Android XML Layout Files](#) for details)
- [Translation editor](#)
- For [drawable resources](#), a preview icon is displayed in the `.java` and `AndroidManifest.xml` files in the left editor gutter next to this resource reference in the code.

Besides the standard way to create [files](#) and [folders](#) , you can create resource definitions right from the `res` node without having to place them in the corresponding folder. IntelliJ IDEA detects the type and the qualifier of the new resource and appoints the folder where the resource definition file will be saved. You can create separate resource definition files and entire folders.

In this topic:

- [Creating a resource folder](#)
- [Creating a resource definition file in the relevant resource folder](#)

## Creating a resource folder

IntelliJ IDEA composes the name for the new resource folder from the resource type and the qualifiers you choose, and creates a folder with this name under the `res` folder. The name is built in compliance with the Android naming conventions.

1. In the Project tool window, right-click the `res` node where all Android resource definitions are stored. Select New | Android resource directory from the context menu. The [New Resource Directory](#) dialog box opens.
2. From the Resource Type drop-down list, select the [type](#) of resources to be stored in the new folder. The selected type is displayed in the Directory name field.
3. Do one of the following:
  - If your application does not need to be compatible with various Android devices and, therefore, no [multiple screens](#) support is required, just click OK .
  - To provide [alternative resources](#) , specify the [resource qualifiers](#) that define a specific device configuration.
    - From the Available Qualifiers list, select the required qualifier, and click the `»` button. The selected item is added to the Chosen qualifiers list. Depending on a particular qualifier, either specify its value manually, or choose the required value from the drop-down list next to Chosen qualifiers .
    - To remove a qualifier, select it in the Chosen qualifiers list and click the `«` button.

IntelliJ IDEA appends all selected qualifiers to the resource type with the dash character as a separator. The resulting name is shown in the Directory name field.

IntelliJ IDEA generates the new folder with the compound name under the `res` node.

## Creating a resource definition file in the relevant resource folder

1. In the Project tool window, right-click the `res` node where all Android resource definitions are stored. Select New | Android resource file from the context menu. The [New Resource File](#) dialog box opens.
2. Specify the name for the new resource definition file in the File name text box. Follow the [Android naming guidelines](#)
3. From the Resource Type drop-down list, select the resource [type](#) . You can scroll through the list of resource types right from the `File name` text box by using the Up and Down keyboard keys.
4. To enable coding assistance, in the Root element field, specify the `http://schemas.android.com/apk/res/android` schema as the value of the `xmlns:android` .
5. Do one of the following:
  - If your application does not need to be compatible with various Android devices and, therefore, no [multiple screens](#) support is required, just click OK .
  - To provide [alternative resources](#) , specify the [resource qualifiers](#) that define a specific device configuration.
    - From the Available Qualifiers list, select the required qualifier, and click the `»` button. The selected item is added to the Chosen qualifiers list. Depending on a particular qualifier, either specify its value manually, or choose the required value from the drop-down list next to Chosen qualifiers .
    - To remove a qualifier, select it in the Chosen qualifiers list and click the `«` button.

IntelliJ IDEA appends all selected qualifiers to the resource type with the dash character as a separator. The resulting name is shown in the Directory name field.

6. Click OK , when ready. IntelliJ IDEA composes the name of the resource folder where the new file is going to be saved. The name is built from the specified resource type and the qualifier in compliance with the Android naming conventions. If such folder exists already, IntelliJ IDEA saves the new file in it. If no such folder is found, IntelliJ IDEA creates it under the `res` node and saves the new resource definition file there.

IntelliJ IDEA allows you to easily create icons for your Android applications with the help of the [Asset Studio](#) wizard. The wizard creates multiple icons for different screen resolutions and lets you see a live preview in the process of creating. You can create icons using your own images, clipart images, or text, configure the background shape, the colors, the fonts, etc.

## To create an image asset

1. In the Project tool window, right-click the `res` where all Android resource definitions are stored. Select New | Image Asset from the context menu. The [Asset Studio](#) wizard opens.
2. On the [first page of the wizard](#) , select the asset type (launcher icons, action bar and tab icons, or notification icons) and the source for your icon: image, clipart or text.
3. Adjust your icon's shape, colors, aspect ratio, etc. depending on the selected asset type and source (for a detailed explanation of the available options, refer to [Asset Studio. Page 1](#) .
4. On the [second page of the wizard](#) , preview output formats of your image asset and click Finish to complete the wizard.

A **layout** defines the user interface of an **activity** or an **app widget** (fragment). Layouts are declared in XML **resource definition files** . See [Creating Resources](#) for instructions on how to create resource folders and resource definition files.

In this topic:

- [Layout Editing Modes](#)
- [Toggling between the Design and the Text Modes](#)
- [Navigating between an activity or a fragment and its related layout definition file](#)

## Layout Editing Modes

IntelliJ IDEA suggests two main ways to design the user interface of your Android application:

- Edit the layout definition files manually, possibly using the Android-specific refactoring provided by IntelliJ IDEA, and [preview the changes](#) that are immediately reflected in the dedicated **Preview** tool window, where you can adjust the layout to various platforms and devices.
- [Compose the layout](#) in the dedicated **Designer** tool window: drag and drop layout elements from the Palette pane and specify their properties in the Properties pane. In this mode, all changes are also reflected immediately in the preview that is displayed right in the editor.

At the IntelliJ IDEA level, this functionality is provided through the bundled Android Support plugin, which is enabled by default. If not, enable it in the [Plugins settings](#) page of the **Settings/Preferences** dialog box.

## Toggling between the Design and the Text Modes

You can toggle between these modes by switching between the Design and Text tabs in the editor where the layout definition file is opened.

Note that the set of available panes and tool windows depends on the current layout editing mode: the Designer tool window with its panes is available in the **Design** mode, while the Preview tool window is available in the **Text** mode.

In the **Design** mode, you can switch to the manual mode by choosing Go to Declaration on the context menu of the Design pane, or by clicking the  icon in the [Preview window Toolbar](#) .

## Navigating between an activity or a fragment and its related layout definition file

You can jump from the source code of an activity or a fragment to the layout definition file which represents its content view and vice versa, from the layout definition to the source code.

- To jump from a component to its related layout definition, open the source code of the component, and do one of the following:
  - Click the icon in the gutter area and choose the layout definition file in the Go To Related Symbol pop-up list.
  - On the main menu, choose **Navigate | Related Symbol** .
- To jump from a layout definition to the source code of the corresponding component, open the layout definition file in the text mode and do one of the following:
  - Click the  icon in the gutter area.
  - On the main menu, choose **Navigate | Related Symbol** .

A **layout** defines the user interface of an [activity](#) or an [app widget](#) (fragment). Layouts are declared in XML **resource definition files** . See [Creating Resources](#) for instructions on how to create resource folders and resource definition files.

With IntelliJ IDEA, you can build the design of your application without editing the layout definition files manually, and check how the application design is rendered in various target environments without running the application on any physical or virtual devices.

**Note** Alternatively, edit the layout definition files manually, possibly using the Android-specific refactoring provided by IntelliJ IDEA and [preview the changes](#) that are immediately reflected in the dedicated [Preview](#) tool window, where you can adjust the layout to various platforms and devices. To switch to the manual mode, click the Text tab or choose Go To Declaration from the [context menu](#) in the Design pane, or click the  icon in the [Preview window Toolbar](#) .

Designing your layout in the visual mode is performed in the [Design](#) pane of the [Android UI Designer](#) tool window. The pane is located in the central part of the UI Designer (assuming the default tool window layout). When you open a layout definition file for editing, the pane appears in the editor tab by default. If you are editing the layout definition file manually and then switch to the visual mode by clicking the Design tab, the pane opens in the tab where the edited layout definition file is opened,

The pane shows a rectangular canvas that is synchronized with the current layout definition file and with the Component Tree view, so any changes to the canvas are reflected there accordingly. If IntelliJ IDEA detects any discrepancy in the code, a warning is displayed.

Note that intention actions and quick fixes are available in the design mode in the same way as when you edit the layout definition files manually. The intention action icon  or the quick-fix icon  is displayed on the canvas, in the Component Tree or in the Properties pane.

To build the design of an Android application, perform the following basic operations:

- [Add predefined components from the Palette](#)
- [Add user-defined components and components from Android SDK](#)
- [Arrange the components](#)
- [Specify component properties](#)
- [Convert components into other types preserving the common properties](#)
  
- [Preview the layout](#)

## To add a predefined component to the canvas

Do one of the following:

- Select the required element in the Palette pane and drag and drop it to the canvas in the Design pane.
- Click the required element in the Palette pane and then click an area on the canvas.
- Click the required element in the Palette pane and then click the Component Tree where you want this element to be positioned.

Every component added in either way is also added to the Component Tree and is declared in the layout definition file.

## To add a component defined either in your project or in the Android SDK

1. Expand the Custom area in the Palette pane.
2. Do one of the following:
  - To embed a layout, click the Include icon. In the Resources dialog box that opens, click the Project tab to search among your layout definitions or click the System tab to search in the SDK.
  - To add a combination of components, click Fragment and choose the fragment to embed in the Resources dialog box that opens.
  - To add a [user-defined view](#) , click CustomView and choose the view to insert in the dialog box that opens.

## To place a component in the right position

The canvas is synchronized with the Component Tree , so you can arrange components by moving them in either of these in either pane.

Select the required component on the canvas or in the Component Tree and drag it to the right position or copy and paste it using the [context menu](#) .

## To specify component properties

You can set the values for the mandatory component properties right in the canvas, or switch to the Properties pane for a more in-depth configuration.

- To assign the values for the essential properties in the canvas, double-click the component in question and specify the values in the pop-up dialog box that appears.

- For an in-depth configuration of the component properties, select the component in the canvas or in the Component Tree , switch to the Properties pane, and specify the values for the properties of your choice. Click the right column in the Properties pane to start editing a property. You can click the Browse button  the appears on the right to select or project or a system resource.
- By default, the pane shows only a standard set of properties, and the most frequently used ones are displayed in bold . To have the pane display all properties that are defined for the selected component according to the specification, click the Show expert properties button  on the toolbar.
- To view a brief documentation for the selected property from [Android reference](#) , click the Show documentation button  on the toolbar or press `Ctrl+Q` .
- Properties with updated values are highlighted in blue. To discard the changes you have made and return to the default value, select the property and click the Restore default value button  on the toolbar.

## To convert a component into another type

In some cases, you may need to transform an already fully configured component into a component of another type. With IntelliJ IDEA, you can do it without losing the specified properties: all properties that are common for both types will be preserved in the new component. This operation is referred to as **morphing** .

1. Select the component that you want to convert in the canvas or in the in the Component Tree and choose Morphing on the context menu of the selection.
2. IntelliJ IDEA displays the list of compatible component types, i.e. the types into which the selected component can be converted. Choose the target type and [configure the properties](#) that were not configured in the original component.

With IntelliJ IDEA, you can preview the output of the currently opened layout definition file without launching a physical or a virtual device. The preview changes dynamically as you update the layout definition file. Using the layout preview, you can adjust your application to different Android platforms, devices, orientations, dock modes, locales, etc.

Depending on the [mode](#) in which you are designing the application layout, you can preview the output in different ways:

- In the dedicated [Preview](#) tool window, when editing the layout definition file manually. The tool window appears when you open a layout definition file and switch to the Text tab.
- Right in the [editor](#), when [editing the layout using Android UI designer](#).

On this page:

- [Accessing layout preview](#)
- [Previewing layout in different environments](#)
- [Adjusting the preview appearance](#)

## To access layout preview

1. Open the required layout definition file in the editor.
2. Choose the editing mode:
  - To edit the layout manually, switch to the Text tab. The [Preview](#) tool window opens.
  - To edit the layout in the [Designer](#) tool window, switch to the Design tab. In this tab you can edit the layout in the visual mode without editing the text definition file.

## To preview a layout in different environments

Use the controls of the Preview tool window or the Design tab to emulate the target configuration to run the application in. The table below lists all available options:

### ItemTooltipDescription

Item	Tooltip	Description
	Configuration to render this layout in the IDE	<p>From this drop-down list, select a layout configuration that you want to preview and edit, create a new layout configuration, or select different preview options. The available options are:</p> <ul style="list-style-type: none"> <li>- Create Landscape Variation : select this option to create a landscape version of your layout. The corresponding layout definition file will be generated in the <code>res\layout-land</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-land option that opens the <code>layout-land\&lt;layout_file_name&gt;.xml</code> file for editing.</li> <li>- Create layout-xlarge Variation : select this option to create a variation of your layout for an extra large screen size (at least 960x720 dp). The corresponding layout definition file will be generated in the <code>res\layout-xlarge</code> folder. Once this variation is created, this menu option will be replaced with the Switch to layout-xlarge option that opens the <code>layout-xlarge\&lt;layout_file_name&gt;.xml</code> file for editing.</li> <li>- Switch to layout : this option is only available if you have created multiple layout versions. Select it to return to the original layout definition file.</li> <li>- Create Other : select this option to create another variation of your layout. In the Select Layout Directory dialog that opens, specify the folder where the layout definition will be stored and select <a href="#">resource qualifiers</a> that determine a specific device configuration. Select the relevant qualifier and click . Then specify the value of the qualifier in the dialog box that opens. The qualifier is added to the Chosen qualifiers list.</li> <li>- Preview Representative Sample select this option to display multiple device configurations and preview the layout on the most important screen sizes.</li> <li>- Preview All Screen Sizes : select this option to display multiple device configurations and preview the layout on all available screen sizes.</li> <li>- Preview All Locales : select this option to preview the layout in all locales where your application is going to be used.</li> <li>- Preview Right-to-Left Layout : select this option to preview the layout in both directions (left-to-right and right-to-left) side by side.</li> <li>- Preview Android Versions : select this option to preview the layout on all installed Android API versions.</li> <li>- Preview Included : select this option to preview your layout nested in another layout. This option is only available if the current layout is included into another layout.</li> <li>- Preview Layout Versions : select this option to display multiple device configurations and preview the layout in all available variations.</li> <li>- None : select this option to return to the default view.</li> <li>- Toggle Layout Mode : select this option to switch between different preview options.</li> </ul>
 Nexus 4+	The virtual device to render the layout with	<p>From this drop-down list, select a virtual or a physical device to preview what your application will look like on this device. To add a new virtual device, select Add Device Definition and configure an emulator in the <a href="#">Android Virtual Device (AVD) Manager</a> that opens (for instructions refer to <a href="#">Managing Virtual Devices</a>).</p>
	Go to next state	<p>From this drop-down list, select the preview orientation ( <a href="#">portrait</a> or <a href="#">landscape</a> ), the UI mode ( <a href="#">Normal</a>, <a href="#">Car Dock</a>, <a href="#">Desk Dock</a>, <a href="#">Television</a>, <a href="#">Appliance</a> ) and switch between the <a href="#">Night</a> (dimmed screen) and <a href="#">Not Night</a> (standard brightness) modes.</p>

	Theme	For details on UI modes refer to <a href="#">UI Mode Manager</a> . Click this button to select a theme from the Select Theme dialog.
	N/A	Click this button to associate the layout with an activity. Select Associate with <activity_name> to associate it with the current activity, or Associate with Other Activity to display a list of available activities to select from.
	Locale to render layout with in the IDE	From this drop-down list, select an existing locale or add a locale for your application. A locale is a combination of the target country and language to have the dates and some other data presented in accordance with the local rules and preferences. You can also preview the layout in all available locales and in both directions (left-to-right and right-to-left).
	Android version to use when rendering layouts in the IDE	From this drop-down list, select an API version or use the Automatically Pick Best option to render the layout using the most suitable Android version. You can also preview the layout on all installed Android API versions.

**Note** Normally, the preview changes on-the-fly as you update the definition file. If it does not, click the Refresh button  to have IntelliJ IDEA update the preview.

## To adjust the preview appearance

When you preview the layout output in the Preview tool window and design the layout manually in the editor, you may need to move the bounds of the tool window so more space is available in the editor. In this case it may be helpful to compress the preview so it fits the tool window size but still reflects the layout output in the emulated environment.

Use the controls in the toolbar to adjust the appearance of the layout preview:

### ItemTooltipDescription

	Zoom to Fit	Toggle this button to have IntelliJ IDEA compress or expand the preview so it fits the <a href="#">target screen size</a> .
	Reset Zoom to 100%	Click this button to have IntelliJ IDEA reset the zoom to preview the actual size.
	Zoom In	Click this button to have IntelliJ IDEA expand the preview.
	Zoom Out	Click this button to have IntelliJ IDEA compress the preview.
	Jump to Source	Click this button to switch to the Text tab where you can edit the application layout in the source <code>.xml</code> file.
	Refresh	Click this button to have IntelliJ IDEA update the preview so that it reflects on-the-fly changes to the current layout definition.
	Save Screenshot	Click this button to take a screenshot of the application preview. <b>Note</b> This button is only available from the Text tab of the layout preview window.
	Options	Click this button to configure the appearance and behavior of the tool window. <ul style="list-style-type: none"> <li>– Hide for non-layout files: select this option to have IntelliJ IDEA temporarily close the tool window when the focus in the editor switches to a non-layout file. As soon as the same or another layout definition file is in focus, the tool window reappears automatically.</li> <li>– Include Device Frames (if available): select this option to make the preview look like it is going to appear on the actual device.</li> <li>– Show Lighting Effect: select this option to display lighting effects to make the preview look more natural.</li> </ul> <b>Note</b> This option is only available if the Include Device Frames option is selected.

In addition to [common refactoring](#) , IntelliJ IDEA provides a number of the Android-specific refactorings for the **Android layout definition XML files** . Most of these refactorings are available in both **design modes** :

- The manual mode, right in the editor tab where the target layout definition file is opened, and from the [Structure tool window](#) .
- In the [Android UI Designer](#) , from the [Design pane](#) or [Component Tree](#) .

You can toggle between these modes by switching between the Design and Text tabs in the editor where the layout definition file is opened.

In this topic:

- [Extract Style](#)
- [Inline Style](#)
- [Extract Layout](#)
- [Inline Layout Refactoring](#)

## Extract Style

[Android styles](#) help separate the application design from the application functionality, just like [Cascading Style Sheets \(CSS\)](#) .

With the **extract style** refactoring, you can create a style from a layout XML tag. IntelliJ IDEA creates a style declaration in the `/res/values/styles.xml` file and converts the tag attributes into style properties declared in the `item` elements. The benefit is that now you no longer need to parse an entire resource definition file updating the tag attributes to edit a layout. All you need to do is update the style definition, whereupon the changes are applied automatically wherever the style is referenced.

### To apply the extract style refactoring

1. Do one of the following:
  - In the **visual mode** , select the component where the source XML tag is used in the definition on the canvas in the Design pane, or in the Component Tree .
  - In the **manual mode** , position the cursor anywhere inside the source XML tag.
2. From the main menu, select Refactor | Refactor This or press `Ctrl+Shift+Alt+T` . In the pop-up that appears, select Style from the Extract group. Alternatively, choose Refactor | Extract | Extract Style on the context menu of the selection.
3. In the Extract Android Style dialog box that opens, specify the name for the style to be created and select the tag attributes to be included as style properties.
4. To have IntelliJ IDEA automatically update the layout definition by replacing tag attributes with references to the newly created style, select the Launch 'Use Style Where Possible' refactoring after the style is extracted checkbox.

## Inline Style

This refactoring is opposite to the **Extract Style** refactoring and results in adding all attributes defined in a style to one or all components where this style is applied. This refactoring is also used when you need to merge a [parent style with its inheritor](#) .

You can invoke the **Inline Style** refactoring from a style definition or from a component to which the style is applied. In the first case, IntelliJ IDEA removes the style definition and adds the corresponding attributes to all components where it is used.

When refactoring is invoked from a component, you can apply it either to all components with this style, or only to the current one.

### To apply the Inline Style refactoring

Do one of the following:

- To invoke the refactoring from a style definition:
  1. Open the style definition file, position the cursor at the name of the style to be inlined, and choose Refactor | Inline from the context menu or press `Ctrl+Alt+N` .
  2. The [Inline Android Style](#) dialog box that opens provides only one option ( [Inline all references and remove the style](#) ) which is selected by default. As a result, IntelliJ IDEA converts the attributes of the style into XML tags, adds them to the definitions of all components where the style is used, and removes the style definition.
    - To apply the changes immediately, click Refactor .
    - To open the [Find tool window](#) and [preview the changes before applying](#) , click Preview .
- To invoke the refactoring from a component definition:
  1. Select a component with the style in question:

- In the **visual mode** , select a component with this style in the Design pane or in the Component Tree .  
Then choose Refactor | Inline Style from the main menu or from the context menu of the selection.
  - In the **manual mode** , select a component with this style in the Structure view and choose Refactor | Inline Style from the main menu or from the context menu of the selection.
2. In the **Inline Android Style** dialog box that opens, configure the refactoring:
    - To have IntelliJ IDEA convert the attributes of the style into XML tags, add them to the definitions of all the components where the style is used, and remove the style definition, choose Inline all references and remove the style .
    - To have the refactoring applied to the current component only, choose Inline this usage and keep the style .
  3. Specify how you want to apply the changes.
    - To apply the changes immediately, click Refactor .
    - To open the [Find tool window](#) and [preview the changes before applying](#) , click Preview .

## Extract Layout

IntelliJ IDEA supports [re-using Android layouts](#) : IntelliJ IDEA moves a part of an existing layout definition to a separate layout definition file and references it in the original layout definition through an automatically inserted `<include/>` tag. In IntelliJ IDEA, this operation is called **extract layout refactoring** .

### To extract a layout

1. Select the fragment to extract as a separate layout. Do one of the following:
  - In the **manual mode** , select the code fragment to extract or position the cursor in the root element of the fragment.
  - In the **visual mode** , select the component or a group of components to be extracted in the Design . pane or in the Component Tree .
2. From the main menu, choose Refactor | Refactor This or press `Ctrl+Shift+Alt+T` . In the pop-up list that appears, choose Layout from the Extract group. Alternatively, choose Refactor | Extract | Extract Layout from the context menu of the selection.
3. In the Extract Android Layout dialog box that opens, specify the name of the file where the extracted layout definition will be stored and the name of its parent folder. You do not need to create the file and the folder in advance, IntelliJ IDEA will create them automatically.
4. Create a list of configuration qualifiers for the layout. This list determines the set of **alternative resources** that must be provided to enable running the application in specific target device configurations.
  - To add a qualifier to the set, select it in the Available Qualifiers list, click the `»` button, and specify the value of the qualifier.
  - To remove a qualifier from the set, select it in the Chosen Qualifiers list and click the `«` button.

For detailed information on the qualifiers, their meaning, acceptable values and format, see [specification of configuration qualifiers for alternative resources](#) .

## Inline Layout Refactoring

This refactoring is opposite to the **Extract Layout** refactoring and results in embedding a layout that was referenced through an `<include/>` tag and removing the tag.

The **Inline Layout** refactoring is invoked from the `<include/>` tag in the layout definition file. You can have IntelliJ IDEA apply it either to all references and remove the layout definition file, or only to the current reference.

### To inline a layout

1. Open the XML definition file from which the layout in question is referenced.
2. Navigate to the `<include/>` tag which references the layout in question and position the cursor at the layout name.
3. Do one of the following:
  - Choose Refactor | Inline from the main menu.
  - Choose Refactor | Refactor This from the main menu, and then choose Inline in the pop-up list that opens,
  - Press `Ctrl+Alt+N` .
  - Choose Refactor | Inline from the context menu.
4. In the Inline Android Layout dialog box that opens, configure the refactoring:
  - To have IntelliJ IDEA embed the layout into all files where it is referenced through `<include/>` tags and remove the referenced layout definition file, select Inline all references and remove the file .
  - To have the refactoring applied to the current reference only, select Inline this usage and keep the file .
5. Specify how you want to apply the changes:
  - To apply the changes immediately, click Refactor .
  - To open the [Find tool window](#) and [preview the changes before applying](#) , click Preview .

On this page:

**Note** You can also monitor an application behavior via the [Android Device Monitor](#) tool (to launch it, navigate to Tools | Android | Android Device Monitor).

## Running or Debugging an entire Android application

1. Start [creating an Android run/debug configuration](#) . On the [Run/Debug Configuration: Android](#) page that opens, specify the configuration name and select the module to which this configuration will be applied.
2. Choose the Default APK from the Deploy drop-down list in the Installation Options area and Default Activity from the Launch drop-down list in the Launch Options area. IntelliJ IDEA will upload the `.apk` built from the module specified in the Module drop-down list above. The `.apk` is built automatically, no preliminary artifact configuration is required from your side.
3. Appoint the device where the application will run:
  - To use a virtual device, select the Emulator option from the Target drop-down list in the Deployment Target Options area. Select a device from the Prefer Android Virtual Device list, or click  to configure a new emulator.
  - To use a physical device, select the USB device option from the Target drop-down list in the Deployment Target Options area, and plug-in the device through a USB cable.
  - Select the Show Device Chooser Dialog option if you want to select the target manually each time upon the application launch.
4. Start [running](#) or [debugging](#) the target activity. If you have not specified a target device, [choose it manually](#) .
5. View and analyze Android system messages in the [Logcat](#) tab of the [Android Monitor tool window](#) .

## Running or debugging a custom .apk that will be later embedded in an application

1. Configure an artifact to generate the `.apk` from:
  - In the main menu, navigate to File | Project Structure .
  - In the left-hand pane, click Artifacts . In the central pane, click the Add button  in the toolbar.
  - Select Android Application from the list of available artifact types and then select Empty from the context menu.
  - In the right-hand pane, add the artifact components. The artifact must contain all resources and code that want packaged in the `.apk` . For details, refer to [Generating a Signed Release APK Through an Artifact](#) and [Output Layout Tab](#) .
2. Start [creating an Android run/debug configuration](#) . On the [Run/Debug Configuration: Android](#) page that opens, specify the configuration name and select the module to which this configuration will be applied.
3. To run or debug a custom `.apk` , choose the Custom Artifact option from the Deploy drop-down list in the Installation Options area and select the artifact to build the `.apk` from. In this case, you have to define the artifact manually before creating a run/debug configuration (see [Generating a Signed Release APK Through an Artifact](#) and [Working with Artifacts](#) for details). Then select the Specified Activity option from the Launch drop-down list in the Launch Options area, and specify the start-up activity from the chosen artifact ( `.apk` ). Type the activity name manually or click the Browse button  and select it in the Select Activity Class dialog box that opens. The list of available activities is determined by the choice of the module.
4. Appoint the device where the application will run:
  - To use a virtual device, select the Emulator option from the Target drop-down list in the Deployment Target Options area. Select a device from the Prefer Android Virtual Device list, or click  to configure a new emulator.
  - To use a physical device, select the USB device option from the Target drop-down list in the Deployment Target Options area, and plug-in the device through a USB cable.
  - Select the Show Device Chooser Dialog option if you want to select the target manually each time upon the application launch.
5. Start [running](#) or [debugging](#) the target activity. If you have not specified a target device, [choose it manually](#) .
6. View and analyze Android system messages in the [Logcat](#) tab of the [Android Monitor tool window](#) .

## Debugging an already running application

Apart from debugging an Android application by initiating a debugging session, you can apply the debugger to an already running application. You can do this in one of the following two ways:

- Attach the debugger to a running process:
  1. Click the Attach debugger to Android process button  in the main toolbar.
  2. In the Choose Process dialog that opens, select a process from the list that shows all currently active processes grouped by the devices where they are running.
- Start a run/debug configuration without deploying a package and launching an activity
  1. Start [creating an Android run/debug configuration](#) . On the [Run/Debug Configuration: Android](#) page that opens, specify the configuration name and select the module to which this configuration will be applied.
  2. Select the Nothing option from the Deploy drop-down list in the Installation Options area and Nothing from the Launch drop-down list in the Launch Options area.
  3. Appoint the device where the application will run:
    - To use a virtual device, select the Emulator option from the Target drop-down list in the Deployment Target Options area. Select a device from the Prefer Android Virtual Device list, or click  to configure a new emulator.
    - To use a physical device, select the USB device option from the Target drop-down list in the Deployment Target Options area, and plug-in the device through a USB cable.

- Select the Show Device Chooser Dialog option if you want to select the target manually each time upon the application launch.
- 4. Start [running](#) or [debugging](#) the target activity. If you have not specified a target device, [choose it manually](#) .
- 5. View and analyze Android system messages in the [Logcat](#) tab of the [Android Monitor tool window](#) .

1. To start creating an Android run configuration, select Run | Edit Configuration from the main menu. Alternatively, click `Shift+Alt+F10` and select Edit Configuration from the pop-up menu. Click the Add New Configuration button  on the toolbar and select Android Application from the pop-up list. On the [Run/Debug Configuration: Android Application](#) page that opens, specify the configuration name and select the module to which this configuration will be applied.
2. Specify the `.apk` file that will be deployed on the target device and appoint the activity that will be launched on the application start.
  - To run or debug the entire application, choose the Default APK from the Deploy drop-down list in the Installation Options area and Default Activity from the Launch drop-down list in the Launch Options area. IntelliJ IDEA will upload the `.apk` built from the module specified in the Module drop-down list above. The `.apk` is built automatically, no preliminary artifact configuration is required from your side.
  - To run or debug a custom `.apk` that will be later embedded in an application, choose the Custom Artifact option from the Deploy drop-down list in the Installation Options area and select the artifact to build the `.apk` from. In this case, you have to define the artifact manually before creating a run/debug configuration (see [Generating a Signed Release APK Through an Artifact](#) and [Working with Artifacts](#) for details). Then select the Specified Activity option from the Launch drop-down list in the Launch Options area, and specify the start-up activity from the chosen artifact ( `.apk` ). Type the activity name manually or click the Browse button  and select it in the Select Activity Class dialog box that opens. The list of available activities is determined by the choice of the module.
  - If you are going to start a debugging session for an already running application, select Do not deploy anything in the Packages area to suppress uploading data to the device, and then select Do not launch activity in the Activity area. Executing a run configuration with these settings is the same as clicking the Attach debugger to Android process button  on the toolbar.
3. In the Deployment Target Options area, specify the device where the application will be launched.
  - To specify a virtual device, select the Emulator option and choose a virtual device from the Prefer Android Virtual Device drop-down list.

**Tip** If no virtual devices are available, click the Browse button  to start the Android Virtual Device (AVD) Manager and configure a new emulator (for details, refer to [Managing Virtual Devices](#) ).

  - If you want to select a target device manually select the Show chooser dialog option. Each time you start a run/debug session and apply this configuration, IntelliJ IDEA will display the [Choose Device](#) dialog.
  - To have IntelliJ IDEA detect a plugged-in USB device upon the application start, select the USB device option.

Selecting the Show chooser dialog or USB device option may be helpful if you are going to run the application on a physical device which will be plugged-in later and, therefore, the set of available devices cannot be foreseen.

When you run or debug your Android application, and no target device is specified in the applied run/debug configuration, you need to choose the target device manually.

You have the following options:

- Choose a physical device:
  - a. Plug-in a physical Android device through a USB cable.
  - b. Start a [run/debug session](#) .
  - c. In the [Choose Device dialog](#) that opens, select the Choose a running device option and choose the plugged-in device.
- Choose a running virtual device:
  - a. Start a [run/debug session](#) .
  - b. In the [Choose Device dialog](#) that opens, select the Launch emulator option and select a virtual device from the Android virtual device drop-down list.  
If you want to use this device emulator without selecting it manually each time you start a run/debug session, select the Use same device for future launches option.
- Configure a new virtual device:
  - a. Start a [run/debug session](#) .
  - b. In the [Choose Device dialog](#) that opens, select the Android virtual device option and click the Browse button  to launch the [Android Virtual Device \(AVD\) Manager](#) . For instructions on how to configure a device emulator using the Android Virtual Device Manager, refer to [Android documentation](#) .

In IntelliJ IDEA, debugging of Android applications is provided through the support of the [logcat](#) functionality that stores a log of system debug output. Log messages include a stack trace when the emulator throws an error, so you can [navigate to the exception location](#) in the source code.

The logcat functionality is handled by the [Android Debug Bridge](#) (adb). This service supports interaction between your development environment, Android devices, emulators and other tools, for example, [DDMS](#) .

If various tools that use ADB are launched simultaneously, they may conflict with each other, so it is recommended to [disable the logcat functionality](#) before switching from IntelliJ IDEA to an ADB-managed tool.

In IntelliJ IDEA, the logcat functionality is available through the Logcat tab of the [Android Monitor tool window](#) . By default, the tab is activated automatically every time an application is deployed and launched successfully.

**Tip** When logcat is attached to a device, it keeps auto-scrolling you to the bottom of the log. If you want to stop the automatic scroll, start scrolling the log with your mouse.

On this page:

- [Switching the Logcat functionality on and off](#)
- [Showing and hiding the Logcat tab](#)
- [Defining the scope of log data to display](#)

## Switching the Logcat functionality on and off

To enable/disable logcat, in the main menu navigate to Tools | Android and toggle the Enable ADB Integration option.

## Showing and hiding the Logcat tab

By default, the Logcat tab is activated automatically every time an application is deployed and launched successfully. You can disable automatic display of the Logcat pane by performing the following steps:

1. [Start creating an Android run/debug configuration](#) or open an existing configuration for editing (in the main menu, navigate to Run | Edit Configurations and select the required configuration).
2. Switch to the Miscellaneous tab and clear the Show logcat automatically checkbox.

## Defining the scope of log data to display

During a debug session, you can switch to the [Android Monitor tool window](#) and configure the scope of log data to be displayed. You can:

- Select to only see messages related to a specific process.
- Define a log level for messages to be displayed.
- Create log data filter configurations.

For detailed instructions on how to configure these options, refer to [Android Monitor tool window](#) .

[Virtual devices](#) are used to run or debug applications intended for Android devices. You can configure virtual devices to emulate actual Android units by defining their hardware and software parameters.

To configure a virtual Android device, you need to open the [Android Virtual Device \(AVD\) Manager](#) . To launch it:

- In the main menu, select Tools | Android | AVD Manager .
- When you [create or edit a run/debug configuration](#) , select the Emulator option from the Target drop-down list in the Deployment Target Options area and click the Browse button  next to Prefer Android Virtual Device .
- In the [Choose Device Dialog](#) that opens if you select the Show chooser dialog when [creating a run/debug configuration](#) , select the Launch emulator option and click the Browse button  next to Android virtual device .

For instructions on how to configure Android virtual devices, refer to [Android documentation](#) .

With IntelliJ IDEA you can generate and run unit tests for your Android applications using [Android Testing Framework](#) .

When the Android project is created, IntelliJ IDEA creates the following test directories containing sample tests:

- test directory - for running [Unit tests](#)
- androidTest directory - for running [Instrumented Unit tests](#)

To execute unit tests, IntelliJ IDEA provides an Android-specific run configuration.

## To run tests for an Android application

1. Specify the tests that you want to run. Do one of the following:
  - To run a single test, open it in the editor and select Run | name of the test from the context menu. IntelliJ IDEA creates a [temporary run configuration](#) for your test.
  - To run all tests in a class or an entire test module, [create an Android Test run/debug configuration](#) .
2. Select a run/debug configuration from the drop-down list on the main toolbar and [start the test](#) according to it.
3. [Monitor the test execution](#) and [view test results](#) in the [Test Runner](#) tab of the [Run](#) tool window.

IntelliJ IDEA supports Android [library projects](#) that hold shared Android source code and resources. Other Android application projects can reference a library project and include its compiled sources in their `.apk` files at build time.

In IntelliJ IDEA, library projects are supported through separate library modules.

To enable sharing Android source code and resources, do one of the following:

- Create a new Library module.
- Convert an Application module that contains sources you want to share into a Library module.

In this topic:

- [Creating a Library module](#)
- [Converting an Application module into a Library module](#)
- [Using a Library module in another project](#)
- [Adding data from AndroidManifest.xml for a library module to AndroidManifest.xml for the entire application](#)
- [Including the .dex file of a library module into the .apk of the entire application without rebuilding \(pre-dexing\)](#)

## Creating a Library module

1. Do one of the following:
  - [Create a project from scratch](#)
  - [Add a module to an existing project](#)
2. On the first page of the wizard, select Android in the left pane and Library Module in the right pane.
3. Complete the wizard.

## Converting an Application module into a Library module

You can convert an Application module into a Library module by updating its Android facet.

1. Open the Project Structure dialog box by choosing File | Project Structure from the main menu.
2. Select Modules in the left pane. In the central pane, expand the node of the module that you want to turn into a Library module and click Android .
3. In the right-hand pane, select the Library module checkbox on top of the [Android facet page](#) .

## Using a Library module in another project

To use a Library module in another project, you need to import this module into it.

1. From the main menu, select File | New | Module from Existing Sources .
2. In the [dialog that opens](#) , browse to the `.iml` module file that you want to import and click OK . The module node will be added to the tree view.
3. Add [dependencies](#) on the imported library module to the modules where its data is going to be used:
  1. Open the settings of the non-library module: navigate to File | Project Structure , select Modules in the left pane and select your non-library module in the central pane.
  2. In the right pane, switch to the Dependencies tab. Click the Add button **+** in the toolbar on the right and select Module Dependency from the context menu.
  3. In the Choose Modules dialog box that opens, select the imported library module from the list and click OK .

## Adding data from AndroidManifest.xml for a library module to AndroidManifest.xml for the entire application

To successfully integrate a library module into another application, its components must be declared in the application `AndroidManifest.xml` file. The manifest file contains the information that is required to run the application (for more information, see [App Manifest](#) ). You can either add this information on a library module manually, or extract it from `AndroidManifest.xml` of the library module and add it to the `AndroidManifest.xml` of the application automatically.

The second approach is referred to as [merging manifests](#) .

To have the manifest of a library module merged with the application manifest automatically:

1. Open the Project Structure dialog box by choosing File | Project Structure from the main menu.
2. Select Modules in the left pane. In the central pane, expand the non-library module and click the Android facet under its node.
3. In the right pane, on the [Android facet page](#) , switch to the Packaging tab and select the Enable manifest merging option.

## Including the .dex file of a library module into the .apk of the entire

## application without rebuilding (pre-dexing)

During the application packaging, the `.class` files of a library module are converted into `.dex` files. This operation is referred to as **dexing**. Finally, the `.dex` files output from the library module is included in the final application `.apk` (learn more about the building procedure from [Building and Running](#)).

As a rule, the contents of a library module remain unchanged. In this case you can have them `dexed` only once, whereupon the output `.dex` files are included in the `.apk`. This approach is referred to as **pre-dexing**.

By default, IntelliJ IDEA pre-dexes library mode dependencies as well as external `jars` that have not been updated since the previous build. You can change these settings so that all `.class` files are always dexed.

1. Open the Project Structure dialog box by choosing File | Project Structure from the main menu.
2. Select Modules in the left pane. In the central pane, expand the non-library module and click the Android facet under its node.
3. In the right pane, on the [Android facet page](#), switch to the Packaging tab and select the Pre-dex external jars and Android library dependencies option.

You may need to have your application built in several versions, which means that several Android application packages ( `.apk` files) will be generated. If these files have the same name, the user will be unable to deploy them on the same device simultaneously. To avoid this, you can have IntelliJ IDEA generate several `.apk` files with different names ( **application IDs** ) from the same source code.

The application package name ( **application ID** ) is specified in the `package` attribute of the `manifest` element (see <http://developer.android.com/guide/topics/manifest/manifest-element.html#package> for details). This name follows the [Java naming conventions](#) and, by default, is the same as the name of the package to which the class implemented for the application belongs.

The name of the application (the `android:name` attribute of the `application` element, see <http://developer.android.com/guide/topics/manifest/application-element.html#nm> ) and activity names (the `android:name` attribute of the `activity` element, see <http://developer.android.com/guide/topics/manifest/activity-element.html#nm> ) are, by default, specified **relative** to the **application ID** and, accordingly, to the parent Java package of the application implementation class. However, renaming the **application ID** does not cause renaming the parent Java package of the application class.

You can either change the application ID through the **Rename** refactoring, or automatically on build time.

On this page:

- [Changing an application ID through the Rename refactoring](#)
- [Renaming an application ID on build time](#)

## Changing an application ID through the Rename refactoring

1. Open the `AndroidManifest.xml` file.
2. Position the cursor at the `package` attribute of the `manifest` element and choose Refactor | Rename from the context menu.
3. In the Rename dialog box that opens, specify the new package name and click OK .

The value of the `package` attribute changes to the newly specified value. However, because this does not cause renaming the parent Java package of the application class, the relative names of the application and activities are replaced with their fully qualified names.

## Renaming an application ID on build time

1. Open the Project Structure dialog box by choosing File | Project Structure from the main menu.
2. Select Modules in the left pane. In the central pane, expand the node of the relevant module and click Android .
3. In the right pane, switch to the Packaging tab and select the Rename manifest package option.

IntelliJ IDEA allows extracting Android application packages ([.apk files](#) ). IntelliJ IDEA supports integration with the **Android Asset Packaging Tool (aapt)** which compiles the application resources (for details, see [Building and Running](#) ).

With IntelliJ IDEA, you can generate both **signed** and **unsigned** `.apk` files. The following options are available:

- Extract **signed packages** to deploy and run your applications on physical devices. Based on this signature, the Android system identifies the author of every deployed application. You do not need to apply for a personal signature to any authority, a signature generated by IntelliJ IDEA is quite sufficient. With IntelliJ IDEA, you can generate a **signed package** in one of the following two ways:
  - Use the [Generate Signed APK Wizard](#) . The package will be signed during extraction.
  - Configure the `.apk` file as an **artifact** by creating an **artifact definition** of the type **Android application** in the Release signed package mode. When IntelliJ IDEA builds the package in accordance with this definition, the package is signed automatically.
- Extract **unsigned packages** to test them on emulators. Unsigned packages can be extracted only through artifact definitions in the Release unsigned package mode.
- Extract and sign **debug** packages. This signature is sufficient for testing and debugging applications but does not allow publishing them. Signing packages in the debug mode is available only through configuring an artifact definition in the Debug package mode.

You can also have your application obfuscated during packaging through integration with the [ProGuard](#) built-in tool.

In this section:

- [Generating a Signed Release APK Using a Wizard](#)
- [Generating a Signed Release APK Through an Artifact](#)
- [Generating an Unsigned Release APK](#)
- [Generating an APK in the Debug Mode](#)
- [Suppressing Compression of Resources](#)

To deploy and run an Android application on a physical device, you need to [sign the application digitally](#) . With IntelliJ IDEA, you can have your Android Application Package ( `.apk` file) signed with an existing release key on package extraction. IntelliJ IDEA also incorporates a release key generation tool that can be invoked during the packaging procedure. Generated keys are saved in a keystore binary file.

You can have as many keystore files and keys as you need and use either existing keys, or create new ones in existing keystores, or even create new keystores.

If you use the [Generate Signed APK Wizard](#) , IntelliJ IDEA signs the package on extraction.

On this page:

- [Extracting and signing an Android application package using a wizard](#)
- [Generating a new release key](#)

## Extracting and signing an Android application package using a wizard

1. From the main menu, select Build | Generate Signed APK . The [Generate Signed APK Wizard](#) starts.
2. On the [first page](#) , specify the release key you want to use and the keystore file that contains it. Do one of the following:
  - To sign the package with a key from an existing keystore file:
    1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#) . In the Key store password text box, type the password to the selected keystore.
    2. Specify the key alias and enter the password to access the key.
  - To generate a new key in an existing keystore:
    1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#) . In the Key store password text box, type the password to the selected keystore.
    2. Click the Create new button and [configure the release key to be generated](#) by filling in the data in the [New Key Store](#) dialog box that opens.
  - To generate a new keystore file with a new key:
    1. Click the Create new button. In the [New Key Store](#) dialog box that opens, specify the location of the file to be generated in the Key store path text box. Type the path manually or click the Browse button  , then select the parent folder and specify the name of the file.
    2. Specify and confirm the password to access the keystore.
    3. [Configure the new release key](#) by filling in the data in the Key area.

Click Next .

3. On the [next step](#) , in the Destination APK path text box, specify the folder where the `.apk` will be saved. Type the path manually, or click the Browse button  and select the target folder in the dialog that opens.
4. To have IntelliJ IDEA [obfuscate the application](#) during the packaging procedure, select the Run ProGuard checkbox and specify the location of the [proguard.txt](#) configuration file. The file is generated on project creation and is stored in the project root. IntelliJ IDEA suggests this default location in the Config file path text box. Accept the suggestion or specify a custom configuration file by clicking the Browse button  and selecting the required file in the [dialog that opens](#) .
5. Click Finish to generate and sign the package. IntelliJ IDEA informs you on successful operation completion.
  - To open the folder where the generated `.apk` file is located, click the Open File Location button.
  - To complete the wizard, click Close .

## Generating a new release key

1. Open the [New Key Store](#) dialog box by doing one of the following:
  - On the [first page](#) of the Generate Signed APK wizard, click the Create new button.
  - When creating an Android Application [artifact definition](#) , click the Create new button in the [Android](#) tab.

2. Specify the keystore location and enter the password to access it.

**Note** If you are going to add a new key to an already existing keystore and have already chosen it in the wizard or in the Artifact tab, these fields are already filled in.

3. Assign an alias to the new key in the Alias text box. The key will be referred to using this alias.
4. Enter the password to the key in the Password text box and confirm it.
5. Specify the validity period for the key in accordance with the [expected lifespan of your application](#) .
6. Provide the following personal information and click Next :
  - First and Last Name
  - Organizational Unit
  - Organization
  - City or Locality

- State or Province

- Country Code

To deploy and run an Android application on a physical device, you need to [sign the application digitally](#) . With IntelliJ IDEA, you can have your Android Application Package ( `.apk` file) signed with an existing release key on package extraction. IntelliJ IDEA also incorporates a release key generation tool that can be invoked during the packaging procedure. Generated keys are saved in a keystore binary file.

You can have as many keystore files and keys as you need and use either existing keys, or create new ones in existing keystores, or even create new keystores.

Apart from using the [Generate Signed APK Wizard](#) , you can configure the `.apk` file as an artifact by creating an [Android application artifact](#) definition. When IntelliJ IDEA builds the package in accordance with this definition, the package is signed automatically.

## Extracting and signing a release Android application package using an artifact definition

1. Select File | Project structure from the main menu and click `Artifacts` in the left pane.
2. Click the New button `+` and select Android Application from the context menu.
3. In the popup menu, define the artifact contents by selecting one of the following options:
  - To create an empty layout definition, select Empty .
  - To include a module data in the artifact, select From module <module name>

The general settings of the new artifact will be displayed in the Artifact Layout pane on the right.

4. Specify the [general settings](#) of the artifact. In the Output directory text box, specify the location of the target package `.apk` file.
5. Complete the artifact definition with the following steps:
  - Configure the [artifact structure](#) .
  - [Add resources](#) to the artifact.
  - [Arrange the elements](#) included in the artifact.
  - If necessary, specify additional activities to be performed before and after building the artifact in the [Pre-processing](#) and [Post-Processing](#) tabs.
6. Switch to the [Android tab](#) and select Release signed from the Type drop-down list.
7. Specify the release key you want to use and the keystore file that contains it. Do one of the following:
  - To sign the package with a key from an existing keystore file:
    1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#) . In the Key store password text box, type the password to the selected keystore.
    2. Specify the key alias and enter the password to access the key.
  - To generate a new key in an existing keystore:
    1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#) . In the Key store password text box, type the password to the selected keystore.
    2. Click the Create new button and [configure the release key to be generated](#) by filling in the data in the [New Key Store](#) dialog box that opens.
  - To generate a new keystore file with a new key:
    1. Click the Create new button. In the [New Key Store](#) dialog box that opens, specify the location of the file to be generated in the Key store path text box. Type the path manually or click the Browse button `...`, then select the parent folder and specify the name of the file.
    2. Specify and confirm the password to access the keystore.
    3. [Configure the new release key](#) by filling in the data in the Key area.

Click Next .

8. To have IntelliJ IDEA [obfuscate the application](#) during packaging, select the Run ProGuard checkbox and specify the location of the [proguard.txt](#) configuration file. The file is generated on project creation and is stored in the project root. IntelliJ IDEA suggests this default location in the Config file path text box. Accept the suggestion or specify a custom configuration file by clicking the Browse button `...` and selecting the required file in the [dialog that opens](#) .

Running an Android application on an emulator does not require a digital signature, so you can use **unsigned packages** for this purpose. An unsigned package can be extracted **only** through an [Android artifact definition](#) with the Release unsigned package mode turned on.

## Extracting an unsigned release Android application package

1. Select File | Project structure from the main menu and click `Artifacts` in the left pane.
2. Click the New button `+` and select Android Application from the context menu.
3. In the popup menu, define the artifact contents by selecting one of the following options:
  - To create an empty layout definition, select Empty .
  - To include a module data in the artifact, select From module <module name>

The general settings of the new artifact will be displayed in the Artifact Layout pane on the right.
4. Specify the [general settings](#) of the artifact. In the Output directory text box, specify the location of the target package `.apk` file.
5. Complete the artifact definition with the following steps:
  - Configure the [artifact structure](#) .
  - [Add resources](#) to the artifact.
  - [Arrange the elements](#) included in the artifact.
  - If necessary, specify additional activities to be performed before and after building the artifact in the [Pre-processing](#) and [Post-Processing](#) tabs.
6. Switch to the [Android tab](#) and select Release unsigned from the Type drop-down list.
7. To have IntelliJ IDEA [obfuscate the application](#) during packaging, select the Run ProGuard checkbox and specify the location of the [proguard.txt](#) configuration file. The file is generated on project creation and is stored in the project root. IntelliJ IDEA suggests this default location in the Config file path text box. Accept the suggestion or specify a custom configuration file by clicking the Browse button `...` and selecting the required file in the [dialog that opens](#) .

Apart from generating signed packages to be deployed on physical devices, or unsigned packages to be run on emulators, you can also have an application package extracted and signed in the [debug mode](#). This signature is sufficient for testing and debugging applications, but does not allow publishing them. Signing an application package in the **debug mode** is available only through configuring an artifact.

In the **debug mode**, you can have an APK signed either with the **default** certificate or with a **custom** one.

If you decide to use the **default certificate**, IntelliJ IDEA signs the extracted package in the **debug mode** using the debug keystore or a key that is generated by the Android SDK tools and has predefined names and passwords:

- Keystore name: `debug.keystore`
- Keystore password: `android`
- Key alias: `androiddebugkey`
- Key password: `android`
- CN ( **common name** ): `CN=Android Debug,O=Android,C=US`

These are the default settings in IntelliJ IDEA. This means that if you do not configure an artifact manually and select the Deploy default APK option in the [Run/Debug Configuration: Android Application dialog box](#), IntelliJ IDEA will use the predefined values in the certificate for the generated `.apk` file.

If you use a **custom certificate**, IntelliJ IDEA signs the extracted package in the **debug mode** using the debug keystore or a key that you specify yourself. You can have a new certificate generated or reuse an existing one. The latter approach is helpful, for example, if you have several applications and you want them all signed with the same certificate so they can be stored in the same folder on the device.

## Signing a package in the debug mode

1. Select File | Project structure from the main menu and click `Artifacts` in the left pane.
2. Click the New button `+` and select Android Application from the context menu.
3. In the popup menu, define the artifact contents by selecting one of the following options:
  - To create an empty layout definition, select Empty.
  - To include a module data in the artifact, select From module <module name>

The general settings of the new artifact will be displayed in the Artifact Layout pane on the right.

4. Specify the **general settings** of the artifact. In the Output directory text box, specify the location of the target package `.apk` file.
5. Complete the artifact definition with the following steps:
  - Configure the [artifact structure](#).
  - [Add resources](#) to the artifact.
  - [Arrange the elements](#) included in the artifact.
  - If necessary, specify additional activities to be performed before and after building the artifact in the [Pre-processing](#) and [Post-Processing](#) tabs.
6. Switch to the Android tab and specify the certificate you want to use from the Type drop-down list:
  - Select Debug signed with default certificate to have IntelliJ IDEA use the debug keystore or a key that is generated by the Android SDK tools and has predefined names and passwords.
  - Select Debug signed with custom certificate to have the package signed with a certificate of your choice. Specify the key to use and the keystore file that contains it by doing one of the following:
    - To sign the package with a key from an existing keystore file:
      1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#). In the Key store password text box, type the password to the selected keystore.
      2. Specify the key alias and enter the password to access the key.
    - To generate a new key in an existing keystore:
      1. Specify the file location in the Key store path text box. Type the path manually or click the Choose existing button and select the file in the [dialog that opens](#). In the Key store password text box, type the password to the selected keystore.
      2. Click the Create new button and [configure the release key to be generated](#) by filling in the data in the [New Key Store](#) dialog box that opens.
  - To generate a new keystore file with a new key:
    1. Click the Create new button. In the [New Key Store](#) dialog box that opens, specify the location of the file to be generated in the Key store path text box. Type the path manually or click the Browse button `...`, then select the parent folder and specify the name of the file.
    2. Specify and confirm the password to access the keystore.
    3. [Configure the new release key](#) by filling in the data in the Key area.

Click Next.

7. To have IntelliJ IDEA [obfuscate the application](#) during packaging, select the Run ProGuard checkbox and specify the location of the [proguard.txt](#) configuration file. The file is generated on project creation and is stored in the project root. IntelliJ IDEA suggests this default location in the Config file path text box. Accept the

suggestion or specify a custom configuration file by clicking the Browse button  and selecting the required file in the [dialog that opens](#) .

By default, the [Android Asset Packaging Tool \(aapt\)](#) compresses resources during packaging. However you can have resources of a certain type included in the `.apk` file uncompressed by changing the settings of the [Android facet](#).

## To suppress compressing resources of a certain type

1. Select File | Project structure from the main menu.
2. In the left-hand pane, select Modules, then in the central pane click the Android facet under the module with the resources to be packaged uncompressed.
3. In the right-hand pane, switch to the Compiler tab.
4. In the Additional command line parameters text box, type `-0 <file extension for this type of resources>`. As a result, all files with the specified extension will be excluded from compression. If the set of additional parameters does not fit into the text box, click  and specify the parameters in the dialog that opens.  
For example, if you want to include resources of a certain type in an uncompressed format, type `-0 <file extension for this type of resources>`.

If your application uses an Android SQLite database, you can access this database right from IntelliJ IDEA through a **data source** of the Android SQLite type. For more information about IntelliJ IDEA data sources, see [Managing data sources](#) .

## Creating an Android SQLite data source

1. Open the Database tool window by selecting View | Tool Windows | Database from the main menu.
2. Click **+** on the toolbar and select Android SQLite from the drop-down menu.
3. In the [Data Sources and Drivers dialog](#) that opens, specify the following:
  - The name of the data source.
  - The physical or virtual device where the target database is stored. If no devices are available in the drop-down list, this means that there are no running devices connected to IntelliJ IDEA. Run and connect a physical device or launch an emulator.
  - Specify the name of the application package the target database is associated with. For more information about application packages [Android documentation](#) . Select a package name suggested by IntelliJ IDEA or type its ID.  
For the database to be accessible, the corresponding application must be built as debuggable and installed on the device or the emulator.

IntelliJ IDEA run configurations, by default, build Android applications in the debug mode. Alternatively, you can [generate the APK in the debug mode](#) .

- In the Storage area, specify where the database is located:
  - Choose Internal if the database is stored in the internal memory of the device or the emulator.
  - Choose External if the database is stored in the external memory of the device or the emulator.
- In the Database drop-down list, specify the database name or location:
  - If the database is stored in the internal memory, choose the database name.
  - If the database is stored in the external memory, specify the database location relative to the memory root. For example, `Android/data/<application_ID>/<database_name>` .
- If the necessary SQLite driver files are missing, download them by clicking the Download link at the bottom of the dialog box.

See also, [Managing data sources](#) .

An Android application is a Java program written against the **Java SDK** and the **Android SDK**. Since IntelliJ IDEA is an integrated development environment (IDE) for any kind of Java applications, it automates and streamlines all steps of an Android application development, from writing the source code to preparing your application for publishing.

IntelliJ IDEA helps you perform the following tasks:

- Create the skeleton of a fully-functional Android application
- Manage the project and add classes and resources, such as strings, layouts, graphics, etc.
- Preview changes to the user interface through a tailor-made graphical designer
- Write and debug your source code
- Create unit tests
- Package and run your application on both physical devices and emulators

These tutorials will help you set up an Android project in IntelliJ IDEA and produce an executable that can run on emulators and physical devices.

Note that the tutorials listed below imply that you are using Windows as your operating system. Instructions for other operating systems may vary slightly.

In this section:

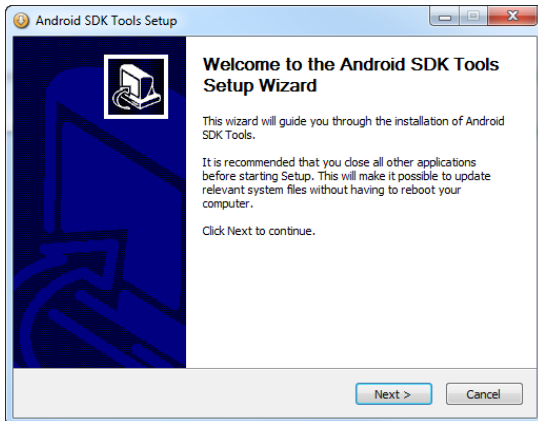

- [Prerequisites for Android Development](#)
- [Creating a New Android Project](#)
- [Importing an Existing Android Project](#)
- [Exploring the Project Structure](#)
- [Building and Running the Application](#)
- [Editing UI Layout Using Designer](#)
- [Editing UI Layout Using Text Editor](#)
- [Making the Application Interactive](#)
- [Creating Unit Tests](#)
- [Packaging the Application](#)

Before you start writing your first "Hello, world" Android application in IntelliJ IDEA, do the following:

1. [Download](#) and install JDK 7.
2. [Download](#) the Android SDK tools.

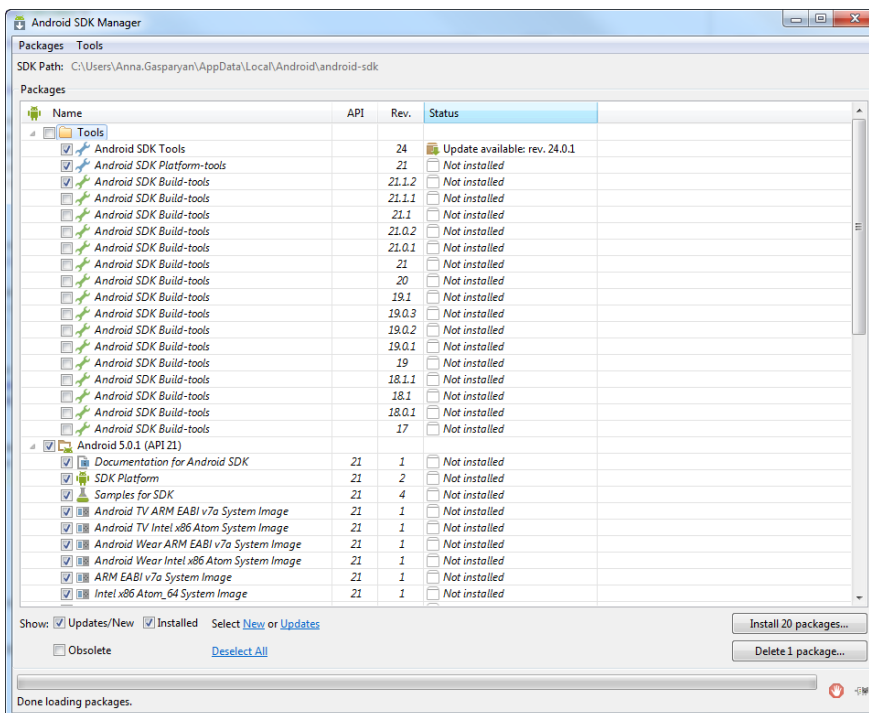

**Note** The [official Android download page](#) provides different download options. The default download option is Android Studio that includes the Android SDK tools. Since you already have IntelliJ IDEA with a bundled Android plugin, you can choose a smaller download and just pick up the Android SDK and platform tools. Scroll to Other Download Options and select the SDK Tools Only package for your operating system.

3. Run the installer to launch the Android SDK Tools Setup wizard:

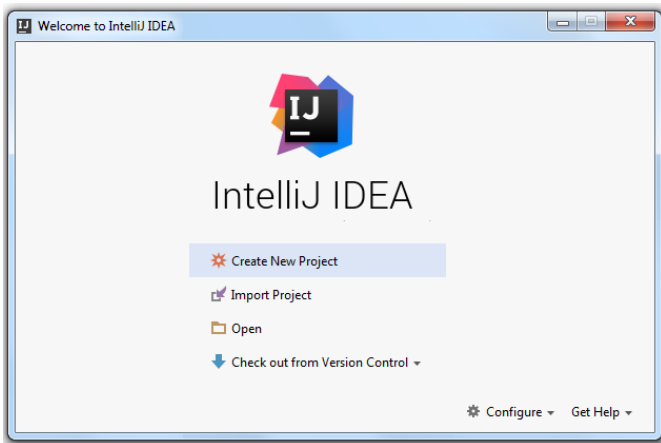

First, the wizard checks if the Java SDK is installed. Next, choose the installation options and specify the destination folder. We strongly recommend that the path to the Android SDK home directory does not contain spaces.

4. After the installation has completed successfully, you need to add SDK packages using the [SDK Manager](#) . On the last page of the Android SDK Tools Setup wizard, select the Start SDK Manager option and click Finish .
5. In the Android SDK Manager , select the packages you want to install (for detailed instructions, refer to [Adding SDK Packages](#) ).

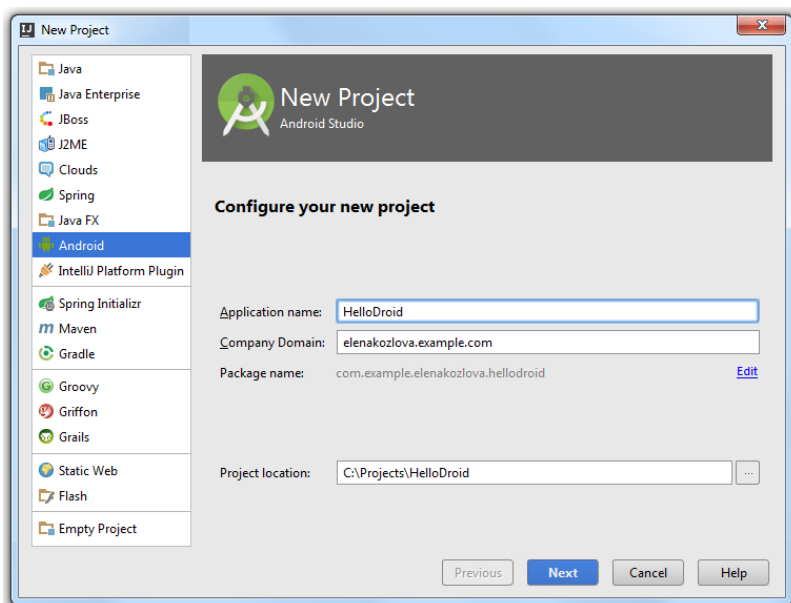

For the procedures covered in our tutorials, you can leave the default selections. You can always launch the SDK Manager if you need to install more packages. To invoke it, in the main menu, choose Tools | Android | SDK Manager .

1. Launch the [New Project wizard](#) . If no project is currently opened in IntelliJ IDEA, click Create New Project on the Welcome screen:

Otherwise, select File | New | Project from the main menu.

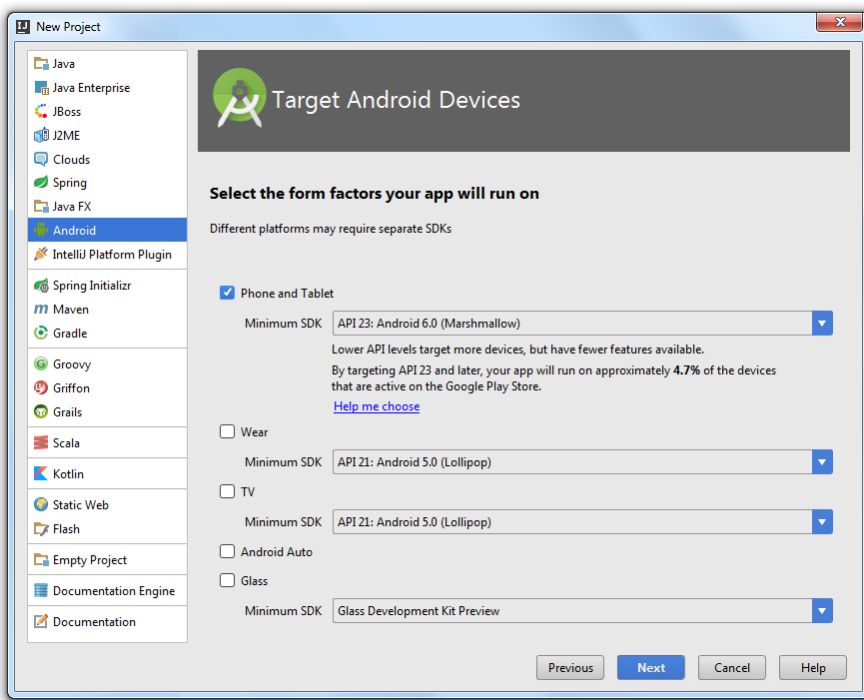

2. On the first page of the wizard, select Android in the left pane. In the right pane, IntelliJ IDEA automatically creates the name of your application, company domain, package name and the project location:

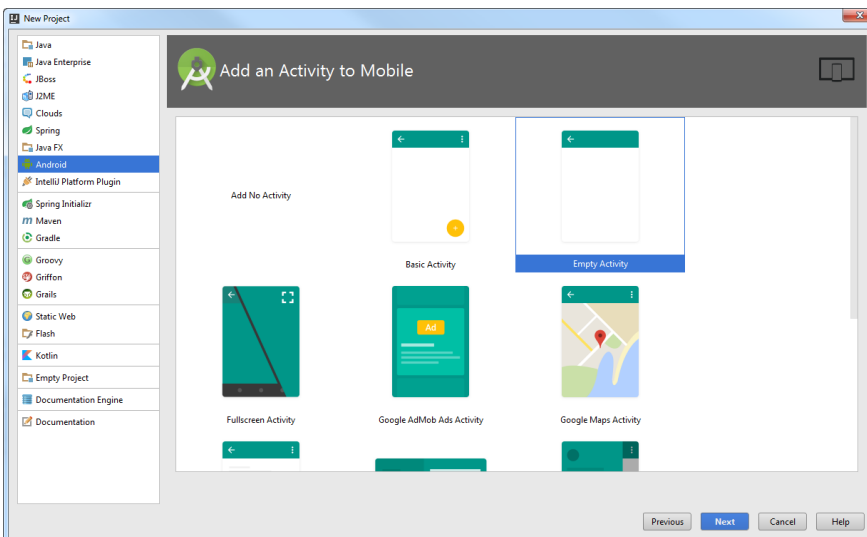

You can edit the specified fields if you like. In our case, we have changed the default name of our application to `HelloDroid` .

Note that the package name must have the following format: `com.xxx.yyy` , where `xxx` usually stands for your company name, and `yyy` is the application name. Note that you can use any names here, but the suggested pattern significantly reduces the risk of name conflicts with other applications.

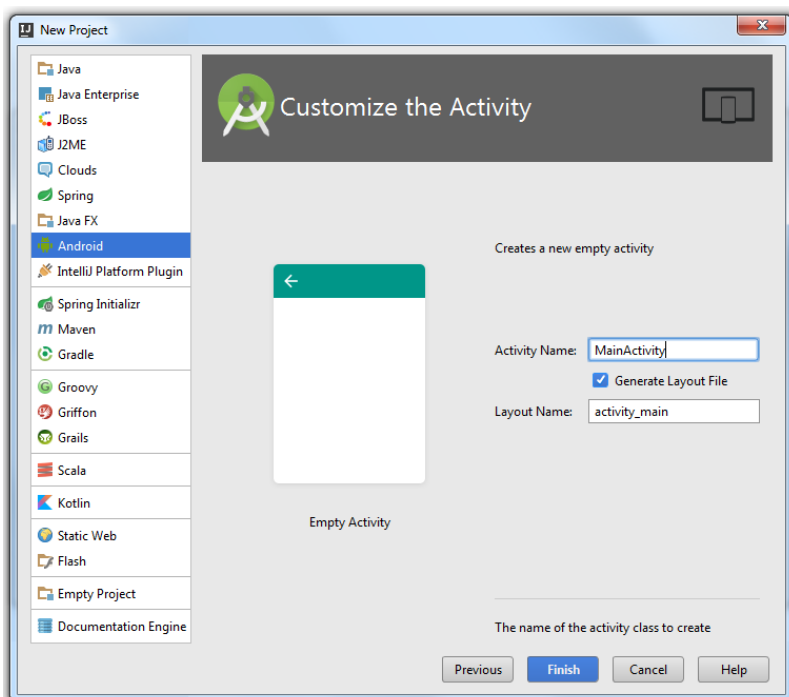

3. On the next page of the wizard, select a target device where the application will be run and debugged.

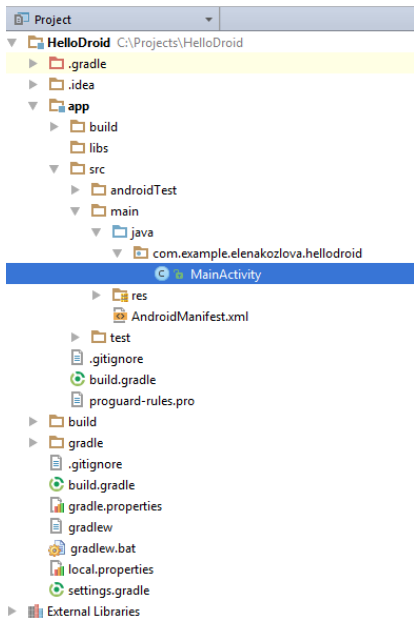

4. On the next page of the wizard, add an activity for your module.

5. On the next page of the wizard, customize the selected activity. Click Finish to complete the wizard.

6. Your Android project will be created with the predefined project structure:

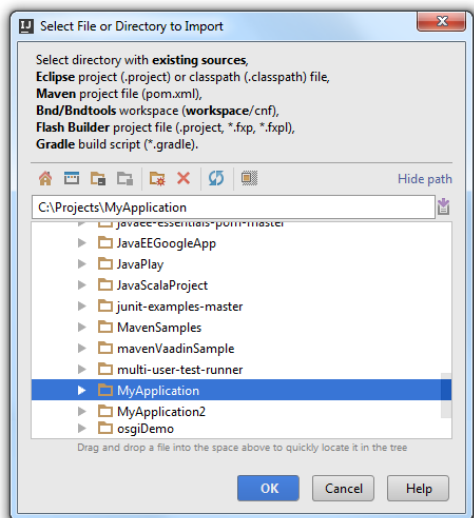

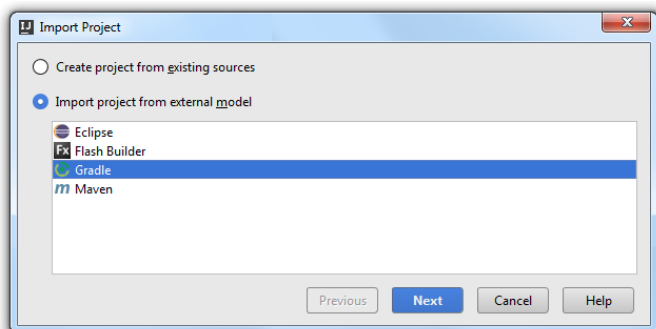

With IntelliJ IDEA you can not only create an Android project from scratch, but also import an existing project developed using other tools. The default scenario is to import an existing [Android-Gradle project](#) . However, you can also import a [Maven](#) , [Eclipse](#) or [Flash Builder](#) project, or even build a new project from a bunch of source files.

As a rule, when you import a project, your source files remain in their original location - IntelliJ IDEA simply creates a superstructure that allows treating your sources, libraries and other assets as an IntelliJ IDEA project. IntelliJ IDEA automatically generates the `.idea` directory that contains a set of configuration files ( `.xml` ), and a project file ( `.iml` ) for each of the project modules (for more details, see [Configuring projects](#) and [Configuring projects](#) ).

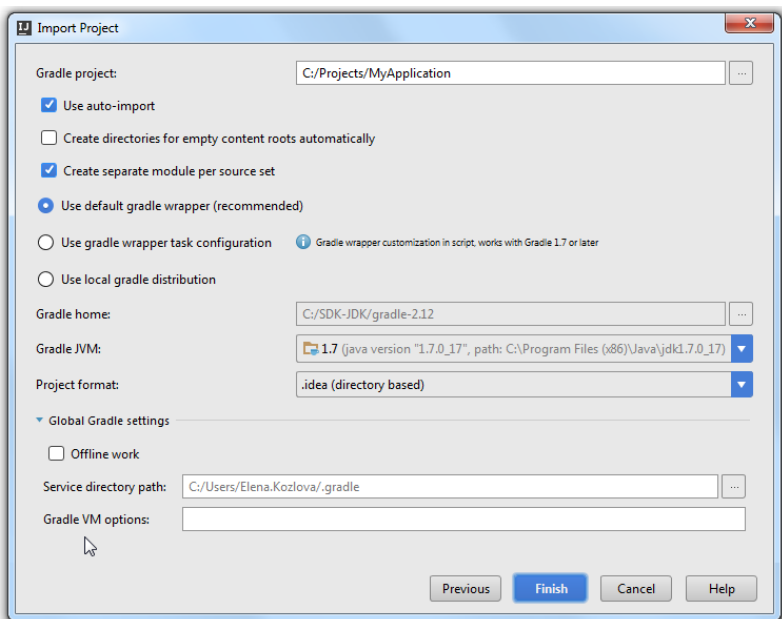

1. Select File | New | Project from Existing Sources from the main menu.
2. In the dialog that opens, browse to the project (or a directory containing source files) that you want to import:

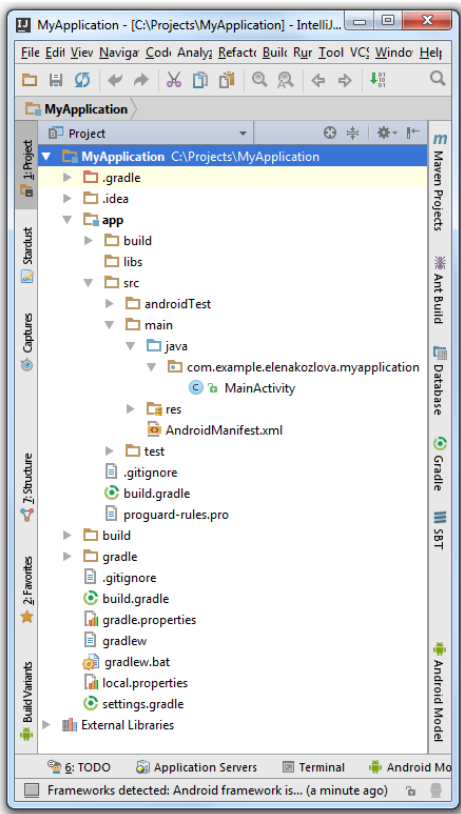

3. On the second step, select whether you want to build a project from scratch using the files under the specified directory, or whether you want IntelliJ IDEA to build a project according to the selected model and proceed in a more automated way. In our case IntelliJ IDEA is aware that this Android project uses the Gradle build system, recognizes the `build.gradle` file and suggests importing from Gradle .

4. On the third step, you can modify Gradle settings and click Finish .

The newly created IntelliJ IDEA project built from the external Gradle model will open.

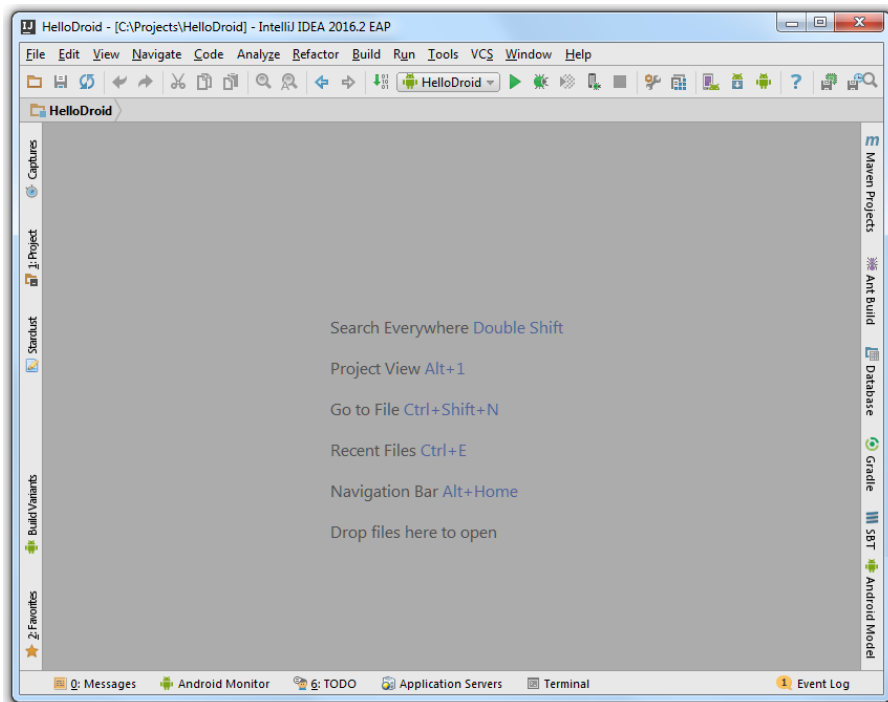

An Android project is primarily a Java project, so it contains many of the standard folders you find in a Java project. Let's find out more.

In this tutorial:

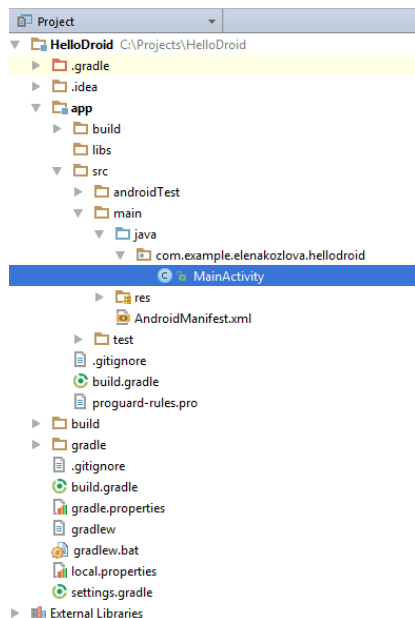

- [Open the Project View](#)
- [Explore Code-Related Folders](#)
- [Explore the Resource Folders](#)
- [Explore the AndroidManifest.xml File](#)

## Open the Project View

If the project view is collapsed to the left edge, click Project in the left gutter, or just press `Alt+1`.

When you expand the [Project Tool Window](#), it shows the typical structure of an Android project that is analogous to the structure of most Java projects:

## Explore Code-Related Folders

An Android project contains the following key folders and files:

- `.idea` folder: contains a few subfolders and various XML files that mostly contain internal IntelliJ IDEA information and general settings. Normally, there is no need to edit the contents of this folder.
- `src` folder: contains all source files that make up the application (activities, helper classes, etc.). You can build any hierarchy of subfolders under the `src` folder to better reflect the structure and the complexity of your application.
- `res` folder: contains all project resources, such as drawable resources, layouts, etc. (for more details, see [Explore the Resource Folders](#)).
- `libs` folder: contains all class libraries (`.jar` files) that you want to reference from the source files of your application. You

can simply drag-and-drop `.jar` files from the disk into this folder.

## Explore the Resource Folders

The `res` folder contains all external resources used by your application, such as image assets, layout files, strings, menus, etc. Most resources (except for images) are expressed through `.xml` files. The `res` folder usually contains the following subfolders:

- `drawable` : contains all images you reference from within the application. There are actually four different drawable folders designed to contain images in different resolutions for devices with different screen density (expressed as `dpi` - dots per inch):
  - `hdpi` (high density, 240)
  - `ldpi` (low density, 120)
  - `mdpi` (medium density, 160)
  - `xhdpi` (extra high density, 320)

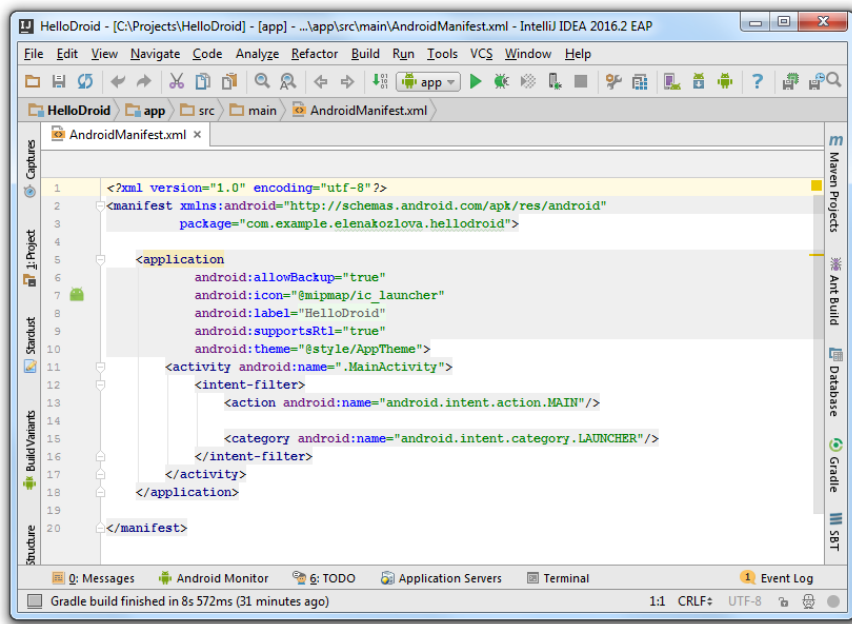

Designing drawable resources in different resolutions is required to support different devices and multiple screens (for more details, see to [Supporting Multiple Screens](#) ).

- `layout` : contains layout files ( `.xml` ) used to define the user interface of an activity or an application widget. You can edit layout definition files manually, or through the integrated graphical designer (for more details, see [Designing Layout of Android Application](#) ).
- `values` : contains `.xml` files that declare strings, graphical styles, and colors. Normally, data stored in these files is expressed in the form of name/value pairs.
- `menu` : contains definitions of menus to be used by the application. The `menu` folder is not generated when you create a new project, and only appears in the project structure after you have created the first menu.

## Explore the AndroidManifest.xml File

Each Android application must have the `AndroidManifest` file in its root directory. This file contains general information about the application processed by the Android operating system. This information is essential to run the application.

Among other things, the `AndroidManifest.xml` file declares the package name (that serves as a unique identifier for your application), and the minimal version of the Android SDK required for the device where the application will run. It also declares the entry point in the code for the operating system to launch the application, along with permissions the application requires. For more details on the `AndroidManifest` file, see [App Manifest](#) .

After you have created your first Android application, you are ready to compile it and deploy it to an Android emulator, or a physical device.

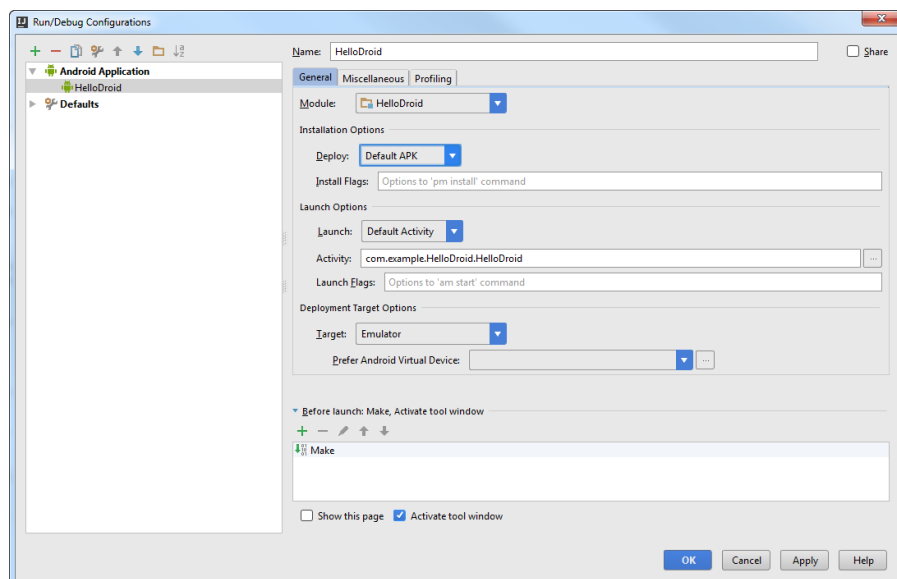

Before you build the project and start testing the application, it is recommended that you review the current build configurations.

In this tutorial:

- [Review the default run/debug configuration](#)
- [Add a New Run/Debug Configuration](#)
- [Test the Application on an Emulator](#)
- [Test the Application on a Physical Device](#)
- [Debug your Application](#)
- [Analyze Debug Output](#)

## Review the default run/debug configuration

Click **Run | Edit Configurations** . The following dialog will be displayed:

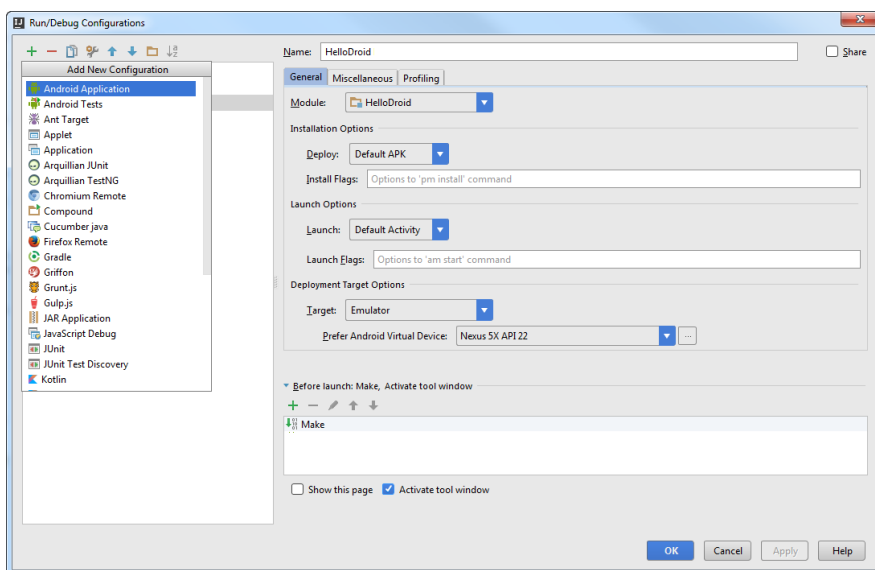

IntelliJ IDEA automatically creates a default run/debug configuration with the same name as your project. For a detailed description of each configuration option in an Android run/debug configuration, see [Run/Debug Configuration: Android Application](#) .

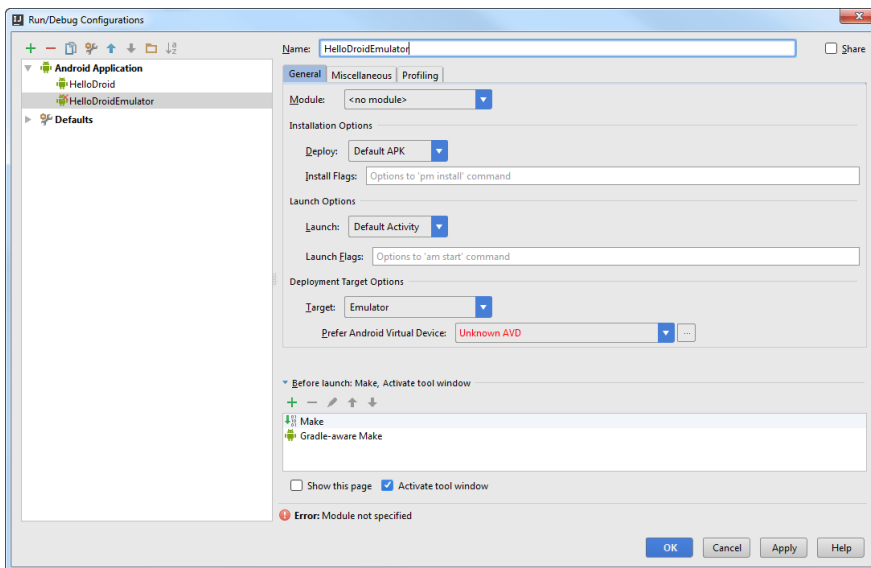

## Add a New Run/Debug Configuration

Let's create a custom build configuration:

1. In the **Run/Debug Configurations** dialog, click the Add button **+** and select **Android Application** from the list:

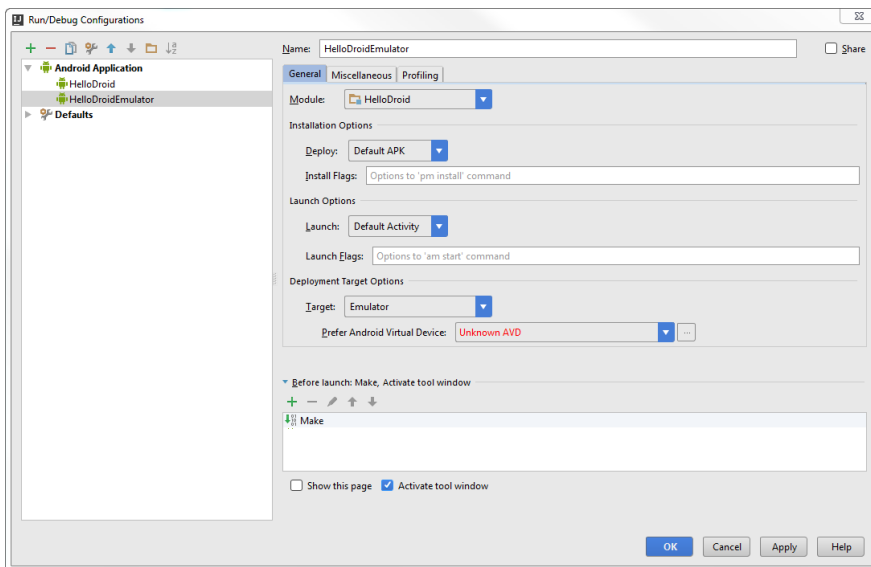

2. A new item will be added to the tree in the left pane with the default name **Unnamed** . Select it and enter a more meaningful name in the Name field, for example, **HelloDroid Emulator** :

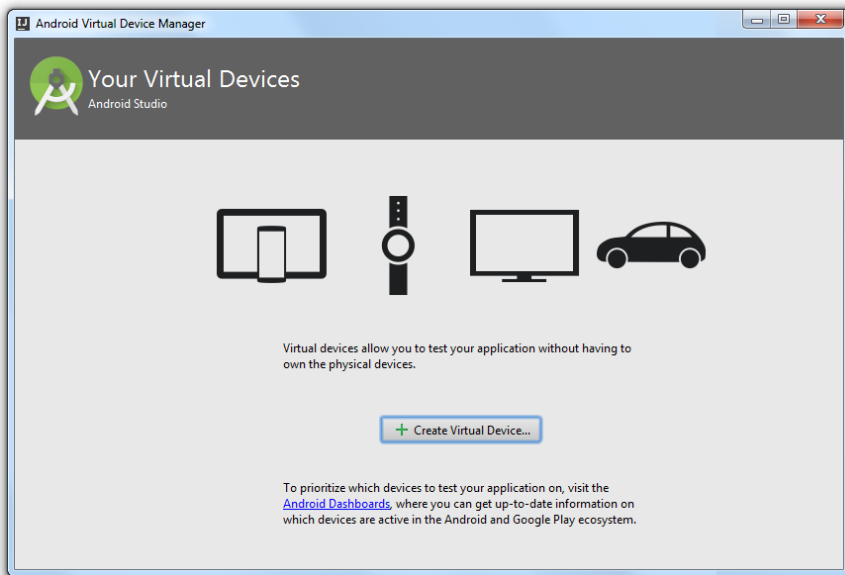

Note that the newly created configuration is shown with a red cross to indicate that it is not yet ready to be used, as no module has been specified.

3. Next, you need to specify the executable module. Expand the Module drop-down list and select `HelloDroid` : it is the only executable module in your project.

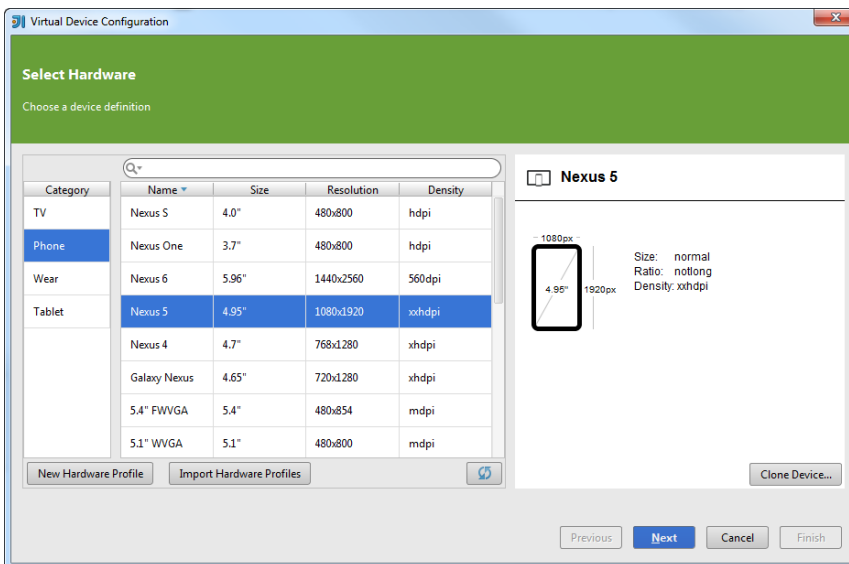

When you have selected a module, the red cross disappears, as now your run/debug configuration is filled with the minimum required information.

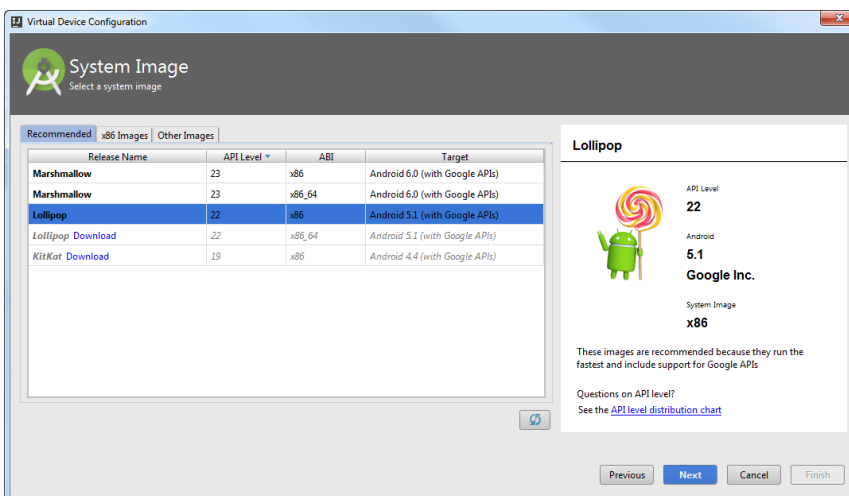

4. Next, make sure the Default APK option is selected under Installation Options . With this option selected, the application will be automatically deployed on the target device.
5. Next, you need to decide which activity you want to launch as a starter activity for your module. You can launch the default activity configured in the `AndroidManifest` file, or select a custom activity. Since your sample application only has one activity, select the Default Activity option.
6. Finally, you need to specify the target device where your application will be launched. Let's select the Emulator option. If you already have Android virtual devices configured, you can select a device from the Prefer Android Virtual Device drop-down list. If you have no devices configured, perform the following steps:
  - a. From the main menu, choose Tools | Android | AVD Manager to launch the Android Virtual Device Manager :

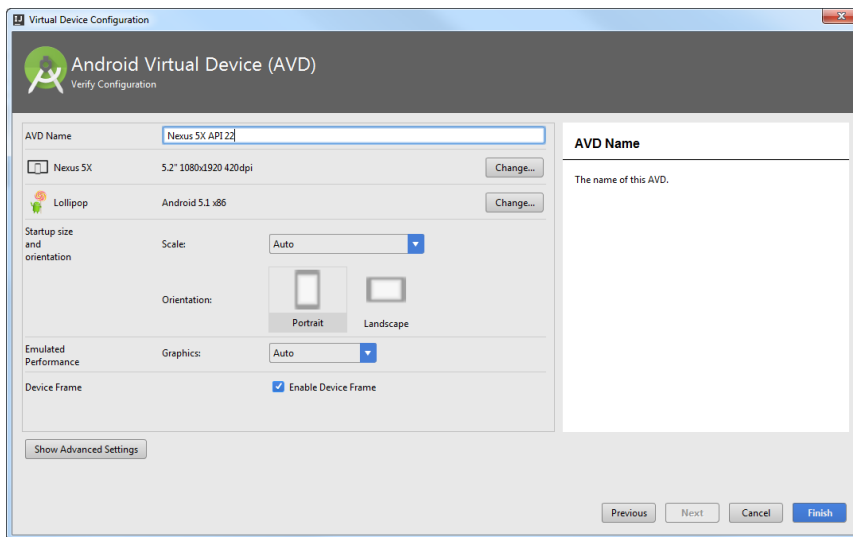

- b. Click Create a virtual device . In the dialog that opens, in the left pane select the type of the Android device you want to mimic: TV , Phone , Wear or Tablet . Let's choose Phone . In the central pane select the phone model (for example, Nexus 5X ) and click Next :

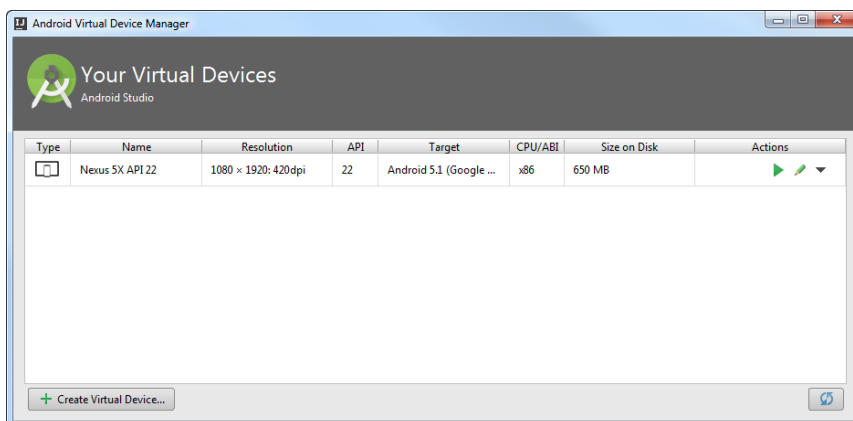

- c. On the next step, select the system image that you want to mimic on the virtual device, i.e. the OS version, the Android API level, the application binary interface (ABI) and the target SDK version:

- d. On the last step, you can modify the AVD name and select the startup size and orientation of the virtual device screen:

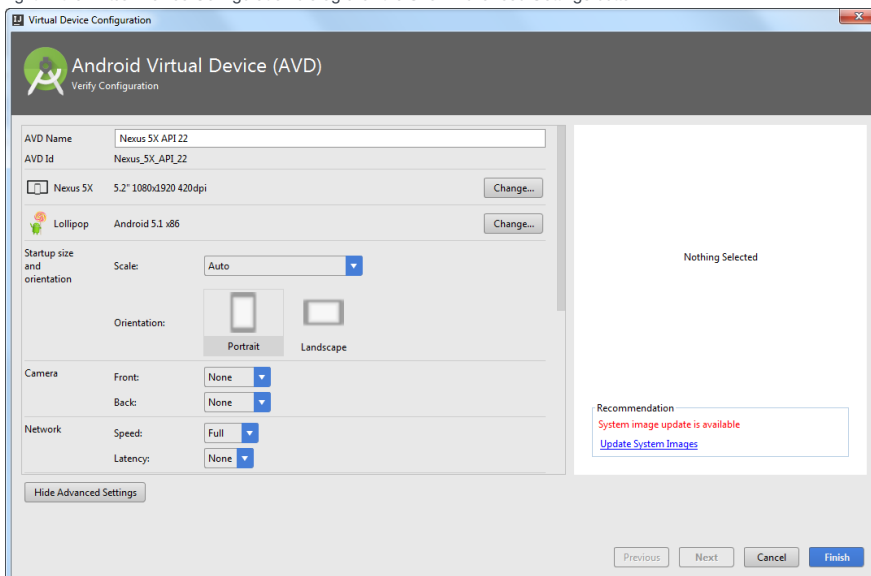

e. Click Finish to complete the wizard. The newly created Android virtual device will be added to the devices list:

f. Return to the Run/Debug Configurations dialog.

7. Note that an Android Virtual Device (AVD) is just a configuration file through which you define the hardware and software options for the emulator to mimic. In addition to AVD settings, you can configure supplementary parameters, such as network transfer rate to be emulated, network latency (the time delay between the initial input and the output), etc. To access these settings, in the AVD Manager, select an emulator from the list, and click the Edit this AVD icon on the right. In the Virtual Device Configuration dialog click the Show Advanced Settings button:

These parameters are then passed to the emulator as command line parameters.

8. In the Run/Debug Configurations dialog, click OK to save the newly created build configuration.

9. Note that if you selected an x86 application binary interface when configuring an Android virtual device, you will also need to install the [Intel x86 Emulator Accelerator](#) before you can run and test the application, otherwise IntelliJ IDEA will throw an error when you try to build your project. To do this:

1. Launch the SDK Manager : in the main menu, select Tools | Android | SDK Manager .
2. Scroll down to the folder called Extras .
3. In this folder, locate **Intel x86 Emulator Accelerator (HAXM installer)** , select the corresponding checkbox and click the Install packages button.
4. In the dialog that opens, accept the license agreement and click Install .

5. Navigate to the Android SDK installation directory (the SDK path is shown on top of the Android SDK Manager window). In the `extras\intel\Hardware_Accelerated_Execution_Manager` folder, locate the `intelhaxm-android.exe` file and double-click to launch it.
6. Follow the instructions of the Intel Hardware Accelerated Execution Manager setup wizard to complete the installation.

## Test the Application on an Emulator

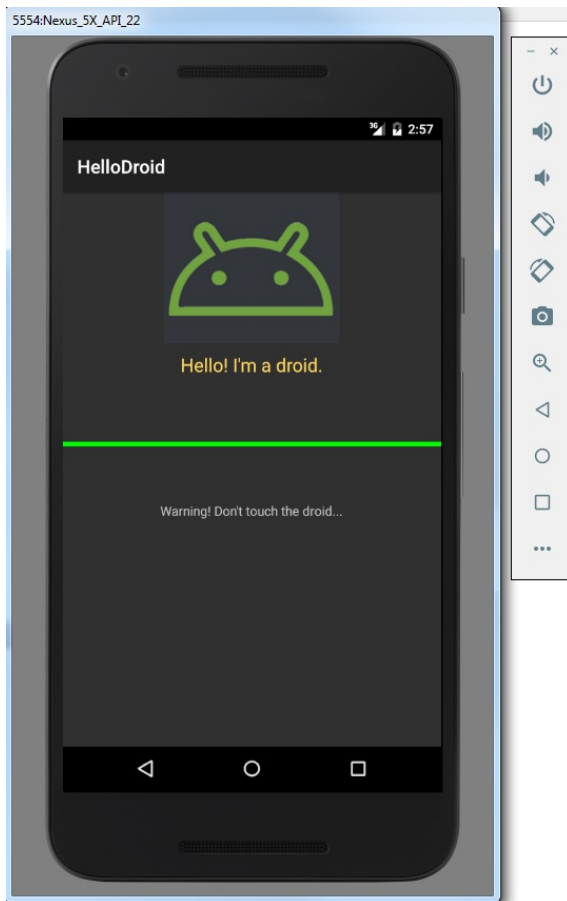

To build your project, press `Shift+F10` or click the Run icon  in the **Navigation bar** in the top-right corner of the editor:

The project will be built according to the run/debug configuration currently selected in the drop-down list. If no errors occur, IntelliJ IDEA packages the binaries and resources into an APK file and uploads it to the Android emulator:

```
Run: .\AVD: Nexus_5X_API_22 | HelloDroidEmulator
07/14 16:29:08: Launching HelloDroidEmulator
$ adb push C:\Idea Projects\HelloDroid\out\production\HelloDroid\HelloDroid.apk /data/local/tmp/com.example.HelloDroid
$ adb shell pm install -r "/data/local/tmp/com.example.HelloDroid"
pkg: /data/local/tmp/com.example.HelloDroid
Success
$ adb shell am start -n "com.example.HelloDroid/com.example.HelloDroid.HelloDroid" -a android.intent.action.MAIN -c android.intent.category.LAUNCHER
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
Connected to process 2209 on device Nexus_5X_API_22 [emulator-5554]
```

If the Android emulator is not already up and running, IntelliJ IDEA will initialize it before uploading the application. The emulator receives and installs the package and starts it by invoking the specified launch activity:

## Test the Application on a Physical Device

To test your application on a real Android device, you need to:

1. [Add a run/debug configuration](#) and make sure that you select USB device under Target Device .
2. Make sure that an Android device is connected to the computer through a USB cable.
3. Press `Shift+F10` or click the Run icon  in the **Navigation bar** in the top-right corner of the editor.

If the installation of your application fails, most probably this means that the device is not configured to install applications outside of the Android application stores. Enable this capability on your device to test the application.

On Android 4.2 or higher, do the following:

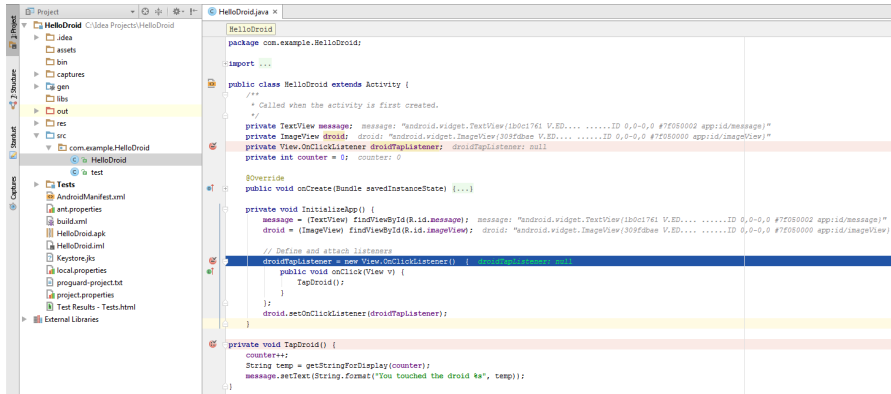

- Open your device's Settings .
- Scroll to About phone or About tablet and tap it.
- Scroll to the bottom and tap Build number 7 times until you see the "You are a developer!" message. By doing so, you've unlocked the USB debugging mode on your device.

- Now navigate to Settings | Developer Options | Debugging | USB Debugging to let your phone deploy non-packaged applications.

## Debug your Application

IntelliJ IDEA allows you to launch your application in the **debug mode** on an emulator or a physical device using the corresponding run/debug configuration.

To debug your application, you need to set breakpoints in the source code: place the caret on an executable line and click the left gutter area. A red circle will appear next to the line where you want to toggle a breakpoint, and the line will be marked with pink:

To start a debug session, press **Shift+F9** or click the Debug icon  in the **Navigation bar** in the top-right corner of the editor. The **Debug tool window** will be activated where you can **step through the program**, examine **variables**, **watches**, **frames** and **threads** and analyse system information and error messages in the **Console tab**.

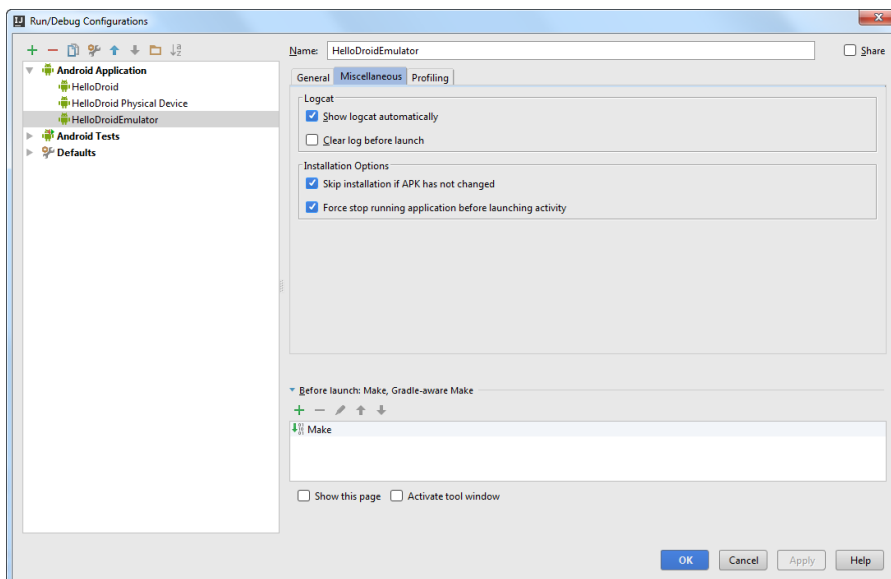

## Analyze Debug Output

In IntelliJ IDEA, debugging of Android applications is provided through the support of the **logcat** functionality that stores a log of system debug output. Log messages include a stack trace when the emulator throws an error, so you can **navigate to the exception location** in the source code.

In IntelliJ IDEA, the logcat functionality is available through the Logcat tab of the **Android Monitor tool window** (for details, see [Debugging with Logcat](#)):

You can also configure additional logcat options in the **Miscellaneous tab** of your run/debug configuration:

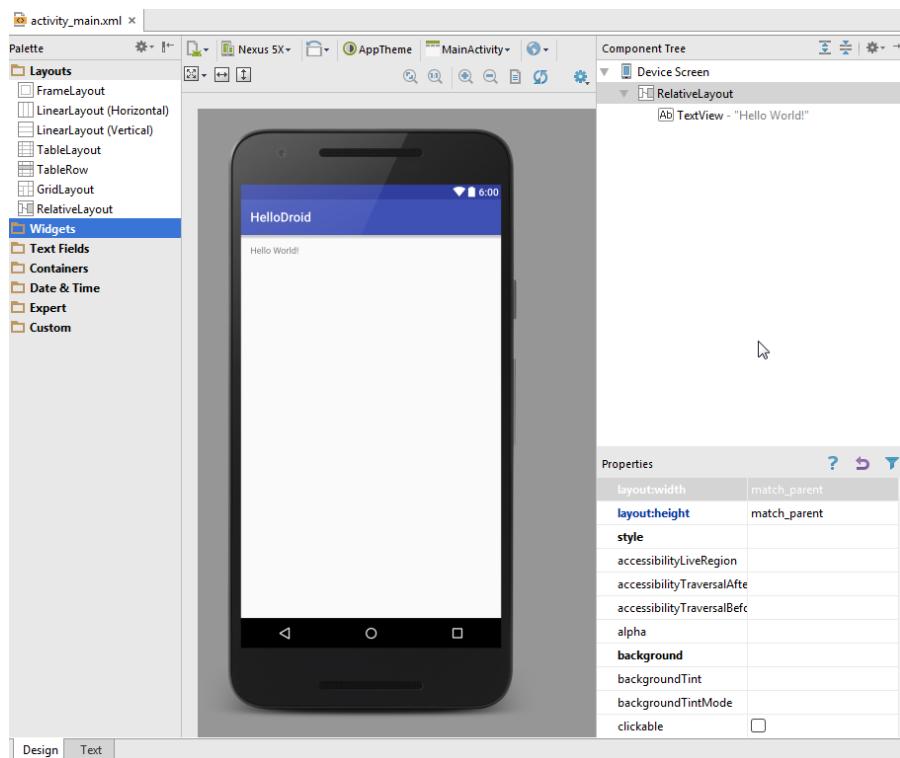

At this stage, the user interface of your sample `HelloDroid` application is based on a very simple layout. The UI layout is defined in the `activity_main.xml` file located in the `res/layout` folder. By default, IntelliJ IDEA provides a graphical view of a layout file, but it also lets you switch to a text-based view where you edit the layout file manually.

Let us modify the auto-generated user interface with the built-in **UI Designer** and see how the application layout is rendered without running it on any physical or virtual devices.

## 1. Open the layout file

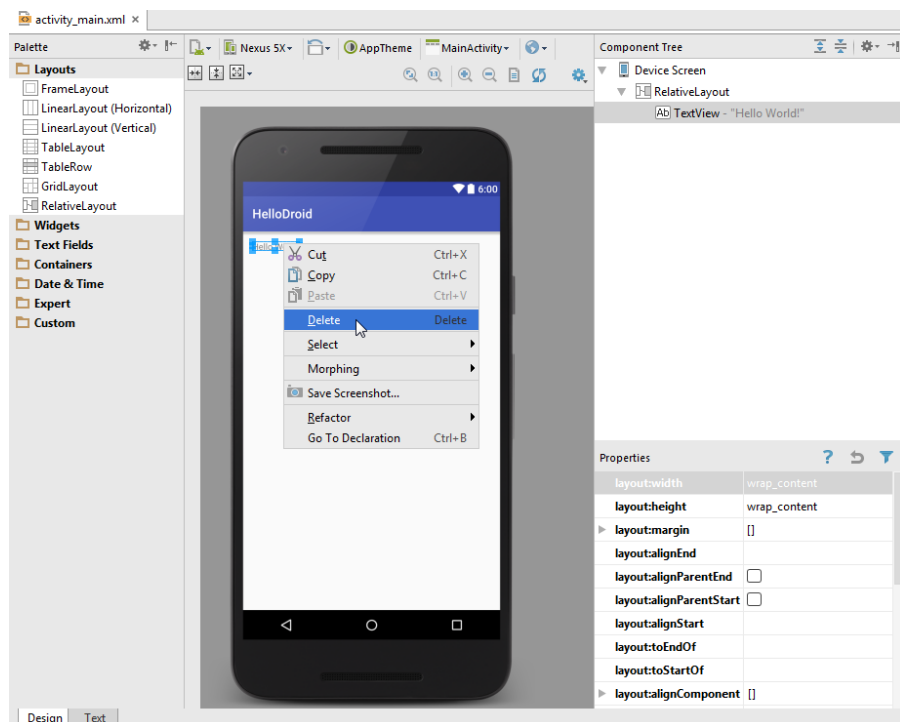

In the **Project view**, navigate to the `res/layout` folder and select the `activity_main.xml` file. The **Design pane** will open in the editor.

The pane shows a rectangular canvas that is synchronized with the current layout definition file and with the Component Tree view, so any changes to the canvas are reflected there accordingly.

## 2. Delete the existing text element

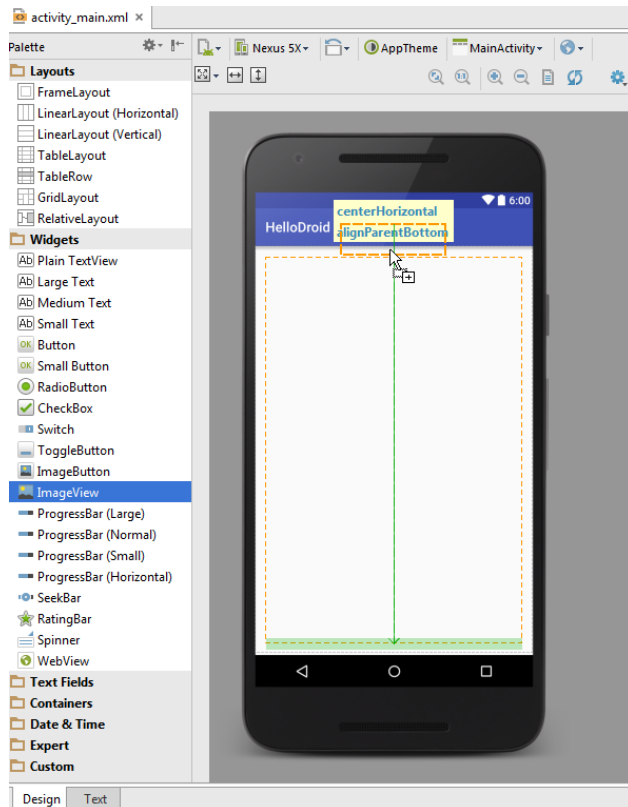

Let's delete the existing text element. To do this, click to select the text label in the view and right-click it to invoke the context menu. Select Delete to clear up the user interface:

## 3. Add an ImageView widget

Now add an `ImageView` widget: select the `ImageView` component from the Widgets palette and then click the canvas where

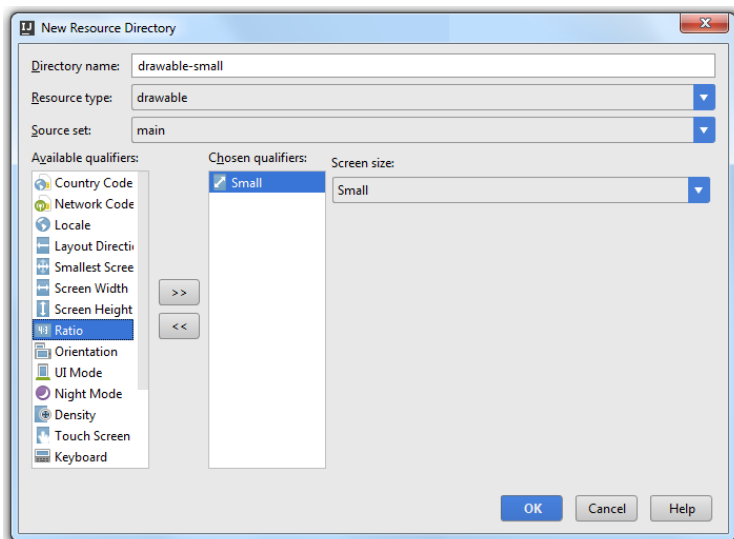

you want to insert the widget. Alternatively, you can drag-and-drop the widget to the Design pane:

At this point, the view contains a placeholder for an image, but there's no image associated with it yet. To add an image to the project, you first need to create a `drawable` folder under `res`.

#### 4. Create the 'drawable' folder

Right-click the `res` node in the Project view and select `New | Android resource directory`. From the Resource type drop-down list, select `drawable`. If necessary, select any of the available qualifiers.

You use qualifiers such as 'small' only if you wish to use a different set of resources for different screens, UI modes, density or locales. If you are going to use a single set of resources, you need no qualifiers.

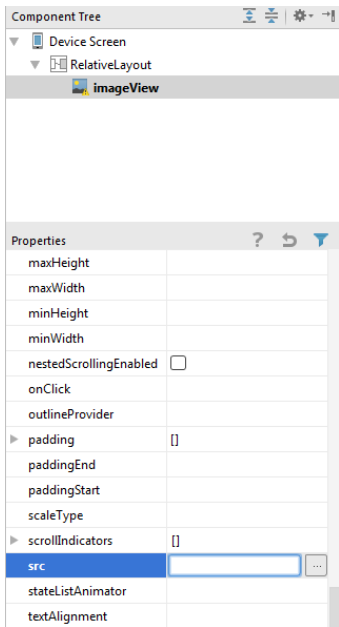

To add images, just pick image files in Windows Explorer and drag them to the `drawable` folder within IntelliJ IDEA.

#### 5. Link an image file to the 'ImageView' widget

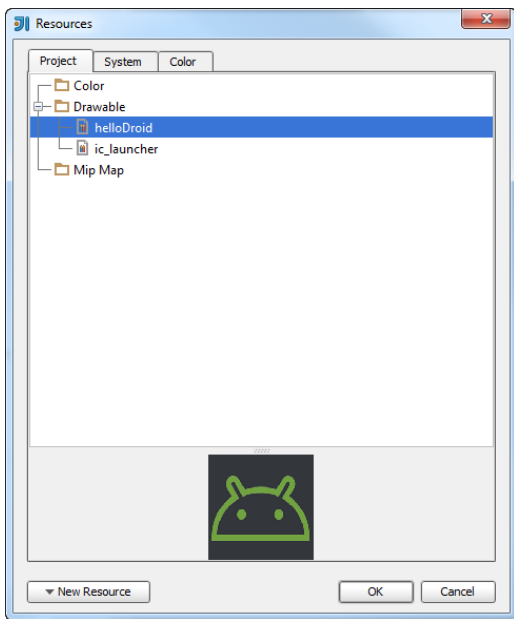

Now you need to link the image file you've added to the `ImageView` widget. In the UI designer, you need to select the widget to edit its properties. You can select the widget by clicking it, however, this sometimes can be a surprisingly hard task. If you have added an image widget but have no image attached to it, the widget is rendered as a very thin box that can be hard to select with the mouse. This is when `Component Tree` comes to a rescue and lets you easily select the visual elements you need.

**Tip** When it comes to adding, editing or removing graphical components of your UI layout, you can use the Component Tree in the same way as the Designer. You can drag-and-drop widgets onto the Component Tree and remove or edit elements from within the displayed hierarchy.

1. In the Component Tree pane, select the `imageView` component and locate the `src` entry in the table of its properties:

2. Click the Browse button  and select the image you want to attach to the widget in the dialog that opens:

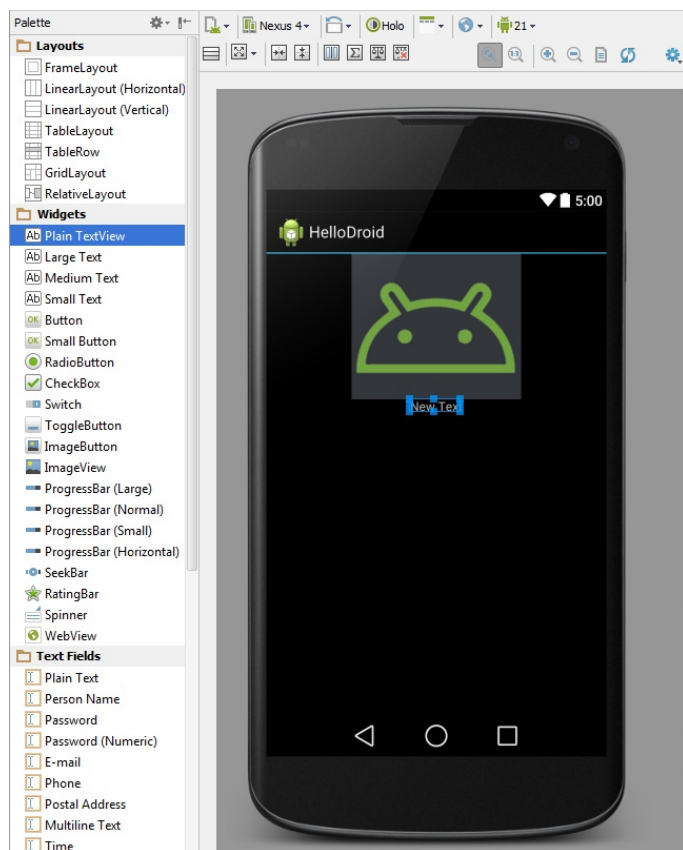

The image will be attached to the widget. You can select it in the designer and adjust its size and position:

6. Add a 'TextView' component

Now let us add a **TextView** component. In the palette, locate the Plain TextView component under Widgets and drag-and-drop it to the view just below the image:

By default, the Plain TextView displays some literal text: `New Text` . To change it and link it to some localizable string, you need to create a new text resource.

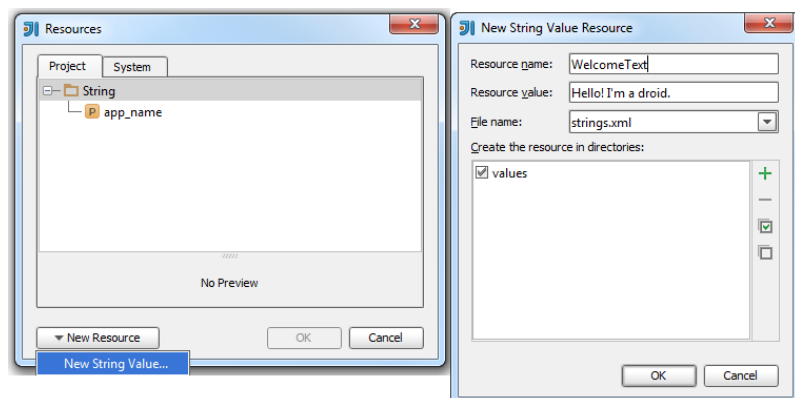

## 7. Create a 'String' resource

1. In the Components Tree , select the TextView element and locate the text property in the properties table below.

2. Click the Browse button  to invoke the Resources dialog box that allows you to pick an existing string value or add a new one.

Note that strings are stored in the `strings.xml` file under the `res | values` folder. If necessary, you can edit the `strings.xml` file directly.

3. Click New Resource | New String Value . In the dialog that opens, enter the resource name and specify the text that will be displayed in the TextView widget:

## 8. Add style to the text

To make the text look a bit more appealing, you need to set a few additional properties. You can do this by editing properties of the TextView component. Let's do the following:

1. Center the label horizontally: set the gravity property to `center_horizontal` .

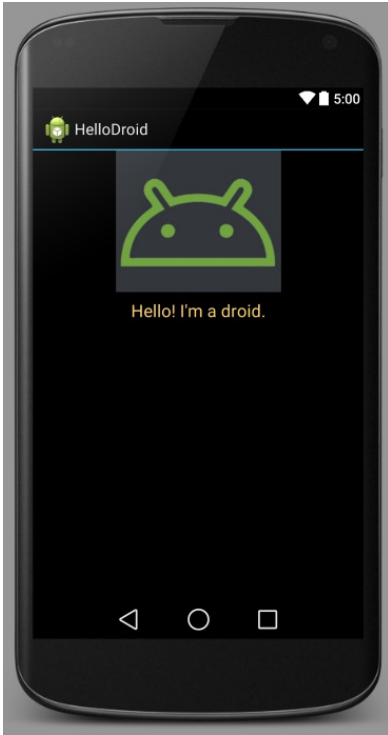

2. Pad the text a bit: locate the padding property and set the value of all to `10dp` .

3. Change the font color: edit the `textColor` property. You can set the property value to a color string, such as `#ffd764` , for example, or you can have it reference a color resource. To add a color resource, click the Browse button  and create a resource named `welcomeText` with the value of `#ffd764` .

4. Change the font size: edit the `TextSize` property. You can set a value, or link it to a size resource in the same way we did with the `TextColor` property above.

Note that you cannot indicate dimensions as plain numbers. You must always add the `dp` suffix.

As a result, your user interface now looks as following:

## 9. Preview your layout in various conditions

The [controls on top of the Designer tool window](#) allow you to preview your UI layout in different conditions: landscape or portrait, on different screen sizes, using different themes, for different locales, etc. This provides a quick and easy way for you to see how the overall application UI looks like in a number of common scenarios.

For example, do the following:

- Click the  icon and select Preview All Screen Sizes from the drop-down menu. IntelliJ IDEA will display the preview of your UI layout on the most common screen types.
- To preview the application layout on different devices, click the icon with the current device name (in our case, it is  Nexus 5 ) and choose from the list.
- Click  to toggle between the layout and portrait preview mode.

Now when you are familiar with the basic UI layout editing options using the [built-in designer](#), let's add more elements to the main view of the application by editing its layout manually.

## 1. Switch to Text view

Switch to the Text tab at the bottom of the editor. IntelliJ IDEA will display the XML source code of the currently selected layout file:

## 2. Add a horizontal ruler

Let's add some markup that inserts a separator. The easiest way to add a horizontal dividing line is adding the following to your source code:

```
<View android:layout_width="fill_parent"
    android:layout_height="5dp"
    android:layout_marginTop="60dp"
    android:background="#00ff00" />
```

The separator is 5 units thick, painted with a green background and placed below the nearest element.

## 3. Add a TextView element

To add another TextView element, add the following to your source code:

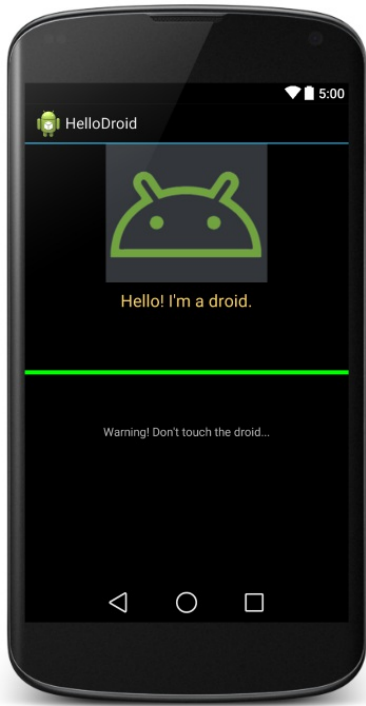

```
<TextView android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginTop="60dp"
    android:text="Warning! Don't touch the droid..."
    android:id="@+id/message"
    android:layout_gravity="center_horizontal" />
```

The new element will be placed 60 units below the separator; it is centered horizontally and uses the default font color. The text string associated with the element is declared explicitly.

Unlike the separator, though, the TextView element also has the id property. Its syntax indicates that what follows the "@" symbol, is a string that must be treated as an ID resource, and will be used to reference the view element. The Android runtime processes this information appropriately and makes it possible for you to write Java code that interacts with the TextView component.

The [Preview](#) pane on the right displays the result of your changes:

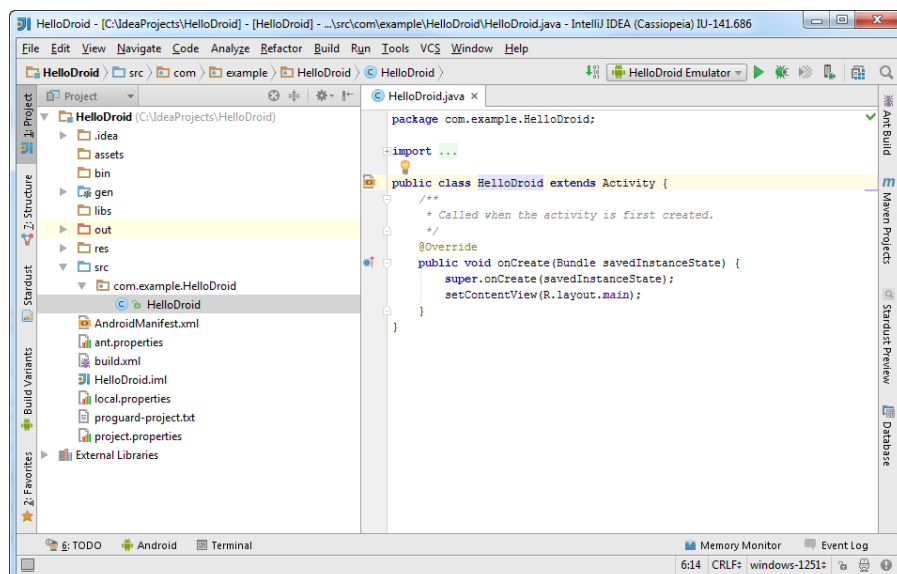

Although our sample application is fully functional at this point, it does not support any form of interaction yet. To make the application support tap events, you need to edit the `HelloDroid` class defined in the `src` folder.

## 1. Open the MyActivity class

In the `Project` view, locate the `HelloDroid.java` file under the `src | com.example.HelloDroid` folder and click on it:

## 2. Add references to visual elements

In Android, you need to explicitly obtain references to visual elements in order to manipulate them programmatically. You need to define private members on the activity class to hold these references, and then initialize these members in a newly created method invoked from within `onCreate`.

1. Add the following code to the `HelloDroid` class:

```
private TextView message;
private ImageView droid;
```

2. Add a call to a new method called `InitializeApp` in `onCreate`. IntelliJ IDEA promptly detects that this method is missing and suggests generating it for you:

3. In the `InitializeApp` method, assign private members a reference to a visual element:

```
message = (TextView) findViewById(R.id.message);
droid = (ImageView) findViewById(R.id.imageView);
```

The expression `R.id.xxx` indicates a member of the auto-generated `R class`.

## 3. Add an event handler

In an application, no interaction is possible without events and event handlers. As an example, let's add a click handler to the `droid` image view and display a message every time the user touches the image.

In Java, an event handler takes the following form:

```
private View.OnClickListener droidTapListener;
```

Add this member to the `HelloDroid` class and initialize it in the `InitializeApp` method. Your code should now look as following:

```

private void InitializeApp() {
    message = (TextView) findViewById(R.id.message);
    droid = (ImageView) findViewById(R.id.imageView);

    // Define and attach listeners
    droidTapListener = new View.OnClickListener() {
        public void onClick(View v) {
            TapDroid();
        }
    };
    droid.setOnClickListener(droidTapListener);
}

```

The net effect of this code is that every time the user taps the image, the `TapDroid` method is invoked.

#### 4. Handle the 'Click' event

1. The `TapDroid` method just counts the times the user touched the image, and displays a message. You need to add a new private member to the `HelloDroid` class to count clicks:

```

public class MainActivity extends Activity
{
    private TextView message;
    private ImageView droid;
    private View.OnClickListener droidTapListener;
    private int counter = 0;

    // More code goes here ...
}

```

2. Next, define the `TapDroid` method as shown below:

```

private void TapDroid() {
    counter++;
    String temp;
    switch (counter)
    {
        case 1:
            temp = "once";
            break;
        case 2:
            temp = "twice";
            break;
        default:
            temp = String.format("%d times", counter);
    }
    message.setText(String.format("You touched the droid %s", temp));
}

```

#### 5. Build an application and launch it on a device

Your sample application is now complete. You can build and deploy it to an Android device.

1. [Create a run/debug configuration](#) and select USB device under Target Device .
2. Connect an Android device to the computer through a USB cable. If the device is connected for the first time, wait until all drivers are installed.
3. If this is the first time you are deploying an application outside of the Android application stores, enable the USB Debugging mode on your device.  
On Android 4.2 or higher, do the following:
  - Open your device's Settings .
  - Scroll to About phone or About tablet and tap it.
  - Scroll to the bottom and tap Build number 7 times until you see the "You are a developer!" message. By doing so, you've unlocked the USB debugging mode on your device.
  - Now navigate to Settings | Developer Options | Debugging | USB Debugging to let your phone deploy non-packaged applications.
4. Make sure the appropriate run/debug configuration is selected in the drop-down in the top-right corner of the editor and click the Run icon:

5. When the application has been successfully deployed on the device, tap the image and look at the changes to the user interface:

Hello! I'm a droid.

You touched the droid 3 times

In Android, unit testing is based on [JUnit](#), and plain use of JUnit is enough to test the features that are exclusively based on Java code.

However, to test Android-specific functionality you need a bunch of wrapper classes built on top of JUnit. IntelliJ IDEA streamlines most of the tasks around the build of an Android test project.

## 1. Make sure your code is testable

Unit testing requires that the source code is composed in such a way that dependencies between modules can be easily neutralized with mocks. In addition, unit testing requires that functions are well isolated from each other.

As is, the code of the `HelloDroid` class is not easy to test. Let's first apply a quick refactoring before we proceed with unit tests.

1. Open the `HelloDroid` class and select the portion of the code in the `TapDroid` method that refers to the production of the display message:

```
    }  
    private void TapDroid() {  
        counter++;  
        String temp;  
        switch (counter)  
        {  
            case 1:  
                temp = "once";  
                break;  
            case 2:  
                temp = "twice";  
                break;  
            default:  
                temp = String.format("%d times", counter);  
        }  
        message.setText(String.format("You touched the droid %s", temp));  
    }  
}
```

2. Rewrite the `TapDroid` method in such a way so that it calls into a newly created public helper method (`GetStringForDisplay`) as shown below:

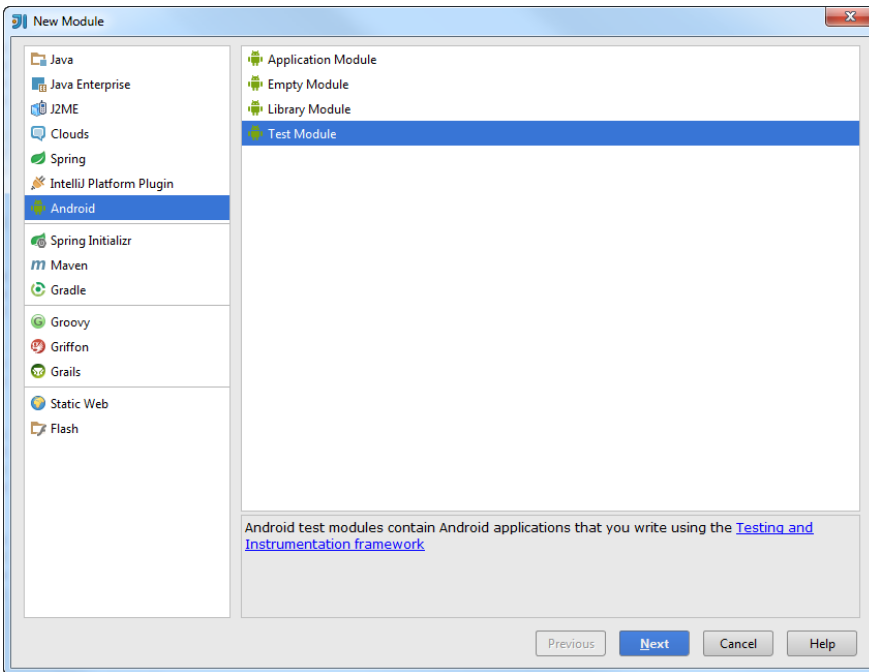

```
private void TapDroid() {  
    counter++;  
    String temp = getStringForDisplay(counter);  
    message.setText(String.format("You touched the droid %s", temp));  
}  
  
public String getStringForDisplay(int count) {  
    String temp;  
    switch(count)  
    {  
        case 1:  
            temp = "once";  
            break;  
        case 2:  
            temp = "twice";  
            break;  
        default:  
            temp = String.format("%d times", count);  
    }  
    return temp;  
}
```

The `getStringForDisplay` method is now much easier to test, and the body of the `TapDroid` method has been greatly simplified.

## 2. Create a test module

Now let's create a new test module and set `HelloDroid` as the tested module. This ensures that the test module holds a reference onto the module that contains the source code you are going to test.

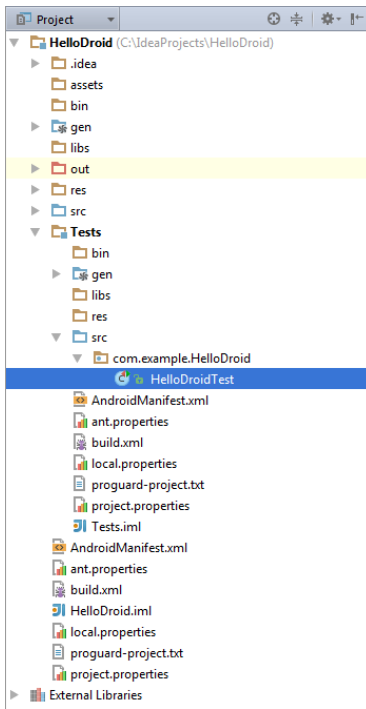

1. From the main menu, select File | New | Module to launch the [New Module wizard](#).
2. On the first page of the wizard, select Android in the left pane, and Test Module on the right:

- On the second page, specify the new module name, for example, `Tests` . Leave the other fields unchanged. The `HelloDroid` module is specified as the tested module automatically, as at this point, this is the only module in the project.

A new node will be appended to the project named `Tests` . This module has its own `manifest` file and `src` directory. The `manifest` file links against the `android.test` library in order to build test classes.

The newly created module has a test file named `HelloDroidTest` in the `src` folder. You can add more test files simply by adding more Java classes as shown below:

```
public class HelloDroidTest extends ActivityInstrumentationTestCase2<HelloDroid> {

    public HelloDroidTest() {
        super("com.example.HelloDroid", HelloDroid.class);
    }
}
```

The test class inherits from `ActivityInstrumentationTestCase2<T>` where `T` is the name of the activity you are going to test.
