  1. The folder where the **Google App Engine for PHP** SDK is stored.
  2. The path to the Python 2.7 executable file.
  3. In the App Engine Account Settings area, choose the way to authenticate to the development server, the available options are:
    - Use passwordless login via OAuth2: choose this option to use the [OAuth 2.0 protocol](#) . To save the `token` achieved through the [Google Developers Console](#) , clear the Do not save token checkbox.
    - Log in with email and password: choose this option to use your **Gmail** address and password.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA provides the possibility to run and debug your applications locally on the [PHP Development Server](#) before uploading them to the [Google PHP Runtime Environment](#). Applications are launched locally according to a dedicated **App Engine for PHP** run/debug configuration.

In this section:

- [Working with the app.yaml file](#)
- [Creating a run configuration of the type App Engine for PHP](#)
- [Running an application on the PHP development server](#)
- [Debugging an application on the PHP development server](#)
- [Uploading an application to the Google PHP runtime environment](#)

## Working with the app.yaml file

A Google App Engine PHP application is configured in the [app.yaml](#) file. If you generate a project stub (see [Preparing to Develop a Google App for PHP Application](#)), the `app.yaml` file is created automatically. If you activate **Google App Engine** support in an existing project, you need to create an `app.yaml` file manually. In either case, make sure the `runtime` property is set to `php55`, because the **Google App Engine for PHP** SDK contains a built-in PHP 5.5 interpreter.

## Creating a run configuration of the type App Engine for PHP

1. On the main menu, choose Run | Edit Configurations, click  and choose App Engine for PHP from the list. The **Run/Debug Configuration: App Engine for PHP** opens.
2. Specify the host to run the development server and the application on (the default is `localhost`).
3. Specify the port through which IntelliJ IDEA will communicate with the development server (the default port is `8080`).
4. Optionally in the Command Line area, specify the settings for running and debugging your application on the PHP development server in the command-line mode:
  - In the Interpreter options field, specify the options to be passed to the PHP executable file of the built-in PHP interpreter, see [Command-Line Arguments](#) for details.
  - In the Custom working directory field, specify the location of the files that are outside the folder with your sources and are referenced through relative paths. Type the path manually or click the Browse button  and select the desired folder in the [dialog that opens](#).
  - In the Yaml files field, specify the `.yaml` configuration files to use. This field is optional, use it when your application consists of several modules and therefore several `.yaml` configuration files are used.
  - In the Environment variables field, in this field, specify the **environment variables** to be passed to the built-in server. See [Environment Variables in Apache](#) for details.

## Running an application on the PHP development server

1. Create an **App Engine for PHP** run configuration as described above.
2. Choose the configuration from the list and click  on the toolbar.
3. View and analyze the output of the application in console of the [Run tool window](#).
4. To view the application execution results, open your browser at `http://localhost:8080`.

## Debugging an application on the PHP development server

1. Create an **App Engine for PHP** run configuration as described above.
2. Set the breakpoints in your code, see [Using Breakpoints](#).
3. Choose the configuration from the list and click .
4. In the **Debug** tool window that opens, [step through the program](#), stop and resume the program, examine it when suspended, etc. See [Stepping Through the Program](#), [Pausing and Resuming the Debugger Session](#), and [Examining Suspended Program](#) for details.

## Uploading an application to the Google PHP runtime environment

After you have tested your application by running and debugging it locally on the development server, you can deploy it to the [Google PHP Runtime Environment](#).

1. On the main menu, choose Tools | Google App Engine for PHP | Upload App Engine PHP app.
2. Visit the application at `http://<your-application-id>.appspot.com/`.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Use IntelliJ IDEA as an IDE for [Joomla!](#) development.

In this part:

- Joomla!
  - [Before you start](#)
  - [Joomla! support](#)
- [Creating and Importing Joomla! Projects](#)
- [Configuring Joomla! Support](#)

## Before you start

1. Download and install [Joomla!](#).
2. Before you start working with Joomla!, make sure that the Joomla! Integration plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

## Joomla! support

Joomla! support includes:

- Ability to [create a new project](#).
- `JHTML::_($argument)`, `JText::_($argument)`, `JText::script()`, `JText::sprintf();` support.

When `JHTML::_($argument)` is used, IntelliJ IDEA navigates with `Ctrl+Click` on the first argument to the corresponding class or method.

For example, consider the following code:

```
<?php
$options[] = JHTML::_('select.option', $eid, $extension_name);
```

`Ctrl+Click` on `select.option` leads to navigation to the `option` method of the class `select`.

When all the other constructs are used, IntelliJ IDEA navigates with `Ctrl+Click` on the first argument to the corresponding property in the `*.ini` file. For example, in the code

```
<?php
msg = JText::sprintf('COM_INSTALLER_INSTALL_ERROR', JText::_('COM_INSTALLER_TYPE_TYPE' . strtoupper($
```

`Ctrl+Click` on `'COM_INSTALLER_INSTALL_ERROR'` leads to navigation to the property `'COM_INSTALLER_INSTALL_ERROR'` in the file `en-GB.com_installer.ini`.

- Joomla! code style can be selected for the code in the [PHP](#) page of the Editor settings, when clicking the link [Set from](#).
- IntelliJ IDEA detects Joomla! when opening a Joomla! module/plugin/extension or a Joomla! root folder, and suggests enabling Joomla! support, and adjusting namespaces.
- [DocBlocks](#) standards for PHP files, classes, class properties, etc. When Joomla! support is recognized, IntelliJ IDEA suggests installing DocBlocks:

**Joomla! Support**  
Joomla DocBlock templates can be installed.  
[Install it?](#)

- IntelliJ IDEA suggests importing the Joomla! code style. See section [Configuring Joomla! Support](#)
- IntelliJ IDEA detects databases in projects. Just click **+** in the [Database tool window](#) tool window and choose Import from sources...

The settings specified in the file `configuration.php` are detected and used for the new data source connection.

- IntelliJ IDEA provides database prefixes support and changes `#__` to the prefix that is defined in the `$dbprefix` field in the `configuration.php` file.

It is worth noting that a database dialect should be selected in the [SQL Dialects](#) page of the Settings/Preferences dialog.

Note also that the type of the selected dialect should be equal to your database type.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

To have a IntelliJ IDEA project set up and configured in accordance with the **Joomla!** requirements, you can either create a project by a dedicated Joomla! template or import an existing Joomla! project.

In this section:

- [How do I create a IntelliJ IDEA project by a Joomla! Integration template?](#)
- [How do I import a Joomla! project?](#)

## How do I create a IntelliJ IDEA project by a Joomla! Integration template?

1. Choose File | New | Project on the main menu or click Create New Project on the Welcome screen. The [Project Category and Options](#) dialog opens.
2. In the left-hand pane, click PHP from the list, then choose Joomla! Integration in the right-hand pane, and then click *Next*.
3. On the second page of the wizard, specify the project name and the folder where it will be created.
  1. Specify the root folder of the Joomla! installation in the Joomla! installation path. Type the path manually or click the Browse button  and select the relevant folder in the dialog box that opens.
  2. Select the desired Joomla! project type (component, module, or plugin).

## How do I import a Joomla! project?

Besides creating a project anew according to the **Joomla!** template, you can open an existing **Joomla!** project in IntelliJ IDEA. IntelliJ IDEA recognizes the **Joomla!**-specific structure and suggests activating the **Joomla!** support in project.

1. **Open the folder with the Joomla! project**

Choose *File | Open Directory* on the main menu, then select the required folder in the dialog box that opens.

2. **Enable Joomla! support in the project**

As soon as IntelliJ IDEA detects the **Joomla!**-specific structure in the project, the following Joomla! Support message is displayed in a pop-up window:

Click *Enable*.

3. **Configure PSR roots**

As soon as IntelliJ IDEA detects PSR roots, it displays a message. Choose *Automatic configuration*.

4. **Install DocBlock templates**

Click *Install* in the pop-up message that IntelliJ IDEA displays.

**Tip** If you prefer NOT enabling Joomla! support, just ignore the pop-up, and it will vanish.

– You can always enable Joomla! support and change the integration settings on the [Frameworks](#) page as described in [Configuring Joomla! Support](#).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

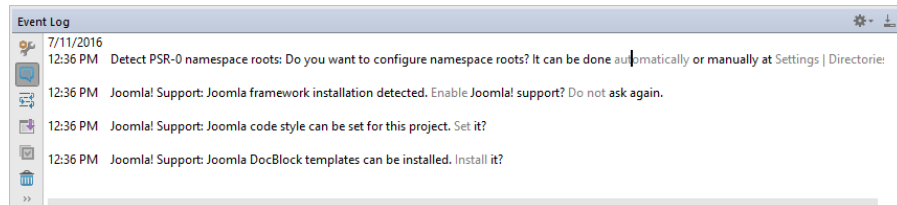

In this section:

- [How do I configure Joomla!-specific development environment?](#)
- [How do I change the Joomla! settings?](#)

## How do I configure Joomla!-specific development environment?

IntelliJ IDEA checks if the development environment is configured properly for Joomla! development.

Any detected inconsistency is reported in the *Event Log* tool window and as a pop-up. For each discrepancy IntelliJ IDEA suggests a fix. To apply a suggestion, click the link next to the reported event.

## How do I change the Joomla! settings?

### 1. Enable or disable Joomla! integration

On the [Frameworks page](#) (*File | Settings | Languages and Frameworks | PHP | Frameworks* for Windows and Linux or *IntelliJ IDEA | Preferences | Languages and Frameworks | PHP | Frameworks* for macOS), toggle the *Enable Joomla! integration* checkbox to activate or deactivate Joomla! in the current IntelliJ IDEA project.

To use another Joomla! installation, type the path to the relevant installation folder.

### 2. Set the code style

Open the [Code Style: PHP page](#) (*File | Settings | Editor | Code Style | PHP* for Windows and Linux or *IntelliJ IDEA | Preferences | Editor | Code Style | PHP* for macOS) and update the settings as necessary.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

IntelliJ IDEA supports integration with the [Phing](#) build framework. Phing is mainly intended for building PHP projects, but it can also be used as a build tool in a number of areas. Phing functionality in IntelliJ IDEA is provided through a dedicated [Phing Build](#) tool window.

In this section:

- [Before you start](#)
- [Accessing Phing Build tool window](#)

## Before you start

1. Make sure Phing is [downloaded](#) and [set up](#) on your computer. If you are using an [AMP](#), the package may already contain Phing.
2. **Install** and **enable** the Phing Support plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Accessing Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
2. Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Before you start](#)
- [Enabling Phing support](#)
  - [Enabling Phing support through the project settings](#)
  - [Enabling Phing support from the Phing Build tool window](#)
  - [Enabling Phing on the fly, when attempting to run a build file](#)

## Introduction

At the project level, you can enable Phing in the following ways:

- Explicitly through the project settings, on the [Phing](#) page of the Settings/Preferences dialog box.
- When adding a file to the list of Phing build files. A correct Phing build file is an `xml` file with the root element `<project>`.
- On the fly, when you attempt to run a build from the editor or from the project tool window.

In either case, the Phing Build tool window becomes available from the View | Tool Windows | Phing Build menu within the scope of the current project.

## Before you start

1. Make sure Phing is [downloaded](#) and [set up](#) on your computer. If you are using an [AMP](#), the package may already contain Phing.
2. **Install** and **enable** the Phing Support plugin. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Enabling Phing support

### To enable Phing support through the project settings

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Phing under PHP.
2. In the [Phing](#) page that opens, specify the location of the file `phing.bat` in the Path to Phing executable text box. Type the path manually or click the Browse button  and choose the file location in the dialog box that opens.

### To enable Phing support from the Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window.

**Tip** A correct Phing build file is an `xml` file with the root element `<project>`.

2. On the context menu of the editor or the selection, choose Add as Phing build file.
3. In the [Phing Build](#) tool window, that opens, click the Settings button  on the toolbar. The button is only available if the list of build files is not empty.
4. In the [Phing Settings](#) dialog box, that opens, specify the location of the `phing.bat` executable file.

### To enable Phing on the fly, when attempting to run a build file

1. Open an Phing build file in the editor.
2. On the context menu of the editor, choose Run Build File.
3. In the [Phing Build](#) tool window, that opens, click the Settings button  on the toolbar. The button is only available if the list of build files is not empty.
4. In the [Phing Settings](#) dialog box, that opens, specify the location of the `phing.bat` executable file.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Accessing Phing Build tool window](#)
- [Managing lists of build files](#)

## Introduction

A correct Phing build file is an `.xml` file with the root element `<project>`. Build files are created outside the [Phing Build](#) tool window and are normally stored under your PHP project root folder. Find more about writing Phing build files in [Phing Getting Started](#).

## Accessing Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
2. Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

## Managing lists of build files

### To configure a list of build files, perform these general steps

1. [Open the Phing Build](#) tool window.
2. To add a build file to the list, click the Add button **+** on the toolbar and choose the required `.xml` build file in the Select Phing Build File dialog box, that opens.
3. To remove a build file from the list, select the file and click the Remove button **-** on the toolbar.
4. To navigate to the source code of a build file, select the desired file and choose Jump to Source on the context menu of the selection.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Phing functionality in IntelliJ IDEA is provided through a dedicated [Phing Build](#) tool window.

In this section:

- [Accessing Phing Build tool window](#)
- [Examining the build targets defined in a build file](#)
- [Hiding targets](#)
- [Associating a shortcut with a Phing target](#)
- [Appointing targets for execution before running or debugging](#)

## Accessing Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
2. Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

## Examining the build targets defined in a build file

1. [Open the Phing Build](#) tool window. The window shows all the build files as nodes.
2. Depending on your goal, do one of the following:
  - To view the build targets defined in a specific build file, expand the corresponding node by clicking  next to the build file name. Note that this expanding does not affect the targets marked as **hidden**.
  - To fold or unfold the build targets defined in all build files, click respectively the Expand All button  or the Collapse All button  on the toolbar. Note that unfolding does not affect the targets marked as **hidden**.
  - To navigate to the definition of a target in the source code, select the desired target and choose Jump to Source on the context menu of the selection.

## Hiding targets

Among the targets defined in a build file, you may have some that are only called by other targets and are never run alone. You can suppress showing such targets in the build file tree by marking them as **hidden**.

**Hidden** targets do not become visible when you expand the node of a specific build file or click Expand All button .

You can mark a target as **hidden** both directly from the Phing Build tool window or from the Phing Settings dialog box. However, the **hidden** status can be removed **only** through the Phing Settings dialog box.

Depending on your goal, do one of the following:

- To mark one or several build targets as **hidden**, do one of the following:
  - In the Phing Build tool window, select the targets under their build file node and choose Mark to Hide on the context menu of the selection.
  - Select the build file in which they are defined and click the Settings button  on the toolbar. Then in the [Phing Settings](#) dialog box that opens, switch to the Hiding targets tab and select the Hide checkboxes next to the targets to be hidden.
- To remove the **hidden** status of a target:
  1. Select the build file in which it is defined and click the Settings button  on the toolbar.
  2. In the [Phing Settings](#) dialog box that opens, switch to the Hiding targets tab where the Hide checkboxes next to the names of the **hidden** targets are selected. Clear the Hide checkboxes next to the targets for which you want the status **hidden** removed.

## Associating a shortcut with a Phing target

You can associate a build target with a keyboard shortcut and execute commonly-used targets with a single key-stroke. If a Phing build file is added to the project, its targets appear under the Phing Targets node in the [Keymap](#) dialog box.

1. In the [Phing Build](#) tool window, right-click the desired build target.
2. On the context menu, choose Assign Shortcut.
3. In the [Keymap](#) dialog box that opens, configure the shortcut as described in [Configuring Keyboard Shortcuts](#).

## Appointing targets for execution before running or debugging

1. [Open the Phing Build](#) tool window.
2. Select the desired target and choose Before Run/Debug on the context menu of the selection.
3. In the Execute Target Before Run/Debug dialog box that opens, select the [configurations](#) before which you want the target executed.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

Phing functionality in IntelliJ IDEA is provided through a dedicated [Phing Build](#) tool window.

In this section:

- [Accessing the Phing Build tool window](#)
- [Running builds](#)
- [Running separate build targets](#)

## Accessing the Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
2. Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

## Running builds

1. [Open the Phing Build](#) tool window.
2. Select the required build file in the list and click the Run button  on the toolbar or choose Run Build on the context menu of the selection.

## Running separate build targets

Do one of the following:

- In the [Phing Build](#) tool window, select the required build target in the list and click the Run button  on the toolbar or choose Run Target on the context menu of the selection.
- Use the [shortcut associated with the target](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

A Phing build file normally contains [property elements](#) that can be configured either manually in the build file itself or externally, in the [Phing Build](#) tool window. Properties that are configured externally are passed to Phing through a command line when build execution is launched and therefore they are every time re-calculated dynamically. Externally configured properties always override the ones set manually in the build file.

In this section:

- [Accessing Phing Build tool window](#)
- [Configuring a property externally](#)

## Accessing Phing Build tool window

1. Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
2. Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

## Configuring a property externally

1. Open the Phing Build tool window.
2. Select the required build file in the list and click the Settings button  on the toolbar.
3. In the [Phing Settings](#) dialog box that opens, switch to the Properties tab and configure a list or properties to be passed to Phing through a command line.
  1. To add a new property to the list, click the Add button.
  2. In the Property text box, type the name of the property.
  3. In the Value text box, specify the property value to be passed. Do one of the following:
    - Type the value manually.
    - To use [IntelliJ IDEA macros](#), click the Insert macro button  and configure a list of relevant macro definitions in the [Macros](#) dialog box that opens. To add a macro, select it in the list and click Insert.
4. When the list of properties is ready, click OK in the Phing Settings dialog box.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Before you start](#)
- [Choosing the Code Sniffer script to use](#)
- [Configuring a local Code Sniffer script](#)
- [Configuring a Code Sniffer associated with a PHP interpreter](#)
- [Configuring advanced PHP Code Sniffer options](#)
- [Configuring PHP Code Sniffer as a IntelliJ IDEA inspection](#)
- [Choosing a custom coding style to check your code against](#)
- [Sharing a custom coding style with the team](#)
- [Running Code Sniffer in the batch mode](#)
- [Excluding files from Code Sniffer inspection](#)

## Introduction

In addition to built-in coding assistance, IntelliJ IDEA provides code style check through integration with the [PHP Code Sniffer](#) tool, which validates your code for consistency with a coding standard of your choice. You can appoint one of the predefined [coding standards](#) or use [your own previously defined coding standard](#) with the root directory outside the default PHP Code Sniffer's Standards directory. Moreover, you can share your custom coding style with your team fellows.

To use PHP Code Sniffer right from IntelliJ IDEA instead of from a command line, you need to register it in IntelliJ IDEA and configure it as a IntelliJ IDEA [code inspection](#). Once installed and enabled in IntelliJ IDEA, the tool is available in any opened PHP file, so no steps are required from your side to launch it. The on-the-fly code check is activated upon every update in the file thus making it extremely easy to get rid of problems reported by PHP Code Sniffer.

Errors and warnings reported by PHP Code Sniffer on-the-fly are displayed as pop-up messages. When the tool is run in the batch mode, the errors and warnings are displayed in the Inspection Results tool window. Anyway, each message has the `phpcs` prefix to distinguish it from IntelliJ IDEA internal inspections.

## Before you start

Make sure the PHP plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Choosing the Code Sniffer script to use

You can use PHP Code Sniffer local scripts or scripts associated with PHP interpreters. There can be a number of local and remote PHP interpreters, the one specified on the PHP page of the Settings dialog box is considered **Project Default**.

Learn more about configuring PHP interpreters in [Configuring Remote PHP Interpreters](#) or in [Configuring Local PHP Interpreters](#).

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Code Sniffer under PHP.
2. From the Configuration drop-down list in the Development Environment area, choose the script to use:
  - To use the script associated with a specific remote PHP interpreter, choose the name of this interpreter.
  - To use the script associated with the default project interpreter, that is, the one chosen on the PHP page of the Settings dialog box, choose By default project interpreter.
  - To use a local script, choose Local. In this case the local Code Sniffer will be executed no matter which PHP interpreter - local or remote - is used in the project. Note that there can be only one **Local** configuration for Code Sniffer because IntelliJ IDEA runs a script (`phpcs.bat` for Windows or `phpcs` for Linux) which contains a path to a PHP engine.

## Configuring a local Code Sniffer script

1. Make sure the [PEAR](#) package manager is installed on your machine.
2. Download and install the [PHP Code Sniffer](#). To check it, switch to the directory with the `pear.bat` file and run the following command: `phpcs --version`  
If the tool is available, you will get a message in the following format: `PHP_CodeSniffer version <version> (stable) by Squiz Pty Ltd. (http://www.squiz.net)`

To have code checked against your own custom coding standard, [create it](#). Store the rules and the `ruleset.xml` file that points to them in the coding standard root directory.

3. Register the local PHP Code Sniffer script in IntelliJ IDEA:

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Code Sniffer under PHP.
2. On the [Code Sniffer](#) page that opens, click  next to the Configuration drop-down list.
3. In the Code Sniffer dialog box that opens, specify the location of the Code Sniffer executable `phpcs.bat` or `phpcs` in

the PHP Code Sniffer path text box. Type the path manually or click the Browse button  and select the path in the dialog box, that opens.

To check that the specified path to `phpcs.bat` or `phpcs` ensures interaction between IntelliJ IDEA and Code Sniffer, that is, the tool can be launched from IntelliJ IDEA and IntelliJ IDEA will receive problem reports from it, click the Validate button. This validation is equal to running the `phpcs --version` command. If validation passes successfully, IntelliJ IDEA displays the information on the detected Code Sniffer version.

## Configuring a Code Sniffer associated with a PHP interpreter

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Code Sniffer under PHP .
2. On the [Code Sniffer](#) page that opens, click  next to the Configuration drop-down list. The Code Sniffer dialog box opens showing a list of all the configured Code Sniffer scripts in the left-hand pane, one of them is of the type **Local** and others are named after the PHP interpreters with which the scripts are associated. Click  on the toolbar.
3. In the Code Sniffer by Remote Interpreter dialog box that opens, choose the remote PHP interpreter to use the associated script from. If the list does not contain a relevant interpreter, click  and configure a remote interpreter in the CLI Interpreters dialog box as described in [Configuring Remote PHP Interpreters](#) .  
When you click OK , IntelliJ IDEA brings you back to the Code Sniffer dialog box where the new **Code Sniffer** configuration is added to the list and the right-hand pane shows the chosen remote PHP interpreter, the path to the Code Sniffer associated with it, and the advanced PHP Code Sniffer options.

## Configuring advanced PHP Code Sniffer options

IntelliJ IDEA provides the ability to specify advanced PHP Code Sniffer options and thus fine tune the PHP Code Sniffer process behavior depending on the configuration of your computer and the rule sets used.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Code Sniffer under PHP .
2. In the Maximum number of messages per file text box, set the upper limit for the total number of messages to be reported for a file. All the messages above this limit will be rejected and IntelliJ IDEA will display the following warning right in the code:

```
Too many PHP Code Sniffer messages
```

3. In the Tool process timeout text box, specify how long you want IntelliJ IDEA to wait for a result from PHP Code Sniffer, whereupon the process is killed to prevent excessive CPU and memory usage.

## Configuring PHP Code Sniffer as a IntelliJ IDEA inspection

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Inspections under Editor .
2. On the [Inspections](#) page that opens, select the PHP Code Sniffer validation checkbox under the PHP node.
3. On the right-hand pane of the page, configure the PHP Code Sniffer tool using the controls in the Options area:
  1. From the Severity drop-down list, choose the **severity degree** for the Code Sniffer inspection. The selected value determines how serious the detected discrepancies will be treated by IntelliJ IDEA and presented in the [inspection results](#) .
  2. In the Coding standard drop-down list, appoint the coding style to check your code against. The list contains all the coding standards installed inside the main `PHP_CodeSniffer` directory structure.  
Use one of the predefined [coding standards](#) or choose Custom to [appoint your own standard](#) .
  3. Optionally, select the Ignore warnings checkbox to have only errors reported and suppress reporting warnings. This option is equal to the `-n` command line argument.

## Choosing a custom coding style to check your code against

You can have code checked against [your own previously defined coding standard](#) with the root directory outside the default PHP Code Sniffer's Standards directory. This root directory should contain the rules themselves and the `ruleset.xml` file that points to them.

1. [Open the Settings dialog box](#) , and click Inspections . The [Inspections](#) page opens. Select the PHP Code Sniffer validation checkbox under the PHP node.
2. From the Coding standard drop-down list, choose Custom .
3. Click the Browse button  .
4. In the Custom Coding Standard dialog box that opens, specify the path to the root directory of your own coding standard in the Root directory . Type the path manually or click the Browse button  and choose the relevant folder in the [dialog that opens](#) .  
The selected root directory should contain the `ruleset.xml` file that points to the rules.

## Sharing a custom coding style with the team

1. Put the root directory of your coding standard under the [project root](#) .

2. [Configure Code Sniffer as a IntelliJ IDEA inspection](#) .
3. [Appoint your coding standard](#) .
4. At the top of the [Inspections](#) page, select the Share Profile checkbox.
5. On the [Version Control](#) page of the Settings dialog box, put the root directory of your coding standard [under version control](#) .

## Running Code Sniffer in the batch mode

1. To [run the inspection](#) , choose Code | Inspect code on the main menu. Specify the inspection scope and profile.
2. View the inspection results in the [Inspection Results Tool Window](#) . Errors and warnings reported by PHP Code Sniffer have the `phpcs` prefix to distinguish them from IntelliJ IDEA internal inspections.

## Excluding files from Code Sniffer inspection

When waiting for Code Sniffer response exceeds the limit specified in the Tool process timeout field on [Code Sniffer](#) page, IntelliJ IDEA suggests adding the file to the **ignore list** . This list is shown on the Code Sniffer page in the Ignored files area. For each file, IntelliJ IDEA displays its name and location.

- To delete a file from the list and have Code Sniffer process it again, select the file and click the Remove file button **—** .
- To remove all the files from the list, click the Clean the list button **✖** .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Before you start](#)
- [Choosing the Mess Detector script to use](#)
- [Configuring a local Mess Detector script](#)
- [Configuring a Mess Detector associated with a PHP interpreter](#)
- [Specifying advanced PHP Mess Detector options](#)
- [Configuring PHP Mess Detector as a IntelliJ IDEA inspection](#)
- [Specifying the rules to apply](#)
- [Running Mess Detector in the batch mode](#)
- [Excluding files from Mess Detector inspection](#)

## Introduction

In addition to built-in coding assistance, IntelliJ IDEA provides checking the source code through integration with the [PHP Mess Detector](#) tool, which detects [potential problems](#) related to code size, inconsistency, unused code, violation of naming conventions, poor design, etc.

You can have [predefined rules](#) applied or define your own [custom set of rules](#).

## Before you start

Make sure the PHP plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Choosing the Mess Detector script to use

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Mess Detector under PHP.
2. From the Configuration drop-down list in the Development Environment area, choose the script to use:
  - To use the script associated with a specific remote PHP interpreter, choose the name of this interpreter.
  - To use the script associated with the default project interpreter, that is, the one chosen on the PHP page of the Settings dialog box, choose By default project interpreter.
  - To use a local script, choose Local. In this case the local Mess Detector will be executed no matter which PHP interpreter - local or remote - is used in the project. Note that there can be only one Local configuration for Mess Detector because IntelliJ IDEA runs a script (`phpmd.bat` for Windows or `phpmd` for Linux) which contains a path to a PHP engine.

## Configuring a local Mess Detector script

1. Download [PHP Mess Detector](#). The easiest way to do that is use the [Composer Dependency Manager](#), see [Composer Dependency Manager](#).
2. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Mess Detector under PHP.
3. On the [Mess Detector](#) page that opens, click  next to the Configuration drop-down list.
4. In the Mess Detector dialog box that opens, specify the location of the Mess Detector executable `phpmd.bat` or `phpmd` in the PHP Mess Detector path text box. Type the path manually or click the Browse button  and select the path in the dialog box, that opens. If you installed the tool through Composer, the default location is `<project root folder>\vendor\bin\phpmd.bat`.  
To check that the specified path to `phpmd.bat` or `phpmd` ensures interaction between IntelliJ IDEA and Mess Detector, that is, the tool can be launched from IntelliJ IDEA and IntelliJ IDEA will receive problem reports from it, click the Validate button. This validation is equal to running the `phpmd --version` command. If validation passes successfully, IntelliJ IDEA displays the information on the detected Mess Detector version.

## Configuring a Mess Detector associated with a PHP interpreter

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Mess Detector under PHP.
2. On the [Mess Detector](#) page that opens, click  next to the Configuration drop-down list. The Mess Detector dialog box opens showing a list of all the configured Mess Detector scripts in the left-hand pane, one of them is of the type Local and others are named after the PHP interpreters with which the scripts are associated. Click  on the toolbar.
3. In the Mess Detector by Remote Interpreter dialog box that opens, choose the remote PHP interpreter to use the associated script from. If the list does not contain a relevant interpreter, click  and configure a remote interpreter in the CLI Interpreters dialog box as described in [Configuring Remote PHP Interpreters](#).

When you click OK , IntelliJ IDEA brings you back to the Mess Detector dialog box where the new **Mess Detector** configuration is added to the list and the right-hand pane shows the chosen remote PHP interpreter, the path to the Mess Detector associated with it, and the advanced PHP Mess Detector options.

## Specifying advanced PHP Mess Detector options

IntelliJ IDEA provides the ability to specify advanced PHP Mess Detector options and thus fine tune the PHP Mess Detector process behavior depending on the configuration of your computer and the rule sets used.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Languages & Frameworks node, and then click Mess Detector under PHP . The [Mess Detector](#) page opens.
2. In the Maximum number of messages per file text box, set the upper limit for the total number of messages to be reported for a file. All the messages above this limit will be rejected and IntelliJ IDEA will display the following warning right in the code:

```
Too many PHP Mess Detector messages
```

3. In the Tool process timeout text box, specify how long you want IntelliJ IDEA to wait for a result from PHP Mess Detector, whereupon the process is killed to prevent excessive CPU and memory usage.

## Configuring PHP Mess Detector as a IntelliJ IDEA inspection

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Inspections under Editor .
2. On the [Inspections](#) page that opens, select the PHP Mess Detector validation checkbox under the PHP node.
3. On the right-hand pane of the page, configure the PHP Mess Detector tool using the controls in the Options area:
  1. From the Severity drop-down list, choose the [severity degree](#) for the Mess Detector inspection. The selected value determines how serious the detected discrepancies will be treated by IntelliJ IDEA and presented in the [inspection results](#) .
  2. [Appoint the rules to apply](#) .

## Specifying the rules to apply

You can have [predefined rules](#) applied or define your own [custom set of rules](#) .

1. [Open the Settings dialog box](#) , and click Inspections .
2. On the [Inspections](#) page that opens, select the PHP Mess Detector validation checkbox under the PHP node.
3. Do one of the following:
  - To use a predefined rules, in the Options area, select the checkboxes next to the validations to be performed. For more details on [predefined rules](#) , see <http://phpmd.org/rules/index.html> .
  - To use a custom ruleset:
    1. Create and save one or several [ruleset files](#) . A valid [ruleset file](#) is an `.xml` file that contains the root element `<ruleset>` with the attribute `name` . For more details on [custom rulesets](#) , see <http://phpmd.org/documentation/creating-a-ruleset.html> .
    2. In the Custom rulesets area, click the Add Rule button `+` and select the relevant rule definition file in the dialog box that opens. When you click OK , a new item is added to the Custom rulesets list, where the File field shows the location of the selected ruleset file and the Name field shows the ruleset name retrieved from the attribute `name` within the `<ruleset>` tag.

## Running Mess Detector in the batch mode

1. To [run the inspection](#) , choose Code | Inspect code on the main menu. Specify the inspection scope and profile.
2. View the inspection results in the [Inspection Results Tool Window](#) . Errors and warnings reported by PHP Mess Detector have the `phpmd` prefix to distinguish them from IntelliJ IDEA internal inspections.

## Excluding files from Mess Detector inspection

When waiting for Mess Detector response exceeds the limit specified in the Tool process timeout field on [Mess Detector](#) page, IntelliJ IDEA suggests adding the file to the [ignore list](#) . This list is shown on the Mess Detector page in the Ignored files area. For each file, IntelliJ IDEA displays its name and location.

- To delete a file from the list and have Mess Detector process it again, select the file and click the Remove file button `-` .
- To remove all the files from the list, click the Clean the list button `✕` .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides full coding assistance for developing **WordPress** including **WordPress**-aware code completion, search for hook registration functions and functions specified as hook registration parameters, navigation between hook registrations and the hook invocations, callbacks, the possibility to configure the coding style in accordance with the **WordPress** code style, viewing the official **WordPress** documentation from the IntelliJ IDEA editor, etc.

You can run **WordPress** from IntelliJ IDEA in two modes:

- Through a dedicated user interface. To get access to this functionality in a project, you need to download **WordPress** , register it in IntelliJ IDEA, and activated the **WordPress** integration within the current project.
- Through a set of command line tools. In this case, you need to download **WP-CLI** and configure it as a IntelliJ IDEA **command line tools** , see [PHP Command Line Tools](#) .

In this section:

- [Preparing to Use WordPress](#)
- [WordPress Specific Coding Assistance](#)
- [Using the WordPress Command Line Tool WP-CLI](#)

This feature is only supported in the Ultimate edition.

In this section:

- [Overview](#)
- [Before you start](#)
- [Downloading and installing WordPress](#)
- [Activating the WordPress installation in a project](#)
- [Generating a WordPress application stub](#)

## Overview

IntelliJ IDEA provides a dedicated interface for developing and running WordPress applications and provides WordPress - aware coding assistance, see [WordPress Specific Coding Assistance](#) . To get access to this functionality in a project, you need to download WordPress , register it in IntelliJ IDEA, and activated the WordPress integration within the current project.

Alternatively, you can download WordPress and create a stub of a WordPress -targeted project. In this case, the WordPress integration in the project will be activated automatically.

Whether you enable the WordPress integration in an existing project or create a stub of a WordPress application, IntelliJ IDEA checks if the development environment is configured properly for WordPress development. If the configuration does not meet the requirements, IntelliJ IDEA displays a pop-up window with a Fix link.

## Before you start

1. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#) , as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#) .
2. Make sure the PHP and WordPress Support plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
3. Configure the [PHP interpreter](#) to use WordPress with, as described [Configuring Remote PHP Interpreters](#) . Note that WordPress requires PHP 5.3 or higher.

## Downloading and installing WordPress

1. Download the `WordPress.zip` archive at <https://wordpress.org/download/> .
2. Extract the archive:
  - To have the possibility to run your WordPress application on a [local Web server](#) , store the extracted file to the [document root](#) of the server where the [PHP interpreter](#) is configured. For local development environment with the [Apache HTTPD Web server](#) , extract `WordPress.zip` to the `htdocs` folder.
  - To run your WordPress application on an [in-place server](#) , store the extracted file under the project root.
  - To run your WordPress application on a [remote server](#) , store the extracted files in your project and then configure automatic upload of them to the document root of the remote server.  
Learn more about [server access configurations](#) , see [Configuring Synchronization with a Web Server](#) . For information on configuring upload to the server, see [Uploading and Downloading Files](#) .
  - If you are not going to run your WordPress application but just need to get coding assistance from IntelliJ IDEA, store the extracted files anywhere on your computer. In this case, you will have to configure the installation as an [include path](#) , see [Configuring Include Paths](#) .

To run WordPress in the command line mode, you will need a set of command line tools which you can acquire by installing the `wp-cli/wp-cli` package using the Composer dependency manager or by downloading the `wp-cli.phar` archive. For details, see [Using the WordPress Command Line Tool WP-CLI](#) .

## Activating the WordPress installation in a project

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Frameworks Page under Languages and Frameworks | PHP .
2. On the [Frameworks page](#) that opens, select the Enable WordPress Integration checkbox.
3. In the WordPress Installation Path text box, specify the folder where WordPress is installed. This folder should contain the `wp-admin` and `wp-includes` subdirectories.
4. Click Apply to save the WordPress registration and click PHP .
5. On the [PHP page](#) that opens, add the path to the WordPress installation folder to the Include Paths list: click the `+` button and specify the path to the installation folder in the dialog box that opens. Learn more in [Configuring Include Paths](#) .

## Generating a WordPress application stub

During project creation, IntelliJ IDEA can generate a project stub for developing WordPress applications. The project structure is set up in accordance with the WordPress requirements.

1. Choose File | New | Project on the main menu or click Create New Project on the Welcome screen. The [Project Category and Options](#) dialog opens.
2. In the left-hand pane, click PHP from the list, then choose WordPress Plugin in the right-hand pane, and then click *Next* .
3. On the second page of the wizard, specify the project name and the folder where it will be created. In the WordPress Installation Path text box, specify the folder where WordPress is installed. This folder should contain the `wp-admin` and

`wp-includes` subdirectories. Click Finish to start the project stub generation.

4. If the newly created project is outside the **WordPress** installation folder, configure it as an **external library** by adding it to the list of **included path**.

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks .
2. On the [PHP](#) page that opens, add the path to the **WordPress** installation folder to the Include Paths list: click the **+** button and specify the path to the installation folder in the dialog box that opens. Learn more in [Configuring Include Paths](#) .

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides full coding assistance for developing **WordPress** including **WordPress**-aware code completion, search for hook registration functions and functions specified as hook registration parameters, navigation between hook registrations and the hook invocations, callbacks, the possibility to configure the coding style in accordance with the **WordPress** code style, viewing the official **WordPress** documentation from the IntelliJ IDEA editor, etc.

In this section:

- [Adding the WordPress to a project](#)
  - [Configuring the WordPress installation as a project include path](#)
  - [Adding the wp-content folder to the project](#)
- [Configuring WordPress code style](#)
- [Hooks support](#)
  - [Completion for parameters of the Action and Filter functions](#)
  - [Navigation from a hook registration to the hook invocation](#)
  - [Callbacks from a hook registration](#)
  - [Navigating to hook invocations](#)
  - [Searching for hook registration functions](#)
- [Viewing the official WordPress documentation from IntelliJ IDEA](#)

## Adding the WordPress to a project

To take advantage of coding assistance provided by IntelliJ IDEA, the **WordPress** installation you are working with should be configured in the project as an **external library**. As a result, the **WordPress** core file will be involved in indexing which is the basis for resolving references and providing code completion, navigation, search, etc.

If the `wp-content` folder is outside the **WordPress** installation, it has to be added either as an **include path** or as a **content root**.

### Configuring the WordPress installation as a project include path

To add **WordPress** to your project as an external library, you need to add it to the list of **include paths**. Learn more in [Configuring Include Paths](#).

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
2. On the [PHP](#) page that opens, add the path to the **WordPress** installation folder to the Include Paths list: click the `+` button and specify the path to the installation folder in the dialog box that opens.

### Adding the wp-content folder to the project

If the `wp-content` folder is located outside the **WordPress** installation, you need to add it to the project individually, apart from the **WordPress** core files. This can be done in two ways:

- To have the `wp-content` folder involved in indexing without putting it under the project version control, add it to the list of include paths:
  1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click PHP under Languages & Frameworks.
  2. On the [PHP](#) page that opens, add the path to the `wp-content` folder to the Include Paths list: click the `+` button and specify the path to the folder in the dialog box that opens.
- To have the `wp-content` folder involved in indexing and put it under the project version control, add it as a **content root**:
  1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
  2. In the left-hand pane, select Modules.
  3. In the pane to the right, select the necessary module.
  4. In the right-hand part of the dialog, select the Sources tab.
  5. Click Add Content Root.
  6. In the [dialog that opens](#), locate the `wp-content` directory and click OK.

Learn more about configuring content roots in [Configuring projects](#). For information about adding files and folders to version control, see [Enabling Version Control](#).

### Configuring WordPress code style

In IntelliJ IDEA, you can use the **WordPress Code Style** in accordance with the [WordPress coding standards](#). To configure the native **WordPress** code style, do one of the following:

- 1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS. Expand the Editor node, and then click PHP under Code Style.

2. On the [Code Style. PHP page](#) that opens, click the Set from... link.
3. On the context menu, choose Predefined Style , then choose WordPress .

- Upon activating of the **WordPress** integration, IntelliJ IDEA displays a pop-up window offering you to set the **WordPress** code style. Click the Set it link in the pop-up window and set the code style on the Code Style. PHP page that opens.

Learn more in [Configuring Code Style](#) .

## Hooks support

IntelliJ IDEA indexes all hooks declared in the **WordPress core** and in the included plugins. This makes the basis for coding assistance when working with hooks.

### Completion for parameters of the Action and Filter functions

Hook names are available in code completion of standard parameters for action and filter functions ( `add_action()` and `add_filter()` ). To invoke completion for a parameter:

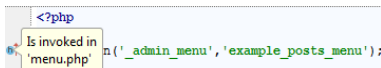

1. Start typing the declaration of an `add_action()` or `add_filter()` function.
2. Press `Ctrl+Space` and choose the relevant parameter from the list.

### Navigation from a hook registration to the hook invocation

To navigate from a hook registration ( `add_action()` or `add_filter()` function) to the hook invocation:

- Click the icon in the gutter area next to the hook registration to navigate from.

IntelliJ IDEA opens the file where the hook is invoked and positions the cursor at the invocation method, in the current example it is `do_action` .

### Callbacks from a hook registration

You can navigate to the declaration of the function or method specified as the second parameter of a hook registration ( `add_action()` or `add_filter()` function). To do that:

- With the `Ctrl` / `⌘` keyboard key pressed, hover the cursor over the parameter of interest. IntelliJ IDEA displays a pop-up information message with the definition of the function or method specified as this parameter:

The parameter turns into a link. When you click this link, IntelliJ IDEA opens the file where the function or method was declared and positions the cursor and declaration.

### Navigating to hook invocations

To search for a hook invocation and navigate to it, do one of the following:

- Use the **Navigate to Symbol** functionality:
  1. Choose **Navigate | Symbol** on the main menu.
  2. In the Enter symbol name pop-up window that appears, start typing the hook name in the search field. If necessary, select the Include non-project items checkbox. The contents of the list below the search field change as you type.

3. Click the relevant hook from the list. IntelliJ IDEA opens the file where it is invoked and positions the cursor at the invocation.

- Use the **Search Everywhere** functionality:
  1. Press the `Shift` keyboard key twice.
  2. start typing the hook name in the search field. If necessary, select the Include non-project items checkbox.

The contents of the list below the search field change as you type.

3. Click the relevant hook from the list. IntelliJ IDEA opens the file where it is invoked and positions the cursor at the invocation.

Learn more about search and navigation in [Searching Through the Source Code](#) and [Navigating Through the Source Code](#).

## Searching for hook registration functions

You can search for occurrences of a hook registration function and for occurrences of a function or method specified as the second parameter of a hook registration.

- To get a list of usages for a hook registration function:
  1. Position the cursor at the name of the desired hook registration function and press `Alt+F7` or choose Edit | Find | Find Usages on the main menu.
  2. From the pop-up list that shows the available options in terms of hook/function name, choose the relevant option. The Find tool window opens with a new tab showing all the detected occurrences of the selected function.
  3. Explore the listed occurrences. To navigate to the relevant one, click it. IntelliJ IDEA opens the file with the selected function or method and positions the cursor at it.
- To get a list of occurrences of a function or method specified as the second parameter of a hook registration:
  1. Position the cursor at the parameter of interest and press `Alt+F7` or choose Edit | Find | Find Usages on the main menu. The Find tool window opens with a new tab showing all the detected occurrences of the function or method specified as the parameter on which the search was invoked.
  2. Explore the listed occurrences. To navigate to the relevant one, click it. IntelliJ IDEA opens the file with the selected function or method and positions the cursor at it.

Learn more in [Finding Usages](#).

## Viewing the official WordPress documentation from IntelliJ IDEA

You can view the official [WordPress Documentation](#) at <http://wordpress.org/> right from the IntelliJ IDEA editor.

1. Select the text you are interested in.
2. On the context menu of the selection, choose Search on WordPress.org .  
IntelliJ IDEA opens the page with the relevant documentation in the default browser.

This feature is only supported in the Ultimate edition.

To run WordPress in the command line mode, you will need a set of command line tools which you can acquire by installing the `wp-cli/wp-cli` package using the Composer dependency manager or by downloading the `wp-cli.phar` archive. The downloaded command line tool must be registered in IntelliJ IDEA as described in [PHP Command Line Tools](#).

For information about **running** the tool in the command line mode, see [PHP Command Line Tools](#).

On this page:

- [Before you start](#)
- [Installing the wp-cli package using the Composer dependency manager](#)
- [Downloading the wp-cli.phar archive](#)
- [Configuring wp-cli as a IntelliJ IDEA command line tool](#)
- [Running the wp-cli tool](#)

## Before you start

1. Make sure the PHP interpreter is configured in IntelliJ IDEA on the [PHP page](#), as described in [Configuring Local PHP Interpreters](#) and [Configuring Remote PHP Interpreters](#).
2. Make sure the **PHP** and **Command Line Tool Support** plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#). Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.
3. Configure the **PHP** interpreter to use **WordPress** with, as described [Configuring Remote PHP Interpreters](#). Note that **WordPress** requires **PHP 5.3** or higher.

## Installing the wp-cli package using the Composer dependency manager

Before you start, make sure Composer is installed on your machine and initialized in the current project, see [Composer Dependency Manager](#).

1. On the context menu of `composer.json`, choose *Composer | Manage Dependencies*.
2. In the [Manage Composer Dependencies Dialog](#) that opens, select the `wp-cli/wp-cli` package from the Available Packages list, possibly using the search field. The list shows all the available packages, the packages that are already installed are marked with a tick. Choose the relevant version from the *Version to install* list.
3. If necessary, expand the Settings hidden area and specify the advanced installation options. In the Command line parameters text box, type the additional command line parameters. For example, to have the package added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.
4. Click **Install**.

When you click *Finish*, the `create-project` command is invoked with the selected package. This results in creating a Composer project whose configuration and structure depends on the selected package, see <https://getcomposer.org/doc/03-cli.md> for details. After that a IntelliJ IDEA project opens.

**TIP** Alternatively choose *Tools | Composer | Manage Dependencies* on the main menu.

## Downloading the wp-cli.phar archive

- Download the `wp-cli.phar` at [WordPress CLI](#).

## Configuring wp-cli as a IntelliJ IDEA command line tool

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing *File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS*, and click **Command Line Tool Support** under **Tools**.
2. On the [Command Line Tool Support](#) page, click the **Add** button. In the **Choose Tool to Add** dialog box that opens, choose **WP-CLI**.
3. In the **WP-CLI** dialog box that opens, choose the way to run **WordPress**:
  - **Installed via PHAR**: Choose this option to launch **WordPress** through a PHP script or have IntelliJ IDEA detect and start the launcher in the `wp-cli.phar` archive. Choose one of the configured PHP interpreters from the **PHP Interpreter** list. See [Configuring Remote PHP Interpreters](#) for details.

In the **Path to phar** text box, specify the location of the `wp-cli.phar` archive. Type the path manually or click the **Browse** button  and choose the desired location in the dialog box that opens.

- Executable available (installed via Composer, etc.): choose this option to launch **WordPress** through an executable file which is available when you install **WordPress** using a package management tool, for example, Composer.  
In the Path to wp.bat field, specify the location of the `wp.bat` or `wp` executable file. If you used Composer, the default location is `\vendor\wp\cli\bin\wp` or `\vendor\wp\cli\bin\wp.bat`. Type the path manually or click the Browse button  and choose the desired location in the dialog box that opens.
- 4. When you click OK, the WP-CLI dialog box closes and IntelliJ IDEA brings you back to the Command Line Tool Support page, where **wp** is added to the list of available tools.
- 5. From the Console encoding drop-down list, choose the character set to show the tool's output in the [Command Line Tools Console Tool Window](#).
- 6. In the *Showconsole in* area, choose *Pop-up* to open the Input pane in a pop-up window or *Tool window* to show it as a text box at the bottom of the [Command Line Tools Console](#) tool window.

## Running the wp-cli tool

You can run **WP-CLI** commands and analyze their output right in IntelliJ IDEA using the dedicated [Command Line Tools Console](#) tool window, just as the commands of any other command line tools, see [PHP Command Line Tools](#).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Playframework Support Plugin is installed and enabled!

IntelliJ IDEA supports the version 1.x.x of the [Play framework](#) . The necessary integration with the framework is provided by the Playframework Support [plugin](#) bundled with with the IDE.

A Play application in IntelliJ IDEA corresponds to a Java [module](#) .

**Note** If you want to use IntelliJ IDEA just for running the `play` command-line utility (also known as the Play console), you can install and use the version 2.x.x of the Playframework.

In this section:

- [Play framework support overview](#)
- [Preparing for Play application development](#)
- [Creating a Play application](#)
- [Accessing the play command-line utility in IntelliJ IDEA](#)
- [Adding Play modules to an IntelliJ IDEA module](#)
- [Running a Play application](#)
- [Running Play application tests](#)
- [Debugging a Play application: process overview](#)
- [Creating a run/debug configuration for debugging](#)
- [Modifying the run configuration for running the application](#)

## Play framework support overview

Please note that the Play framework version 1.x is supported by the IntelliJ IDEA version 11. The later versions of IntelliJ IDEA support the Play 2.x version. Moreover, for the IntelliJ IDEA version 14.0, the Play 2.x framework is merged with the Scala plugin.

The Play framework support in IntelliJ IDEA includes:

- An ability to use the `play` command-line utility (the Play console) right in the IDE.
- Coding assistance:
  - Navigation between the methods of `Application.java` and the corresponding templates.
  - Updating templates through the variables of the corresponding `Application.java` methods.
  - [Code completion](#) for keywords, labels, variables, parameters and functions.
  - Error and syntax highlighting.
  - Code [formatting](#) and [folding](#) .
- Advanced source code [search and replace capabilities](#) .
- [Structure view](#) .

## Preparing for Play application development

To prepare for Play application development:

1. [Download](#) and install the desired Play framework version [supported by IntelliJ IDEA](#) . See the [installation instructions](#) .
2. [Create a new Play application](#) ( `play new` ) or get an existing one (the one that you are going to work with in IntelliJ IDEA).
3. [Prepare your application](#) for opening it in IntelliJ IDEA ( `play idea` or `play idealize` ).
4. Make sure that the [Play framework settings](#) are properly specified in IntelliJ IDEA.
5. [Open the application](#) in IntelliJ IDEA.
6. Optionally, convert the project into the [directory-based format](#) .

## Creating a Play application

To create a new Play application, run the `play new` command in a command-line shell, outside IntelliJ IDEA:

1. Open your command-line shell.
2. Switch to the directory in which you want to create your Play application.
3. Run the following command:

```
play new <dir>
```

where `<dir>` is the name of your new Play application directory (e.g. `helloworld` ) which will be created in the current directory.

4. When asked for the application name, type the name and press `Enter` .

As a result, the Play application with the specified name is created in the specified directory.

## Preparing a Play application for opening it in IntelliJ IDEA

To prepare a Play application for opening it in IntelliJ IDEA, run the `play idea` or the `play idealize` command from the root directory of your Play application:

1. Open your command-line shell.
2. Switch to the root directory of your Play application.
3. Run the following command:

```
play idea
```

(Alternatively, you can use the `play idealize` command.)

As a result, all the necessary IntelliJ IDEA configuration files are created in the current directory. These include the `<app_name>.ipr` project file which you can now [open in IntelliJ IDEA](#).

## Specifying Play framework settings

In IntelliJ IDEA, the Play framework settings are specified in the Settings dialog, on the Play Configuration page.

1. Open the Settings dialog (e.g. `Ctrl+Alt+S`).
2. In the left-hand pane of the dialog, select Play Configuration.
3. On the [Play Configuration page](#) that opens in the right-hand part of the dialog:
  - In the Home field, specify the Play framework installation directory.
  - In the Working directory field, specify the Play framework working directory. This is the directory from which the commands of the `play` command-line utility are run.
  - Depending on your preferences, turn the [Show on console run](#) option on or off.
4. Click OK in the Settings dialog.

## Opening a Play application in IntelliJ IDEA

To open a Play application in IntelliJ IDEA, you should open the `<app_name>.ipr` project file [you have previously generated](#):

1. Select File | Open.
2. In the Open File or Project dialog, go to your Play application root folder, select the `<app_name>.ipr` file, and click OK.

In the project that opens your Play application is represented by an IntelliJ IDEA [module](#).

If necessary, convert your project into the [directory-based format](#).

## An alternative way to create an IntelliJ IDEA project for a Play application

The quickest and the most convenient way to start working with a Play application in IntelliJ IDEA is to [run the play idea command](#) and then [open the generated .ipr file](#) in IntelliJ IDEA.

As an alternative, you can create a new project for your Play application sources using File | New | Project from Existing Sources and then add the necessary Play framework assets ( `<play_dir>\framework\lib` and `<play_dir>\framework\play-<version>.jar` ) to [dependencies](#) of the resulting IntelliJ IDEA module:

1. Select File | New | Project from Existing Sources.
2. In the [dialog that opens](#), select your Play application root directory.
3. On the [first page](#) of the Import Project wizard, select Create project from existing sources and click Next.
4. On the [next page of the wizard](#), in the Project location field, specify the path to your Play application root directory. The rest of the settings are not that important. Click Next.
5. Follow the instructions of the wizard. (Normally, all you have to do is to click Next on each of the pages accepting the default settings.)

When the project has been created, add the necessary module dependencies:
6. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
7. In the left-hand pane of the dialog, select Modules.
8. On the [Module page](#) shown in the right-hand part of the dialog, select the [Dependencies tab](#), click `+` and select Jars or directories.
9. In the Attach Files or Directories dialog, go to the Play framework installation directory, select the directory `framework\lib` and the file `framework\play-<version>.jar`, and click OK.
0. Click OK in the Project Structure dialog.

## Accessing the play command-line utility in IntelliJ IDEA

If a Play application is currently open in IntelliJ IDEA, you can access the `play` command-line utility (the Play console) and run it right from the IDE:

1. Select Tools | Play with Playframework.

2. In the [Play Configuration dialog](#) specify the Play framework settings and click OK . (This dialog is not shown if the [Show on console run option](#) is off in the [Play framework settings](#) .)

As a result, the `play` command-line utility is started in the [Run tool window](#) .

## Adding Play modules to an IntelliJ IDEA module

The Play modules used by your Play application should be added to the corresponding IntelliJ IDEA module as the [module content roots](#) . For example, if your application uses (or is about to be using) the Play module `secure` :

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the left-hand pane of the dialog, select **Modules** .
3. On the [Module page](#) shown in the right-hand part of the dialog, select the [Sources tab](#) and click **Add Content Root** .
4. In the Select content root directory dialog, go to the Play framework installation folder, select the directory `modules\secure` , and click OK . (If the Play module you want isn't included in the Play framework distribution, you should download that module first to make it available locally.)
5. Click OK in the Project Structure dialog.

## Running a Play application

To run your play application, you can use the `play run` command:

1. [Start the play command-line utility](#) ( [Tools | Play with Playframework](#) ).
2. In the Run tool window, after `play` , type `run` and press `Enter` .
3. Open a Web browser and go to `http://localhost:9000` to see the application home page.

As an alternative, you can create an IntelliJ IDEA [run/debug configuration](#) , and use that configuration for running your application.

To create a run configuration for running your Play application:

1. Open the Run/Debug Configurations dialog (e.g. [Run | Edit Configurations](#) ).
2. Click **+** (`Alt+Insert` ) and select **Application** .
3. In the following fields, specify:
  - Main class. Type `play.server.Server`
  - VM options. Type `-Dapplication.path="."`
  - Working directory. Specify your Play application root directory.
4. If necessary, change the run configuration name and click OK .

Now, to execute this run configuration, you can, for example, use [Run | Run](#) . (For more information, see [Running Applications](#) .)

## Running Play application tests

To run tests for your Play application, you can use the `play test` command:

1. [Start the play command-line utility](#) ( [Tools | Play with Playframework](#) ).
2. In the Run tool window, after `play` , type `test` and press `Enter` .
3. Open a Web browser and go to `http://localhost:9000/@tests` to run the tests.

To be able to use an IntelliJ IDEA run/debug configuration for running your tests:

- Add `<play_dir>\modules\testrunner\lib\play-testrunner.jar` to the dependencies of your module. (See an [example of the procedure](#) to be used.)
- Modify the [run configuration for running the application](#) : in the VM options field, after `-Dapplication.path="."` , type space and then type `-Dplay.id=test`

So, finally, the VM options field will contain:

```
-Dapplication.path="." -Dplay.id=test
```

(If you want a separate run configuration for the tests, you can create a copy of the existing run configuration ([+](#)) and then modify that copy accordingly.)

## Debugging a Play application: process overview

1. [Create a run/debug configuration for debugging](#) . This should be a Remote type of configuration; the port specified in this configuration should correspond to a Java debugger port ( `8000` by default).
2. Set one or more [breakpoints](#) in your code. See [Using Breakpoints](#) .
3. If you are going to use an IntelliJ IDEA run configuration for starting the application, [modify the corresponding run configuration](#) , or create a new one.
4. Run the application by using the `play run` command (without any options and arguments) or by executing the corresponding run configuration.
5. Start the run/debug configuration intended for debugging.

6. In a Web browser, go to `http://localhost:9000` and, by using the application, try to reach a breakpoint.
7. When a breakpoint is reached, switch to IntelliJ IDEA and scrutinize the suspicious code fragments.
8. Continue debugging unless you localize the problem in your code.

See also, [Debugging](#) .

## Creating a run/debug configuration for debugging

1. Open the Run/Debug Configurations dialog (e.g. Run | Edit Configurations ).
2. Click **+** (`Alt+Insert`) and select Remote .
3. In the Port field, specify `8000` . (This is the port to which a Java debugger will connect. By default, the Play framework uses the port `8000` .)
4. If necessary, change the run/debug configuration name and click OK .

## Modifying the run configuration for running the application

If you are using an IntelliJ IDEA [run configuration for running your Play application](#) , this configuration has to be modified so that a Java debugger could connect to the running application. This is done by adding the corresponding JVM options. The necessary options can be copied from the run/debug configuration intended for debugging.

1. Open the Run/Debug Configurations dialog (e.g. Run | Edit Configurations ).
2. In the left-hand pane of the dialog, select the run/debug configuration intended for debugging.
3. Click **⌘** to the right of the upper field containing JVM command-line arguments. As a result, the field contents are copied to the clipboard.
4. Select the run configuration for running the application, and paste the options into the VM options field. This field should finally contain `-Dapplication.path=". "` , then a space and then the options you've just pasted. Here is an example:

```
-Dapplication.path=". " -agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=8000
```

(If you are using the same run configuration for running the application and the [tests](#) , you may need to delete `-Dplay.id=test` .)

5. Click OK .

In this section:

- [Plugin Development Guidelines](#)
  - [Before you start](#)
  - [Developing plugins](#)
- [Configuring IntelliJ Platform Plugin SDK](#)
- [Creating a Project for Plugin Development](#)
- [Running and Debugging Plugins](#)
- [Preparing Plugins for Publishing](#)
- [Viewing PSI Structure](#)

## Before you start

1. Download and install a JDK.
2. Make sure that the Plugin DevKit plugin is enabled, see [Enabling and Disabling Plugins](#) .
3. Optionally, [download](#) the IntelliJ IDEA Community Edition sources. This will make debugging your plugins much easier.

## Developing plugins

### To develop an IntelliJ IDEA plugin

Follow these general steps:

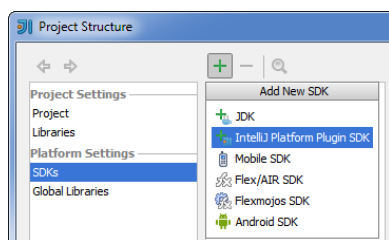

1. Start IntelliJ IDEA.
2. [Configure the IntelliJ Platform Plugin SDK](#) .
3. [Create a project for plugin development](#) .
4. Create the necessary source elements and write the source code.
5. [Run and debug](#) your plugin.
6. [Prepare the plugin for publishing](#) .

For more information on IntelliJ IDEA plugin development, refer to the [Writing Plug-ins](#) page.

To be able to develop plugins for IntelliJ IDEA, you have to configure an IntelliJ Platform Plugin SDK . You can do that separately - as described on this page, or [when creating a project](#) .

## To configure the IntelliJ Platform Plugin SDK

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Under Platform Settings , select SDKs and then click **+** to define a new SDK.
3. Select IntelliJ Platform Plugin SDK from the Add New SDK list.

4. If you haven't defined a JDK in IntelliJ IDEA yet, a dialog is shown suggesting that you do that now. Click OK in that dialog, and then select the installation folder of the desired JDK in the [dialog that opens](#) .
5. In the [dialog that opens](#) , select the installation folder of the necessary IntelliJ IDEA version. (An IntelliJ IDEA installation acts as an IntelliJ Platform Plugin SDK).
6. In the Select internal Java platform dialog, select the desired JDK from the list and click OK . (Listed in this dialog are the JDKs defined in IntelliJ IDEA.)
7. If necessary, change the path to the sandbox in the Sandbox Home field. (The sandbox is a folder where IntelliJ IDEA will copy your plugins for debugging.)
8. Optionally, configure the source path for the IntelliJ IDEA Community Edition sources (if you are going to use them and have them available on your computer). To do that, select the Sourcepath tab and click **+** . In the [dialog that opens](#) , select the folder containing the sources and click OK . Click OK in the Detected Source Roots dialog.
9. Click OK to save the changes and close the Project Structure dialog.

Now, the IntelliJ Platform Plugin SDK is in the list of available SDKs, so in the future, when necessary, you will be able to simply select it from the corresponding lists.

To develop a plugin for IntelliJ IDEA, you need a project with a plugin [module](#) .

## To create a new project with a plugin module

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the [Welcome screen](#) . Otherwise, select File | New | Project .  
As a result, the [New Project wizard](#) opens.

2. On the [first page of the wizard](#) , in the left-hand pane, select IntelliJ Platform Plugin .

3. In the right-hand part of the page:

– Specify the [SDK](#) to be used.

If the necessary SDK is already defined in IntelliJ IDEA, select it from the list. Otherwise, click New and select the installation folder of the desired IntelliJ IDEA version. (An IntelliJ IDEA installation acts as an IntelliJ Platform Plugin SDK.) If asked to specify a JDK first, do so.

– If necessary, enable Groovy support by selecting the corresponding checkbox. If the necessary Groovy version is already defined in IntelliJ IDEA as a [library](#) , select that library from the list. Otherwise, click Create and select the installation folder of the desired Groovy version in the dialog that opens.

– If necessary, enable SQL support by selecting the corresponding checkbox. Select the SQL dialect to be used by default from the list.

Click Next .

4. Specify the name and location settings for your project and module. For more information, see [Project Name and Location](#) .

Click Finish .

When a project is created, populate it with [new actions](#) , components, etc. To create the necessary items, use the New menu. To access this menu, select the required location, package, etc. in the [Project Tool Window](#) and then do one of the following:

– Select File | New in the main menu.

– Select New from the context menu.

– Press [Alt+Insert](#) .

To run or debug your plugin, you should create the corresponding [Run/Debug configuration](#) first.

## To create a Run/Debug configuration for a plugin

1. On the main menu, choose Run | Edit Configurations .
2. In the [Run/Debug Configuration dialog](#) , click **+** , or press `Insert` , and select Plugin .
3. Specify the settings as necessary and click OK .

## To run or debug a plugin

Depending on whether you are going to run or debug your plugin:

- To run the plugin, select Run | Run from the main menu, or press `Shift+F10` .
- To debug the plugin, select Run | Debug from the main menu, or press `Shift+F9` .

As a result, IntelliJ IDEA will start an instance of itself. This will be the instance in which your plugin will be available.

When your plugin is ready, you might want to upload it to the JetBrains Plugin Repository (<http://plugins.intellij.net>) or to the [repository of your own](#). Yet, before uploading a plugin, you need to create a ZIP or JAR plugin archive. This section provides instructions for creating such an archive.

## To create a plugin archive

- Right-click the plugin module in the Project view and select Prepare Plugin Module <module-name> For Deployment in the context menu.

As a result, IntelliJ IDEA will create the necessary archive.

**Note** If the plugin module does not depend on libraries, a JAR archive will be created. Otherwise, a ZIP archive will be created that will include all the necessary libraries.

## Introduction

the PSI viewer enables you to explore the internal structure of the source code, as it is interpreted by IntelliJ IDEA.

## Important note

PSI viewer command is only available when there is at least one plugin module in project.

If you want this information to be available for any project, add the following line to the file `bin/idea.properties` under the product installation:

```
idea.is.internal=true
```

## Viewing PSI structure of the source code

### To view PSI structure of the source code

1. On the main menu, choose Tools | View PSI Structure .
2. In the [PSI Viewer](#) dialog box, type or paste the fragment of source code to be analyzed in the Text area, select file type, and specify the other options.
3. Click Build PSI Tree , and preview the generated PSI tree in the PSI Structure pane.

If the source code in the Text area has been changed, click the same button to refresh preview.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- Python Plugin
  - [Introduction](#)
  - [Prerequisites](#)
  - [Changes to the UI](#)
- [Python Language Support](#)
- [Django Framework Support](#)
- [Remote Debugging](#)
- [Type Hinting in IntelliJ IDEA](#)
- [Using Docstrings to Specify Types](#)

## Introduction

Python Plugin extends IntelliJ IDEA with the full-scale functionality for Python development.

## Prerequisites

Before you start working with Python, make sure that Python plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Python SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

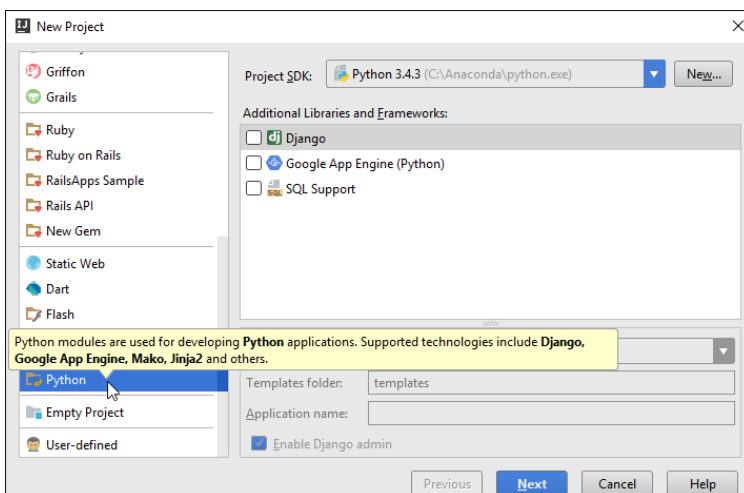

Refer to their respective download and installation pages for details:

- [Python](#)
- [Django](#)

## Changes to the UI

Being installed, the Python Plugin introduces the following changes to the IntelliJ IDEA UI:

- Python module type is added to the [New Project](#) and [New Module](#) wizards.

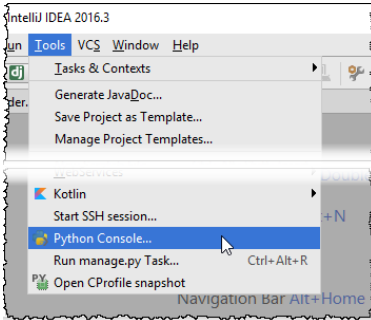

- Python SDK can be specified in the Add new SDK popup under the SDKs node of the [Project Structure](#) dialog.

- Django , Buildout and Google App Engine are implemented as the facets , which can be attached to a Python module, either in the [New Project](#) dialog, or in the [Modules](#) or [Facets](#) pages of the [Project Structure](#) dialog:

- Python-related commands are added to the Tools menu:

- Python and framework-specific [run/debug configurations](#) , [inspections](#) , [intention actions](#) , and [refactorings](#) .

Besides that, the following changes are made to the Settings/Preferences dialog:

- Python code style, colors and fonts, live templates.
- [Python Debugger](#) is added under the Debugger node.
- Python-related options add to the [Stepping](#) page.
- Python [console pages](#) are added.
- [Syntax and error highlighting](#)
- More Python-specific options are added to the [Coverage](#) page.
- [Python Template Languages](#) , [Python External Documentation](#) and [Python Integrated Tools](#) pages are added.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

This section provides descriptions of the Python-specific procedures that are used in projects of all supported [types](#) , and the procedures that pertain to the empty projects only.

## Prerequisite

At least one [Python](#) interpreter is properly installed on your machine.

## Python support

IntelliJ IDEA supports Python from version 2.4 up to the version 3.6.

IntelliJ IDEA provides support for Python 3.5 and (since 2016.3) Python 3.6, with the backing of the following:

- [PEP-0484 -- Type Hints](#)
- [PEP 0448 -- Additional Unpacking Generalizations](#)
- [PEP 0492 -- Coroutines with async and await syntax](#)
- [PEP 526 -- Syntax for variable annotations](#)
- [PEP 498 -- Literal String Interpolation](#)
- [PEP 515 -- Underscores in Numeric Literals](#)
- [PEP 525 -- Asynchronous Generators](#)
- [PEP 530 -- Asynchronous Comprehensions](#)
- and more.

Python support in IntelliJ IDEA includes:

- Dedicated [module type](#) .
- Ability to [configure](#) interpreters. .
- [Python console](#) .
- Run/debug configurations for [Python](#) , and [Python remote debug](#) .
- Code insight
- [Code inspections](#) .
- [Intention actions](#) .
- [Code completion](#) and resolve.
- Built-in code formatter and separate set of Python [code style settings](#) .
- [Find usages](#) in Python code.
- [Testing frameworks](#) .
- [Quick documentation](#) .
- Recognizing Python [documentation comments](#) .
- Configuring [Python debugger](#) .
- [UML Class diagrams for Python classes](#) .

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Configuring Python SDK](#)
  - [Basics](#)
- [Configuring Available Python SDKs](#)
- [Configuring Python Interpreter for a Project](#)

## Basics

In IntelliJ IDEA, you can define several Python SDKs. So doing, you can choose the one to be used in your project, from the list of the interpreters available on your machine.

IntelliJ IDEA supports:

- Standard [Python interpreters](#)
- [IronPython](#)
- [PyPy](#)
- [Jython](#)
- [CPython](#)

Python SDKs can be configured on the following levels:

- Current project : selected Python interpreter will be used for the current project.
- New project : selected Python interpreter will be used for the new project instead of the default one.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Overview](#)
- [Viewing the list of available interpreters](#)
- [Configuring the list of available interpreters](#)
- [Removing interpreters from the list](#)

## Overview

The list of Python SDKs, available for the various projects, can include interpreters installed locally, remotely, as well as the virtual environments.

The available Python interpreters are defined as the global SDKs. The procedure described below supposes that the necessary Python interpreters are already installed on your computer.

## Viewing the list of available interpreters

### To view the list of available interpreters

- On the main menu, choose File | Project Structure (or click , or press `Ctrl+Shift+Alt+S` ).

## Configuring the list of available interpreters

### To configure the available Python interpreters

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Click , and then choose Python SDK from the Add New SDK popup menu.
4. In the [Select Python Interpreter](#) dialog box, choose the desired Python executable, and click OK .  
The selected Python interpreter appears in the list of available SDKs.

Having selected an interpreter, you can configure its paths.

5. Repeat steps 1 - 4 to add more Python interpreters to the list.

## Removing interpreters from the list

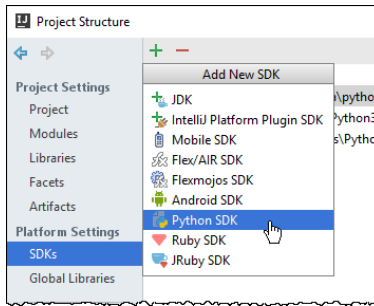

### To remove an interpreter from the list of available interpreters

1. In the list of available interpreters, select the one to be deleted.
2. Click  .

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## To configure a local Python interpreter, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the **Project Structure** dialog, click the node SDKs, click **+**, and from the popup menu, choose Python SDK

3. Select the desired interpreter location (local, remote etc.). In this case, choose Add local.
4. In the **Select Python Interpreter** dialog box, click the desired Python executable.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Prerequisite](#)
- [Configuring remote Python interpreter](#)

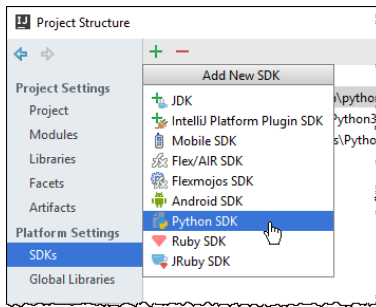

## Prerequisite

Before you start working with remote interpreters, make sure that the SSH Remote Run plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

## Configuring remote Python interpreter

### To configure a remote Python interpreter, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the [Project Structure](#) dialog, click the node SDKs, click **+**, and from the popup menu, choose Python SDK

3. Select the desired interpreter location (local, remote etc.). In this case, choose Add remote.
4. In the Configure Remote Python Interpreter dialog box, select the desired option (Deployment configuration, SSH Credentials etc.).

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA makes it possible to create a virtual environment using the [virtualenv](#) tool. So doing, IntelliJ IDEA tightly integrates with `virtualenv`, and enables configuring virtual environments right in the IDE.

`virtualenv` tool comes bundled with IntelliJ IDEA, so the user doesn't need to install it.

## To create a virtual environment

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Click **+**, and then choose Virtual environment from the Add New SDK popup menu.
4. In the Create Virtual Environment dialog box, do the following:
  - In the Name field, type the name of the new virtual environment, or accept the suggested default name.
  - In the Location field, specify the target directory, where the new virtual environment will be created, or accept the suggested default location.
  - From Base interpreter drop-down list, select one of the configured Python interpreters, which will be used as the base for the new virtual environment.  
If the desired base interpreter is missing in the drop-down list, you can locate it manually by clicking `...`.
  - If you want the `site-packages` of the base interpreter to be visible from the virtual environment, select the checkbox `Inherit global site-packages`. If you leave this checkbox cleared, the new virtual environment will be completely isolated.

Click OK to apply changes and close the dialog box.

**Tip** You can create as many virtual environments as required. To easily tell them from each other, use different names.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Prerequisite

Make sure that [Anaconda](#) or [Miniconda](#) is downloaded and installed on your computer.

Whether you install Anaconda or Miniconda, [depends](#) on you needs.

## Creating Conda environment

### To create a Conda environment

1. On the main toolbar, click .
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Click , and then choose Conda environment from the Add New SDK popup menu.
4. In the Create Conda Environment dialog box, do the following:
  - In the Name field, type the name of the new Conda environment, or accept the suggested default name.
  - In the Location field, specify the target directory, where the new Conda environment will be created, or accept the suggested default location.
  - From Python version drop-down list, select one of the configured Python interpreters, which will be used as the base for the new Conda environment.

Click OK to apply changes and close the dialog box.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

Once a virtual environment is created, it can be added to the list of available interpreters, as a local interpreter.

### To add an existing virtual environment to the list of available interpreters

1. On the main toolbar, click .
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Click , and then choose Add Local from the Add New SDK popup menu, and add this virtual environment as the local one.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

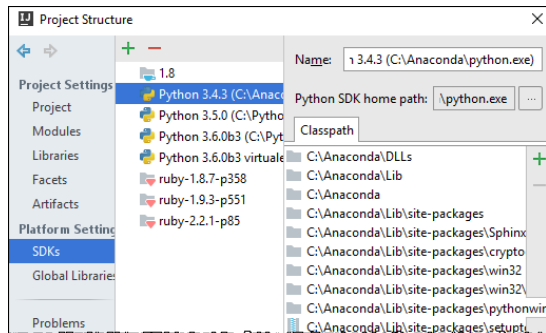

## Introduction

IntelliJ IDEA makes it possible to add paths to the selected interpreter. In doing so, these paths will be added to the environment variable `PYTHONPATH`. Also, IntelliJ IDEA will index these paths and (potentially) resolve the objects of the code (for example, imports of packages)

## Viewing interpreter paths

### To view the interpreter paths

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Select the desired interpreter.
4. View the interpreter paths in the Classpath tab:

## Adding interpreter paths

### To add an interpreter path

1. In the toolbar of the [SDKs page of the Project Structure](#) dialog box, click `+`.
2. Choose the desired path in the [Select Path dialog](#).

## Removing interpreter paths

### To delete interpreter paths

1. Select the paths to be deleted.
2. In the toolbar of the [SDKs page of the Project Structure](#) dialog box, click `-`.

## Reloading interpreter paths

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Introduction](#)
- [Configuring Python interpreter on the project level](#)
- [Configuring Python interpreter on a module level](#)

## Introduction

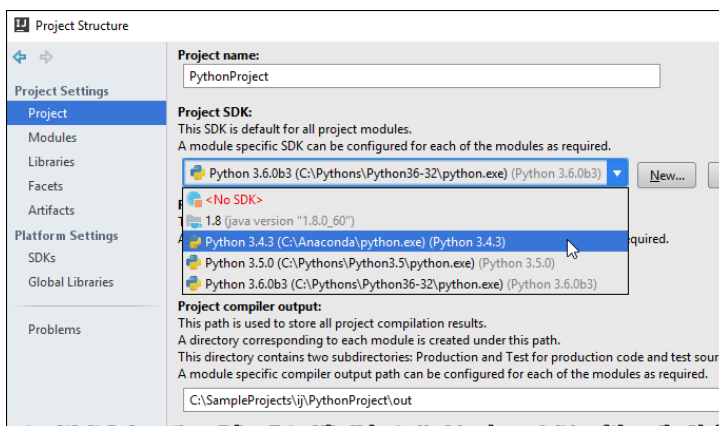

Python interpreter can be assigned on the project level, and on the level of a Python module.

Note that IntelliJ IDEA stores only the interpreter name in the project settings.

## Configuring Python interpreter on the project level

### To configure Python SDK as the project-level SDK, follow these steps

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the Project Structure dialog box, click Project node under the Project Settings.
3. On the General Settings for Project <project name> , click the Project SDK drop-down list, and select the project level SDK from the list of available SDKs.

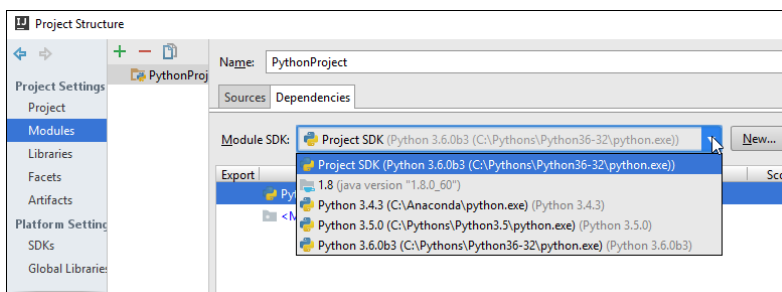

4. Apply changes.

## Configuring Python interpreter on a module level

### To configure Python interpreter for a Python module, follow these steps

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the Project Structure dialog box, click Modules node under the Project Settings.
3. In the Module <module name> pane of the selected Python module, click the Dependencies tab.
4. Click Module SDK drop-down list, and select the desired Python interpreter from the list of the previously configured available Python interpreters.

If the interpreter you need is missing in the list of available interpreters, click New next to the Module SDK field, choose Python SDK from the pop-up menu, choose interpreter type (local, remote, etc.) and then select the desired executable.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

Empty projects are intended for pure Python programming.

## To create an empty project

1. Do one of the following:

- On the main menu, choose File | New | Project
- On the [Welcome screen](#), click New Project

New Project dialog box opens.

2. In the New Project dialog box, do the following:

- In the Project type section, click the desired project type, in this case, Python.
- Specify the project SDK. If the desired SDK is missing in the list, click New .
- Click Next .
- Specify the project name and location.

3. Click Finish .

**Warning!** The following is only valid when Python Plugin is installed and enabled!

With IntelliJ IDEA, one can easily discern numerous Python interpreters and virtual environments by their names, rather than by the long paths to the executables.

## To change visible name of a Python interpreter

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the **Project Structure** dialog, click the node SDKs under the Platform Settings.
3. In the Name field, change the name the interpreter as required:

4. Apply changes.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Basics](#)
- [Invoking 'Manage Python Packages' dialog box](#)
- [Installing packaging tools](#)
- [Installing packages](#)
- [Uninstalling packages](#)
- [Upgrading packages](#)

## Basics

IntelliJ IDEA provides a dedicated tool for installing, uninstalling, and upgrading Python packages. So doing, if a packaging tool is missing, IntelliJ IDEA suggests to install it.

IntelliJ IDEA smartly tracks the status of packages and recognizes outdated versions by showing the number of the currently installed package version (column Version ), and the latest available version (column Latest ). When a newer version of a package is detected, IntelliJ IDEA marks it with the arrow sign ➡ .

## Invoking 'Manage Python Packages' dialog box

### To invoke the 'Manage Python Packages' dialog box

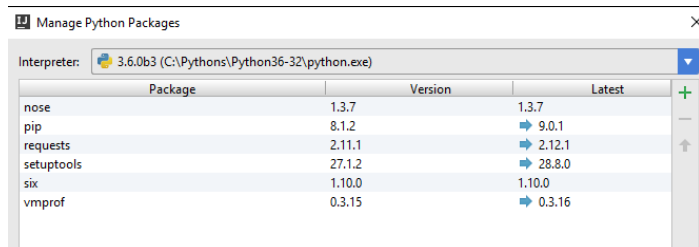

- On the main menu, choose `Tools | Manage Python Packages` . The Manage Python Packages dialog box opens.

## Installing packaging tools

### To install packaging tools

1. In the Manage Python Packages dialog box, choose the desired Python interpreter from the drop-down list of available Python interpreters.
2. If no distribute package management tool has been detected for the selected interpreter, click the Install 'distribute' link that appears in the lower part of the dialog box.
3. If no pip packaging tool has been detected for the selected interpreter, click the Install 'pip' link that appears in the lower part of the dialog box.

With the packaging tools installed, the existing packages are detected and shown in the dialog box.

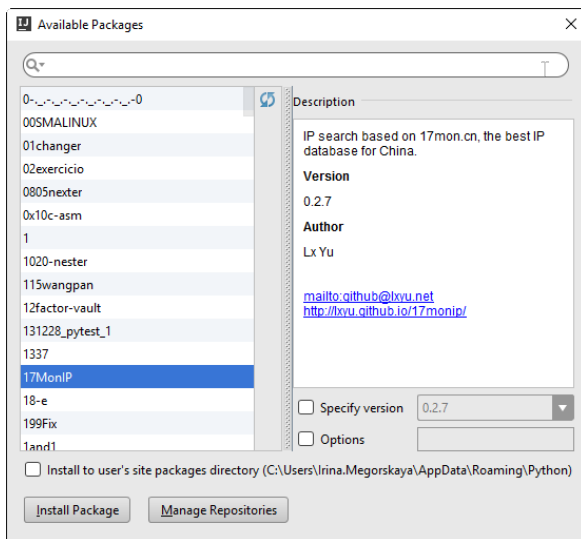

Note that outdated packages are marked with the blue arrows ➡ .

## Installing packages

### To install a package

1. In the Manage Python Packages dialog box, click `Install`
2. In the dialog box that opens, select the desired package from the list.  
If necessary, use the Search field, where you can enter any string. So doing, the list of packages shrinks to show the matching packages only.

3. If required, select the following checkboxes:
  - Specify version : if this checkbox is selected, you can select the desired version from the drop-down list of available versions. By default, the latest version is taken.
  - Options : if this checkbox is selected, you can type the options in the text field.
4. Click Install Package .

You can use the various packaging tools, including [devpi](#) or [PyPi](#) .

### To specify a custom repository, follow these steps

1. In the Project Interpreter page of the project settings, click **+** , and then, in the dialog box that opens, click Manage Repositories .
2. In the Manage Repositories dialog box that opens, click **+** to add a URL of a local repository, for example, something like `http://somehost/alice/dev` .
3. In the Manage Repositories dialog box, click OK .
4. In the Available Packages dialog, click  to reload the list of packages. As a result, the packages that exist on the local server appear.

**Tip** IntelliJ IDEA provides a quick fix that automatically installs the package you're trying to import: if, after the keyword `import` , you type a name of a package that is not currently available on your machine, a quick fix suggests to either ignore the unresolved reference, or download and install the missing package:

## Uninstalling packages

### To uninstall a package

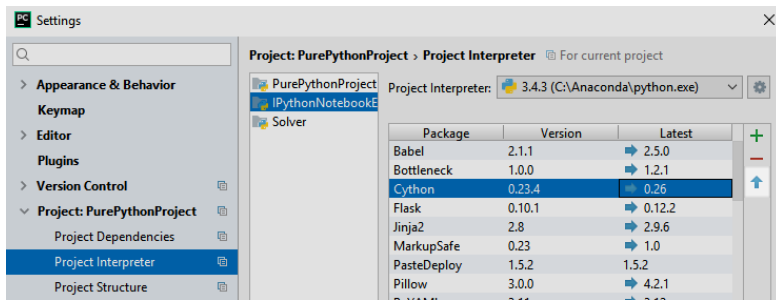

1. In the Packages column of the Manage Python Packages dialog box, select the packages to be uninstalled.
2. Click **-** . The selected packages are removed from disk.

## Upgrading packages

### To upgrade a package

1. In the Packages column of the Manage Python Packages dialog box, select the package to be upgraded.
2. Click **↑** .

The selected package is upgraded to the latest available version.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA makes it possible to track the unsatisfied dependencies in your projects, and provides integration with the major means of dependencies management.

In this section:

- [Creating and Running setup.py](#)
- [Creating Requirement Files](#)
- [Populating Dependencies Management Files](#)
- [Resolving Unsatisfied Dependencies](#)

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Introduction

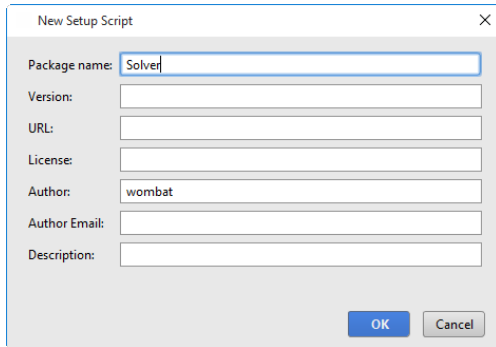

IntelliJ IDEA provides an action that helps create `setup.py` script, intended for building, distributing, and installing modules.

Once `setup.py` is created, the corresponding action becomes disabled, but instead appears the action that allows running tasks of this utility.

## Creating setup.py

### To create setup.py for a project

1. In the Project tool window, choose the project you want to package.
2. On the main menu, choose Tools | Create setup.py .
3. In the New Setup Script dialog box, specify package name, version and the other required information:

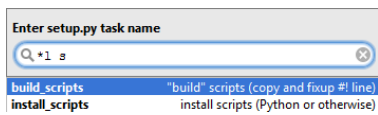

4. Click OK when ready. IntelliJ IDEA creates `setup.py` and opens it in the editor.

## Running setup.py

### To run a task of the setup.py utility

1. On the main menu, choose Tools | Run setup.py .
2. In the Enter setup.py task name dialog box, type the letters of the task names. Note that asterisk wildcard and initial letters of the snake\_case names are honored. As you type, the suggestion list shrinks to show the matching names only. Choose the desired task, and press `Enter` .

**Warning!** The following is only valid when Python Plugin is installed and enabled!

On this page:

- [Creating requirements](#)
- [Configuring the default requirements file](#)

## Creating requirements

### To define requirements, follow these general steps

1. [Create new file](#) in the root directory of your project.
2. In the New File dialog box, specify the file name.
3. Type the names of the required packages as plain text. Note that recursive requirements syntax is supported: you can use the main requirements file, and include the other requirements with `-r` syntax.

## Configuring the default requirements file

### To configure the default requirements file

1. [Open the Settings/Preferences dialog box](#) , and then click the page [Python Integrated Tools](#) .
2. In the Package requirements file field, type the name of the requirements file. By default, `requirements.txt` is suggested. You can either accept default, or click the browse button and locate the desired file.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

Though you can edit the dependencies management files according to their syntax, IntelliJ IDEA provides quick fixes that enable populating these files.

## To populate dependency management files

1. Create `setup.py` or `requirements.txt`, as described in the sections [Creating and Running setup.py](#) and [Creating Requirement Files](#).
2. In an `import` statement of a Python file, click a package which is not yet imported. IntelliJ IDEA suggests a quick fix:

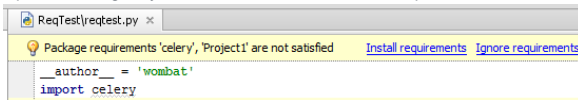

3. Select and apply the suggested quick fix. The package in question is added to the dependency management file.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA provides quick fixes and notification related to the unsatisfied dependencies.

## To resolve unsatisfied dependencies, do one of the following

- Open for editing a Python file that contains unsatisfied dependencies. A notification bar is displayed on top:

Click one of the provided links to satisfy or ignore requirements.

- If no dependencies management files are present, IntelliJ IDEA suggests a quick fix to just install a missing package:

**Warning!** The following is only valid when Python Plugin is installed and enabled!

In this section:

- [Basics](#)
- [Removing Python compiled files](#)

## Basics

Depending on the selected Python interpreter, the following Python compiled files are created:

- `.pyc` (for Python interpreter)
- `$py.class` (for Jython interpreter)

By default, the `.pyc` and `$py.class` files are ignored, and thus are not visible in the Project tool window. However, IntelliJ IDEA makes it possible to delete `.pyc` files from projects or directories.

Please note the following:

- If you [rename](#) or [delete](#) a Python file, the corresponding compiled file is also deleted.
- Python compiled files are deleted recursively.
- If you perform [update from VCS](#) and skip automatic cleanup, then removing Python compiled files is vital. The reason is that after update from version control, some of the Python files could have been deleted, and executing the Clean Python compiled files command will help you get rid of the unnecessary Python compiled files.

## Removing Python compiled files

### To remove Python compiled files

1. In the [Project Tool Window](#), right-click a project or directory, where Python compiled files should be deleted from.
2. On the context menu, choose Clean Python compiled files .  
The `.pyc` and `$py.class` files residing in the selected directory are silently deleted.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Prerequisite

[Django framework](#) and the corresponding [Python](#) interpreter are properly installed on your machine.

## Supported versions of Django and Python

IntelliJ IDEA supports the latest Django versions. The corresponding Python versions depend on Django. See [What Python version can I use with Django?](#)

## Django support

Django support in IntelliJ IDEA includes:

- Dedicated [project and module type](#) .
- Ability to [run the tasks](#) of the `manage.py` utility.
- Django templates support (syntax and error highlighting, code completion, navigation, completion for block names, resolve and completion for custom tags and filters, and quick documentation for tags and filters).
- Ability to [create templates from usage](#) .
- Ability to debug Django templates .
- Live templates (snippets) for the quick development of Django templates.
- Run/debug configuration for [Django server](#) .
- [Navigation between views and templates](#) .
- Code insight support for Django ORM.
- [Code completion](#) and resolve in

- `views.py` and `urls.py` files:

```
class AboutView(  
    template_  
    abs(number)   
    all(iterable)
```

- Models:

```
class Ox(models.M  
    Model   
    Manager   
    ManyToManyField
```

- Meta model options:

```
class Meta:  
    ordering = ["horn_length"]  
    verbose_name_plural
```

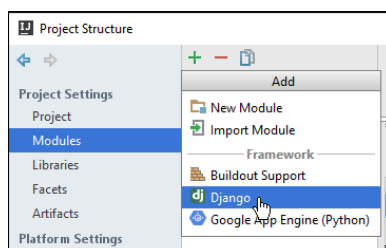

- Class-based views. IntelliJ IDEA provides [Intention action](#) to convert Django function-based generic views to class-based views.
- [Generating model dependency diagrams](#) for Django models.

## Enabling or disabling Django support

Django support can be turned on or off by attaching or detaching the Django facet .

### To enable Django support, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the Modules node, select the desired module to which Django support should be added, and click **+** .
3. Choose **Django** from the popup menu:

4. Select the Django node under the module node

and specify the required parameters in the right-hand pane.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Overview

With IntelliJ IDEA, you can run Django `manage.py` utility from within the IDE. Each task of this utility is executed in the `manage.py` console.

Note that Run `manage.py` task command is available for both local and remote interpreters.

## Configuring `manage.py` utility

It's important to note that configuration of the `manage.py` utility is done in the Django facet page of the [Project Structure dialog](#).

### To configure `manage.py` utility, follow these steps

1. In the [Project Structure dialog](#), click the module with Python support, and add Django facet.
2. Click the Django facet.
3. In the Manage.py tasks section, specify the following:
  - In the field Manage script, specify the desired `manage.py` script.

Note that by default IntelliJ IDEA shows the `manage.py` script that resides under the Django project root. If you are not happy with this suggestion, you can choose any other `manage.py` script by clicking the browse button .

- In the Environment variables field, specify the environment variables to be passed to the script. By default, this field is empty.  
Click the browse button  to open the Environment Variables dialog box. Use the toolbar buttons to make up the list of variables.

If you want to see the system environment variables, click Show link in this dialog box.

## Running `manage.py` utility

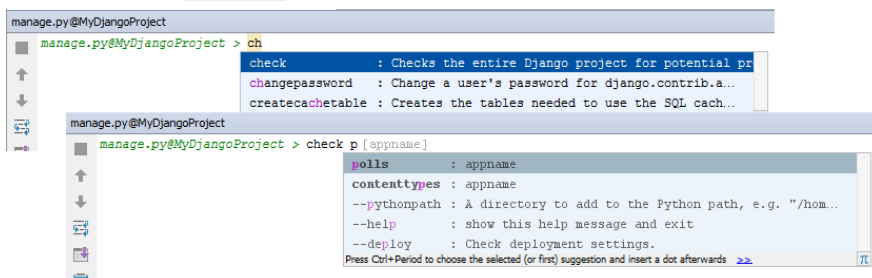

### To run a task of the `manage.py` utility

1. On the main menu, choose Tools | Run `manage.py` task.  
The `manage.py` utility starts in its own console.
2. Type the name of the desired task.

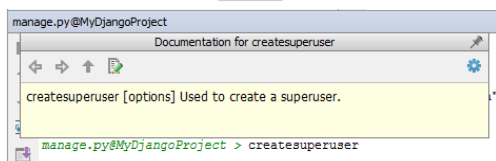

## Working in the `manage.py` utility console

In the `manage.py` console, one can:

- Scroll through the history of executed commands using the up and down arrow keys.
- Use [code completion](#) (`Ctrl+Space`):

- View [quick documentation](#) (`Ctrl+Q`):

## Handling error

IntelliJ IDEA smartly handles errors. When your Django project can't run due to an error, this error displays in the `manage.py` console instead of the command line:

```
Django errors
Failed to get real commands on module "py": python process died with code 1: Traceback (most recent call last):
File "C:\Program Files (x86)\JetBrains\PyCharm
4.5\helpers\pycharm\django_manage_commands_provider\provider.py", line 20, in <module>
django.setup()

File "C:\SampleProjects\py\MyDjangoApp\models.py", line 4, in <module>
raise Exception("Failed to load models")
Exception: Failed to load models
```

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

The storage for templates can be specified on creating a Django template to a Python module ; at a later time, one can configure the directories for templates, using the [Python Template Languages](#) page of the Settings/Preferences dialog.

## To create a template for a view

Suppose you reference a template file that doesn't yet exist. IntelliJ IDEA marks such a reference as unresolved, and provides an intention action to create a template file "from usage".

1. Place the caret at the unresolved reference to a template.
2. Press `Alt+Enter` , or click the yellow light bulb to show the list of available intention actions.
3. From the suggestion list, choose action Create template <name> :

Create Template dialog box appears, showing the read-only template name ( Template path field), and a drop-down list of possible template locations ( Templates root field).

Note that IntelliJ IDEA automatically discovers the directories specified in the `TEMPLATE_DIRS` or `TEMPLATE_LOADERS` fields of the `settings.py` file. You can specify the other directories in addition.

4. In the Create Template dialog box, select the template directory, where the new template will be created. The Template root field provides a list of possible locations for the new template. This list includes the template directories specified in the [Python Template Languages](#) page of the Settings dialog, plus the directories, which are automatically detected in the `TEMPLATE_DIRS` or `TEMPLATE_LOADERS` variables of the `settings.py` file.
5. Click OK . The empty `*.html` file with the name in question is created in the specified location.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA makes it possible to easily navigate between templates and views, using the gutter icons  and .

### To navigate from a view to a template

1. Open `views.py` file in the editor.
2. Click the gutter icon next to the desired function:

### To navigate from a template to the referencing view

1. Open the desired template file in the editor.
2. Click the gutter icon:

**Tip** If there are more related files (for example, a view and a style sheet), select the desired target from the pop-up that appears:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

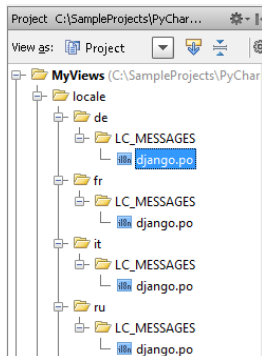

IntelliJ IDEA stores locales in the language-related subdirectories of the `locale` directory. For creating locales, run the `makemessages` task of the `manage.py` utility.

## To create a message file

1. On the main menu, choose Tools | Run manage.py task , or press `N/A` .
2. In the `manage.py task` window, enter `makemessages` , type `--locale <locale name >` and press `Enter` .

Repeat this step for each locale you want to create.

If there are strings marked for localization, IntelliJ IDEA will produce a directory and `django.po` file for each locale:

If there are no such strings, only an empty directory structure is created.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA provides a dedicated intention action to wrap strings in Django templates in `{% trans %}`, or `{% blocktrans %}` tags.

The lines with `i18n` tags are marked with  icon in the gutter.

## To wrap block of text in translation tags

1. Open the desired Django template for editing, and select strings to be marked for translation.
2. Press `Alt+Enter` , or click the light bulb to reveal the list of available intention actions:

3. Select intention action `Wrap with 'trans' tag` , and press `Enter` . IntelliJ IDEA wraps selected text in translation tags, and adds `{% load i18n %}` , if extracting text is performed for the first time.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

For compiling locales, run the `compilemessages` task of the `manage.py` utility.

## To compile a message file

1. On the main menu, choose Tools | Run manage.py task .
2. In the Enter manage.py task name dialog box, select `compilemessages` , and press `Enter` .  
`django.mo` files are produced for each locale.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

Use the  gutter icons to navigate from a template to a localization file. To jump from localization file to the corresponding template, use `Ctrl+Click`.

## Navigating from template to locale

### To navigate from a template to locale

1. Click  icon in the gutter next to the desired tag.
2. If a tag is referenced from several locales, select one from the pop-up window:

The selected `django.po` file opens in the editor, with the caret resting at the `msgid` that corresponds to the tag in question.

## Navigating from locale to template

**Note** According to the Django documentation, each `django.po` file contains comments with the path a template above each `msgid`.

### To navigate from a locale to template

1. In the desired `django.po` file, place the caret at the comment above the locale in question:

```
#: templates/my_view/detail.html:11
msgid "Author:"
msgstr ""
```

2. On the main menu, choose `Navigate | Declaration`, or use any other method, described in [Navigating to Declaration or Type Declaration of a Symbol](#). The corresponding template files opens in the editor.

## Viewing references

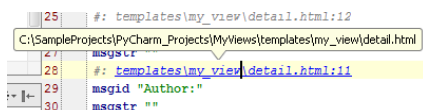

### To view references to a localization tag

- Hover your mouse pointer over the gutter icon next to the desired tag. A balloon that pops up, shows a list of locale files that reference the selected tag:

### To view which template a locale references

- Keeping `Ctrl` key pressed, hover your mouse pointer over the comment above the locale in question. The comment turns into a hyperlink, and the balloon shows reference:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

IntelliJ IDEA provides two ways to debug remotely:

- [Using a remote interpreter](#)
- [Using Python Debug Server](#)

## Remote debug with a remote interpreter

If remote debugging is performed with a remote Python interpreter, then everything is done within a single SSH connection, and port numbers are not required.

### To debug remotely using a remote interpreter, follow these general steps

1. Make sure that a remote interpreter is configured.
2. [Launch the debug process](#) with a regular run/debug configuration.

**Tip** The Python debugger is available in [PyPi](#) so that it can be installed for doing remote debugging with `pip`.

When debugging a process that runs in another machine, it's possible to `pip install pydev` instead of copying archives from `debug-eggs` directory under IntelliJ IDEA's installation.

## Remote debug with a Python Debug Server

For remote debugging, IntelliJ IDEA provides archives with `pydev` directory. Depending on the Python version, these archives are:

- `pycharm-debug.egg` for Python up to version 2
- `pycharm-debug-py3k.egg` for Python 3

This archive resides in the following location, depending on the platform:

- Windows: under the `.IntelliJIDEAXXXX.X\config\plugins\python` directory of the user home.
- \*nix: under the `.IntelliJIDEAXXXX.X/config/plugins/python` directory of the user home.
- macOS: under `/Users/jetbrains/Library/Application Support/IntelliJIDEAXXXX.X/python/` directory.

The process of remote debugging involves the following general steps:

- [Configuring a remote debug server](#).
- [Preparing for debugging](#).
- [Launching the debug server](#).
- [Launching the script externally](#).

### To configure a remote debug server

1. Open the Run/Debug Configuration dialog box, as described in the section [Creating and Editing Run/Debug Configurations](#), and select the [Python Remote Debug](#) configuration type.
2. Specify the local host name and the number of the port where the debug server will run. If you don't specify any value, IntelliJ IDEA will provide port number at random.
3. If you are going to debug a script that resides on a remote machine, specify the source root of the remote script, and the root of the local sources to keep mapping.

### To prepare for remote debugging

1. In IntelliJ IDEA, open the local script for editing, and add the following command (you can copy it from the remote debug configuration dialog):  
`pydevd.settrace(<host name>, port=<port number>)`

Also, add the corresponding import statement to your script:

```
import pydevd
```

2. Copy the local script to the remote location, where you want to debug it.
3. Include the `pycharm-debug.egg` archive. You can do it in a number of ways, for example:
  - Add the archive to `PYTHONPATH`.
  - Append the archive to `sys.path`.
  - Just copy the `pydev` from the archive to the directory where your remote script resides.

### To launch the debug server

1. Select the desired remote configuration:

2. Click , or press `Shift+F9`. IntelliJ IDEA launches debug server at the specified host and port, which is shown in the Console pane of the [Debug tool window](#).

If the process doesn't stop, but you still want to stop tracing and disconnect from Python Remote Debug Server, add the following function to the end of a remote script being debugged:

```
pydevd.stoptrace()
```

This function stops remote debug process that has been launched with `pydevd.settrace()`. Thus the Python Remote Debug Server will pass to the state of waiting for a new connection.

## To debug a remote script

1. Locate your remote script, and launch it as required by your specific operating system. For example, on Windows, use the command:

```
python <script name>
```

If the corresponding local script exists, IntelliJ IDEA opens it in the editor in the suspended mode; the first executable statement is marked with the blue stripe. Also, IntelliJ IDEA shows the frames and variables for its first executable statement in the [Debug tool window](#). If the corresponding local script cannot be found, IntelliJ IDEA opens a dedicated editor tab, and suggests to do one of the following:

- Edit the local and remote roots in the remote debug configuration dialog box.
- Detect the mapping files automatically, and then select the one to be used as the local version from the list of encountered files with the matching names.
- Download the remote file to the specified location.

2. [Step through the script](#), [set watches](#) and [evaluate expressions](#).

**Warning!** The following is only valid when Python Plugin is installed and enabled!

**Warning!** The following is only valid when Python Plugin is installed and enabled!

On this page:

- [Introduction](#)
- [Prerequisite](#)
- [Parameter type specification](#)

## Introduction

You debug your code permanently, and now in course of debugging you can also collect type information and specify these types in docstrings.

IntelliJ IDEA provides an intention action that makes it possible to collect type information at runtime, and define type specifications.

However, it is quite possible to specify the types of parameters manually, without the debugger.

Both cases are explored in the section [Examples](#) .

## Prerequisite

Make sure that the checkbox Insert type placeholders in the [Smart Keys](#) page of the editor settings is selected.

Note also, that reStructuredText is used for all the subsequent examples, but it is possible to use any of the supported formats of the documentation strings, whether it is plain text, Epytext, Google or NumPy. Refer to the description of the page [Python Integrated Tools](#) for details.

## Parameter type specification

### To specify the parameter types, follow these general steps

1. Place the caret at the function name, and press `Alt+Enter` .
2. In the list of intention actions that opens, choose Insert documentation string stub . IntelliJ IDEA creates a documentation stub, according to the selected docstring format, with the type specification, collected during the debugger session.

This feature is only supported in the Ultimate edition.

In this section:

- RESTful WebServices
  - [Introduction](#)
  - [Developing RESTful Web services](#)
- [Preparing for REST Development](#)
- [Coding Assistance for REST Development](#)
- [Testing RESTful Web Services](#)
- [Creating and Running Your First RESTful Web Service on GlassFish Application Server](#)

## Introduction

IntelliJ IDEA lets you develop, debug and test [RESTful Web Services](#) . The REpresentational State Transfer (REST) specification [JSR-339 specification](#) version 2.0 and [Jersey reference implementation](#) are supported.

Because **RESTful Web services** can be of various types, there is no definite workflow to develop them. In this section we will outline some specific tasks that can be performed when developing a REST application in IntelliJ IDEA.

## Developing RESTful Web services

### To develop a RESTful Web service, follow these general steps

1. Make sure that the RESTful Web Services plugin is enabled. Create a new project or module for the service development, or enable the RESTful Web Services development support for an existing module. For more information, see [Preparing for REST Development](#) .
2. Populate the RESTful Web service module with the necessary classes and methods.
3. Configure the [artifacts](#) to deploy.
4. [Create a run configuration](#) . On the Deployment tab, specify the artifacts to deploy.
5. Deploy the Web service on an HTTP server and start the server.
6. [Run](#) the application locally or on a remote host.
7. [Test the RESTful Web service](#) .

This feature is only supported in the Ultimate edition.

At the IntelliJ IDEA level, the RESTful Web Services development support is based on the Java EE: RESTful Web Services (JAX-RS) [plugin](#) . This plugin is bundled with IntelliJ IDEA and enabled by default.

At a [module](#) level, the service development support can be enabled when creating a project, adding a new module to an existing project, and also for an existing module.

- [Making sure that the RESTful Web Services plugin is enabled](#)
- [Enabling REST support when creating a project](#)
- [Enabling REST support when adding a module to a project](#)
- [Enabling REST support for an existing module](#)

## Making sure that the RESTful Web Services plugin is enabled

1. Open the Settings dialog (e.g. `Ctrl+Alt+S` ).
2. In the left-hand part of the dialog, select Plugins .
3. In the right-hand part of the dialog, on the [Plugins page](#) , type `restful` in the search box. As a result, only the plugins whose names and descriptions contain `restful` are shown in the list of plugins.
4. If the checkbox to the right of Java EE: RESTful Web Services (JAX-RS) is not selected, select it.
5. Click OK in the Settings dialog.
6. If suggested, restart IntelliJ IDEA.

## Enabling REST support when creating a project

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the [Welcome screen](#) . Otherwise, select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  2. On the [first page of the wizard](#) , in the left-hand pane, select Java Enterprise . In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.
  3. Under Additional Libraries and Frameworks , select the Restful Web Service checkbox.
  4. You'll need a [library](#) that implements the JAX-RS API. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
    - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files (`.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
    - Download. Select this option to download the files that implement the JAX-RS API. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
    - Set up library later. Select this option to postpone setting up the library until a later time.
- Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.
- Click Next .
5. Specify the name and location settings for your project and module. For more information, see [Project Name and Location](#) .  
Click Finish .

## Enabling REST support when adding a module to a project

1. Open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.
2. On the [first page of the wizard](#) , in the left-hand pane, select Java Enterprise . In the right-hand part of the page, select the Java EE version to be supported.
3. Under Additional Libraries and Frameworks , select the Restful Web Service checkbox.
4. You'll need a [library](#) that implements the JAX-RS API. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
- Download. Select this option to download the files that implement the JAX-RS API. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .

5. Specify the name and location settings for your module. For more information, see [Module Name and Location](#) .

Click Finish .

## Enabling REST support for an existing module

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the module of interest and select Add Framework Support .
3. In the left-hand pane of the [Add Frameworks Support dialog](#) that opens, select the RESTful Web Service checkbox.
4. You'll need a [library](#) that implements the JAX-RS API. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the files that implement the JAX-RS API. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

5. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

Besides the common [Web services support](#), IntelliJ IDEA provides the following facilities for developing RESTful Web services:

- Code completion for MIME type.
- [Code inspections and quick fixes](#).
- [REST Client tool window](#) for testing RESTful Web services.

## Code Inspection and Quick Fixes

IntelliJ IDEA supports [code inspections](#) and suggests [quick fixes](#) in the following cases:

Issue	Default Quick Fix
Inconsistency between a method annotation and the method return type: a <code>@GET</code> annotated method returns void value.	Change to String.
Resource methods errors.	Remove <code>@Path</code> annotation.
Incorrect parameter type.	Validation for parameters annotated with <code>@QueryParam</code> or <code>@PathParam</code> annotations.
<code>@DefaultValue</code> issues.	<pre>@GET public String get(@DefaultValue("33.5") @QueryParam("str") int str){     return "Hello"; }</pre> <p><code>DefaultValue</code> is marked red with the description "Can't convert to int".</p>
Rest <code>@Path</code> and <code>@PathParam</code> annotations inspections.	
Rest References resolve problems.	References in <code>@PathParam</code> annotations are resolved to templates in <code>@Path</code> annotations
This method should have only one HTTP method designator.	Example: <pre>@GET @POST public String get(){     return "Hello"; }</pre> <p><code>@POST</code> is marked red.</p>
WADL configuration errors.	
<h2>REST Client Tool Window</h2>	
Dedicated <a href="#">REST Client tool window</a> supports:	
<ul style="list-style-type: none"><li>- Constituting URL addresses semiautomatically from the specified Deployment point and the <code>@Path</code> annotation.</li><li>- Submitting requests to the server.</li><li>- Displaying server responses in the Response tab.</li><li>- Code integration between the Java code and the contents of the REST Client window controls.</li></ul>	
<b>Change in the Java code</b> <b>Change in the REST Client tool window</b>	
<code>@Path</code> annotation is updated.	The contents of the Path to resource drop-down list change.
<code>@Produces</code> annotation is updated.	The contents of the Accept drop-down list change.

This feature is only supported in the Ultimate edition.

## Introduction

Testing RESTful Web Services is supported via the REST Client bundled plugin, which is by default enabled. If not, activate it in the [Plugins settings](#) page of the [Settings](#) dialog box.

There are two main use cases when you need to compose and run requests to a RESTful Web service:

- When you have developed and deployed a RESTful Web service and want to make sure it works as expected: that it is accessible in compliance with the specification and that it responds correctly.
- When you are developing an application that addresses a RESTful Web service. In this case it is helpful to investigate the access to the service and the required input data before you start the development. During the development, you may also call the Web service from outside your application. This may help locate errors when your application results in unexpected output while no logical errors are detected in your code and you suspect that the bottleneck is the interaction with the Web service.

Testing a RESTful Web service includes the following checks:

- That URL addresses are constituted correctly based on the service deployment end-point and the method annotations.
- That the generated server requests call the corresponding methods.
- That the methods return acceptable data.

IntelliJ IDEA enables you to run these checks from the REST Client tool window by [composing and submitting requests](#) to a server, viewing and analyzing [server responses](#).

If necessary, configure the Proxy settings on the [HTTP Proxy](#) page of the [Settings](#) dialog box.

## Composing and submitting a test request to a Web service method

1. If you are going to test your own Web service, make sure it is deployed and running.
2. Choose [Tools | Test RESTful Web Service](#). The [REST Client dedicated tool window](#) opens.
3. To have IntelliJ IDEA generate an [authentication header](#) which will be used in [basic authentication](#), click the [Generate Authorization Header](#) button and in the dialog box that opens, specify your user name and password for accessing the target RESTful Web service through. Based on these credentials IntelliJ IDEA will generate an [authentication header](#) which will be used in [basic authentication](#). Learn more at [http://www.ics.uci.edu/~fielding/pubs/dissertation/rest\\_arch\\_style.htm](http://www.ics.uci.edu/~fielding/pubs/dissertation/rest_arch_style.htm).
4. Select the test [request method](#) from the HTTP method drop-down list. The available options are:
  - [GET](#)
  - [POST](#)
  - [PUT](#)
  - [PATCH](#)
  - [DELETE](#)
  - [HEAD](#)
  - [OPTIONS](#)
5. Provide the data to calculate the URL address of the target method:
  1. In the [Host/port](#) text box, type the URL address of the host where the Web service is deployed.
  2. From the [Path](#) drop-down list, choose the [@path](#) annotation that corresponds to the method the call to which you need to test.

**Tip** IntelliJ IDEA supports integration between the contents of this list and Web service Java source code. Any changes to the [@Path](#) annotations are reflected in the contents of the [Path](#) to Resource list.

To synchronize the contents of the [Path](#) drop-down list with the [@Path](#) annotations, click the [Update resource paths from code](#) button .

You can enter the entire URL address of a method to test in the [Host/port](#) text box. Regardless of the chosen [HTTP method](#), upon pressing  IntelliJ IDEA will split the URL address into the [host/port](#) and the path to the method. The extracted relative path will be shown in the [Path](#) text box and the extracted parameters will be added to the list in the [Request Parameters](#) pane of the [Request](#) tab.

6. In the [Header data](#) pane, specify the technical data included in the [request header](#). These data are passed through header fields and define the format of the input parameters ([accept](#) field), the response format ([content-type](#) field), the caching mechanism ([cache-control](#) field), etc.  
To add a field to the list, click [Add](#) , then specify the field name in the [Name](#) text box and the field value in the [Value](#) drop-down list.

The set of fields and their values should comply with the Web service API. In other words, the specified input format should be exactly the one expected by the Web service as well as the expected response format should be exactly the one that the service returns.

For [accept](#), [content-type](#), and some other fields IntelliJ IDEA provides a list of suggested values. Choose the relevant format type from the [Value](#) drop-down list.

7. Create a set of parameters to be passed to the target method and specify their values. Depending on the chosen request method, you can create a list of parameters in two ways:
  - For [GET](#) requests, specify the parameters to be passed as a query string inside the URL. Use the [Request Parameters](#) pane. By default, the pane shows an empty list with one line.

- To add a parameter, click Add , then specify the name of the parameter in the Name text box and the value of the parameter in the Value drop-down list.
- To delete a parameter from the list, select it and click Remove .
- To suppress sending the specified query string parameters and disable the controls in the Request Parameters pane, press the Don't send anything toggle button .
- To have the parameters passed to the target method inside a [request message body](#), use the Request Body pane or have them inserted in the request from a local file. The Request Body pane is disabled when the `GET`, `DELETE`, `HEAD`, or `OPTIONS` request method is selected.
- To specify the parameters explicitly, choose the Text option and type the parameters and values in the text box.
- To have the parameters inserted from a text file, choose the File contents option and specify the file location in the File to send field.
- To have a binary file converted and sent in the request, choose the File upload(multipart/form-data) option and specify the file location in the File to send field.

In either case, the set of parameters and their types should comply with the Web service API, in particular, they should be exactly the same as the input parameters of the target method.

8. To submit a request to the server, click the Submit request button .

Note that the server may lack certificate, or be untrusted.

**Note** If a server is not trusted, IntelliJ IDEA shows a dialog box suggesting to accept the server, or reject it. If you accept the server as trusted, IntelliJ IDEA writes its certificate to the trust store. On the next connect to the server, this dialog box will not be shown.

## Viewing and analyzing responses from Web services

1. To view the response to the server request, switch to the Response tab. The tab is opened automatically when a response is received. By default, the server response is shown in the format, specified in the request header through the [content-type](#) field.
2. To have the response converted into another format and opened in a separate tab in the editor, use the View as HTML , View as XHTML , or View as JSON  buttons.
3. To view the technical data provided in the [header of a Web service response](#), switch to the Response Headers tab.

## Working with cookies

Using the dedicated Cookies tab, you can create, save, edit, and remove cookies, both received through responses and created manually. The **name** and **value** of a cookie is automatically included in each request to the URL address that matches the **domain** and **path** specified for the cookie, provided that the **expiry date** has not been reached.

The tab shows a list of all currently available cookies that you received through responses or created manually. The cookies are shown in the order they were added to the list. When you click a cookie, its details become editable and are displayed in text boxes. See [REST Client Tool Window](#) for details.

- No specific steps are required to save a cookie received through a response, all the cookies received from servers are saved automatically. To edit a received cookie, click the row with the cookie in the list and update the details that are now shown in editable text boxes.
- To create a cookie manually, click  and specify the following:
  - The **name** and **value** of the cookie to be included in requests.
  - The **domain** and **path** the requests to which must be supplied with the **name**, **value**, and **expiry date** of the cookie.
- To remove a cookie from the list, select the row with the cookie and click .

## Configuring Proxy settings

1. Click the Configure HTTP Proxy icon .
2. In the [Proxy dialog](#) that opens, specify the following:
  - Enter the Proxy host name and Proxy port number in the Proxy host and Proxy port text boxes respectively.
  - To enable authorization, check the Use authorization checkbox and type the User name and password in the relevant fields.

## Reusing requests

During an IntelliJ IDEA session, IntelliJ IDEA keeps track of requests and you can run any previously executed request. You can also save the settings of a request in an XML file so they are available in another IntelliJ IDEA session. When necessary, you can retrieve the saved settings and run the request again.

## Rerunning a request within an IntelliJ IDEA session

1. Click the Replay Recent Requests button .
2. From the Recent Requests pop-up list, select the relevant request. The fields are filled in with the settings of the selected request.
3. Click the Submit Request button .

## Saving the settings of a request so they can be retrieved in another IntelliJ IDEA session

- Click the Export Request button . In the dialog box that opens, specify the name of the file to save the settings in and its parent folder.

## Running a request saved during a previous IntelliJ IDEA session

1. Click the Import Request button .
2. In the dialog box that opens, select the relevant XML file. The fields are filled in with the settings of the selected request.
3. Click the Submit Request button .

This feature is only supported in the Ultimate edition.

This tutorial illustrates developing a simple **RESTful** web service and deploying it to the **GlassFish** application server.

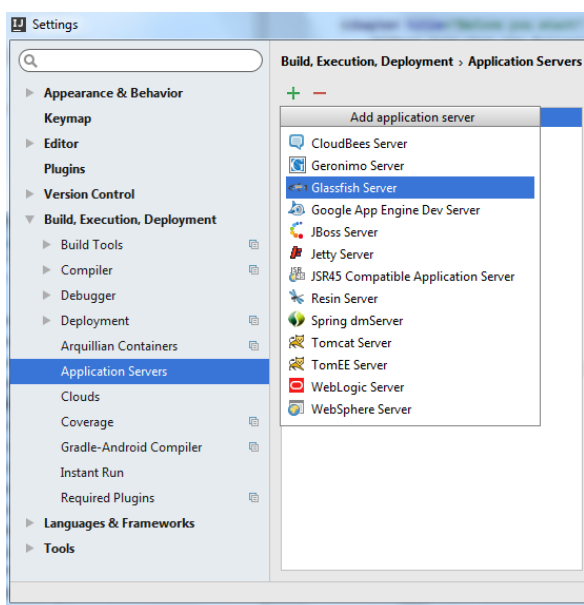

- [Before you start](#)
- [Configuring the GlassFish server in IntelliJ IDEA](#)
- [Configuring the JDK](#)
- [Creating a project](#)
- [Exploring the project structure](#)
- [Developing source code](#)
- [Examining the generated artifact configuration](#)
- [Exploring and completing the run configuration](#)
- [Running the application](#)

## Before you start

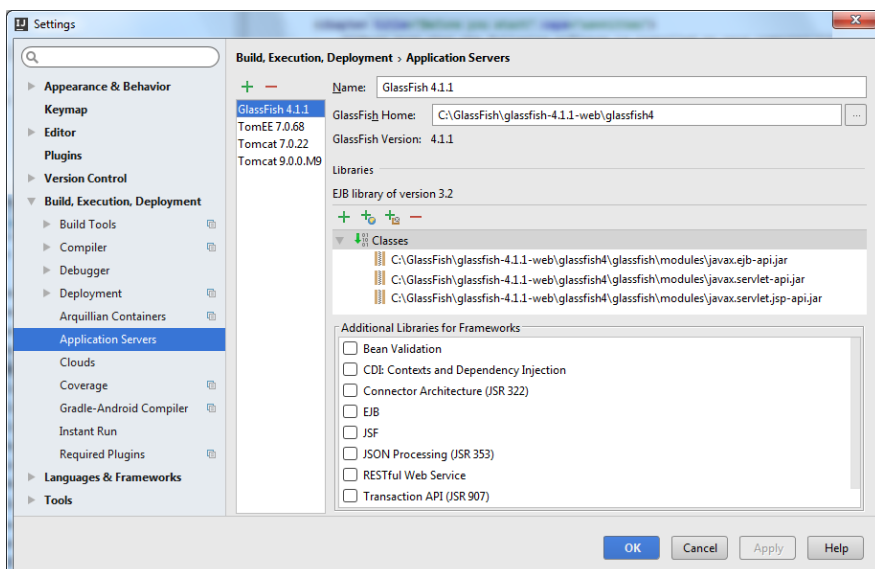

1. Make sure you are using IntelliJ IDEA ULTIMATE Edition.
2. Install the Java SE Development Kit (JDK), version 1.8 or later, see [Download Oracle JDK](#) .
3. Download the **GlassFish** application server, version 3.0.1 or later, see [Download GlassFish](#) .
4. Make sure a web browser is available on your computer.

## Configuring the GlassFish server in IntelliJ IDEA

1. Open the [Settings / Preferences Dialog](#) by pressing `Ctrl+Alt+S` or by choosing File | Settings for Windows and Linux or IntelliJ IDEA | Preferences for macOS, and click Application Servers under Build, Execution, Deployment .
2. On the [Application Servers](#) page that opens, click **+** above the central pane and choose GlassFish Server from the list.

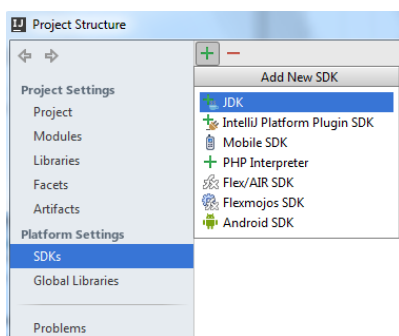

3. In the right-hand pane, specify the GlassFish Server installation folder in the GlassFish Home field. Type the path to it manually or click `...` and choose the installation folder in the dialog box that opens. IntelliJ IDEA detects the version of the application server and automatically fills in the Name field as follows: **GlassFish <version>** . In our example it is **GlassFish 4.1.1** .

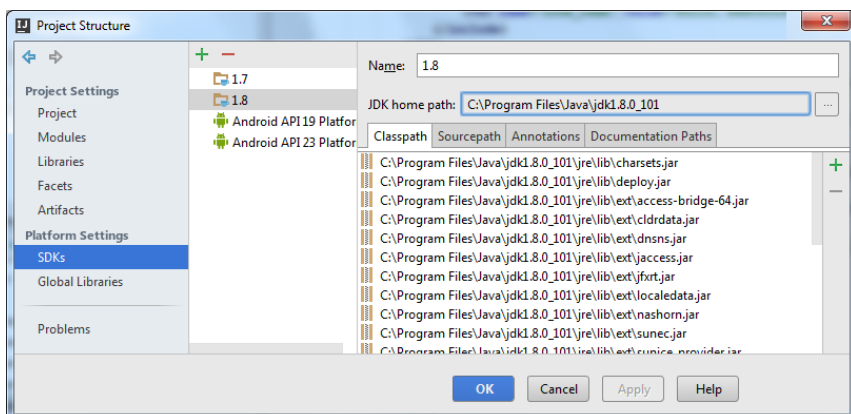

The other fields are filled automatically or are optional, so just click **OK** .

## Configuring the JDK

1. Press `Ctrl+Shift+Alt+S` or choose `File | Project Structure` on the main menu.
2. In the [Project Structure Dialog](#) that opens, choose SDK's under the Platform Settings .
3. On the [SDKs](#) page that opens, click `+` above the central pane and choose `JDK` .

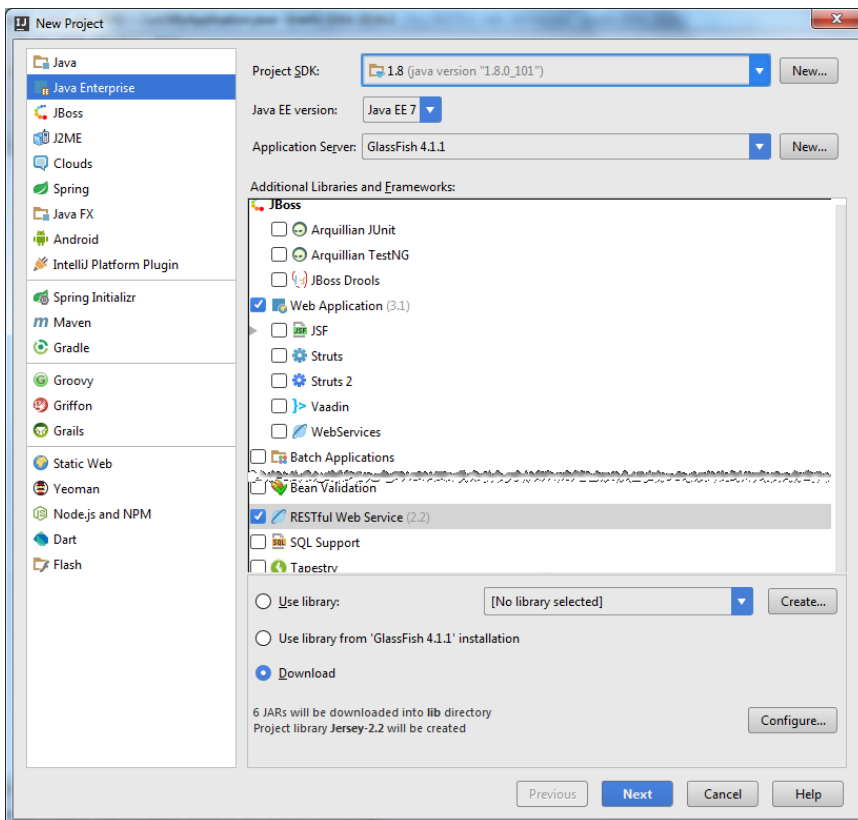

4. In the right-hand pane, specify the installation folder of the Java SE Development Kit (JDK) to use. Type the path manually or click `...` and choose the installation folder in the dialog box that opens. IntelliJ IDEA detects the version of the JDK and automatically enters it in the Name field. In our example it is `1.8` .

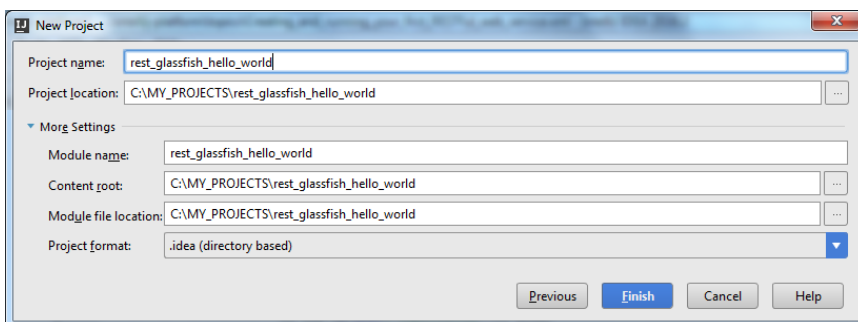

All the mandatory fields in the other tabs are filled in automatically, so just click `OK` .

## Creating a project

1. Click `Create New Project` on the Welcome screen, or choose `File | New | Project` on the main menu. The New Project wizard opens.
2. On the first, [Project Category and Options](#) page of the Wizard:
  1. In the left-hand pane, select `Java Enterprise` .
  2. From the Project SDK list, select the JDK to use. In our example, it is `1.8` .
  3. From the Application Server drop-down list, choose `GlassFish 4.1.1` .
  4. From the JavaEE Version drop down list, choose `JavaEE 7` .
  5. In the [Additional Libraries and Frameworks](#) area, select the `Web Application` and `RESTful Web Service` checkboxes.
  6. Choose the `Download` option in the area below the Additional Libraries and Frameworks list. The area is displayed only after you have selected the `Web Application` and `RESTful Web Service` checkboxes.
  7. Click `Next` .

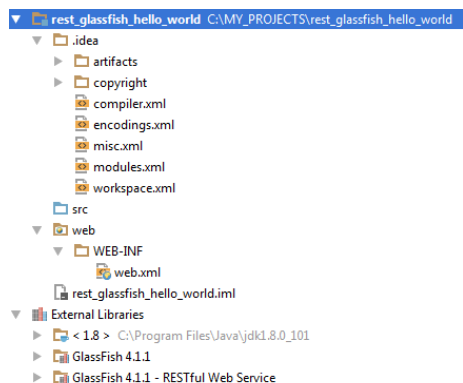

- On the second, **Project Name and Location** page of the Wizard, specify the name for your new project, in our example it is `Rest_glassfish_hello_world` .  
Click **Finish** and wait while IntelliJ IDEA is creating the project.

## Exploring the project structure

When the project is created, you will see something similar to this in the Project tool window:

- `rest_glassfish_hello_world` is a module folder (which in this case coincides with the project folder).
- The `.idea` folder and the file `Rest_glassfish_hello_world.iml` contain configuration data for your project and module respectively.
- The folder `src` is for your Java source code.
- The folder `web` is for the web part of your application. At the moment this folder contains the deployment descriptor `WEB-INF/web.xml` .
- External Libraries include your JDK and the JAR files for working with the **GlassFish Server** .

## Developing source code

Our **Hello World** application will contain a resource class `HelloWorld.java` and a configuration class `MyApplication` . Its

only function will be to output the text **Hello World** .

1. In the `src` folder, create the `HelloWorld.java` class with the following code:

```
import javax.ws.rs.GET;
import javax.ws.rs.Path;
import javax.ws.rs.Produces;

// The Java class will be hosted at the URI path "/helloworld"
@Path("/helloworld")
public class HelloWorld {
    // The Java method will process HTTP GET requests
    @GET
    // The Java method will produce content identified by the MIME Media type "text/plain"
    @Produces("text/plain")
    public String getClichedMessage() {
        // Return some cliched textual content
        return "Hello World";
    }
}
```

2. In the `src` folder, create the `MyApplication.java` class with the following code:

```
import javax.ws.rs.ApplicationPath;
import javax.ws.rs.core.Application;
import java.util.HashSet;
import java.util.Set;

//Defines the base URI for all resource URIs.
@ApplicationPath("/")
//The java class declares root resource and provider classes
public class MyApplication extends Application{
    //The method returns a non-empty collection with classes, that must be included in the published
    @Override
    public Set<Class<?>> getClasses() {
        HashSet h = new HashSet<Class<?>>();
        h.add( HelloWorld.class );
        return h;
    }
}
```

## Examining the generated artifact configuration

Besides building a RESTful-specific project structure, IntelliJ IDEA has also configured an **artifact** for us.

The word artifact in IntelliJ IDEA may mean one of the following:

- An artifact configuration, i.e. a specification of the output to be generated for a project;
- An actual output generated according to such a specification (configuration).

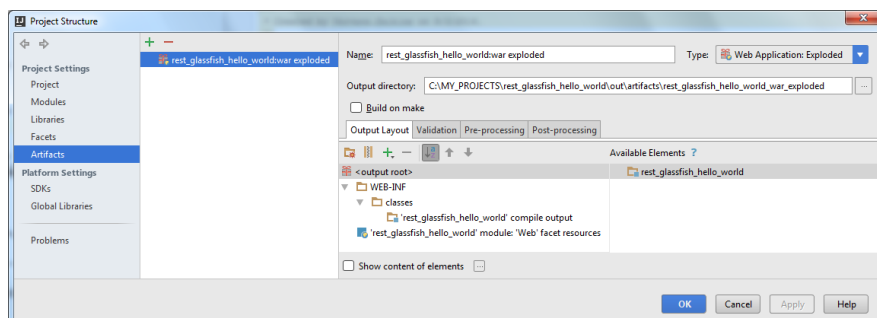

Let's have a look at this configuration.

1. Open the Project Structure dialog by pressing `Ctrl+Shift+Alt+S` or choosing `File | Project Structure` on the main menu.

2. Under Project Settings , select Artifacts .

The available artifact configurations are shown in the central pane under `+` and `-` . Currently there is only one configuration `rest_glassfish_hello_world:war exploded` , it is a decompressed web application archive (WAR), a directory structure that is ready for deployment onto a web server.

3. The artifact settings are shown in the right-hand pane of the dialog:

Learn more about artifacts at [Working with Artifacts](#) and [Artifacts](#) .

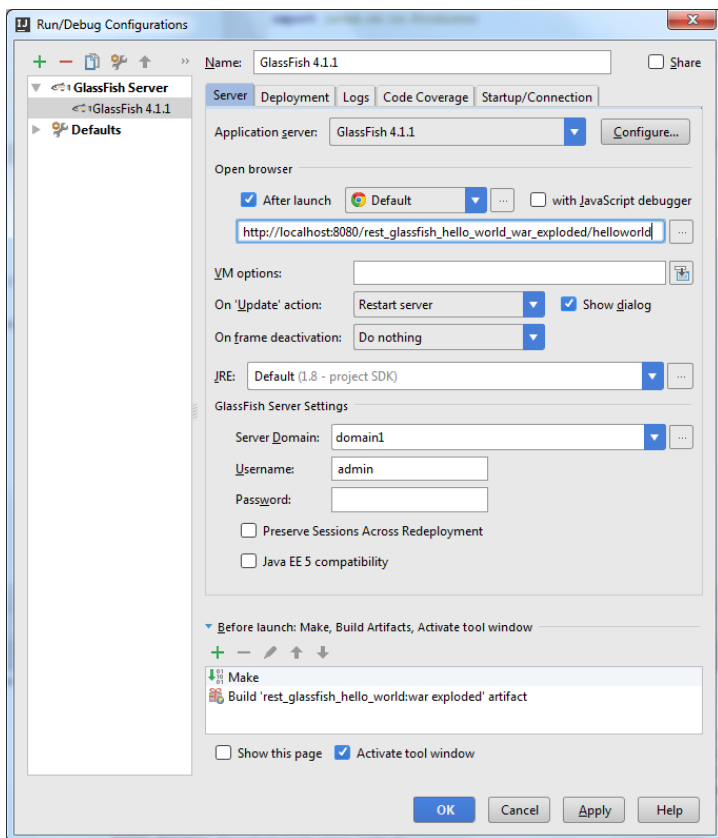

IntelliJ IDEA has already filled in all the mandatory fields, no changes are required from our side, so just click `Cancel` to leave the dialog.

## Exploring and completing the run configuration

In IntelliJ IDEA, any application is launched according to a dedicated **run configuration**. During the project creation, we have specified the **GlassFish Server** as the application server for running our application. Based on this choice and the annotations from the code, IntelliJ IDEA has created a run configuration and filled almost all the mandatory fields.

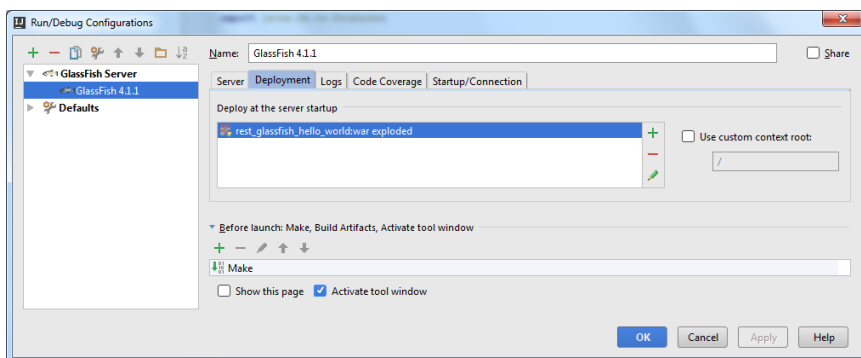

1. Choose Run | Edit Configuration on the main menu.
2. In the Edit Configuration dialog box that opens, expand the GlassFish Server node and click GlassFish 4.1.1. The right-hand pane shows the settings of the automatically generated run configuration.

- The Application Server field shows `GlassFish 4.1.1`, which is the installation of the GlassFish Server that was chosen during the project creation. The Name field also shows `GlassFish 4.1.1`, IntelliJ IDEA has automatically named the generated configuration after the appointed application server.
- In the Open browser area, the After launch checkbox is selected, so the page with the application output will be opened automatically.  
In the text box below, we need to specify the URL address of the page to open. In our example, it is `http://localhost:8080/rest_glassfish_hello_world_war_exploded/helloworld`.
- To have `rest_glassfish_hello_world:war exploded` deployed automatically on launching the run configuration, the artifact has to be marked for deployment. If you have completed the project creation steps successfully, the artifact is marked for deployment automatically. If it is not, IntelliJ IDEA displays a warning **No artifacts marked for deployment** and a Fix button.

When you click Fix, IntelliJ IDEA opens the Deployment tab where the `rest_glassfish_hello_world:war exploded` is added to the Deploy on the server startup list.

All the other fields are filled in automatically or are optional, so just click OK to save the run configuration.

## Running the application

Click  on the toolbar. After that:

1. IntelliJ IDEA compiles your source code and builds an application artifact.
2. The [Run Tool Window](#) opens. IntelliJ IDEA starts the server and deploys the artifact on it.
3. Finally, your default web browser starts and you see the application output `Hello World` there.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

In this section:

- Ruby Plugin
  - [Introduction](#)
  - [Prerequisites](#)
  - [Changes to the UI](#)
- [Ruby Language Support](#)
- [Rails Framework Support](#)
- [Rake Support](#)
- [Remote Ruby Debug](#)
- [Puppet](#)

## Introduction

Ruby Plugin extends IntelliJ IDEA with the full-scale functionality for Ruby development.

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

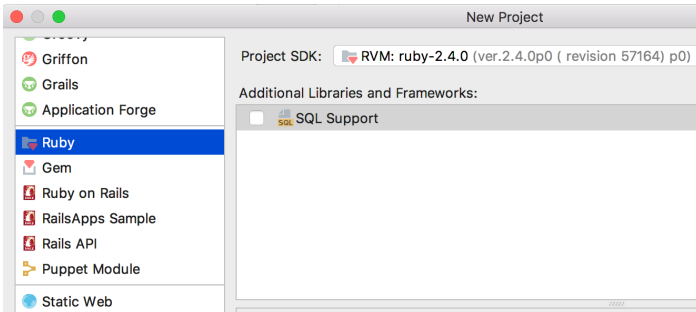

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

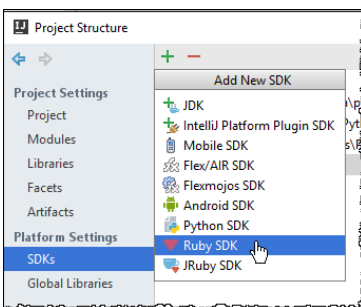

## Changes to the UI

Being installed, the Ruby Plugin introduces the following changes to the IntelliJ IDEA UI:

- Ruby module type is added to the [New Project](#) and [New Module](#) wizards.

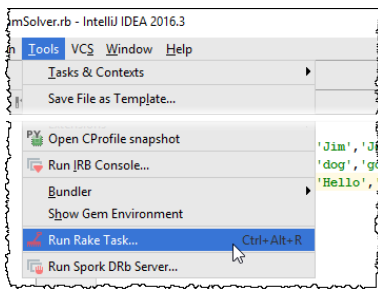

- Ruby SDK can be specified in the Add new SDK popup under the [SDKs](#) node of the [Project Structure](#) dialog.

- Rails is implemented as the facet , which can be attached to a Ruby module, either in the [New Project](#) dialog, or in the [Modules](#) or [Facets](#) pages of the [Project Structure](#) dialog:

- Ruby-related commands are added to the Tools menu:

- Ruby and framework-specific [run/debug configurations](#) , [inspections](#) , [intention actions](#) , and [refactorings](#) .

Besides that, the following changes are made to the Settings/Preferences dialog:

- Ruby code style, colors and fonts, live templates.
- Ruby-related options add to the editor settings (pages [Appearance](#) , [Code Folding](#) and [Smart Keys](#) ).
- Ruby-related options add to the [Stepping](#) page.
- [Syntax and error highlighting](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

- Ruby Language Support
  - [Prerequisite](#)
  - [Important notes](#)
  - [Ruby- and Ruby-on-Rails- specific procedures](#)
- [Configuring Ruby SDK](#)
- [Managing JRuby Facet in a Java Module](#)
- [Creating Empty Ruby Project](#)
- [Creating Gem Project](#)
- [Creating Ruby Class](#)
- [Configuring Load Path](#)
- [Ruby Gems Support](#)
- [Ruby Version Managers](#)
- [RuboCop](#)
- [Ruby Tips and Tricks](#)

## Prerequisite

Ruby SDK should be [downloaded and installed](#) on your computer.

For the Windows platform, use the [Ruby Installer and Development Kit](#) .

## Important notes

- IntelliJ IDEA supports the following range of Ruby SDK versions:
  - 1.8.x
  - 1.9.x, with the lambda syntax, local variables semantics, new method parameters declarations, etc.
  - 2.0, with named arguments, Ruby 2.0 debugger, %i/%I syntax parsing, prepend support.
  - 2.1 and 2.2.
  - [2.3](#) with the following features:
    - [ActionCable](#)
    - Code completion, resolve and documentation include new additions to version 2.3, for example, `Array::dig`
    - Safe navigation operator, with the new [Ruby intention actions](#) Replace safe navigation with chained calls conjunction and Replace safe navigation with nested nil checks , and [Ruby code inspection](#) that suggests replacement of chained && checks to safe navigation operator usage.
    - [squiggly HEREDOCs support](#)
- Language level is detected and derived from SDK.
- Depending on your platform, you can use [IronRuby](#) , [MacRuby](#) , [Rubinius](#) , [MRI Ruby](#) , or [JRuby](#) .
- IntelliJ IDEA supports [cygwin](#) as the Ruby interpreter platform.

## Ruby- and Ruby-on-Rails- specific procedures

The following sections contain procedures that pertain to both pure Ruby and Ruby-on-Rails programming.

- [Configuring Ruby SDK](#)
  - [Configuring Available Ruby Interpreters](#)
  - [Choosing Ruby Interpreter for a Project](#)
  - [Configuring Local Ruby Interpreter](#)
  - [Configuring Remote Ruby Interpreter](#)
- [Managing JRuby Facet in a Java Module](#)
- [Creating Empty Ruby Project](#)
- [Creating Gem Project](#)
- [Creating Ruby Class](#)
- [Configuring Load Path](#)
- [Ruby Gems Support](#)

- [Ruby Version Managers](#)
  - [RVM Support](#)
  - [Rbenv Support](#)

- [PIK Support](#)
- [RuboCop](#)
- [Ruby Tips and Tricks](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- Configuring Ruby SDK
  - [Basics](#)
  - [Configuring Ruby SDK for the selected project](#)
- [Configuring Available Ruby Interpreters](#)
- [Choosing Ruby Interpreter for a Project](#)
- [Configuring Local Ruby Interpreter](#)
- [Configuring Remote Ruby Interpreter](#)

## Basics

In IntelliJ IDEA, you can define several Ruby SDKs. So doing, you can choose the one to be used in your project, from the list of the interpreters available on your machine.

IntelliJ IDEA supports:

- Standard Ruby SDKs
- IronRuby
- MacRuby

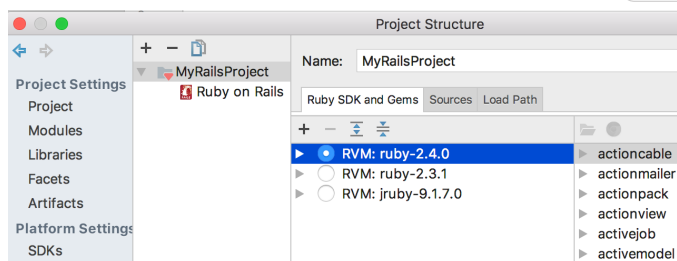

Ruby SDKs can be configured on the following levels:

- Current project : selected Ruby interpreter will be used for the current project.  
Configuring Ruby SDK on this level is described [below](#) .
- New project : selected Ruby interpreter will be used for the new project instead of the default one.  
Refer to the section [Creating Rails-Based Projects](#) for details.

## Configuring Ruby SDK for the selected project

### To configure Ruby SDK for the current project, follow these steps:

1. [Open the Project Structure dialog](#) , and click Gems tab.
2. If all the desired Ruby SDKs are already installed and added to your project, select one from the list of Ruby SDKs. To do that, click the radio button to the left of the desired Ruby SDK, or press `Space` :

If the desired Ruby SDK is missing from the list of available SDKs, click `+` .

3. Apply changes.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Overview](#)
- [Viewing the list of available interpreters](#)
- [Configuring the list of available interpreters](#)
- [Removing interpreters from the list](#)

## Overview

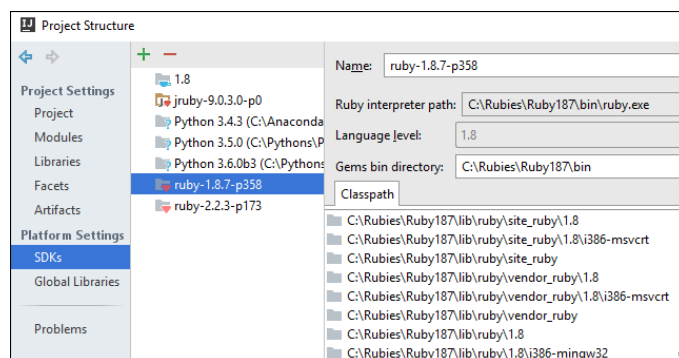

The list of Ruby SDKs, available for the various projects, can include interpreters installed locally or remotely.

The available Ruby interpreters are defined as the global SDKs. The procedure described below supposes that the necessary Ruby interpreters are already installed on your computer.

## Viewing the list of available interpreters

### To view the list of available interpreters

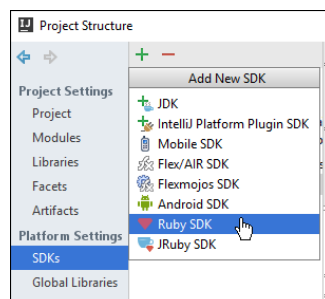

1. Do one of the following:
  - On the main menu, choose File | Project Structure
  - On the main toolbar, click 
  - Press `Ctrl+Shift+Alt+S`
2. Under Platform Settings, click the node SDKs :

## Configuring the list of available interpreters

### To configure the available Ruby interpreters

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the Project Structure dialog box, click SDKs node under the Platform Settings.
3. Click **+**, and then choose Ruby SDK from the Add New SDK pop-up menu.

4. From the Select Interpreter Path popup, select whether you want to add an interpreter from your local computer, or the one located remotely.  
The next step depends on the selected interpreter location. When an interpreter is added, it is included in the list of available interpreters.
5. Repeat steps 1 - 4 to add more Ruby interpreters to the list.

## Removing interpreters from the list

### To remove an interpreter from the list of available interpreters

1. In the list of available interpreters, select the one to be deleted.

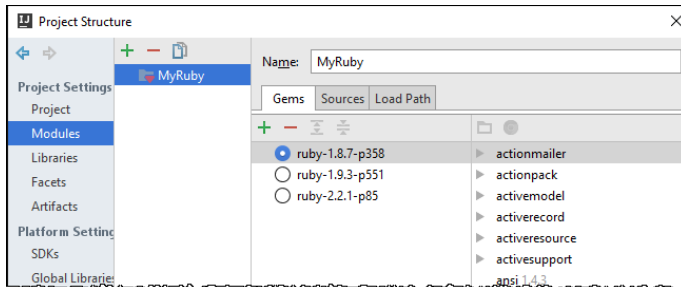

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## Choosing interpreter for a project

1. Open the Project Structure dialog.
2. In the [Project Structure](#) dialog, click the node Modules .
3. Click the module to which a Ruby interpreter should be assigned.
4. Select the desired interpreter and click the radio button to its left, or press `Space` .

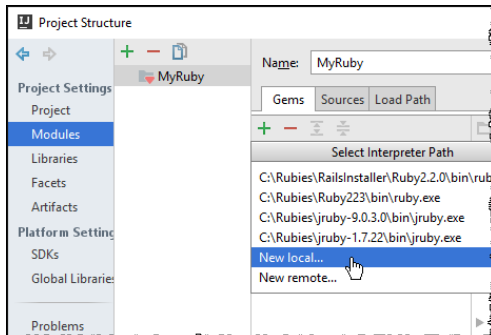

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## To configure a local Ruby interpreter, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the [Project Structure](#) dialog, click the node Modules .
3. In the Gems tab, click **+**, and from the popup menu, choose New local... :

4. In the [Select Ruby Interpreter Path](#) dialog box, click the desired Ruby executable.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

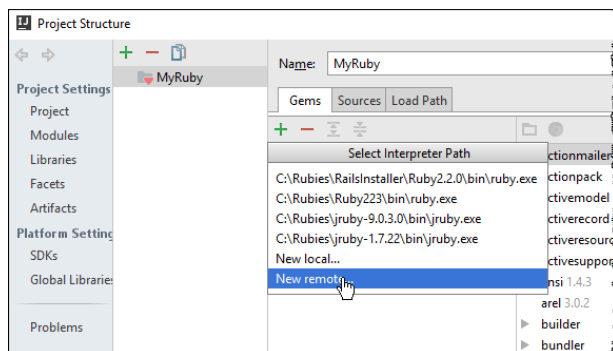

## Prerequisite

Before you start working with remote interpreters, make sure that the SSH Remote Run plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

## Configuring remote Ruby interpreter

### To configure a remote Ruby interpreter, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. In the [Project Structure](#) dialog, click the Modules node.
3. In the Gems tab, click **+**, and from the popup menu, choose **New remote...**:

4. In the [Configure Remote Ruby Interpreter](#) dialog box, select the desired option (Deployment configuration, SSH Credentials etc.).

## Important notes

- [rbern](#): when configuring a remote interpreter, you have to specify ruby executable located under the directory `versions`, rather than `shims`.
- [RVM Support](#): When adding an rvm-based remote interpreter, it is important to specify the gemset folder instead of the Ruby binary itself:

```
<rvm root>/gems/<gemset>
```

For example, on MacOS/Linux:

```
~/ .rvm/gems/ruby-2.2.2@rails
```

Note that the name of an rvm-based SDK is automatically prepended with the prefix RVM.

- An additional icon appears on the toolbar: . Clicking this icon results in opening the [Edit Project Path Mappings](#) dialog box, where you can add or delete the desired path mappings.

Find the detailed tutorial on configuring a remote SDK [here](#).

## Basics

IntelliJ IDEA makes it possible to attach a [JRuby](#) facet to a Java module. This can be required for working with Ruby code, having resolve and code completion.

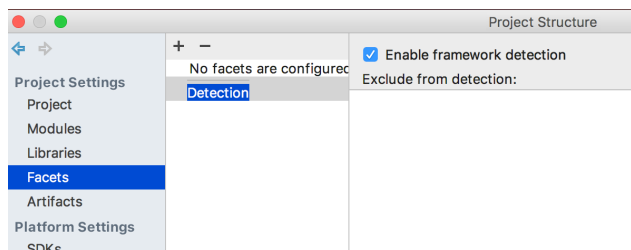

Suppose, you've created a project that contains a Java [module](#) , and you want to attach a facet to it. You must [install JRuby](#) on your computer.

By the way, if you create a module of, say, Ruby type, you may attach any available Ruby SDK.

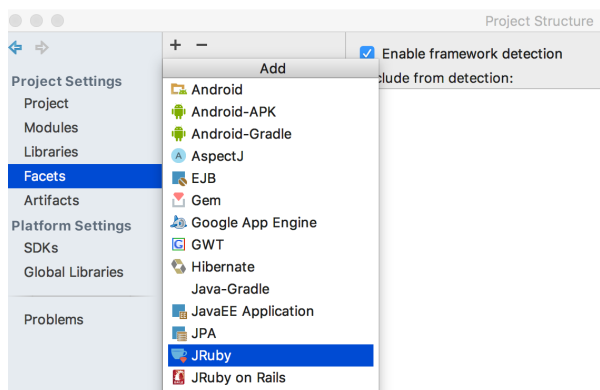

## Adding a JRuby facet

Having installed JRuby (for example, `rvm install jruby` ), follow these steps:

1. Open the [Project Structure Dialog](#) dialog.
2. In this dialog, select the [Facets](#) page.
3. Click **+**:

4. From the pop-up menu of the possible facets that appears, choose JRuby facet:

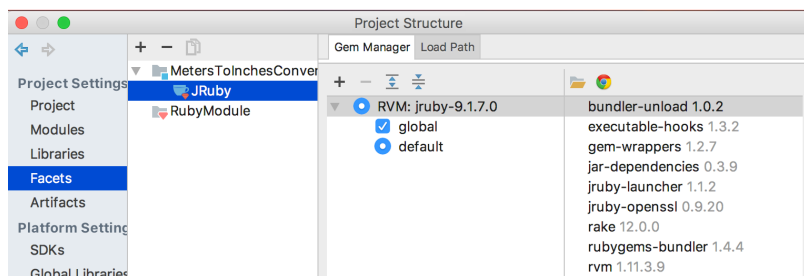

5. If JRuby has been installed previously, IntelliJ IDEA recognizes it and suggests to choose a Java module to which the facet should be added:

Select the desired module.

After that, JRuby facet appears under the module name:

## Deleting a JRuby facet

To delete a JRuby facet, follow these steps:

1. Open the [Project Structure Dialog](#) dialog.
2. In this dialog, select the [Facets](#) page.
3. Click **-**.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Empty projects are intended for pure Ruby programming.

## To create an empty project

1. Do one of the following:

- On the main menu, choose File | New | Project .
- On the [Welcome screen](#) , click the link Create New Project .

New Project dialog box opens.

2. In the New Project dialog box, do the following:

- In the Project type section, click the desired project type, in this case, Ruby.
- Specify the project SDK. If the desired SDK is missing in the list, click New .
- Click Next .
- Specify the project name and location.

3. Click Finish .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Gem projects are intended for developing, building and pushing gems to github.

## To create a Gem project

1. On the main menu, choose File | New | Project , or click New Project on the [Welcome screen](#) . New Project dialog box opens.
2. In the New Project dialog box, do the following:
  - Select **Gem** .
  - Select Ruby interpreter, or accept the suggested one. If the desired Ruby interpreter is missing, click New , and configure the interpreter of your choice.
  - Observe the suggested Bundler version.
  - Click [Minitest](#) or [RSpec](#) radio-buttons as required.

Select or clear the checkboxes below. Refer to the [Bundler documentation](#) for details.

  - Click Next .
  - Specify the project name and location.
3. Click Finish .

## Introduction

IntelliJ IDEA allows you to generate Ruby classes. So doing, it's possible to create classes nested in the right modules, and select between a class or a module.

## Generating a Ruby class

This how it's done.

1. In the Project tool window, select the directory where you want a class to be created, and press `Alt+Insert`.
2. From the pop-up menu, choose Ruby Class.
3. In the New Ruby Class dialog box, enter the Ruby class name:

Note that IntelliJ IDEA allows you to create classes prepended by modules. If required, prepend the class name with module name:

IntelliJ IDEA creates a new Ruby class and opens it for editing. If a module name has been specified, it is displayed in the editor:

## Changing type of the created object

To change the kind of an object being created, do the following:

1. Create a Java class, as described [above](#).
2. With the New Ruby Class dialog box opened, press up/down arrow keys to change the type of the created object.

**Tip** Alternatively, click the Kind drop-down list and choose between class and module.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Basics](#)
- [Configuring load paths via project structure](#)
- [Configuring load paths via context menu](#)

## Basics

The load path is the path where `require` and `load` statements will look for files. The specified paths will be used in [code completion](#) for `require` and `load`. If the load path is not defined, code completion will suggest only the paths relative to the project root.

A directory that belongs to the load path is marked as the source root directory  in the project view.

## Configuring load paths via project structure

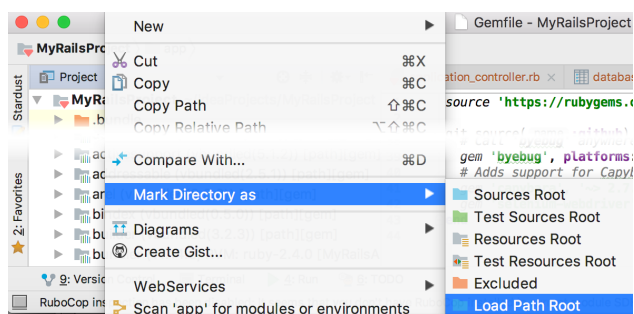

### To define load paths via Load Path page of the project structure

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`), and then click [Load Path](#).
2. Click [+](#).
3. Locate the desired path in the [Select Path](#) dialog box.

## Configuring load paths via context menu

### To define load paths via context menu of the Project tool window

1. Right-click the desired directory in the [Project Tool Window](#).
2. On the context menu, point to Mark Directory As node.
3. Choose Load Path Root.

The directory in question is marked with the source root icon .

To unmark a directory, choose Unmark directory as load path on the context menu. The directory is then denoted with regular folder icon .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Many types of the Ruby [projects](#) make use of the Ruby gems.

The approach of IntelliJ IDEA to the gems depends on the presence of the bundler .

- If a project uses the [bundler](#) , then all the required gems are taken according to the Gemfile.
- If there is no bundler, IntelliJ IDEA scans all the project files for the calls to Ruby gems, and produces a set of the required gems.

If for some reason you are not happy with the set of gems defined by IntelliJ IDEA, you can create a Gemfile yourself and specify the gems of your choice.

**Tip** Gemfile is automatically generated by Rails version 3.x. In all other cases, if you need the Gemfile, you have to create it yourself.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- Using the Bundler
  - [Basics](#)
  - [Prerequisites](#)
  - [SUDO permission](#)
- [Creating Gemfile](#)
- [Bundling Gems](#)

## Basics

IntelliJ IDEA implements the [bundler](#) as a powerful way of handling gem dependencies. The bundler is required to execute an application with the same set of gems it has been created and tested with.

IntelliJ IDEA supports the bundler since version 0.8, but it is recommended to use version 0.9 and higher.

## Prerequisites

To start using the bundler with IntelliJ IDEA, make sure that the following prerequisites are met:

- RubyGems version 1.3.7 or higher is installed.
- The [bundler](#) gem is installed.

## SUDO permission

On the UNIX-like computers, if the permissions are required to invoke the Bundler commands in a project, IntelliJ IDEA automatically understands from the command output that running with `sudo` is needed, and suggests to re-run this command with `sudo`.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA helps create Gemfile, when the [bundler](#) gem is installed.

## To create Gemfile

1. On the main menu, point to Tools | Bundler .
2. On the submenu, choose Init . IntelliJ IDEA generates the stub Gemfile in the project root directory. Later you can add more gems if required.

**Note** The Bundler | Init command is only available, when the Gemfile doesn't exist.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- Basics
- Managing gem dependencies with the Bundler version 0.9 or higher
- Managing gem dependencies using the legacy Bundler versions

## Basics

The procedure of bundling gems in IntelliJ IDEA depends on the bundler version you are working with.

In any case, the Bundler displays its output in [Run tool window](#), and creates the necessary infrastructure under the `vendor` directory.

## Managing gem dependencies with the Bundler version 0.9 or higher

To manage gem dependencies using the Bundler version 0.9 or higher, follow these steps:

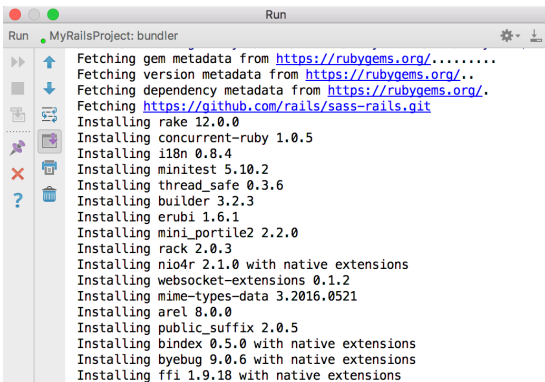

- On the main menu, point to Tools | Bundler - Install .
- In the Bundle Install dialog box, specify the installation options if any, and click OK .

Note the following:

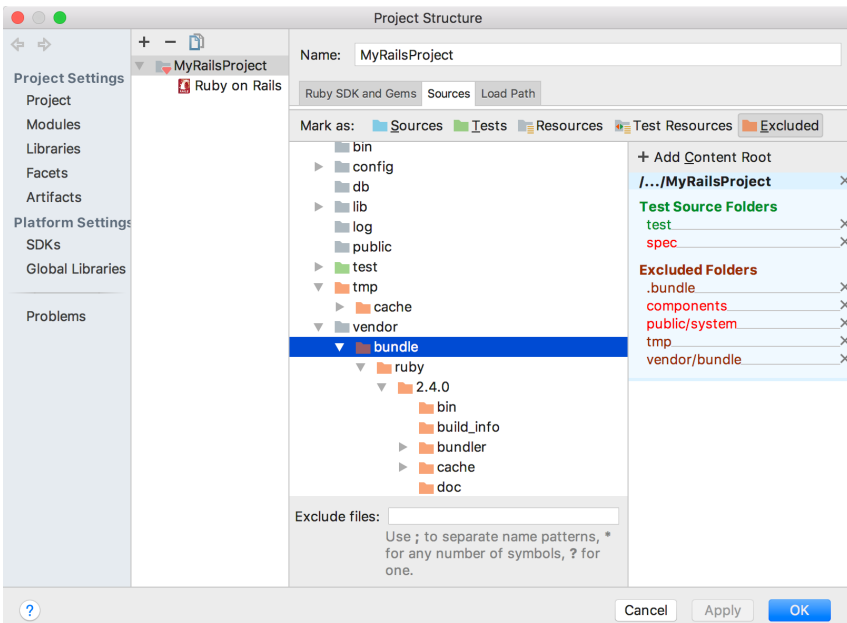

- IntelliJ IDEA understands the gems bundled inside projects.  
If the path is specified in the Bundler - Install command

```
--path vendor/bundle
```

the output looks as follows:

- IntelliJ IDEA adds the directory `.bundle` to the project root.  
This directory is automatically included in the project structure to make the gems parsed.
- The directory `vendor/bundle` is excluded from the project scope to avoid searching inside the gems (unless you specifically ask for it).

- The local gems are added to the node External Libraries :

## Managing gem dependencies using the legacy Bundler versions

To manage gem dependencies using the legacy Bundler versions:

- On the main menu, choose Tools | Bundler - Bundle Gems .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

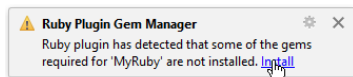

IntelliJ IDEA detects unsatisfied dependencies in the following cases, and helps resolve them:

- In the [Gemfile](#) for the whole project.
- In a particular file. IntelliJ IDEA recognizes unsatisfied dependencies in the absence of Gemfile only.

### To resolve unsatisfied gem dependencies, do one of the following

- If IntelliJ IDEA detects unsatisfied dependencies, it displays the notification balloon, suggesting the appropriate action.

Click the hyperlink in the balloon:

- If in course of editing a Ruby file, IntelliJ IDEA detects that some of the required gems are missing, it displays an [intention action](#) Install missing gem using 'bundler' gem .

Choose the suggested intention action:

The bundler starts in a separate pop-up window:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Introduction](#)
- [List of Ruby SDKs](#)
- [List of gemsets](#)
  - [RVM gemset](#)
    - [Creating RVM gemsets](#)
    - [Creating a dedicated RVM gemset on project creation](#)
    - [Creating RVM gemset in the Setting/Preferences dialog](#)
  - [Rbenv gemset](#)
    - [Creating rbenv gemsets](#)
- [List of gems](#)

## Introduction

**Gemsets** are a convenient way to deal with the different gem environments for your applications. IntelliJ IDEA supports both [RVM](#) and [rbenv](#) gemsets.

**Warning!** Note that `rvm` and `rbenv` gemsets work for macOS and \*NIX platforms only!

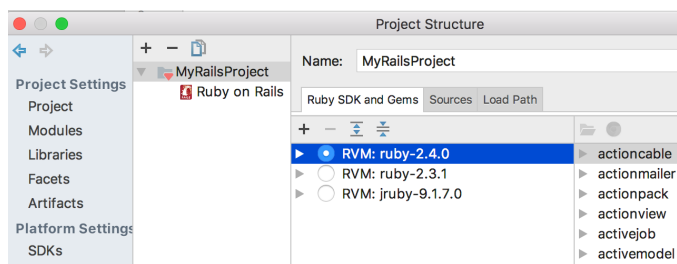

Gemsets are supported for the following types of projects:

- All [Ruby](#) projects types
- All [Rails](#) project types
- [Puppet Module](#)

## List of Ruby SDKs

### To view the list of Ruby SDKs, available to the computer, follow these steps

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S`).
2. Click Modules and choose the desired module with Ruby support.
3. Next, click the Gems tab, and observe the list:

To select an SDK for a project, click the radio button to the left of the desired Ruby SDK, or press `Space`.

Note the following:

- IntelliJ IDEA automatically detects Ruby versions installed.
- Add or remove any local or remote SDKs with the buttons `+` and `-`.
- Expand/collapse buttons `▾` / `▸` are only available for macOS and \*NIX platforms, as the ones having gemsets. For Windows platform, these buttons are disabled.
- [Speed search](#) works for the list SDKs.

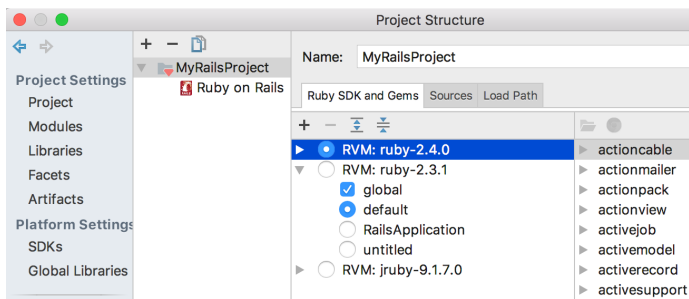

## List of gemsets

For each SDK, open the list of available gemsets.

### To view the list of gemsets for the selected SDK, follow these steps

1. In the list of available SDKs, select the one marked with the icon `▶` to the left:

2. Do one of the following:

- Press `Enter`.
- Double-click the SDK node.
- Click the button `>`.
- Press right arrow key.

Note that the previous selection of a gemset per Ruby module is preserved. You can quickly return to it by merely selecting the SDK in question.

## RVM gemset

If you haven't specified any [RVM](#) gemset to use with the project yet, then the [default](#) and [global](#) gemsets are selected.

However, one can select any desired gemset by hitting `Space` or clicking the radio button to the left of the gemset name.

It's also possible to decide whether to use the [global gemset](#) (hit `Space`, or select/clear the checkbox). Global gemset (if selected) is used to share gems to all the gemsets within an SDK.

The [default gemset](#), marked with a radio button, is used for any specific interpreter.

## Creating RVM gemsets

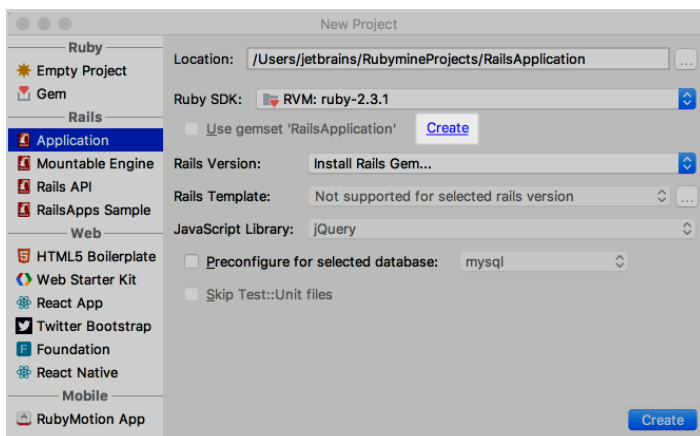

For configuring [RVM](#) gemsets, one should use the files `.ruby-gemset` and `.ruby-version`. Refer to the [rvm documentation](#).

## Creating a dedicated RVM gemset on project creation

### To create a gemset for the new Ruby/Rails project, follow these steps:

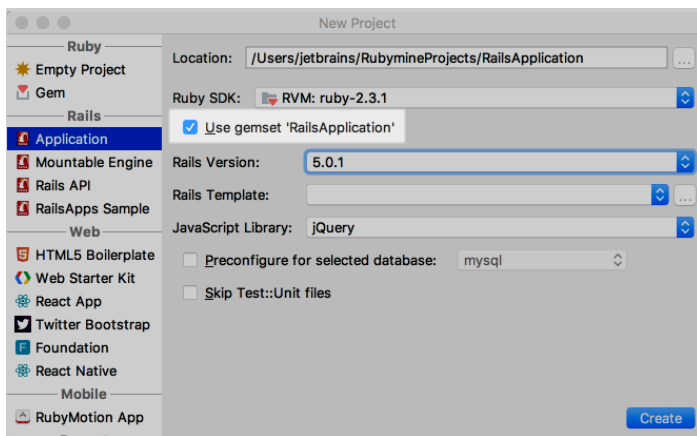

1. Create a new project.

As you type the new project name, IntelliJ IDEA suggests a gemset with the same name:

Click the link `Create` to create the gemset (empty directory under the selected SDK).

Next, select the checkbox `Use gemset <name>` to use the newly created gemset for your project:

If you need to install Rails, note that Rails will be installed in this gemset.

2. Now you are ready to create a new project with the gemset. Click the button Create for that.

## Creating RVM gemset in the Setting/Preferences dialog

**Warning!** Note that `rvm` gemset can be created for macOS and \*NIX platforms only!

IntelliJ IDEA allows you to create an RVM gemset in the Setting/Preferences dialog. This is how it's done.

### To create an RVM gemset

1. Open the Setting/Preferences dialog.
2. In this dialog, do the following:
  - Choose Ruby SDK. If an RVM SDK has been selected for your project, then it is used. If an SDK has not been selected or a non-RVM SDK has been selected (for example, `system`, `chef` or `remote`), then the default SDK is used.
  - Specify the desired gemset name.

The gemset with the specified name appears under the selected SDK.

### Rbenv gemset

For `rbenv`, the `default` gemset means the set of gems installed to the SDK folder, so you cannot unselect it (the checkbox to the left is disabled).

`global` gemset has no special behavior.

`rbenv` enables you to select as many gemsets as required (hit `Space`, or select/clear the checkbox to the left of the desired gemset).

### Creating rbenv gemsets

#### Prerequisite

Before you start working with `rbenv`, make sure that `rbenv-gemsets` plugin is [installed and enabled](#). The plugin is not bundled with IntelliJ IDEA.

**Tip** This is a third-party plugin. Download it at [jfrbenv-gemset](#) page.

There are the following ways of creating gemsets: using the [commands of the](#) `rbenv-gemsets` plugin, or using the `.rbenv-gemset` [file](#).

### To create a gemset commands of the rbenv-gemsets plugin, follow these steps:

1. [Open](#) the Terminal tool window.
2. Enter command in the format

```
rbenv gemset create <rbenv version number> <gemset name>
```

For example:

**To create a rbenv gemset in the editor, follow these steps:**

1. [Open for editing](#) the file `.rbenv-gemset` (if the file does not exist, [create it](#)).
2. Type the new gemset name. The following steps depend on the existence of a gemset:

– If the gemset with the entered name exists, the completion is suggested:

– If the gemset with the entered name does not exist, then press `Alt+Enter` and choose the intention action `Create gemset <gemset name>` :

Refer to the [rbenv documentation](#) .

**Tip** It's also possible to use `.ruby-gemset` file for configuring `rbenv` gemsets.

As a result, the created gemset appears in the [Project Structure Dialog](#) dialog. Note that this gemset is already selected.

**List of gems**

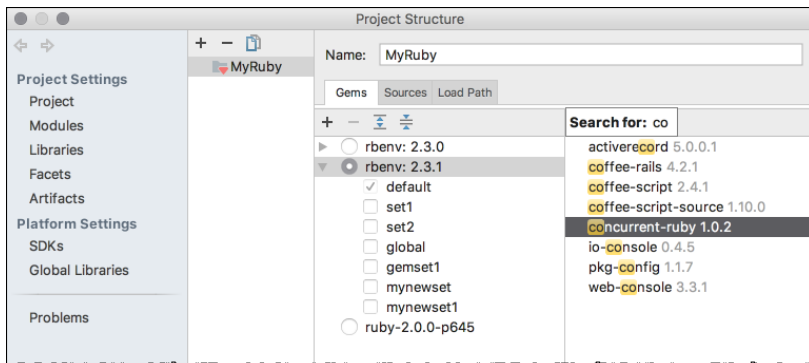

In the Gems tab to the right of the selected Ruby module in the [Project Structure Dialog](#) dialog, there is the list of gems, available for an SDK or a gemset.

If you select an SDK, you'll see see all the gems available for the current project with that version. So doing, the gems of all gemsets are selected for the SDK in question.

Note the following:

- If an SDK has no gemsets (as on Windows platform), then all the gems installed with the selected SDK are shown in the right-hand pane.
- If an SDK has gemsets (as on macOS or \*NIX platforms), then, when one selects a gemset, the gems for the selected gemset are shown in the right-hand pane. This is valid for both `rvm` and `rbenv` .
- If an SDK has gemsets, and this SDK is selected, then the contents of the right-hand pane depends on the version manager used:
  - `rbenv` : the gems list shows all the gems from all the gemsets. So doing, the gems in the gems list have the note from which gemset they are taken. Same is valid for the External Libraries node in the [Project Tool Window](#) .
  - `rvm` : the gems list shows both the `global` gemset and one gemset selected (by default, this is the `default` gemset). So doing, the gems list bears no marking, as well as the External Libraries node in the [Project Tool Window](#) .

[Speed search](#) also work for the gems: just type a string, and speed search shows the matching entries only:

It's also possible to see the gem path, using the button , and the web page with the gem description, using the button .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

On this page:

- [Introduction](#)
- [Prerequisite](#)
  - [Windows](#)
  - [macOS](#)
  - [Linux](#)
- [Downloading gems with RSync](#)

## Introduction

IntelliJ IDEA enables you to download the remote gems in case [remote interpreters](#) are configured for the applications.

## Prerequisite

The application `rsync` must be installed on your computer!

## Windows

`rsync` can be used on Windows systems, but is only available through the various ports (such as [Cygwin](#)).

To learn how to run `bash` on Windows, refer to the articles [Run Bash on Ubuntu on Windows](#) and [Announcing Windows 10 Insider Preview](#).

## MacOS

`rsync` is installed by default.

## Linux

```
sudo apt-get -y install rsync
```

## Downloading gems with RSync

No matter whether you use a prepared Deployment configuration or SSH credentials to set up a remote Ruby interpreter configuration, IntelliJ IDEA makes use of `rsync`.

When setting up with SSH credentials, use one of the following values of the field Auth type :

- Key pair (OpenSSH or PuTTY) (recommended)
- Password : in this case, IntelliJ IDEA emulates Terminal to use it. So doing, the command looks as follows:

```
rsync -zarv user@host:/remote/path /local/path
```

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

IntelliJ IDEA helps quickly get information about the current gem environment.

### **To view gem environment information**

- On the main menu, choose Tools | Show Gem Environment.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA makes it possible to visualize gem dependencies, based on the Gemfile information. The gem dependency diagrams are not editable.

If Gemfile is missing, the Show Gem Dependency Diagram/Show Gem Dependency Diagram Popup commands are not available.

## To open the Gem Dependency diagram of a project with a Gemfile

1. Do one of the following:
  - On the context menu of the Project tool window, or the editor, point to Diagrams , and choose Show Diagram or Show Diagram Pop-up .
  - Press `Ctrl+Shift+Alt+U` , or `Ctrl+Alt+U` .
2. From the pop-up menu, choose Gem Dependency Diagram :

## In the Gem Dependency diagram, you can perform the following operations

- [Select elements](#) .
- [Add or delete notes](#) .
- [Change diagram layout](#) .
- [Change diagram scale](#) .
- [Navigate to source code](#) .
- [Navigate through the gems using the Structure view](#) (`Ctrl+F12` ) .

**Tip** Keeping the `Alt` key pressed invokes the magnifier tool, which will help you have a closer look at the most interesting or problematic areas of your Model dependency diagram.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Depending on the platform you are working on, you can use one of the Ruby version managers. IntelliJ IDEA provides integration with the version managers, which enables switching between the various available Ruby SDKs right inside the IDE.

In this section:

- [RVM Support](#)
- [Rbenv Support](#)
- [PIK Support](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

On this page:

- [Overview](#)
- [Prerequisites](#)
- [RVM-based remote interpreters](#)
- [File .ruby-gemset](#)

## Overview

`rvm` is intended for \*NIX and macOS !

IntelliJ IDEA supports `rvm` versions up to the latest.

At startup, IntelliJ IDEA scans your `~/rvm` folder or `/usr/local/rvm` folder , and automatically configures SDK's for each Ruby interpreter and gemset pair . The detected interpreters and gemsets are shown in the Modules page of the [Project Structure Dialog](#) dialog . Thus, a single SDK may appear in the list of available interpreters several times, with the different named gemset, which helps you switch between the independent sandboxes.

IntelliJ IDEA also detects newly installed `rvm` interpreters and gemsets "on-the-fly". On reopening the Project Structure dialog, you will find updates in the Gems tab of the Modules page .

If you have provided `.rvmrc` file for your project, IntelliJ IDEA parses this file on project opening. The Ruby SDK and gemsets, specified in the project `.rvmrc` file, are shown in the in the Gems tab of the Modules page of the Project Structure dialog. If `rvm use` command is commented out, IntelliJ IDEA doesn't change settings.

Any changes made to the project `.rvmrc` file are only applied after project restart.

## Prerequisites

- `rvm` is installed on your computer.
- Ruby interpreters are installed.
- Ruby gemsets are created using the [system console](#) .
- IntelliJ IDEA supports `rvm` Ruby interpreters and gemsets installed in the default `rvm` folder `~/rvm` , or in `/usr/local/rvm` only.

## RVM-based remote interpreters

When adding an rvm-based [remote interpreter](#) , it is important to specify the gem set:

```
~/rvm/gems/<gem set>
```

Note that the name of an rvm-based SDK is automatically prepended with the prefix `RVM` .

## File .ruby-gemset

IntelliJ IDEA provides code insight for the `.ruby-gemset` file:

- Code highlighting
- [Inspections](#)
- [Intention actions and quick fixes](#)

etc.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Overview](#)
- [Prerequisites](#)
- [Support for rbenv-gemsets plugin](#)
- [File .rbenv-gemset](#)
- [Important note about remote interpreters](#)

## Overview

`rbenv` is intended for \*NIX and macOS !

IntelliJ IDEA supports `rbenv` versions up to the latest.

At startup, IntelliJ IDEA scans your `~/.rbenv` folder, and automatically configures SDK's for each Ruby interpreter. The detected interpreters are shown in the Modules page of the [Project Structure Dialog](#) dialog.

IntelliJ IDEA also detects newly installed `rbenv` interpreters "on-the-fly". On reopening the Project Structure dialog, you will find updates in the Gems tab of the Modules page.

## Prerequisites

- `rbenv` is installed on your computer.
- Ruby interpreters are installed.
- IntelliJ IDEA supports `rbenv` Ruby interpreters installed in the default `rbenv` folder `~/.rbenv` only.
- `rbenv` is incompatible with `rvm` ! Any references to `rvm` should be removed before using `rbenv`.

**Tip** As of this writing, IntelliJ IDEA only supports `rbenv` installed in the default location. However, there is a workaround. One can install `rbenv` in a different location using a command like the following:

```
In -s /usr/local/var/rbenv ~/.rbenv
```

See issue [RUBY-16035](#).

## Support for rbenv-gemsets plugin

IntelliJ IDEA supports [rbenv-gemsets](#) plugin for \*NIX and macOS.

- The gemsets are shown as the children of `rbenv` SDK. When a gemset is selected, its gems are shown to the right, `rbenv` SDK with gemsets is selected, then all the gems of this SDK and the gemsets are shown.
- IntelliJ IDEA provides libraries for gems from the current gemset list ( by '`rbenv-gemsets`' ) including the default 'global' gemset
- IntelliJ IDEA invokes all commands with the environment of the specified gemsets and selected SDK ( e.g. `$ RBENV_GEMSETS="gemset1 gemset2" RBENV_VERSION="1.9.3-p125" #command` )

## File .rbenv-gemset

IntelliJ IDEA provides code insight for the `.rbenv-gemset` file:

- Code highlighting
- IntelliJ IDEA provides [code completion](#) for the current SDK gemsets in the `.rbenv-gemsets` file.
- IntelliJ IDEA provides the ability to create a new gemset using the quick fix Create gemset <gemset name> . Just press `Alt+Enter` on a new name in the `.rbenv-gemsets` file:

**Warning!** The quick fix to create a new gemset is only available, if `rbenv-gemsets` plugin is installed !

etc.

## Important note about remote interpreters

If you are configuring a [remote interpreter](#) using [rbenv](#) version manager, you have to specify ruby executable located under the directory `versions`, rather than `shims`.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## Prerequisites

- `pik` is installed on your computer.
- Ruby interpreters are installed.
- IntelliJ IDEA supports `pik` Ruby interpreters installed in the default `pik` folder `~/pik` only.

## Overview

`pik` is intended for Windows !

IntelliJ IDEA supports `pik` versions up to 0.3.0pre and 0.2.8.

At startup, IntelliJ IDEA scans your `~/pik` folder , and automatically configures SDK's for each Ruby interpreter . The detected interpreters are shown in the Modules page of the [Project Structure Dialog](#) dialog .

IntelliJ IDEA also detects newly installed `pik` interpreters "on-the-fly". On reopening the Project Structure dialog, you will find updates in the Gems tab of the Modules page. .

All the gems, installed apart from the default gems (that come with Ruby SDK, installed via `pik`) are visible.

## Important note

There is no IntelliJ IDEA's implementation of RuboCop. IntelliJ IDEA only executes the RuboCop installed by the users, reads the output and visualizes it in the editor.

## Prerequisites

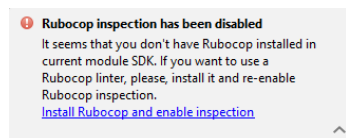

To make use of the [RuboCop](#) , make sure that the following prerequisites are met:

- You are working with IntelliJ IDEA version 2017.1 or higher.
- The gem [rubocop](#) is installed.

## Using the RuboCop inspection

The RuboCop inspection is enabled by default. If your project SDK has the `rubocop` gem installed, then you'll immediately see the results of this inspection in the Editor, in the same way as the other [IntelliJ IDEA inspections](#) .

Otherwise, IntelliJ IDEA suggests to install the missing gem to your project's SDK and enable this inspection:

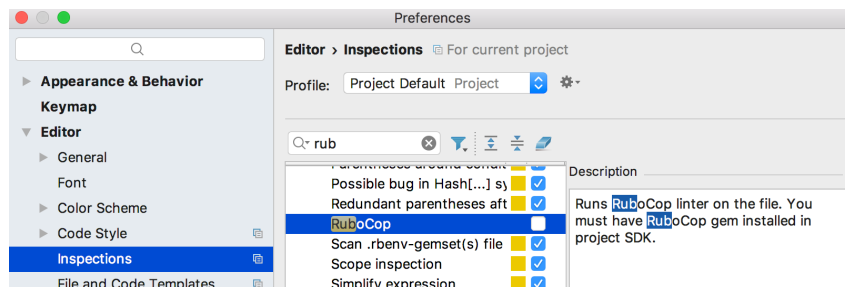

The banner shows only once per project. If you don't want to use RuboCop in your project, just skip this notification.

**Tip** Mapping of RuboCop severities to the IntelliJ IDEA severities is hardcoded the following way:

- Refactor and Convention => Weak Warning
- Warning => Warning
- Error and Fatal => Error

It is impossible to change these severities manually.

To switch off RuboCop inspections, [open Settings/Preferences dialog](#) , open the page [Inspections](#) and then uncheck the inspection RuboCop:

RuboCop runs through the main menu commands `Code | Inspect Code` and `Code | Run Inspection by Name` , which is pretty handy if one wants to find all the code style offenses in an application.

IntelliJ IDEA can autocorrect the entire files using RuboCop, and fix errors by [a cop department](#) . You can discover new options by showing new intention actions ( `Alt+Enter` ).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

On this page:

- [Fill paragraph](#)
- [Highlight exit points](#)
- [Running the Bundler](#)

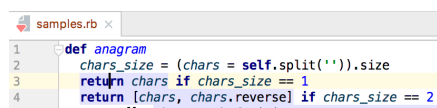

## Fill paragraph

Fill Paragraph action is supported for Ruby comments. This action creates soft wraps in comments. To make use of this action, follow these steps:

1. Place the caret somewhere inside a comment in Ruby class.
2. Do one of the following:
  - On the main menu, choose Edit | Fill Paragraph
  - Press `Ctrl+Shift+A` , in the pop-up frame, type Fill Paragraph , and then press `Enter` ,

## Highlight exit points

If you place the caret at an exit point of a function, the other exit points are also highlighted:

```
1 def anagram
2   chars_size = (chars = self.split('')).size
3   return chars if chars_size == 1
4   return [chars, chars.reverse] if chars_size == 2
```

## Running the Bundler

On the UNIX-like computers, IntelliJ IDEA suggests to run the [Bundler](#) with the `sudo` privileges, if SDK so requires. For example, Chef DK by default, requires installing gems under `sudo` :

Also, when running commands, IntelliJ IDEA automatically understands from the command output that running with `sudo` is required, and suggests to re-run this command with `sudo` .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

In this section:

- [Prerequisite](#)
- [Important notes](#)
- [Rails support](#)
- [Rails-specific procedures](#)

## Prerequisite

Rails framework should be [downloaded and installed](#) on your computer.

## Important notes

- IntelliJ IDEA supports Rails framework versions from 1.2 to 5
- Rails 3.x requires Ruby 1.8.6 or higher.
- Rails 4 requires Ruby 1.9.x or higher.
- Rails 5 requires Ruby 2.2.2 or higher.

## Rails support

Rails support in IntelliJ IDEA includes:

- Dedicated [project types](#) , where the desired Rails version is defined.
- Special [Rails view](#) to represent the logical structure of a Rails application.
- [Rails generators](#) .
- Means of [navigation between Rails components](#) .
- Possibility to [run Rake tasks](#) .
- Possibility to define [object-relational mappings](#) .
- Analysis of the models and their relationships with [Model Dependency diagram](#) .
- Complete editing assistance (syntax and error highlighting, code completion for Rails application elements and Rake tasks)
- Rails-aware refactorings ([Rename Refactorings](#) , [Extract Partial](#) , etc.).
- [Rails console](#) , where you can execute Rails commands without leaving the IDE.
- [Sprockets](#) are supported.

## Rails-specific procedures

- [Creating Rails-Based Projects](#)
- [Creating Rails Application Elements](#)
- [Creating Controllers and Actions](#)
- [Creating Views from Actions](#)
- [Injecting Ruby Code in View](#)
- [Generating Archives](#)
- [Generating Tests for Rails Applications](#)
- [Running Rails Scripts](#)
- [Running Rails Server](#)
- [Rails-Specific Navigation](#)
- [Running Rails Console](#)
- [Working with Models in Rails Applications](#)
- [Zeus](#)
- [Rails/Spring Support in IntelliJ IDEA](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Basics](#)
- [Creating Rails-based projects](#)
- [Creating Rails samples](#)

## Basics

In IntelliJ IDEA, one can create several Rails-based project types.

- [Rails applications](#) are intended for productive web development with Ruby on Rails.
- [Rails API](#) projects are intended for building REST APIs with Rails.

**Tip** Rails API projects are only available for Rails 5.0 or higher versions.

- [RailsApp Sample projects](#) are intended for mastering Rails.

## Creating Rails-based projects

### To create a Rails-based project, follow these general steps

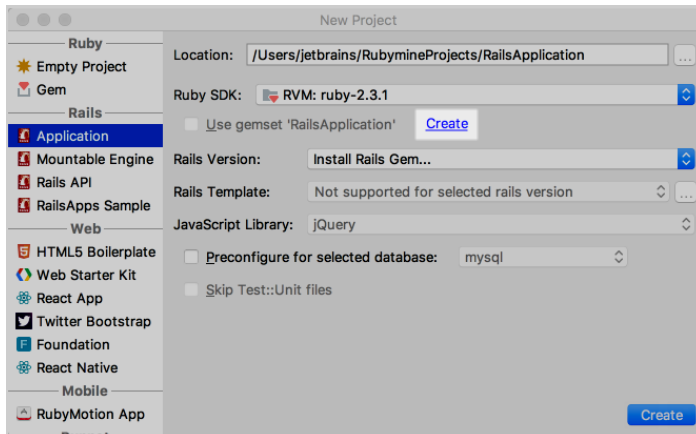

1. Do one of the following:
  - On the main menu, choose File | New | Project .
  - Click Create New Project on the [Welcome screen](#) .

New Project dialog box opens.

2. In the New Project dialog box, specify the project name and location. In the left-hand pane, select the desired Rails-based project type.

3. Specify the following:

- In the Project SDK drop-down list, select the Ruby SDK you want to use from the list of available Ruby interpreters, installed on your computer.  
If the desired Ruby interpreter is not found in the list, you can specify a new one by clicking Add Ruby SDK , and locating Ruby SDK in the file system.
- If you are working with [RVM](#) , you have an additional settings:

When you specify a name for your project, IntelliJ IDEA automatically suggests a gemset with the same name. Click the link Create to have IntelliJ IDEA install a gemset for your new project. Leave the checkbox selected, so that the gems are put in this gemset when generating your new project.

- In the Rails Version drop-down list, select the desired Rails version from those installed on your machine. If the desired version is missing, choose Install Rails Gem... command from the drop-down list. IntelliJ IDEA downloads the list of gems. Next, you have to choose one from the drop-down list in the Install rails gem dialog box:

- In the field Rails Template , type the fully qualified path to the desired template file, or click the button  , and locate the template file in the file system.

- For the Ruby on Rails application , you can select the JavaScript library to be used to generate the target application.
- For the Ruby on Rails application or Rails API project types, specify which database will be used for your new application.  
By default, IntelliJ IDEA suggests using SQLite3. If you want to use a different database, select the Preconfigure for the selected database checkbox, and choose the desired database from the drop-down list.
- For the Ruby on Rails application specify whether IntelliJ IDEA should generate the testing directory structure and template files. To do that, select or clear the checkbox Skip Test:Unit files . If you leave the checkbox cleared, IntelliJ IDEA will produce the `test` folder, marked as a test root  , with all the necessary infrastructure. If you select this checkbox, the testing infrastructure will not be generated.
- For the [RailsApps Sample](#) , project type select the sample type from the list of available types.

When ready, click Finish . The generator executes and displays its output in the console of the Run tool window.

## Creating Rails samples

If you are going to study Rails, choose the option RailsApps Sample . Specify the project location and Ruby SDK, and then choose the exact sample project.

If there are changes to the list of sample projects, click  .

### Notes for macOS and Linux users:

- When choosing the project interpreter, keep in mind that Ruby version may be different from the one provided in the file `.ruby-version` .
- If you choose `rvm` with the a gemset, note that this gemset applies to the file `.ruby-gemset` .

In both cases, IntelliJ IDEA provides the ability to revert:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Introduction](#)
- [Creating Rails application elements](#)

## Introduction

IntelliJ IDEA helps populate your Rails applications with the stubs of all the required elements, and provides the following ways of launching the generators:

- The standard `Alt+Insert` functionality.
- Tools | Run Rails Generator command on the main menu.
- File | New command on the main menu

Thus IntelliJ IDEA launches the `generate` script with the element name specified as a parameter, and a list of arguments. As a result, IntelliJ IDEA produces the required application elements and places them to the proper locations of the directory structure.

## Creating Rails application elements

### To create a stub of a Rails application element

1. Do one of the following:
  - On the main menu, choose Tools | Run Rails Generator .
  - Press `Ctrl+Shift+A` , start typing `Run Rails generators` and press `Enter` :

2. In the pop-up frame that opens, start typing the desired generator name, or its part. As you type, the suggestion list shrinks to show the matching entries only:

**Tip** If you cannot find the generator you need, reload generators. To do that, just choose [Reload generators list] from the pop-up menu.

3. In the dialog box that opens, specify the name of the new application element, and a list of arguments. Besides that, choose the desired environment:

4. If necessary, select the checkboxes that correspond to the general options of the `generate` script.
5. Click OK . IntelliJ IDEA runs the `generate` script and displays output messages in the dedicated tab of the [Run tool window](#) :

Note that the action of creating Rails application elements can be rolled back. So doing, all the created files will be deleted:

Generation completed  
Generator 'migration' has been successfully completed. [Got it!](#) [Rollback](#)

This feature is only supported in the Ultimate edition.

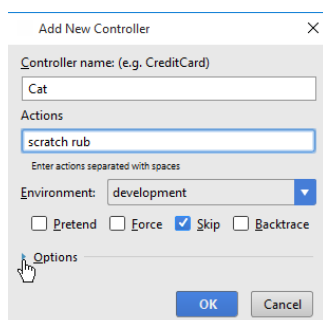

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

When creating a controller, use the IntelliJ IDEA approach described in the section [Creating Rails Application Elements](#).

IntelliJ IDEA suggests two ways of defining actions in controllers. First, you can define actions on creating a controller. Alternatively, it is also possible to edit the source code, enjoying the powerful IntelliJ IDEA coding assistance features.

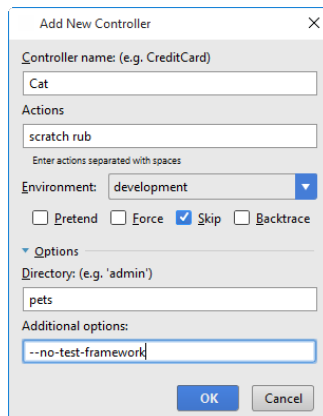

## To create a controller and define actions and options in it, follow these steps

- As described in the section [Creating Rails Application Elements](#), do one of the following:
  - On the main menu, choose Tools | Run Rails Generator.
  - With the editor, or the [Project tool windows](#) having the focus, press `Alt+Insert`, or choose New on the context menu of the Project tool window. Then choose Run Rails Generator.
- In the pop-up window, type `controller`.
- In the Add New Controller dialog box, type the controller name and actions delimited with spaces. Next, click the right arrow  $\blacktriangleright$  to reveal the fields for entering directory and additional options:

The screenshot shows the 'Add New Controller' dialog box. The 'Controller name' field contains 'Cat'. The 'Actions' field contains 'scratch rub'. The 'Environment' dropdown is set to 'development'. The 'Skip' checkbox is checked. The 'Options' section is collapsed.

- In the Options section, specify the target directory and options, and then click OK:

The screenshot shows the 'Add New Controller' dialog box with the 'Options' section expanded. The 'Directory' field contains 'pets'. The 'Additional options' field contains '--no-test-framework'.

Alternatively, [open](#) the desired controller in the editor, type the `def` keyword, then the action name, and press `Enter`. IntelliJ IDEA automatically adds the closing end keyword, and marks the new action with the view icon in the left gutter.

```
def make_a_pest  
end
```

Using private and public modifiers results in hiding or showing view icons in the gutter, and, respectively disabling or enabling [creation of views](#). In the Project tool window, such methods are marked as  $\text{m}$  and  $\text{m}$  icons respectively.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Though a view for a controller is added by default on controller creation, it is also possible to define individual views for each public method of a controller.

## To create a view for a method

1. Open a controller in the editor, and locate the desired method.
2. Click the view icon in the left gutter of the editor:

```
def make_a_pest  
end
```

3. If a view associated with the method exists, it is opened in the editor. If a view doesn't exist, IntelliJ IDEA informs that the corresponding view is not found, and suggests to create a new one:

Specify the name of the view file. By default, IntelliJ IDEA suggests `.html.erb`. However, you can specify `.haml` file as well. Click OK. The new view file opens in the editor.

4. Edit view contents as required. Note that you can insert Ruby code in view, surrounded with the `<%` and `%>` characters. Refer to the section [Injecting Ruby Code in View](#) for details.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

View files contain markup and islands of Ruby code. Any text in view files will be perceived as Ruby code in the following cases:

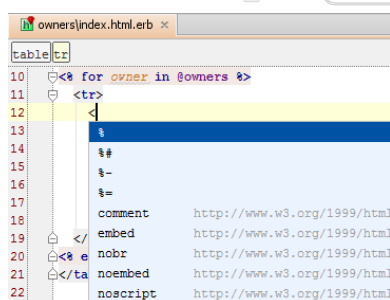

- In \*.html.erb files, if such text is surrounded with `<%` and `%>` characters.
- In \*.html.haml files, if such text follows the equals sign. Besides that, Ruby strings are correctly interpreted if preceded with `==`.

Thus, having inserted the enclosing characters in view, you can type Ruby code, enjoying the Ruby-aware syntax and error highlighting and all sorts of coding assistance:

```
<h1>Cats#foo</h1>
<p>Find me in app/views/cats/foo.html.erb</p>
<div class="cat hunts">
  <% if flash[:notice] %>
    <h4><%= flash[:notice] %></h4>
  <% end %>
</div>
%h1 Cats#foo
%p = 'Find me in app/views/cats/foo.html.haml'
%q = 'Find me in app/views/cats/foo.html.haml'
%div
%class = 'cat hunts'
%p = if flash[:notice]
%h4 = flash[:notice]
```

## To inject Ruby code in a \*.html.erb view, do one of the following

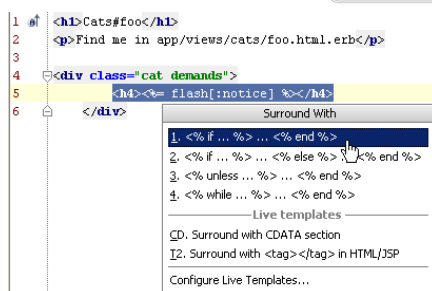

- Type the opening angle bracket `<`, press `Ctrl+Space`, and select `%` from the suggestion list:

IntelliJ IDEA automatically completes the closing characters. So doing, the caret rests in the next editing position within the `<%` and `%>` characters.

- Press `Ctrl+Shift+Period` to insert both opening and closing characters.

- Apply one of the [surround templates](#), using `Ctrl+Alt+T`:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA integrates with [Warbler](#), providing the possibility to generate `.war` archive of an application. Integration with Warbler requires JRuby.

Upon installing the `warbler` gem, the `warble` command becomes available from the console. Besides that, the Tools | Build WAR command appears on the main menu.

Note that Build WAR file command recognizes the type of the interpreter and gems in project, and suggests to configure the proper versions.

## To generate a web archive

1. On the main menu, choose Tools | Build .WAR file .
2. Specify the name of the target archive in the field Output file name .
3. In the Build .WAR file dialog box, select the checkboxes next to the directories and files you want to include in the target archive.
4. Enable or disable the following behavioral options, as required: Executable - if this checkbox is selected, the target archive will be executable.

Precompiled - if this checkbox is selected, the Ruby files will be compiled into `.class` files.

Include gem repository - if this checkbox is selected, the gem repository will be included into the archive.

Turn on invoke/execute tracing, enable full backtrace - if this checkbox is selected, the tracing mode will be enabled.

5. Select one or more files to be included into the `WEB-INF` directory of the web archive, and press the WEB-INF config button.
6. Click OK to generate the archive.

In this section:

- [Introduction](#)
- [Generating tests](#)

## Introduction

If for some reason you have a Rails entity without a related test, note that IntelliJ IDEA suggests a way to generate tests for the controllers, mailers, models, and helpers in the [RSpec](#) and [Test:Unit](#) testing frameworks.

## Generating tests

### To generate a test for a Rails entity, follow these general steps

1. In the editor, place the caret at the desired Rails entity.
2. Do one of the following:
  - On the main menu, choose `Navigate | Test`.
  - On the context menu, choose `Go To | Test`.
  - Press `Ctrl+Shift+T`.
3. If the desired test doesn't yet exist, the pop-up `Generate Test` appears. In this window, choose the testing framework:  
If the related testing framework is missing, IntelliJ IDEA will suggest to install the missing gem (for example, `rspec-rails`):

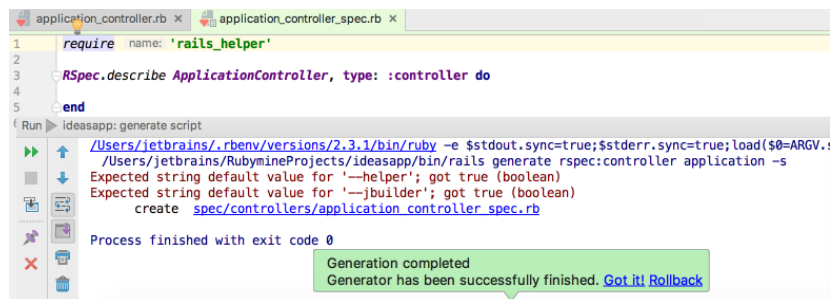

Missing gem  
Gem 'rspec-rails' not found. [Bundle it](#) [Dismiss](#)

4. Click `Bundle it` to add the gem to the Gemfile, and in the `Bundle Install` dialog run the bundler:

The IDE will install the missing gem and generate the test in the specified format in the directory with the Rails entity name (for example, `controllers` or `models`) under the `spec` or `test` directory, depending on the testing framework selected.

You can roll this action back in case something goes wrong.

- Note**
- `Generating missing tests` feature doesn't create helpers. So the test helpers for the generated tests should be created manually.
  - Other new frameworks will be added later. See <https://youtrack.jetbrains.com/issue/RUBY-19144>.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

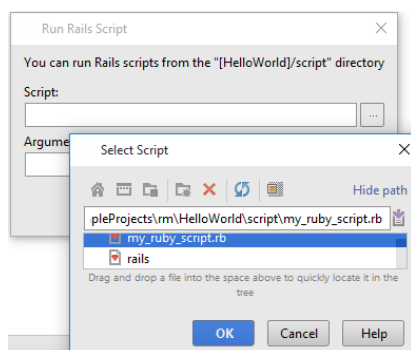

IntelliJ IDEA enables you to execute Rails scripts using a single menu command. By default, IntelliJ IDEA suggests the scripts that reside in the `[<project name>]/script` directory of your Rails application.

Results for each script are displayed in its own Run Rails Script tab of the Run tool window, where you can review the script output, change arguments if necessary, and rerun the script.

## To run a Rails script

1. On the main menu, choose Tools | Run Rails Script . Run Rails Script dialog box is displayed.
2. In the Script field, specify the desired script. If the script resides in the `[<project name>]/script` directory, type its name only. If the script resides in another directory, type its fully qualified name.

Alternatively, click the browse button  (`Shift+Enter`) and select the necessary location in the [dialog that opens](#) . Note that this dialog displays only the contents of the `[<project name>]/script` directory.

3. In the Arguments field, specify the script's arguments, if any. The arguments should be separated with spaces.

Alternatively, open the Edit Arguments dialog box by clicking the editor button , or pressing `Shift+Enter` , and type the list of arguments.

4. Click Run .

## To rerun a Rails script with new arguments

1. In the Run tool window, click the desired Run Rails Script tab.
2. In the toolbar of the Run tool window, click  . Edit Command Line Arguments dialog box is displayed.
3. In the Edit Command Line Arguments dialog box, type the new arguments separated with spaces, and click OK .
4. In the toolbar of the Run tool window, click  , or press `Ctrl+F5` .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

For each Rails application project, IntelliJ IDEA provides default Rails run/debug configurations for the production and development environments.

IntelliJ IDEA supports a number of Rails servers (Mongrel, WEBrick, Phusion Passenger, etc., depending on the specific platform).

Rails server runs in the dedicated tab of the [Run tool window](#), named after the respective run/debug configuration. So doing, the server output is displayed in the Console tab, and the other information is displayed in the Server <environment type> log tab:

```
Run Development: my_app
Console Server development log x
"C:\Program Files (x86)\JetBrains\RubyMine 8.0\bin\runnerw.exe" C:\Rubies\jru
io/console not supported; tty will not be manipulated
=> Booting WEBrick
=> Rails 4.2.5 application starting in development on http://127.0.0.1:3000
=> Run 'rails server -h' for more startup options
=> Ctrl-C to shutdown server
[2015-11-17 17:27:40] INFO WEBrick 1.3.1
[2015-11-17 17:27:40] INFO ruby 1.9.3 (2015-08-20) [java]
[2015-11-17 17:27:40] INFO WEBrick::HTTPServer#start: pid=9588 port=3000
```

## To run a Rails server

1. Press `Shift+Alt+F10`, and choose the desired Rails run/debug configuration type.
2. If necessary, change the run/debug configuration settings. To do that, choose Edit configurations... in the Run popup menu, and choose the desired Rails configuration type. [Rails run/debug configuration](#) dialog box appears.

In this dialog box, modify the desired settings. For example, IntelliJ IDEA suggests WEBrick as the default Rails server. You can select a different server from the list of supported servers.

3. Click the  button on the main toolbar.

**Tip** You can opt to preview results of your Rails application immediately in a browser. For this purpose, [change](#) the selected Rails run/debug configuration to enable launching a built-in browser. To do it, select the Run browser checkbox, and specify the desired IP address.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

[Phusion Passenger](#) (including version 5 with the code name [Raptor](#) ) can be selected as a Rails server in a [Rails run/debug configuration](#) .

## Prerequisite

– The corresponding gem should be installed. If the gem is missing, IntelliJ IDEA suggests to install it.

## Notes and limitations

- [Raptor](#) support is available for macOS and Linux systems.
- IntelliJ IDEA creates an initializer file `config/initializers/rubymine-passenger-debug.rb` .
- Phusion Passenger initializer is used only for Phusion Passenger debugger; execution of Rails applications is not affected.
- Use Phusion Passenger with only those settings that are specified in the console.
- The Phusion Passenger `prespawn` script should load the dynamic content generated by Rails, but not a static page.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

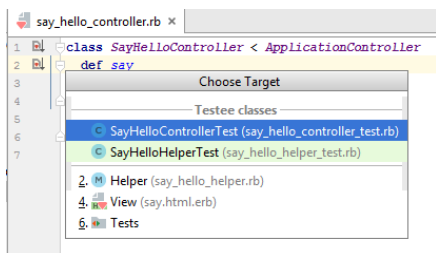

This section describes navigation features that are specific for Rails applications:

- [Navigating Between Rails Components](#)
- [Navigating to Controllers, Views and Actions Using Gutter Icons](#)
- [Navigating to Partial Declarations](#)
- [Navigating with Model Dependency Diagram](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA helps easily navigate between the Rails components: controllers, views, models, helpers and tests, using the `Navigate | Related Symbol` command, which is available from the editor, tool windows, and the Model Dependency diagram:

## To navigate between the Rails components

1. Do one of the following:
  - On the main `Navigate` menu, choose `Related Symbol`.
  - Press `Ctrl+Alt+Home`.
2. Select the desired target from the pop-up menu, or press a mnemonic key, specified to the left of the desired Rails component name.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In the editor, use the following gutter icons to jump between controllers, views, and actions:

- : This layout is associated with a controller.
- : This layout is associated with an action.
- : This action is associated with a view, or this controller is associated with a partial view.

The target component is opened in the editor tab.

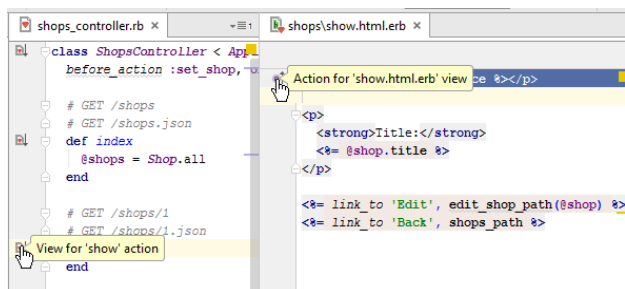

## To navigate between Rails components in the editor

- Open a component in the editor, and click the desired gutter icon. For example, if you want to jump to a view file associated with an action, open the corresponding controller, locate the desired action, and click the gutter icon next to the action definition.

If several different types of views are available (for example, localized views or HAML files), IntelliJ IDEA suggests the list of all available views, from which you can select the one you need:

To navigate from a view to the corresponding action, open the view file in the editor, and click the gutter icon:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

The gutter icon in the editor marks a partial declaration. Pointing to this icon shows quick information about the other parts of the same declaration.

You can navigate to the desired part of the declaration that will be opened in a separate editor tab.

## To navigate to a partial declaration

1. Open the desired component in the editor, and click the gutter icon in the left gutter.
2. In the Select Partial Declaration pop-up menu, choose the desired part of the declaration:

The selected component is opened in a separate editor tab, and gets the focus.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

With IntelliJ IDEA, you can navigate between Model Dependency and the corresponding models and associations.

In this section:

- [Navigating between Model Dependency diagram and the source code](#)
- [Tips and tricks](#)

## Navigating between Model Dependency diagram and the source code

### To navigate from a Model Dependency diagram to the source code

1. On the Model Dependency diagram, select the desired node or edge.
2. Do one of the following:
  - Press **F4**
  - On the context menu, choose Jump to Source.
  - Double-click selected node.

### Tips and tricks

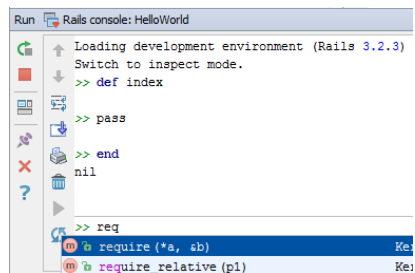

- In a model declaration source code, it is enough to choose Show Model Dependency Diagram on the context menu.
- If you have selected an edge that corresponds to a one-to-many or many-to-many association, IntelliJ IDEA suggests to choose which part of the association should be navigated to:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

If you are used to working in the Rails console, you can do it without leaving IntelliJ IDEA. The console provides syntax highlighting, and commands history. Once started, the Rails console opens in a separate tab in the [Run tool window](#) . Note that you can launch as many Rails consoles as required.

```
Run Rails console: HelloWorld
Loading development environment (Rails 3.2.3)
Switch to inspect mode.
>> def index
>> pass
>> end
nil
>> req
require (*a, sb) Ke:
require_relative (p1) Ke:
```

## To launch the Rails console

1. On the main menu, choose Tools | Run Rails console .
2. In the Select Rails Environment dialog box, select the desired environment from the drop-down list, and click OK .

**Tip** IntelliJ IDEA provides a dedicated [run/debug configuration for consoles](#) . When a console is launched, it is done via the corresponding temporary run/debug configuration. You can save such configuration as permanent for further use.

– For the techniques of working with the console, refer to the section [Using Consoles](#) .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

IntelliJ IDEA completely supports ORM in Rails, which includes model and migration generators, and the ability to view models and their relationships over a Rails application in the Model Dependency diagram.

**Warning!** Make sure that the desired database server is installed on your machine and is running in the background.

In this section:

- [Creating Models](#)
- [Viewing Model Dependency Diagram](#)
- [Editing Model Dependency Diagrams](#)
- [Creating Relationship Links Between Models](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Generators for creating models](#)
- [Creating models](#)

## Generators for creating models

IntelliJ IDEA makes it possible to stub out models using the Rails generators:

- The model generator creates a model class that defines a database table, and a migration that defines columns within the table. Besides that, a unit test and a test fixture are created.
- The scaffold generator creates a model class that defines a database table, and a migration that defines columns within the table. Besides that, a controller, forms and the other necessary resources are created.

### To create a model

1. Do one of the following:
  - Choose New on the context menu of an editor or Project tool window, or press `Alt+Insert`, and then choose New - Run Rails Generator.
  - Run Rails generator: choose Tools | Run Rails Generator.
  - With a Model Dependency diagram having the focus, choose New - Model on the context menu of the diagram background, or press `Alt+Insert`.
2. In the dialog box that opens, start typing the generator name, for example, `model` or `scaffold`.

Note that for creating models in diagram, only `model` generator is used.

3. Type the name of a model to be created, in singular, and the list of fields and their types. Note that [code completion](#) is available for the field types.

A migration is created.

4. Create columns in the table. To do that, you have to run the migration in one of the following ways:
  - Run migration as a [script with the temporary run configuration](#). Click the migration hyperlink in the console to open the migration file in the editor:

Then press `Ctrl+Shift+F10`. In this case the current migration runs in the `development` environment, or in the one defined in the `environment.rb` file.

- Run migration as a [Rake task](#). For example, you can choose Tools | Run Rake Task on the main menu, and start typing `mig`. Then select `db:migrate` from the suggestion list. In the Execute `db:migrate` dialog box, select the desired migration, and the environment that defines the database to which the migration will be applied.

The results is shown in the Run tool window:

```
Run db:migrate: RubymineProjects
/Users/.rvm/gems/ruby-2.3.1/bin/ruby -e $stdout.sync=true;$stderr.sync=true;load($0=ARGV.shift)
/Users/.rvm/gems/ruby-2.3.1/bin/spring rails db:migrate
== 20161219142747 CreateLibraries: migrating =====
-- create_table(:libraries)
=> 0.0013s
== 20161219142747 CreateLibraries: migrated (0.0013s) =====
Process finished with exit code 0
```

Once a model is created, you can view all the fields declared in this model, in the [Rails view](#) , and navigate from these table column to the corresponding methods.

**Note** A model can be created without fields. In this case, the corresponding table in the target database will contain no columns. You can add fields later using migrations.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Model dependency diagram enables you to get an overview of the models within your application, and analyze their relationships.

## To open the Model Dependency diagram of a project

1. Do one of the following:
  - On the context menu of the Project tool window, or the editor, point to Diagrams , and choose Show Diagram or Show Diagram Pop-up .
  - Press `Ctrl+Shift+Alt+U` , or `Ctrl+Alt+U` .
2. Select the type of diagram from the pop-up window:

**Tip** If you invoke Model Dependency diagram for a specific model, the diagram will open with the model in question centered and having the focus, and zoomed to actual size.

## In the Model Dependency diagram, you can perform the following operations

- [Select elements](#) .
- [Add notes, delete elements](#) .
- [Change diagram layout](#) .
- [Change diagram scale](#) .
- [Navigate to source code](#) .
- [Navigate through the models using the Structure view](#) (`Ctrl+F12` ) .
- [Find usages of the selected node element](#) .
- [Invoke refactoring commands](#) .

**Tip** Keeping the `Alt` key pressed invokes the magnifier tool, which will help you have a closer look at the most interesting or problematic areas of your Model dependency diagram.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

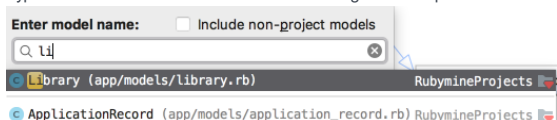

Once a model exists in a IntelliJ IDEA project, it can be shown in a Model Dependency diagram either by [adding](#) , or by [dragging](#) . So doing, all relationship links between models are built automatically.

It is also possible to [remove from view](#) the models that are irrelevant to the current presentation. So doing, no files are physically deleted.

A new model can be created from a Model Dependency diagram, as described in the section [Creating Models](#) .

## To add a model to a Model Dependency diagram

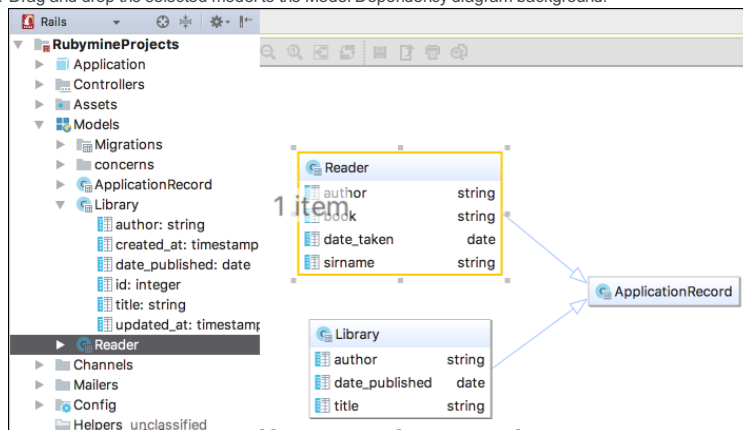

1. Press `Space` .
2. Type the name of the desired model in the dialog box that opens.

3. Select model from the suggestion list, and press `Enter` .

## To drag a model to a Model Dependency diagram

1. Select the desired model in the [Rails view](#) .
2. Drag and drop the selected model to the Model Dependency diagram background.

## To remove elements from view

1. In the diagram, select one or more elements to be deleted.
2. Press `Delete` .

The Model Dependency diagram reflects links between the models, specified in the source code.

## To show relationship links between models, follow these general steps

1. Open for editing the desired model classes. You can do that by choosing a model class in the Rails view, or in the Model Dependency diagram, and pressing **F4**.

2. In the editor, add relationship statements to the respective classes. For example:

```
class Owner < ActiveRecord::Base
  attr_accessible :first_name, :last_name, :pet_name
  has_many :pets
end

...

class Pet < ActiveRecord::Base
  attr_accessible :age, :nickname, :species, :owner
  belongs_to :owner
end
```

3. Switch to the Model Dependency diagram, and see the relationship links between the models, with edge labels.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Executing Rails development tasks sometimes involves overheads, because every time the entire Rails environment should be reloaded. You can avoid it using the [Zeus server](#), which loads the environment only once.

- Zeus
  - [Changes to the UI](#)
  - [Launching Zeus server](#)
  - [Managing Zeus server](#)
- [Debugging Rails Applications under Zeus](#)
- [Debugging Rake Tasks under Zeus](#)
- [Executing Tests on Zeus Server](#)

## Prerequisites

- You are working with macOS or Linux operating system.
- Prior to launching Zeus server, make sure [zeus](#) gem, and the corresponding testing gems (`rspec-rails`, `cucumber`, `cucumber-rails`, etc.) are used in your application.
- It is possible to run Zeus server without adding [zeus](#) gem to Gemfile. It is enough to install the zeus gem to the currently selected sdk/gemset.

## Changes to the UI

- As soon, as [zeus](#) is added to your application, the command Tools | Run Zeus server... appears on the main menu.
  - Default [run/debug configuration for Zeus server](#) is added.
- When Zeus server is launched for the first time, IntelliJ IDEA creates a temporary [run/debug configuration](#). Later you can change this run/debug configuration as required, save it as permanent, and use it to run the server.

### To launch Zeus server

- On the main menu, choose Tools | Run Zeus server... .

The Zeus server starts in a separate tab of the Run tool window.

## Managing Zeus server

Refer to the description of the [Run tool window](#). In particular, use the following buttons:

-  - stop the Zeus server without closing its tab in the Run tool window.
-  - close the Zeus server tab.
-  - rerun Zeus server in the same tab.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## To debug a Rails application, when using Zeus, follow these general steps

1. Make sure the breakpoints are set in the Rails application script you want to debug.
2. Do one of the following:
  - On the main menu, choose Tools | Run Zeus Server
  - On the main toolbar, click the run/debug configuration selector, and choose Edit Configurations . Then, in the [Run/Debug Configurations Dialog](#) dialog box, create run/debug configuration for Zeus server. Refer to the section [Creating and Editing Run/Debug Configurations](#) for detailed description of the procedure. Note that you must specify `start` in the Commands field to start the server.
3. Launch Zeus in the debug mode. To do that, with the Zeus run/debug configuration selected, click  , or press `Shift+F9` .
4. With the Zeus server running in the debug mode, run the desired Rails application script.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## To debug a Rake task, when using Zeus, follow these general steps

1. Make sure the breakpoints are set in the Rake task script you want to debug.
2. Do one of the following:
  - On the main menu, choose Tools | Run Zeus Server
  - On the main toolbar, click the run/debug configuration selector, and choose Edit Configurations . Then, in the [Run/Debug Configurations Dialog](#) dialog box, create run/debug configuration for Zeus server. Refer to the section [Creating and Editing Run/Debug Configurations](#) for detailed description of the procedure. Note that you must specify `start` in the Commands field to start the server.
3. Launch Zeus in the debug mode. To do that, with the Zeus run/debug configuration selected, click  , or press `Shift+F9` .
4. With the Zeus server running in the debug mode, run the desired Rake task script.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Basics](#)
- [Tips and tricks](#)

## Basics

Running test suits sometimes involves overheads, because every time a test suit is executed, the whole environment (for example, the entire environment for applications) should be reloaded. You can avoid it using the [Zeus server](#), which loads the environment only once.

With the Zeus server running in the background, you have a choice to execute any testing script [using the Zeus server](#), or locally.

### To run a test script using the Zeus server

1. Make sure that Zeus server is launched using IntelliJ IDEA and is running in the background.
2. [Run](#) a test script, or one of its examples. Note that the option Zeus is automatically selected in the corresponding run configuration. If you want to run this test locally, you have to select the option None .

**Tip** If you are going to run RSpec tests under Zeus server, make sure to use Zeus version 0.13.4.pre2, or higher.

### To debug tests, when using Zeus, follow these general steps

1. Make sure the breakpoints are set in the test script you want to debug.
2. On the main toolbar, click the run/debug configuration selector, and choose Edit Configurations .
3. In the [Run/Debug Configurations Dialog](#) dialog box, create run/debug configuration for Zeus server. Refer to the section [Creating and Editing Run/Debug Configurations](#) for detailed description of the procedure.
4. Launch Zeus in the debug mode. To do that, with the Zeus run/debug configuration selected, click , or press `Shift+F9` .
5. With the Zeus server running in the debug mode, run the desired test script.

**Note** Note that if you debug a test script, it will be executed without Zeus server.

## Tips and tricks

- IntelliJ IDEA creates a temporary run/debug configuration for Zeus server. Later you can change this run/debug configuration as required, save it as permanent, and use it to launch the server.
- If both Zeus and Spork DRb servers are running simultaneously, it is Zeus that gets priority.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Executing Rails development tasks sometimes involves overheads, because every time the entire Rails environment should be reloaded. You can avoid it using the [Spring server](#), which loads the environment only once.

## Prerequisites

- You are working with macOS or Linux operating system.
- Prior to launching Spring server, make sure [spring](#) gem, and the corresponding testing gems ( `rspec-rails`, `cucumber`, `cucumber-rails`, etc.) are used in your application.
- [spring](#) gem is added to the Gemfile.  
Since Rails version 4.1, spring is added to the Gemfile by default.

## Changes to the UI

When spring is installed, Spring appears in the list of pre-loaded servers in the default run/debug configurations for [RSpec](#), [Test::Unit/Shoulda/Minitest](#), and [Cucumber](#).

It is important to note that there is no dedicated run/debug configuration for the Spring server. Spring server is launched by default.

## Special notes

- IntelliJ IDEA always uses [Spring server](#), if it is available for [Rails generators](#) and [Rake tasks](#).
- When debugging, the Spring server is turned off.
- Note that if you debug a test script, it will be executed without Spring server
- Use [additional commands](#) for running tests. However, `spring-commands-spinach` is not used.
- It's possible to turn the Spring pre-loader off by clicking `Ctrl+Shift+A`, typing Spring and choosing Spring pre-loader from the suggestion list:

- IntelliJ IDEA runs spring related commands with the custom `SPRING_TMP_PATH={temp_dir}/RMSpring` property. To deal with IntelliJ IDEA `spring`, you should prepend spring server commands with `SPRING_TMP_PATH={temp_dir}/RMSpring`. Exact spring working directory can be found in a log file using the pattern `"Moving Spring to "`.

IntelliJ IDEA tries to stop spring on project closing and on modules gems rebuilding.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

## Prerequisites

- In Rails applications , Rake tasks are recognized when placed in `.rake` files under `lib/tasks` directory, or in Rakefile.
- In plain Ruby applications , Rake tasks are recognized when placed in Rakefile.

## Rake support

Rake support in IntelliJ IDEA includes:

- Syntax and error highlighting.
- Structure view that shows the structure of a Rake task opened in the editor.

- Possibility to [create](#) and [run](#) Rake tasks.
- Available Rake tasks appear in the [Go to Symbol](#) suggestion list.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Sometimes you cannot find the task you need in the list of available Rake tasks. If this is the case, reload Rake tasks.

### **To reload Rake tasks**

1. On the main menu, choose Tools | Run Rake Tasks .
2. In the pop-up menu that opens, choose Reload Rake tasks list .

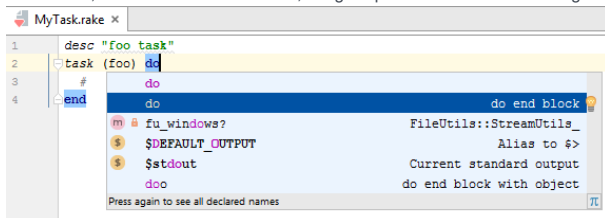

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

After IntelliJ IDEA restart, or after reloading Rake tasks, the \*.rake files become available in the [Run Rake Task pop-up](#).

## To create a Rake task

1. Right-click the target directory `lib/tasks` where you want the new Rake script to be added, and choose New | File on the context menu.
2. In the New File dialog box, specify the Rake task name, followed by the `.rake` extension, and click OK.
3. In the editor, create the desired contents, using the powerful IntelliJ IDEA coding assistance:

```
1 desc "foo task"
2 task :foo do
3   #
4   do
5     FileUtils::StreamUtils_
6   end
7 end
8
9 $DEFAULT_OUTPUT Alias to $>
10 $stdout Current standard output
11 doo do end block with object
12
13 Press again to see all declared names
```

After IntelliJ IDEA restart, or after reloading Rake tasks, the new \*.rake files will be included in the list of available Rake tasks.

**Tip** If a Rake task has a description, it is included in the list of available tasks by default.

– If a Rake task description is missing, you can still see it in the list of Rake tasks, if the you select the checkbox [Include undocumented](#) in the [Run Rake Task pop-up](#).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Use Run Rake Task command on the Tools menu, and select the desired task from the list.

## To run a Rake task

1. On the main menu, choose Tools | Run Rake Task .
2. In the pop-up window, start typing the task name, or its part. IntelliJ IDEA shows the list of matching Rake tasks. If you want to see all the available tasks, including those without description, select the checkbox Include undocumented .
3. Select the desired task from the suggestion list, and press `Enter` .
4. In the Execute '<Rake task>' dialog box, specify the script arguments, if any, and select the desired environment from the drop-down list.  
If necessary, enable the `--trace` option by selecting the Full backtrace checkbox. This option is the same as in the Rake run/debug configuration; as soon as this option is set in the run configuration dialog box, it is also set in the Run Rake Task dialog box, and vice versa.

This behavior is common for the majority of Rake tasks. However, the migration tasks behave differently. Instead of the list of arguments, one should specify the migration version. By default, IntelliJ IDEA suggests the latest migration version, while all the other migrations that exist in project, are available in the suggestion list.

For the following migration tasks

- `db:migrate:up`
- `db:migrate:down`

depending on the context where they are invoked, IntelliJ IDEA suggests by default the migration that is currently selected in the Project tool window, or open in the editor. So doing, the editor has the priority: if a certain migration is selected in the Project tool window, and another one is open in the editor, and the editor gets the focus, the default migration version will be the one in the editor .

5. Click OK .

**Tip** Note for macOS users: If [Zeus server](#) is already running, all Rake tasks run by default on Zeus.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Introduction](#)
- [Debugging a script or an application remotely](#)

## Introduction

IntelliJ IDEA provides the possibility of remote debugging for Ruby and Rails applications, using the dedicated [Ruby remote debug configuration](#). So doing, IntelliJ IDEA keeps mapping between the local sources, and the sources on the server side.

Several debug processes can be launched simultaneously. So doing, each remote debug process starts in a separate tab in the Debug tool window, with the name Remote debug for <script name>. You can work with each debugging session as usual.

## Debugging a script or an application remotely

### To debug a script or an application remotely, follow these general steps

1. Start remote debug session.

The common format of the command to be run on the remote host is as follows:

```
rdebug-ide --host 0.0.0.0 --port <port number> --dispatcher-port <port number> -- $COMMAND$
```

You can see this command as a tip in the [Ruby remote run/debug configuration](#) dialog.

Note that there is a difference between a Ruby script and a Rails application. For example, the command for a Ruby script will be:

```
rdebug-ide --host 0.0.0.0 --port 1234 --dispatcher-port 26162 - /home/user/RubymineProjects
```

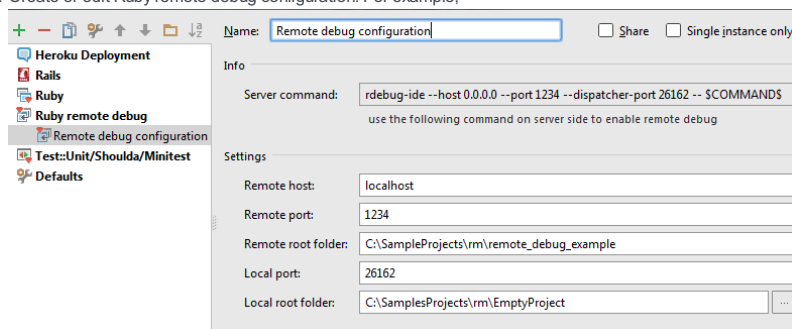

The command for a Rails application will be:

```
rdebug-ide --port 1236 --dispatcher-port 26166 --host 0.0.0.0 - bin/rails s -b 0.0.0.0
```

In both cases port is the port number on the remote host. dispatcher-port is the port number on the local host.

2. Create local copy of the script or application to be debugged, and then set the required breakpoints.

3. Create or edit Ruby remote debug configuration. For example,

4. In IntelliJ IDEA, select the desired Ruby remote debug configuration, open Ruby script or Rails application in the editor, and click  on the main toolbar.

**Tip** Note that a cancel button has been added to the Connecting to debugger progress bar, giving you the way to manually cancel remote debugging session, rather than waiting for a timeout.

See the detailed instructions in the [tutorial](#).

In this section:

- [Prerequisites](#)
- [Puppet support](#)
- [Creating a Puppet module](#)
- [Installing dependencies](#)
  - [Typical workflow](#)

## Prerequisites

Before you start working with Puppet, make sure that the Puppet Support plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#).

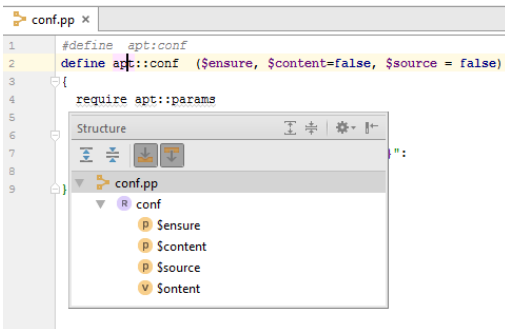

Also, `puppet` gem should be installed on your Ruby SDK.

## Puppet support

Puppet files are marked with .

Puppet support in IntelliJ IDEA includes:

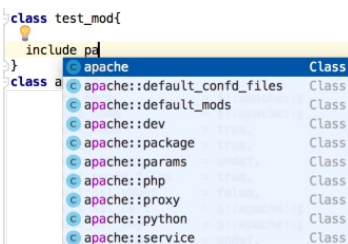

- Compliance with the [Puppet Style Guide](#).
- Syntax and error highlighting.
- Ability to [rename](#) Puppet elements.
- Code completion in `*.pp` files.
- Configuring code style for Puppet files.
- Structure view:

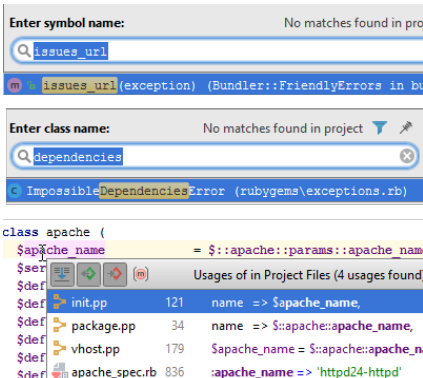

- [Code completion](#) :

Moreover, with the [dependencies installed](#), navigation and completion for each module work in strict accordance with the dependencies. For example, if you are editing a module depending on `puppetlabs-apache`, then you see `apache` in code completion:

- Navigation to a class definition, symbol, class or a usage is available:

- [Future parser](#).

- Support for the [EPP template language](#) .
- IntelliJ IDEA correctly identifies the `.epp` files, recognizes the native EPP syntax and [auto-completes](#) expressions and parameter tags:

```

1  <% | Boolean $firstparam, $secondparam, Enum[Boolean,
2  Boolean Data Type
3  #C Use → to overwrite the current identifier with the chosen variant
4  <% if $firstparam == 1{
5  notice 'foo'
6  }

```

Moreover, IntelliJ IDEA allows you to navigate between a manifest and a template called.

- **Rename** refactoring is available for the variables and parameters in the `.epp` files:

```

1  <% | Boolean $firstparameter, $secondparam, Enum[Boolean, Integer] $thirdparam | %>
2
3  #condition
4  <% if $firstparameter == 1{
5  notice 'foo'
6  }

```

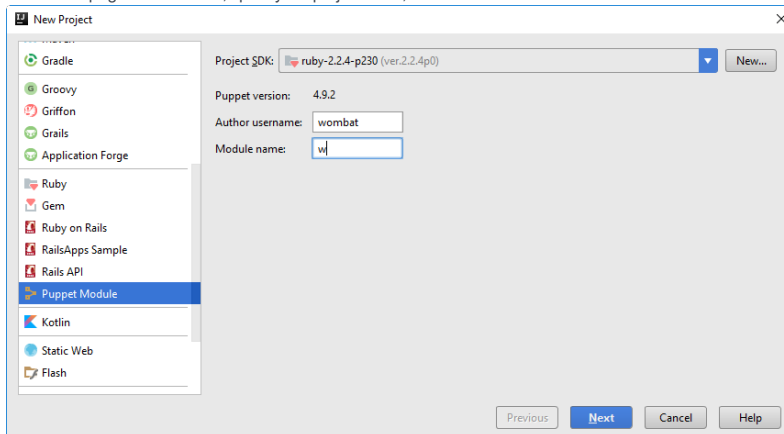

- **Finding usages** is available for template files (`Alt+F7`).

For more information, see the blog post [here](#) .

## Creating a Puppet module

### To create a Puppet Module, follow these steps

1. On the main menu, choose File | New | Project... . You can also click the Create New Project link on the [Welcome Screen](#) .
2. On the first page of the wizard, specify the project SDK, author's username and module name.

If Puppet gem is not installed, then instead of the Puppet gem version you'll see the suggestion to install the gem:

Puppet version: [Install Puppet gem](#)

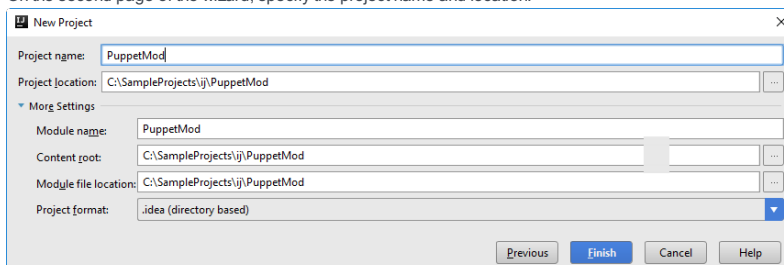

For the macOS and \*NIX users: When choosing project SDK, you can select an RVM gemset from the existing ones, or create a new one:

Refer to the page [Configuring Gemsets](#) for details.

Click Next

3. On the second page of the wizard, specify the project name and location:

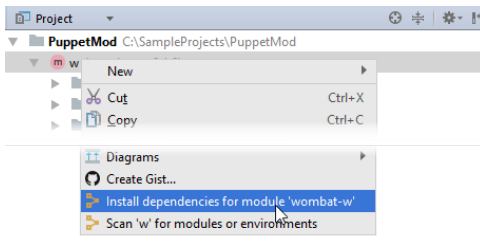

4. When ready, click Finish .

The project is created in the specified location. So doing, the created project features the structure of a Puppet module.  
Refer the [Puppet documentation](#) for details.

## Installing dependencies

There is an action in the Project tool window that enables installing dependencies into a Puppet module:

Puppet modules recognize dependencies from 3 different sources:

1. If the file `.fixtures.yml` exists in a Puppet module, then the dependencies are installed into the directory `spec/fixtures/modules`, no other sources being checked.
2. If a `Puppetfile` exists in a Puppet module, then the dependencies are installed using `librarian-puppet` into `.dependencies` directory. If a `Puppetfile` exists, `librarian-puppet` ignores dependencies specified in `metadata.json`.
3. If a `metadata.json` file exists in a Puppet module, then the dependencies are installed using `librarian-puppet` into `.dependencies` directory.

## Typical workflow

Here's how it works...

### To work with a Puppet project, follow these general steps:

1. Open or [create a Puppet module](#).
2. If installing dependencies from the files `Puppetfile` or `metadata.json`, make sure that the gem `librarian-puppet` is installed. If the gem is not yet installed, IntelliJ IDEA notifies you about the missing gem and suggests to install it:

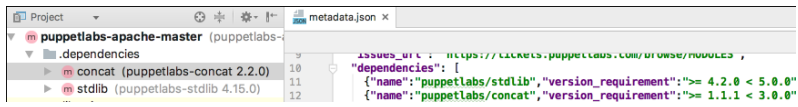

The screenshot shows a notification message in a red box: 'Gem 'librarian-puppet' is not available in SDK 'ruby-2.2.3-p173''. Below the message is a blue link: 'Try to install gem 'librarian-puppet''.

(If the dependencies are installed from `.fixtures.yml` file, this gem is not required, and no notification will be shown.)

IntelliJ IDEA can find all modules/environments in a project automatically, based on dependencies files, and updates the project structure accordingly, if anything has changed. Even if IntelliJ IDEA fails to update your project structure after installing additional modules into the project using the terminal, you can manually rescan the directory for modules or environments by using Scan for modules and environments action on the context menu.

3. Having placed the dependencies in the file `.fixtures.yml`, `Puppetfile` or `metadata.json`, right-click the [Project Tool Window](#), and then choose Install dependencies for module <module name> on the context menu.

So doing, the dependencies are taken from the files `.fixtures.yml`, `Puppetfile` or `metadata.json`, located in the project root. The folder `.dependencies` (in case of creating dependencies from `Puppetfile` or `metadata.json`) or `spec/fixtures/modules/` (in case of creating dependencies from `.fixtures.yml`) is created under the project root, if it didn't exist before.

The screenshot shows a code editor window with a file named 'metadata.json'. The left sidebar displays a project tree for 'puppetlabs-apache-master' with a subfolder '.dependencies' containing 'concat (puppetlabs-concat 2.2.0)' and 'stdlib (puppetlabs-stdlib 4.15.0)'. The main editor area shows the following JSON content:

```
issues_url : https://tickets.puppetlabs.com/browse/modules ,
"dependencies": [
  {"name": "puppetlabs/stdlib", "version_requirement": ">= 4.2.0 < 5.0.0"}
  {"name": "puppetlabs/concat", "version_requirement": ">= 1.1.1 < 3.0.0"}
]
```

If you want to add more dependencies, invoke this command again.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

The [Scala](#) Plugin extends IntelliJ IDEA with the full-scale functionality for Scala development.

The Scala plugin support include the following features:

- Full Scala language support
- [Syntax and error highlighting](#)
- Scala [run/debug configurations](#) , [inspections](#) , [intention actions](#) , and [refactorings](#) .

The Scala plugin also supports the following tools and frameworks:

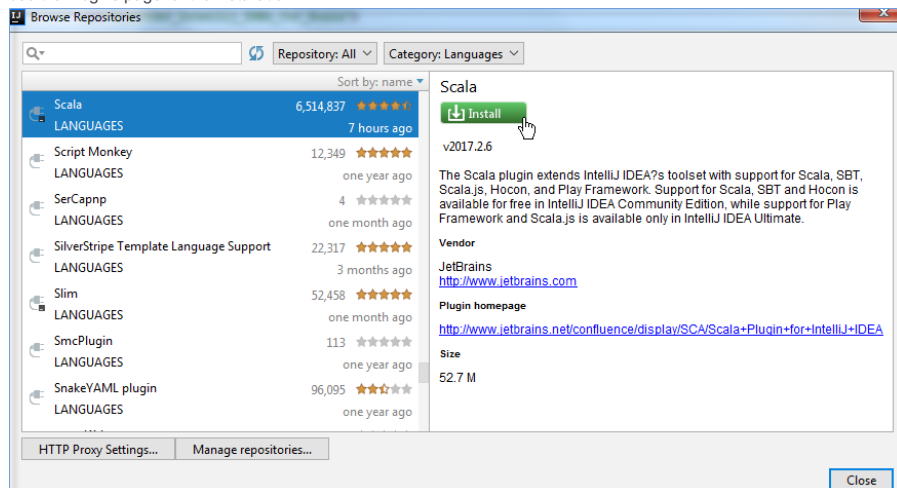

- [SBT](#)
- [SSP](#)
- [HOCON](#)
- [Play 2](#)
- [Dotty](#)

Before you start working with the plugin make sure that the following prerequisites are met:

- The Scala SDK is downloaded and installed on your machine. IntelliJ IDEA supports the Scala versions 2.8 and later.
- The Scala plugin is downloaded and enabled in IntelliJ IDEA.

## Install Scala plugin

To start working with Scala in IntelliJ IDEA you need to download and enable the Scala plugin. If you [run IntelliJ IDEA for the first time](#), you can [install the Scala plugin](#) when IntelliJ IDEA suggests you to download featured plugins. Otherwise, you can use the [Plugins page](#) for the installation.

After the installation, IntelliJ IDEA will keep track of the plugin updates and will suggest you to update the plugin when a new version is available. You can also use the Plugin update channel at the *Updates* tab, located in Settings | Languages & Frameworks | Scala to check for Scala nightly, EAP, or release builds.

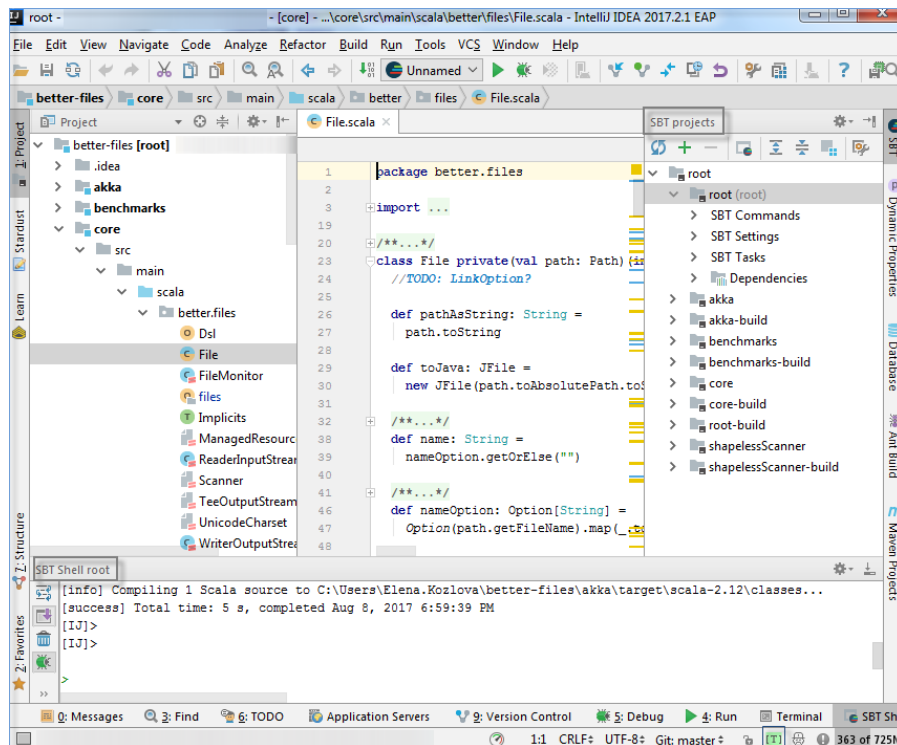

**Tip** To install Scala plugin from the Plugins page do the following:

1. Since you've already [installed and launched IntelliJ IDEA](#), select Configure | Plugins on the [Welcome screen](#). Alternatively, press `Ctrl+Alt+S` to access Settings. In a search field type *plugins* to locate Plugins from options on the left.
2. Click Browse Repositories and search for *Scala*.
3. Select the Scala plugin and click *Install* from the right-hand side of the page.
4. Restart IntelliJ IDEA

Now you can successfully check out from [VCS](#), create, or import Scala projects.

## User interface

The user interface for Scala looks similar to a regular one unless you work with SBT projects, in that case the *SBT projects* tool window and *SBT Shell* become available.

Also IntelliJ IDEA lets you keep track of error analysis based on the Scala type system using the Scala type-aware highlighting. By default, it is enabled and you can see the  icon located at the bottom of the user interface. You can click the icon or press `Ctrl+Shift+Alt+E` to disable this feature.

The most interesting part of the user interface is the IntelliJ IDEA [Editor](#) since it lets you invoke almost any IDE feature without leaving it, which helps you organize a layout where you have more screen space because auxiliary controls like toolbars and windows are hidden.

Accessing a tool window via its shortcut moves the input focus to it, so you can use all keyboard commands in its context.

When you need to go back to the editor, press `Escape` .

Below is a list of shortcuts that invoke the tool windows you will most often need:

Tool Window	Shortcut
Project	<code>Alt+1</code>
Version Control	<code>Alt+9</code>
Run	<code>Alt+4</code>
Debug	<code>Alt+5</code>
Terminal	<code>Alt+F12</code>
Editor	<code>Escape</code>

The *SBT projects* tool window and *SBT Shell* can be accessed via main menu ( `View | Tool Windows` ) or you can always press `Ctrl+Shift+A` to quickly search for these items.

When you want to focus on the code, try the [Distraction Free Mode](#) . It removes all toolbars, tool windows, and editor tabs. To switch to this mode, on the main menu select `View | Enter Distraction Free Mode` .

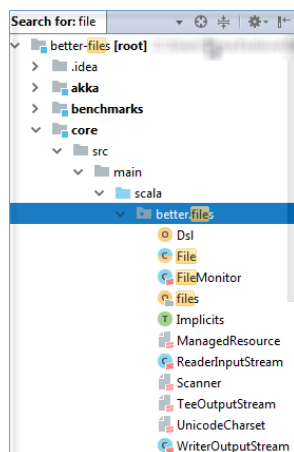

An alternative to the Distraction Free Mode may be hiding all tool windows by pressing `Ctrl+Shift+F12` . You can restore the layout to its default by pressing this shortcut once again.

The [Navigation Bar](#) is a compact alternative to the [Project Tool Window](#) . To access the Navigation Bar, press

`Alt+Home` .

Most components in IntelliJ IDEA (both tool windows and pop-ups) provide [speed search](#) . This feature allows you to filter a list, or navigate to a particular item by using a search query.

**Tip** When you don't know the shortcut for an action, try using the [Find action](#) feature by pressing `Ctrl+Shift+A` . Start typing to find an action by its name, see its shortcut or call it.

For more details, refer to [Guided Tour around the User Interface](#) , [Editor](#) , and [Tool Windows](#) .

## Editor basics

Since in IntelliJ IDEA you can undo refactorings and revert changes from [Local History](#) , it makes no sense to ask you to save your changes every time.

The most useful Editor shortcuts are:

Action	Description
Move the current line of code	<code>Ctrl+Shift+Up</code> <code>Ctrl+Shift+Down</code>
Duplicate a line of code	<code>Ctrl+D</code>
Remove a line of code	<code>Ctrl+Y</code>
Comment or uncomment a line of code	<code>Ctrl+Slash</code>
Comment a block of code	<code>Ctrl+Shift+Slash</code>
Find in the currently opened file	<code>Ctrl+F</code>
Find and replace in the current file	<code>Ctrl+R</code>
Next occurrence	<code>F3</code>
Previous occurrence	<code>Shift+F3</code>
Navigate between opened tabs	<code>Alt+Right</code> <code>Alt+Left</code>

Navigate back/forward	<code>Ctrl+Alt+Left</code> <code>Ctrl+Alt+Right</code>
Expand or collapse a code block in the editor	<code>Ctrl+NumPad Plus</code> <code>Ctrl+NumPad -</code>
Generate	<code>Alt+Insert</code>
Surround with	<code>Ctrl+Alt+T</code>
Highlight usages of a symbol	<code>Ctrl+F7</code>

To expand a selection based on grammar, press `Ctrl+W` . To shrink it, press `Ctrl+Shift+W` .

IntelliJ IDEA can select more than one piece of code at a time. You can select next occurrence via `Alt+J` and deselect by pressing `Shift+Alt+J` . You can even select all occurrences at once, by pressing `Ctrl+Shift+Alt+J` .

For more details, refer to [Editor](#) .

## Code completion

When you access **Basic Completion** by pressing `Ctrl+Space` , you get basic suggestions for variables, types, methods, expressions, for a parameter name you get type suggestions and so on. When you call **Basic Completion** twice, it shows you more results, including methods from implicit conversions that you can import.

The **Smart Completion** feature is aware of the expected type and data flow, and offers the options relevant to the context. To call **Smart Completion** , press `Ctrl+Shift+Space` . When you call **Smart Completion** twice, it shows you more results, including chains.

**Tip** To overwrite the identifier at the caret, instead of just inserting the suggestion, press `Tab` . This is helpful if you're editing part of an identifier, such as a file name.

To let IntelliJ IDEA complete a statement for you, press `N/A` . **Statement Completion** will automatically add the missing parentheses, brackets, braces and the necessary formatting.

If you want to see the suggested parameters for any method or constructor, press `Ctrl+P` . IntelliJ IDEA shows the parameter info for each overloaded method or constructor, and highlights the best match for the parameters already typed.

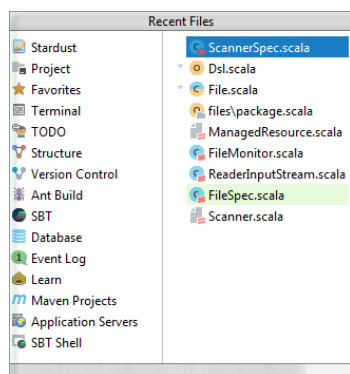

The **Postfix Completion** feature lets you transform an already typed expression to another one, based on the postfix you type after a dot.

For more details, refer to [Auto-Completing Code](#) .

## Navigation

### Recent files

Most of the time you work with a finite set of files, and need to switch between them quickly. A real time-saver here is an action called **Recent Files** invoked by pressing `Ctrl+E` . By default, the focus is on the last accessed file. Note that you can also open any tool window through this action:

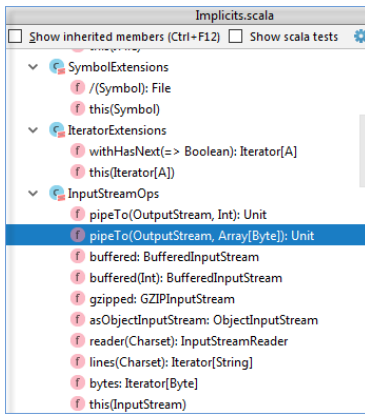

**Navigate to Class** is available by pressing `Ctrl+N` and supports sophisticated expressions, including camel humps, paths, line navigate to, middle name matching, and many more. If you call it twice, it shows you the results out of the project classes.

**Navigate to File** works similarly by pressing `Ctrl+Shift+N` , but is used for files and folders. To navigate to a folder, end your expression with the `Slash` character.

**Navigate to Symbol** is available by pressing `Ctrl+Shift+Alt+N` and allows you to find a method or a field by its name.

### Structure

When you are not switching between files, you are most probably navigating within a file. The simplest way to do it is to press `Ctrl+F12` . The pop-up shows you the structure of a file, and allows you to quickly navigate to any of them:

## Select in

If you need to open a file in a particular tool window (or Finder/Explorer), you can do so via the **Select In** action by pressing

**Alt+F1** :

Navigation shortcuts include:

### Action Shortcut

Search everywhere	Double Shift
Navigate to class	Ctrl+N
Navigate to file	Ctrl+Shift+N
Navigate to symbol	Ctrl+Shift+Alt+N
Recent files	Ctrl+E
File structure	Ctrl+F12
Select in	Alt+F1
Navigate to declaration	Ctrl+B
Navigate to type hierarchy	Ctrl+H
Show UML pop-up	Ctrl+Alt+U

For more details, refer to [Navigating Through the Source Code](#) .

## Quick pop-ups

**Quick Pop-ups** are helpful for checking additional information related to the symbol at the caret. Below is a list of pop-ups you should know if you want to be more productive:

### Action Shortcut

Type Info	Alt+Equals
Documentation	Ctrl+Q
Quick definition	Ctrl+Shift+I
Show usages	Ctrl+Alt+F7
Show implementation	Ctrl+Alt+B
Implicit conversions	Ctrl+Shift+Q
Implicit parameters	Ctrl+Shift+P

**Tip** Quick Pop-ups are available for symbols in the editor; however, they are also available for items in any other list via the same shortcuts.

## Refactoring basics

IntelliJ IDEA offers a comprehensive set of automated code refactorings that lead to significant productivity gains when used correctly. Firstly, don't bother selecting anything before you apply a refactoring. IntelliJ IDEA is smart enough to figure out what statement you're going to refactor, and only asks for confirmation if several choices are possible.

**Tip** To undo the last refactoring, switch the focus to the [Project Tool Window](#) and press `Ctrl+Z`.

### Action Shortcut

Rename	<code>Shift+F6</code>
Extract variable or type	<code>Ctrl+Alt+V</code>
Extract field	<code>Ctrl+Alt+F</code>
Extract a constant	<code>Ctrl+Alt+C</code>
Extract a method	<code>Ctrl+Alt+M</code>
Extract a parameter	<code>Ctrl+Alt+P</code>
Inline	<code>Ctrl+Alt+N</code>
Copy	<code>F5</code>
Move	<code>F6</code>
Refactor this	<code>Ctrl+Shift+Alt+T</code>

For extracting a trait, use main menu ( Refactor | Extract | Trait ).

**Tip** A real time-saver is the ability to extract part of a string expression with the help of the **Extract** refactorings. Just select a string fragment and apply a refactoring to replace all of the selected fragment usages with the introduced constant or variable.

For more details, refer to [Refactoring Source Code](#).

## Finding usages

**Find Usages** helps you quickly find all pieces of code referencing the symbol at the caret (cursor), no matter if the symbol is a class, method, field, parameter, or another statement. Just press `Alt+F7` and get a list of references grouped by usage type, module, and file.

If you want to set custom options for the **Find Usages** algorithm, press `Ctrl+Shift+Alt+F7`, or click the first button on the right panel with search results.

If what you're looking for is plain text, use **Find in Path** by pressing `Ctrl+Shift+F`.

For more details, refer to [Finding Usages](#).

## Inspections

**Inspections** are built-in static code analysis tools that help you find probable bugs, locate dead code, detect performance issues, and improve the overall code structure.

Most inspections not only tell you where a problem is, but also provide quick fixes to deal with it right away. Press

`Alt+Enter` to choose a quick fix.

**Tip** The editor lets you quickly navigate between the highlighted problems via keyboard shortcuts. Press `F2` to go to the next problem, and `Shift+F2` to go to the previous one.

Inspections that are too complex to be run on-the-fly are available when you perform code analysis for the entire project. You can do this in one of the following two ways: by selecting **Analyze | Inspect Code** from the main menu, or by selecting **Analyze | Run Inspection by Name** to run an inspection by its name.

Note that while inspections provide quick-fixes for code that has potential problems, intentions help you apply automatic changes to code that is correct. To get a list of intentions applicable to the code at the caret, press `Alt+Enter`.

For more details, refer to [Code Inspection](#).

## Code style and formatting

IntelliJ IDEA automatically applies a code style you've configured in the [Code Style settings](#) as you edit, and in most cases you don't need to call the **Reformat Code** action explicitly.

Useful formatting shortcuts:

### Action Shortcut

Reformat code	<code>Ctrl+Alt+L</code>
Auto-indent lines	<code>Ctrl+Alt+I</code>
Optimize imports	<code>Ctrl+Alt+O</code>

Desugar Scala code (file)

Ctrl+Alt+D

You can also use the [Scalastyle](#) inspection for checking your Scala code. Simply place `scalastyle_config.xml` in the `<root>/idea` or `<root>/project` directory and inspect your code.

Note that by default, IntelliJ IDEA uses regular spaces for indents instead of tabs. If you have files with lots of indents, you may want to optimize their size by enabling the Use tab character option located in Settings | Editor | Code Style | Scala .

For more details, refer to [Reformatting Source Code](#) .

## Run and debug

Once you've created a [Run/Debug configuration](#) by selecting Run | Edit Configurations from the main menu, you are able to run and debug your Scala code.

For SBT projects you are also able to run and debug your code using SBT shell. Options Use SBT shell for build and import and Enable debugging for SBT shell , located on SBT page in settings, will enable you to do so.

For quick code evaluation, you can use a Scala worksheet that enables you to interactively run your code. Press

Ctrl+Shift+Alt+X

to create a light version of the Scala worksheet and

Ctrl+Alt+W

to run it.

The regular actions for run/debug are as follows:

### Action Shortcut

Run	Shift+F10
Debug	Shift+F9

When in the debug mode, you can [evaluate any expression](#) by using the **Evaluate expression** tool, which is accessed by pressing `Alt+F8` . This tool provides code completion in the same way as in the editor, so it's easy to enter any expression.

Sometimes, you may want to step into a particular method, but not the first one which will be invoked. In this case, use **Smart step into** by pressing `Shift+F7` to choose a particular method.

### Action Shortcut

Toggle breakpoint	Ctrl+F8
Step into	F7
Smart step into	Shift+F7
Step over	F8
Step out	Shift+F8
Resume	F9
Evaluate expression	Alt+F8

If you want to "rewind" while debugging, you can do it via the **Drop Frame** action. This is particularly helpful if you mistakenly stepped too far. This will no revert the global state of your application, but will at least let you revert to a previous stack frame.

**Tip** Any breakpoint can be quickly disabled by clicking on the gutter while holding `Alt` . To change breakpoint details (e.g. conditions), press `Ctrl+Shift+F8` .

For more details, refer to [Running](#) and [Debugging](#) .

## Reloading changes and hot swapping

Sometimes, you need to insert minor changes into your code without shutting down the process. Since the Java VM has a HotSwap feature, IntelliJ IDEA handles these cases automatically when you call Make .

## Application servers

If you need, you can deploy your Scala application to a server.

For more details, refer to [Working with Application Servers](#) .

## Build

When you've imported or created your SBT project, you can edit its `build.sbt` file directly in the editor. In `build.sbt` you can specify compiler options, information about your sub-projects, and also define your tasks and settings. Every time you change the `build.sbt` file, you need to synchronize your changes with the project model in IntelliJ IDEA.

You can select the Use Auto-import option to synchronize the changes made to `build.sbt` automatically. To access this option, select File | Settings | Build, Execution, Deployment | Build Tools | SBT .

For manual synchronization, use the corresponding action on the *SBT projects* tool window toolbar:  .

Note that any SBT task can be attached to be run before a run configuration.

IntelliJ IDEA also lets you use other build tools such as [Gradle](#) or [Maven](#) to build your Scala project.

IntelliJ IDEA lets you use different Scala intention actions, convert your code from Java to Scala, and use different Scala templates while working in the IntelliJ IDEA editor.

## Strings in Scala

You can add different intentions for strings, perform different actions, and set a different format for multi-line strings.

Check the following examples:

**Note** Use a Scala worksheet to quickly evaluate your results.

– Insert gap with concatenation ("+" +) into a string.

1. Enter a string and press `Alt+Enter`. The list of appropriate intentions opens.

2. Select Insert gap with concatenation ("+" +) and press `Enter`. Now you can insert a value into your string.

– Invoke the Convert to interpolated string intention.

1. Select a value with concatenation in your string and press `Alt+Enter`. The list of appropriate intentions opens.

2. Select Convert to interpolated string, press `Enter` and view the result.

**Note** The Convert to formatted string option will get you basic Java formatted string.

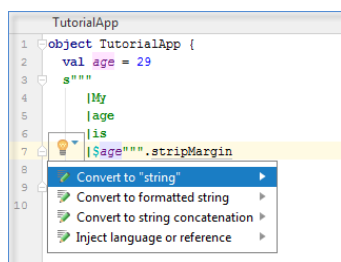

– Convert a string into a multi-line string using the Convert to ""string"" intention and vice versa.

**Note** Converting to multi-line strings removes escaped sequences such as `\\` or `\n`.

1. Enter your string, press `Alt+Enter` and from the drop-down list of intentions, select Convert to ""string"".

2. You also can convert the multi-line string into the regular string. Press `Alt+Enter` to open the drop-down list of intentions. Select Convert to "string" and press `Enter`.

View the result.

```

TutorialApp
1 object TutorialApp {
2   val age = 29
3   s"\nMy \nage \nis \n$age"
4
5 }
6

```

- 3. To enter a multi-line string, simply type triple quotes in your editor. If you press `Enter`, it will automatically invoke the `stripMargin` method. The `stripMargin` method removes the left-hand part of a multi-line string up to a specified delimiter.

```

TutorialApp.scala x AppEvaluation.sc x
Use REPL Mode (Beta) Interactive Mode Make project
TutorialApp
1 object TutorialApp {
2   val age = 29
3   s""
4   |My
5   |age
6   |is $age"".stripMargin
7
8 }
9
age: Int = 29
res0: String =
  My
  age
  is 29

```

The white spaces are also preserved. Check the following example:

```

TutorialApp.scala x AppEvaluation.sc x
Use REPL Mode (Beta) Interactive Mode Make project
TutorialApp
1 object TutorialApp {
2   val age = 29
3   s""
4   | My
5   | age
6   | is $age"".stripMargin
7
8 }
9
age: Int = 29
res0: String =
  My
  age
  is 29

```

- Add the `.replace("\n", " ")` intention. This intention lets you keep the caret in the correct place on the next line in the multi-line strings regardless of what operating system you have at the moment.

Simply enter a multi-line string, press `Alt+Enter` and select the appropriate intention from the drop-down list.

```

TutorialApp
1 object TutorialApp {
2   val age = 29
3   s""
4   |age
5   |is """".stripMargin + age
6
7 }
8
Add 'replace("\n", " ")
Convert to "string"
Convert to formatted string
Convert to interpolated string
Convert to string concatenation
Inject language or reference
Insert gap with concatenation: (" + + ")
Provide implicit conversion

```

- Use the Inject Language/Reference intention to insert a language or a reference into your multi-line string literals.
- 1. Enter a multi-line string, press `Alt+Enter` and from the drop-down list select Inject Language/Reference .

The list of available languages and references opens.

```

TutorialApp
1 object TutorialApp {
2   val age = 29
3   s""
4   |My
5   |age
6   |is
7   |
8   |
9   |
10 }
11
<Generic SQL> (SQL Files)
AIDL (Android IDL files)
AndroidDataBinding (Android data binding expression)
Angular2HTML (HTML files)
AngularJS (JavaScript files)
Apple JS (JavaScript files)
AspectJ (AspectJ source files)
CSS (Cascading style sheet)
CoffeeScript (CoffeeScript Files)
CoffeeScriptLiterate (LiterateCoffeeScript Files)

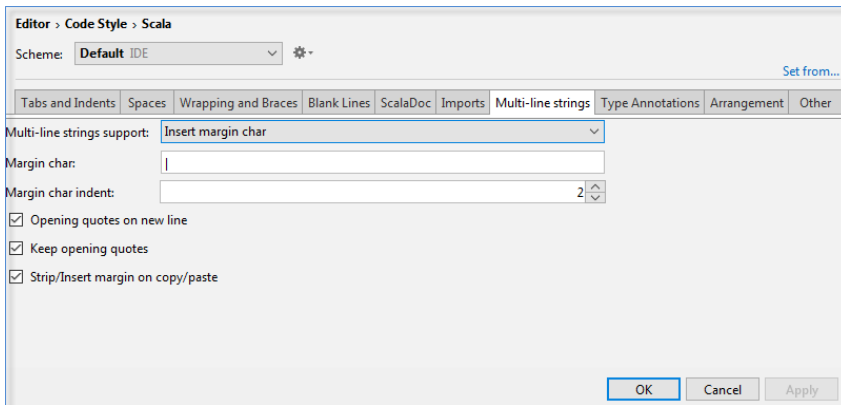

```

- 2. Choose the appropriate one and press `Enter` .

To cancel the language injection, simply choose the Un-Inject Language/Reference intention.

- Use the Multi-line strings tab in Scala settings to set a different format for multi-line strings' options such as `Margin char` indent or disable a multi-line strings support.

1. In the main menu, select File | Setting | Editor | Code Style | Scala .
2. On the Scala page, select the Multi-line strings tab.

3. Edit the settings and click OK .

– Turn simple string into the interpolated one adding a variable reference.

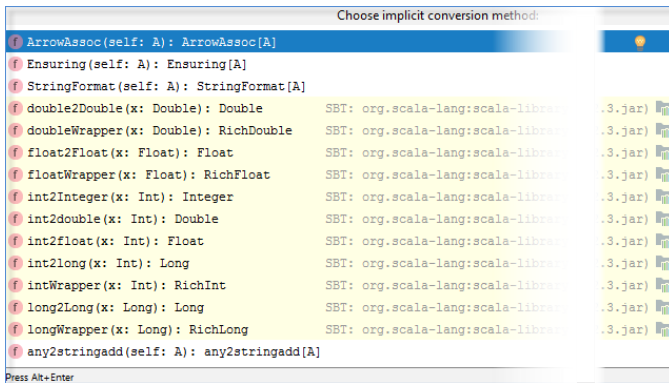

## Implicit conversions

IntelliJ IDEA lets you invoke implicit conversion methods and parameters:

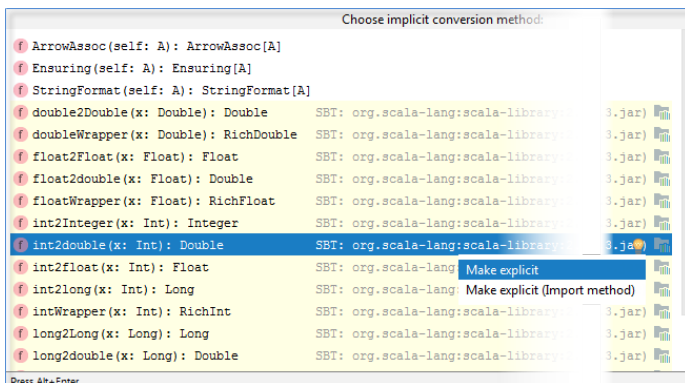

– Implicit conversion methods

1. Select an expression and press `Shift+Ctrl+Q` (`Ctrl+Q` for macOS) to invoke the list of applicable implicit conversions. The list shows the regular scope displayed on the top and the expanded scope that is displayed on the bottom of the list.

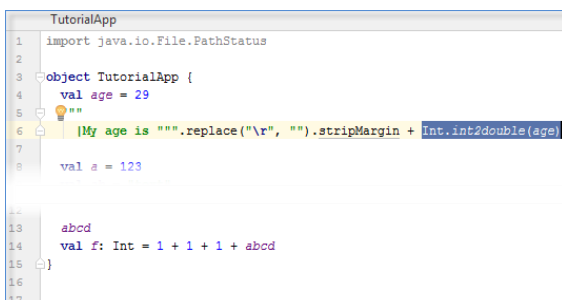

**Note** IntelliJ IDEA highlights an implicit conversion that was used for the selected expression. If IntelliJ IDEA cannot find the implicit conversion or if it finds more than one match then the list of Introduce Variable opens.

2. You can make the implicit conversion method explicit. Press `Alt+Enter` and select Make explicit or Make explicit (Import method) :

3. If you select Make explicit then IntelliJ IDEA returns a method call with the class name. It might be helpful if you need to make sure that the compiler imports a particular implicit conversion method that you originally wanted:

4. If you select Make explicit (Import method) then the method is imported statically and IntelliJ IDEA returns just its call without the class name. Also, the next time you open the list of useful implicit conversions you will see this method in the regular scope:

```

TutorialApp
1 import java.io.File.PathStatus
2
3 import scala.Int.int2double
4
5 object TutorialApp {
6   val age = 29
7   ""
8   |My age is ""\r".replace("\r", "").stripMargin + int2double(age)
9
10  val a = 123
11
12
13
14
15  abcd
16  val f: Int = 1 + 1 + 1 + abcd
17 }

```

– Implicit parameters

1. Place a cursor to the method where implicit conversion was used and press `Ctrl+Shift+P` to invoke implicit parameters. It might be helpful for code analyzing when you want to find out what implicit parameters were passed to the particular call. IntelliJ IDEA also lets you view the recursive implicit parameters.

**Note** IntelliJ IDEA highlights the method call where implicit parameters were used.

```

ImplicitParameters
1 class ImplicitParameters {
2   implicit val s: String = "text"
3   implicit def foo (implicit string: String): Int = 123
4   def goo (implicit i: Int) = i
5   goo
6
7 }

```

Implicit parameters:

- foo()
- s()

2. If IntelliJ IDEA cannot find method calls where implicit parameters were passed, it displays a pop-up message:

```

ImplicitParameters > foo(string: String)
1 class { No implicit parameters }
2 implicit val s: String = "text"
3 implicit def foo (implicit string: String): Int = 123
4 def goo (implicit i: Int) = i
5   goo
6
7 }

```

## Type Info action

IntelliJ IDEA lets you work with type inferences using the Scala **Show Type Info** action:

- To invoke the Show Type Info action in the editor, navigate to the value and press `Alt+Equals` or `N/A` (for Mac OS):

```

ShowTypeInfo
1 object ShowType String {
2   val a = 123
3   val ab = "text"
4   a
5
6   val f: Int = 1 + 1 + 1
7
8 }

```

**Note** If you selected the Show type info on mouse hover after, ms checkbox on the Editor tab in Settings | Languages and Frameworks | Scala, you can simply navigate with the mouse to a value to see its type information.

- You can also see the type information on a value definition. Simply put the caret on a value definition and press

`Alt+Equals` or `N/A` (for Mac OS):

```

ShowTypeInfo
1 object ShowTypeInfo {
2   val a = 123
3   val ab = "text"
4   a
5   Type: Int
6   val f: Int = 1 + 1 + 1
7
8 }

```

**Note** You can use the same shortcuts to see the type information on expressions.

- To add a type annotation, highlight the value, press `Alt+Enter` and from the context menu select Add type annotation to value definition:

```

ShowTypeInfo
1 object ShowTypeInfo {
2   val a = 123
3   val ab = "text"
4   a
5
6   val f: Int = 1 + 1 + 1
7
8 }

```

Context menu:

- ✓ Add type annotation to value definition
- Adjust code style settings

As a result, the type annotation is added:

```

1 object ShowTypeInfo {
2   val a = 123
3   val ab: String = "text"
4   a
5
6   val f: Int = 1 + 1 + 1
7
8 }
9

```

To remove the type annotation, press **Alt+Enter** and select Remove type annotation from value definition .

- You can also use the **Adjust types** action to shorten types with full qualified names. Select the code in question, press **Alt+Enter** and from the context menu, select Adjust types .

```

AdjustTypes > abc(...)
1
2 object ShowTypeInfo {
3   val a = 123
4   val ab: String = "text"
5   a
6
7   val f: Int = 1 + 1 + 1
8 }
9
10 trait AdjustTypes {
11   def abc(s: Predef.String, r: scala.util.Random): scala.collection.mutable.Seq[String]
12 }
13
14

```

In this case the necessary imports are added.

```

AdjustTypes
1 import scala.collection.mutable
2 import scala.util.Random
3
4 object ShowTypeInfo {
5   val a = 123
6   val ab: String = "text"
7   a
8
9   val f: Int = 1 + 1 + 1
10 }
11 trait AdjustTypes {
12   def abc(s: String, r: Random): mutable.Seq[String]
13 }
14

```

## Create from usage

IntelliJ IDEA lets you create new code elements without declaring them first:

1. In the editor, type a name of a new code element and press **Alt+Enter** .
2. From the list of intentions, select the one you need.

```

TutorialApp
1 object TutorialApp {
2   val age = 29
3   """
4   |My age is """.replace("\r", "").stripMargin + age
5
6   val a = 123
7   val ab = "text"
8
9   a
10
11 abcd
12 val
13
14

```

Press **Enter** .

## Structure view

IntelliJ IDEA lets you view a structure of your code:

- To open the Structure tool window, press **Alt+7** .

- To navigate from the Structure tool window to the code item in the editor, press **F4** .

To simply highlight the code, press **Ctrl+Enter** .

## Java-to-Scala code conversion

IntelliJ IDEA lets you convert Java code into Scala:

1. Copy your Java code (expression, method, class) and paste it into a Scala file.

```
public class Hello {
    public static void main(String[] args) {
        System.out.println("Hello World!");
    }
}
```

2. IntelliJ IDEA displays the Convert the code from Java dialog suggesting a conversion.

Click OK .

```
object Hello {
    def main(args: Array[String]): Unit = {
        System.out.println("Hello World!")
    }
}
```

If you do not want to use the copy/paste actions, you can open your Java file in the editor and select Refactor | Convert to Scala or press `Ctrl+Shift+G` .

In this case IntelliJ IDEA will create a Scala file with the converted code.

## Scala templates

IntelliJ IDEA lets you use predefined Scala templates:

1. In the editor start entering your code, press `Ctrl+J` .

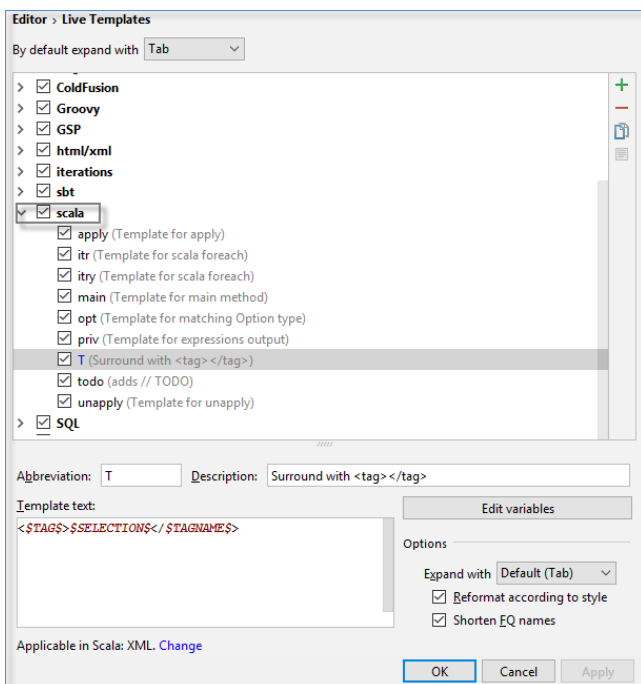

IntelliJ IDEA displays the list of available Live templates for Scala.

2. Select the one you need and press `Enter` .

You can also define a new template or edit the existing one:

1. Select Settings/Preferences | Editor | Live Templates .
2. From options on the right, open the list of Scala templates.

3. If you want to add a new template, click `+` .

If you want to edit the existing template, select the one you need and change the default definitions.

IntelliJ IDEA lets you run, debug and test your Scala applications as you would normally do with any other applications in IntelliJ IDEA. IntelliJ IDEA also lets you run your Scala code with coverage and configure code coverage settings.

**Tip** To adjust configuration settings when you perform running or debugging processes, use the Run/Debug Configurations dialog. To access the dialog, select Run | Edit Configurations on the main menu.

## Run Scala applications

You can run your Scala code through IntelliJ IDEA, use sbt shell, or use Scala worksheet for a quick code evaluation.

### Run a Scala application via IntelliJ IDEA

1. Create or import a Scala project as you would normally [create or import](#) any other project in IntelliJ IDEA.
2. Open your application in the editor.
3. Press `Shift+F10` to execute the application. Alternatively, in the left gutter of the editor, click the  icon and select Run 'name'.

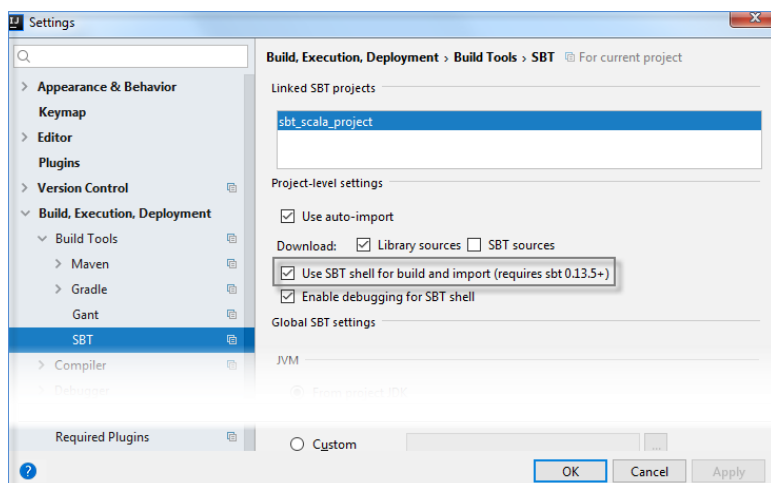

**Tip** You can also click the  icon on the main toolbar to run your application.

### Run a Scala application using the sbt shell

You can run your application using the sbt shell that is a part of any [sbt project](#).

1. Open your sbt project.
2. If you want to delegate your builds and imports to sbt, in the sbt projects tool window, click the  icon to open the sbt settings.

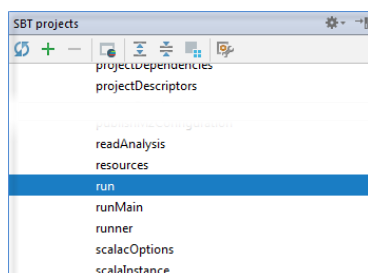

On the sbt settings page, select the Use sbt shell for build and import (required sbt 0.13.5+) option and click OK.

(This option is also available when you create or import an sbt project.)

If you don't want to delegate your builds and imports to sbt, you can still work in the sbt shell () and [run sbt commands](#) directly from it including running your application.

3. In the sbt projects tool window, click sbt Tasks node.
4. In the list that opens, select the run task that will run a main method.

The result of execution is displayed in sbt shell tool window.

```

SBT Shell sbt_scala_project
[info] Running scalaApp
Hello, Scala!
[success] Total time: 0 s, completed Sep 19, 2017 8:50:28 PM
[!]>
[!]> {file:/C:/Users/Elena.Kozlova/sbt_scala_project/}sbt_scala_project/run
[info] Running scalaApp
Hello, Scala!
[success] Total time: 0 s, completed Sep 20, 2017 3:26:40 PM
[!]>

```

## Run Scala code using Scala worksheet

IntelliJ IDEA lets you create a Scala worksheet and use it to evaluate your Scala code results in a special window of the Scala editor.

1. Right-click on your project and select New | Scala Worksheet .

We recommended that you create your worksheet in src directory to simplify an inclusion of the project's classes in the classpath. That might be helpful for testing purposes.

2. In the New Scala Worksheet window type a name of your Scala worksheet and click OK .

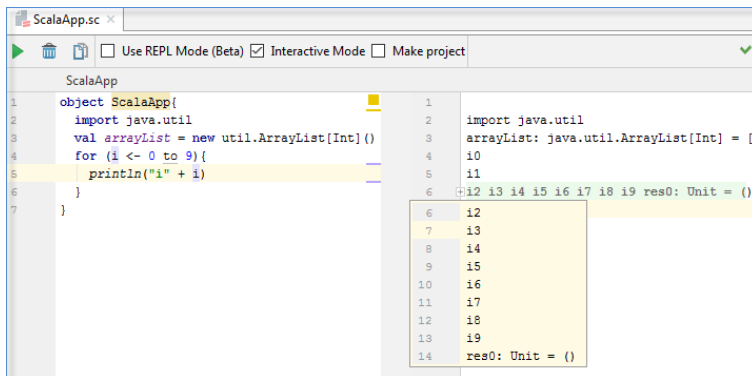

As a result, a file with .sc extension opens.

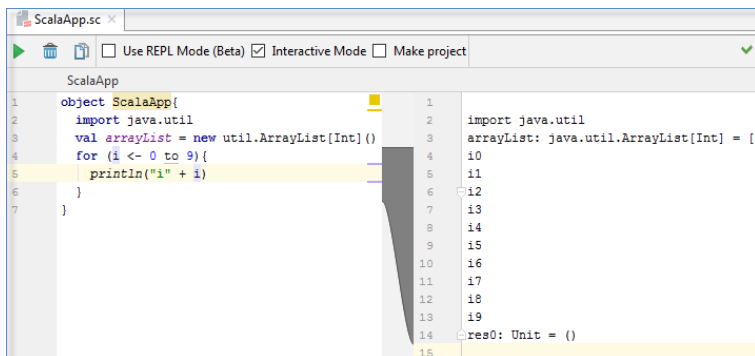

3. Enter your code and press ▶ to see the results. If you select the Interactive Mode checkbox then the code results will be displayed automatically.

4. While working with the .sc file, you can perform the following actions:

- You can clear the Make project checkbox to improve evaluation performance. In this case, the automatic checking of project's changes is disabled. The results appear in the view on the right side of your code.
- You can evaluate a Scala object.

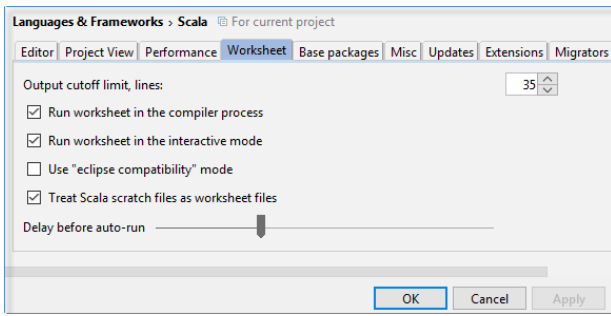

- You can fold the output without affecting your code on the left side and expand only that block of the output that matches a specific statement.

- You can also configure worksheet settings.

1. Select File | Settings | Languages and Frameworks | Scala and click Worksheet tab.
2. On the Worksheet tab, you can set the output cutoff limit and configure in what mode you want to run the worksheet.

**Note** If you select the Use "eclipse compatibility" mode checkbox then all the statements inside the object will be included in the worksheet's output.

**Tip** To remove the worksheets results, press  icon.

To copy your code and evaluation results into one file, click  icon.

## Debug Scala code

IntelliJ IDEA lets you debug your code using IntelliJ IDEA debugger or the sbt shell .

### Debug Scala code using IntelliJ IDEA

1. Open your Scala application in the editor.
2. In the left gutter, set your breakpoints for the lines of code you want to debug. For more information on breakpoints, please see the [Using Breakpoints](#) topic.
3. If you need, you can access the Run/Debug configurations (Run | Edit Configurations) and adjust the settings, but usually the default settings are enough to successfully start and complete your debugging session.
4. Press `Shift+F9` . Alternatively, on the main toolbar, click the  icon to start a debugging process.
5. Evaluate the results in the Debug tool window.

For information on how to use options in the Debug tool window, please see [Debug tool window references](#) .

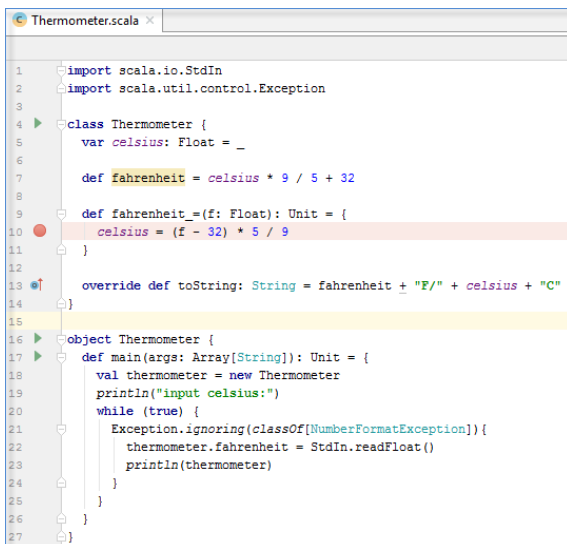

### Debug Scala code using sbt shell

**Note** If you have

```
fork in Test := true
```

set in your sbt project, debugging tests run via the sbt shell will not work.

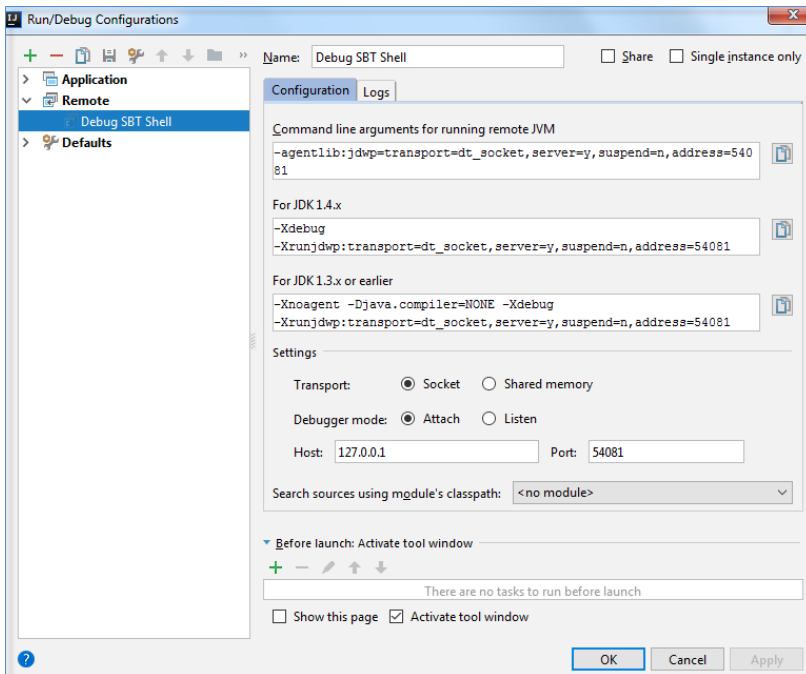

1. Open your sbt project.
2. Open your application in the editor.
3. In the editor, in the left gutter, set your breakpoints for the lines of code you want to debug.

**Note** You cannot debug code defined in actual `.sbt` files, but you can debug code in Scala files that can be invoked from `build.sbt` .

4. In the sbt projects tool window, click the  icon, to start the sbt shell.
5. In the sbt shell tool window, click the  icon to connect to the debugger server and start debugging session.

IntelliJ IDEA also creates a Run/Debug configuration for the debugging session.

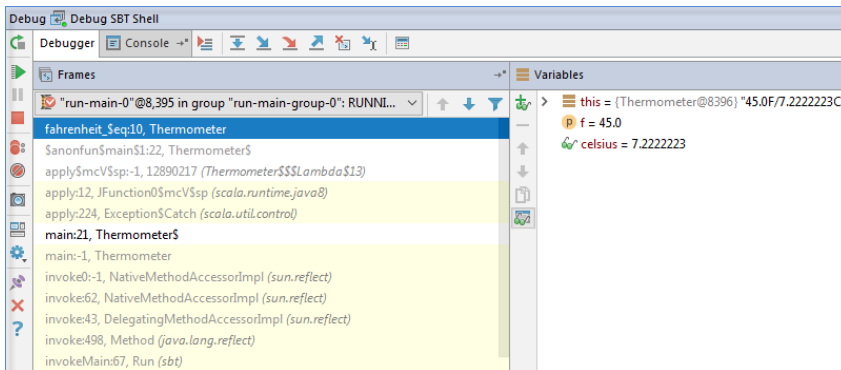

If you need, you can edit the run/debug configuration settings, but the default settings should be enough to successfully debug your code.

#### 6. Run your program.

Evaluate your results in the Debug tool window.

## Test Scala applications

IntelliJ IDEA lets you test your Scala applications using [ScalaTest](#) and [Specs2](#). You can also set and run the test scopes.

### Test Scala applications using Scala Test

#### 1. Open your project.

- If you have an sbt project, open the `build.sbt` file and specify the following dependencies for ScalaTest:

```
libraryDependencies += "org.scalactic" %% "scalactic" % "3.0.1"
```

```
libraryDependencies += "org.scalatest" %% "scalatest" % "3.0.1" % "test"
```

Click  icon in the sbt projects tool window to refresh your project or use the Auto-import option specified in the sbt settings to automatically refresh your project each time you make changes to `build.sbt`.

- If you have a regular Scala project, use the [Project Structure](#) dialog, to configure test libraries.

#### 2. Open a class in the editor, for which you want to create a test and place the cursor within the line containing the class declaration.

#### 3. Press `Ctrl+Shift+T` and select Create New Test.

#### 4. In the dialog that opens, specify your test settings and click OK.

#### 5. Open the test in the editor, press `Ctrl+Shift+F10` or right-click on the test class and from the context menu select Run 'test name'.

#### 6. IntelliJ IDEA creates a run/debug configuration for the test automatically, but if you want to edit settings in your configuration, click Run | Edit Configurations on the main menu.

#### 7. In the Run/Debug Configurations dialog, on the right-hand side, specify settings for the test suite and click OK.

The configuration has standard options and you can find further details in the [Testing](#) section. However, you can also specify the following Scala-related options:

- You can select the Use sbt shell checkbox to run your test via sbt shell and the Use UI with sbt to display the test results in the same format as for platform test runner.
- You can select the Test kind option to specify what kind of test you want to run. For example, you can select Regular expression and set class and test patterns.

8. On the main toolbar, click the  icon to run the test.

9. Evaluate the results in the Run tool window.

**Tip** You can open the sbt shell, run your tests and evaluate the results from the sbt shell using the `test` command.

**Tip** Alternatively, to create a test suite, right-click on the class and from the context menu select Go to | Test.

**Tip** To create a new run/debug configuration for a test after opening the Run/Debug configurations dialog, click the  in the upper-left corner and from the list that opens select ScalaTest or Specs2 to create either a ScalaTest run configuration or a Specs2 run configuration respectively.

## Test a Scala application using Specs2

The procedure for testing a Scala application using Specs2 is the same as the procedure described in the [Test a Scala application using ScalaTest](#) section except for the following options:

- You need to specify the following dependency for your sbt project:

```
libraryDependencies ++= Seq("org.specs2" %% "specs2-core" % "3.9.5" % "test")
```

For regular Scala projects, use the [Project Structure](#) dialog, to configure the test library.

- The Use UI with sbt option that displays the test results in the same format as for platform test runner is not available.

## Testing scopes in Scala

IntelliJ IDEA lets you test scopes using *ScalaTest* or *Specs2*.

You can run tests inside a scope or test the whole scope in your Scala projects.

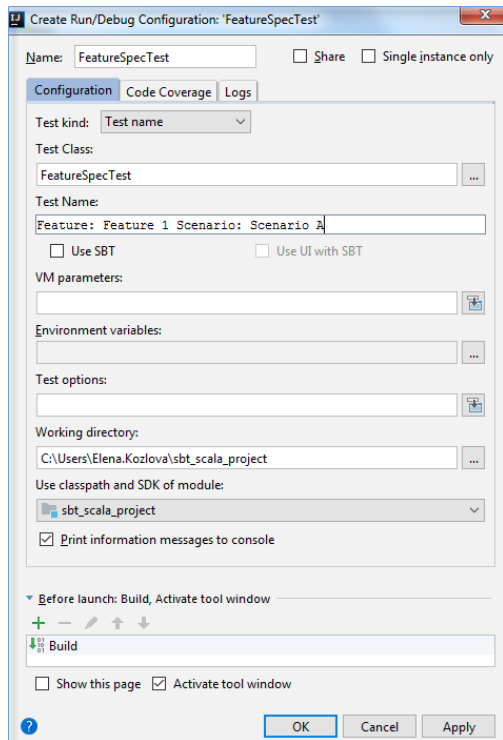

1. Create your code. Check the following example:

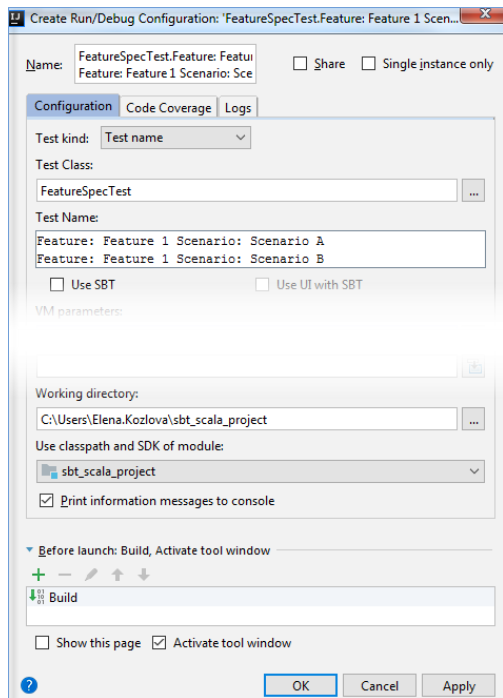

```
1 FeatureSpecTest
2 import org.scalatest.{FeatureSpec, GivenWhenThen}
3 class FeatureSpecTest extends FeatureSpec with GivenWhenThen {
4   feature("Feature 1") {
5     scenario("Scenario A") {
6     }
7     scenario("Scenario B") {
8     }
9   }
10  feature("Feature 2") {
11    scenario("Scenario C") {
12    }
13  }
14  feature("empty") {}
15 }
16
```

2. In the editor, depending on your test scope you can perform the following:

- If you open context menu for one of the tests inside the scope, you can create a run configuration just for the specified test inside that scope.

– If you open a context menu for the whole scope, you can create a run configuration for all tests inside the scope.

3. Run your tests and view the output in the Run tool window.

You can also use the [sbt shell](#) to run scope tests.

## Run Scala tests with coverage

IntelliJ IDEA lets you run your test suite with code coverage.

1. Open your project.
2. Open the test in question in the editor.
3. In the left gutter, click the  icon and select the Run 'name' with Coverage option.

IntelliJ IDEA runs the test and displays the Coverage tool window with code coverage information.

You can also adjust default code coverage settings or code coverage behavior if you need.

If you have already run your test suite, IntelliJ IDEA creates the run/debug configuration automatically. You can open the created run configuration and adjust the settings.

If you want to create a new run configuration for the test suite, do the following:

1. From the main menu, select Run | Edit Configurations .
2. In the Run/Debug Configurations dialog, click the **+** icon from the options on the left.
3. From the list that opens, select the configuration you need.
4. From the options on right, click the Code Coverage tab.
5. Adjust the default settings and click OK .

For more information, please see [Configuring Code Coverage Measurement](#)

You can also adjust code coverage behavior.

1. Press **Ctrl+Alt+S** to open the Settings/Preferences page.
2. From the options on the left, select Build, Execution, Deployment | Coverage .
3. From the options on right, adjust the settings and click OK .

**Tip** Alternatively, you can select Run | Run with Coverage from the main menu, to run your code with coverage.

## Creating an sbt project

Launch the [New Project wizard](#) and follow the steps suggested in the wizard such as:

1. Selecting Scala and sbt .
2. Specifying your project's name, location, JDK along with sbt and Scala versions. (The sbt and Scala versions are fetched automatically.)

## Importing an sbt project

1. Click Import Project on the welcome screen or select File | New | Project from Existing Sources from the main menu.
2. In the dialog that opens, select a directory that contains your sbt project or simply `build.sbt` . Click OK .
3. Follow the steps suggested in the Import Project wizard.

You can use the suggested default settings since they are enough to successfully import your project.

We recommend that you enable the Use sbt shell for build and import (requires sbt 0.13.5+) option when you use code generation or other features that modify the build process in sbt. If your sbt project is not in the IntelliJ IDEA project root directory, we suggest you skip this option.

## Ensuring sbt and Scala versions compatibility

Often you share your project across a team and need to use a specific version of sbt.

You can override the sbt version in your project's `build.properties` file.

1. [Create](#) or [import](#) your sbt project.
2. In the Project tool window, in the source root directory locate the `build.properties` file and open it in the editor.
3. In the editor explicitly specify the version of sbt that you want to use in the project.

```
sbt.version=xxx
```

**Note** Note that newer sbt versions will create the `build.properties` file automatically if it doesn't exist.

4. Refresh your project. (Click the  in the sbt projects tool window.)

**Note** When you try to import an sbt project that contains an old version of sbt, you might get an error. We recommend that you upgrade to sbt versions 1.0 and later which are compatible with the Scala version 2.12 (requires Java 8).

## Managing sbt projects

### Sbt project structure

When you create or import an sbt project, IntelliJ IDEA generates the following sbt structure:

- sbt project (proper build) which defines a project and contains `build.sbt` file, `src` , and `target` directories, modules; anything related to a regular project.
- sbt **build** project which is defined in the `project` subdirectory. It contains additional code that is part of the build definition.
- sbt projects tool window which contains sbt tasks, commands, and settings that you can execute.

For more information on sbt project structure, see the related [sbt documentation](#) .

### Linking an external sbt project

You can link an external sbt project to the sbt project that you already have.

1. Open your `build.sbt` .
2. Specify the following code:

```
val localDep = RootProject(file("/path/to/project"))
```

where `localDep` in this case is a project that is located somewhere on the file system and will be imported as a module.

3. Refresh your project. (Click the  in the sbt projects tool window.)

IntelliJ IDEA displays the added project in the Project tool window as well as in the sbt projects tool window.

### Working with an sbt multi-module project

You can add a sub project or a module that would depend on your main sbt project using the `build.sbt` file.

1. Open `build.sbt` in the editor.
2. Specify, for example:

```
lazy val sampleModule = (project in file("sampleModule"))
```

where "sampleModule" is a sub project that you want to add. You can specify more than one sub project.

3. Refresh your project. (Click the  in the sbt projects tool window.)

IntelliJ IDEA generates a sub project directory with the appropriate information and displays it in both Project and sbt projects tool windows.

If you want the sub projects to automatically update when you change the version of Scala, specify `commonSettings` and `settings` method call for each sub project.

1. Open `build.sbt` .
2. Specify, for example, the following code:

```
lazy val commonSettings = Seq(  
  organization := "com.example",  
  version := "0.1.0-SNAPSHOT",  
  scalaVersion := "2.12.3"  
)  
  
lazy val moduleSample = (project in file("moduleSample"))  
  .settings(  
    commonSettings  
  )
```

The appropriate Scala version is added to the sub project's directory in the Project tool window and also to the sbt projects tool window as a dependency in the sub project.

## Working with dependencies in sbt projects

IntelliJ IDEA lets you use external dependencies in your sbt project.

You can use both managed dependencies and unmanaged dependencies:

- Managed dependencies are the ones that are added through `build.sbt` and managed by sbt.
- The unmanaged dependencies are the ones that you add to the `lib` directory in your project and manage manually.

We recommend that you use `build.sbt` for configuring all of the dependencies to ensure portability of the project.

1. Open `build.sbt` in the editor.
2. Specify your dependency which have the following syntax:

```
libraryDependencies += groupID % artifactID % revision
```

You can also declare several dependencies:

```
libraryDependencies ++= Seq(  
  groupID % artifactID % revision,  
  groupID % otherID % otherRevision  
)
```

You can also configure dependencies externally in the Maven POM file or Ivy configuration file and let sbt use those files.

For more information, please refer to the [sbt Library Management](#) page.

You can let sbt import a library that you would add via `import` statement.

1. Open a `.scala` file in the editor.
2. Specify a library you want to import.
3. Put the cursor on the unresolved package and press `Alt+Enter` .
4. From the list of available intention actions, select Add sbt dependency .

The dependency is added to the `build.sbt` file and downloaded by sbt.

5. Refresh  the sbt project.

**Tip** By default, sbt uses standard Maven2 repository to retrieve dependencies. The repository can locate most libraries when you specify a `libraryDependencies` line in the `build.sbt` file. You don't need to specify the location of the library. However, when a library is not in a standard repository, you can tell sbt where to search by adding a [resolver](#) .

## Working with sbt shell

An sbt shell is the embedded version of `sbt` command that you usually run on the command line. The sbt shell is part of an sbt project so you don't need to perform any additional installation.

- To open the sbt shell, click the  on the toolbar located in the sbt projects tool window.
- To use the sbt shell for build and import procedures, select the Use sbt shell for build and import (requires sbt 0.13.5+) option located in the [sbt settings](#) and perform steps described in the [Run a Scala application using the sbt shell](#) section.

Note that sbt versions 0.13.16.+ / 1.0.3.+ are recommended.

- You can use the sbt shell for debugging as described in the [debugging with sbt shell](#) section.
- You can run your tests from the sbt shell.
  1. Open a run/debug configuration ( `Run | Edit Configurations` ).
  2. Create a [test configuration](#) and select the use sbt option from the available settings.
- You can also run `test` or `test/only` command by entering it in the sbt shell.

## Running sbt tasks

### Running an sbt task via the sbt projects tool window

You can run sbt tasks by selecting the one you need from the sbt projects tool window.

1. In your sbt project, in the sbt projects tool window, click a project or module for which you want to execute a task.
2. In the list that opens, click sbt Tasks directory.
3. From the list that opens, double-click the appropriate task to run. Alternatively, right-click the task and from the context menu, click Run .
4. If you want to perform an action other than execution, right-click the task and from the context menu, click the appropriate action.
5. Check the results in the sbt Shell window.

### Running an sbt task via the sbt shell

You can enter and run your task directly in the sbt Shell .

1. In the sbt projects tool window, click  to launch the sbt shell.
2. In the sbt Shell window, start typing a name of the task you need to run, IntelliJ IDEA supports code completion.
3. Press  .

### Creating a run configuration for an sbt task

You can create a run configuration for an sbt task. For example, you can create a custom task which is not part of the list of tasks located in the sbt projects tool window.

1. On the main menu, select Run | Edit Configurations .
2. In the dialog that opens, click the  icon to open a list of new configurations.
3. In the list that opens, locate and select sbt Task .
4. On the right side of the sbt task configuration page, specify a name of your configuration, tasks that you want to include for this configuration and other related options.

If you need, you can add another configuration or a task to execute before running your configuration. Click the  icon in the Before Launch section and from the list that opens select what you need to execute.

5. Click OK .
6. Run  your configuration and check the results in the Run tool window.

 You execute sbt commands and settings the same way as you would execute [sbt tasks](#) .

### Working with sbt settings

To access sbt settings, click  in the sbt projects tool window. You can use sbt settings for the following notable actions:

- If you want sbt automatically refresh your project every time you make changes to `build.sbt` , select Use auto-import .
- To delegate running builds to sbt, select Use sbt shell for build and import(requires sbt 0.13.5+) .
- To debug your code via the sbt shell, select Enable debugging for sbt shell option that enables a debug button () in the sbt shell tool window. To start the debugging session, simply click this button. For more information on debugging, see [debugging with sbt](#) .
- To change the .ivy cache location in your project or set other [sbt properties](#) , use the VM parameters field.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

## – Creating a project

IntelliJ IDEA lets you create a Scala project with the Dotty SDK.

### Creating a project

Before you create a project make sure that the Scala plugin is [downloaded and enabled](#) in IntelliJ IDEA.

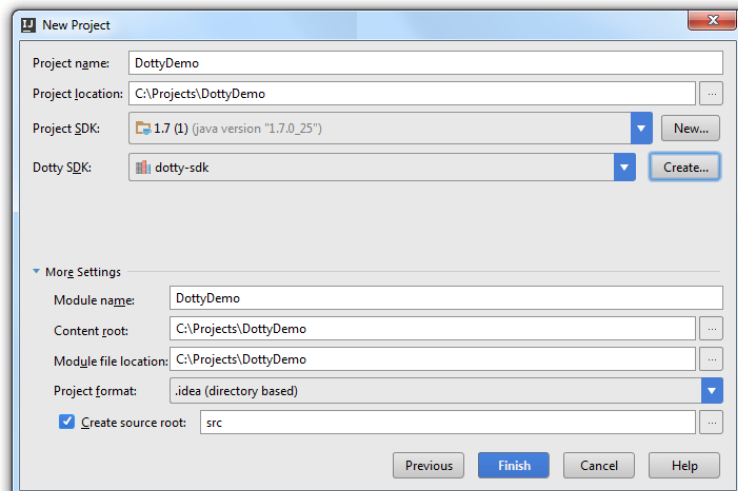

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the Welcome screen. Otherwise, select File | New | Project .  
As a result, the New Project wizard opens.
2. In the left-hand pane, select Scala .
3. In the right-hand pane, select Dotty .

You can also select [Scala](#) for creating a project with the Scala module, [SBT](#) for creating a project with the SBT module, [Play 2.x](#) for creating a project with the Play 2.x framework or [Activator](#) for creating a project with Typesafe Activator templates.

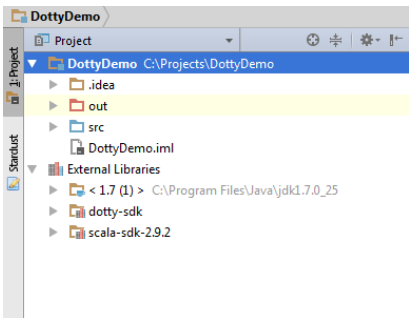

Click Next .

4. On the next page of the wizard, specify your project's information and click Finish .

The IntelliJ IDEA will create a project with the Dotty SDK. For more information on Dotty, please refer to the [Dotty](#) page.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

- [Creating a project](#)
- [Importing a Play 2.x project](#)
- [Checking project settings](#)
- [Using code assistance](#)
- [Running a Play 2.x application](#)
- [Debugging a Play 2.x application](#)

## Creating a project

Before you create a project make sure that the Scala plugin is [downloaded and enabled](#) in IntelliJ IDEA.

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the Welcome screen. Otherwise, select File | New | Project .

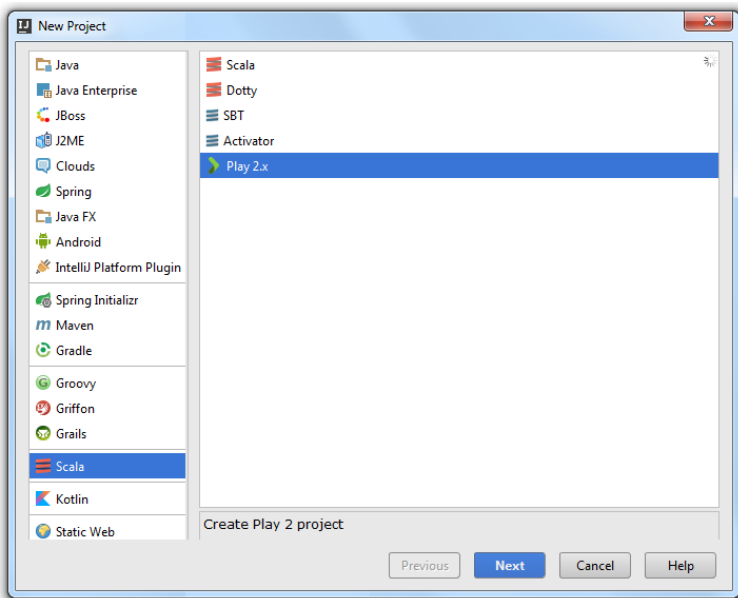

As a result, the New Project wizard opens.

2. In the left-hand pane, select Scala .

Note that for creating a Java project with the Play 2.x framework, you need to select Java .

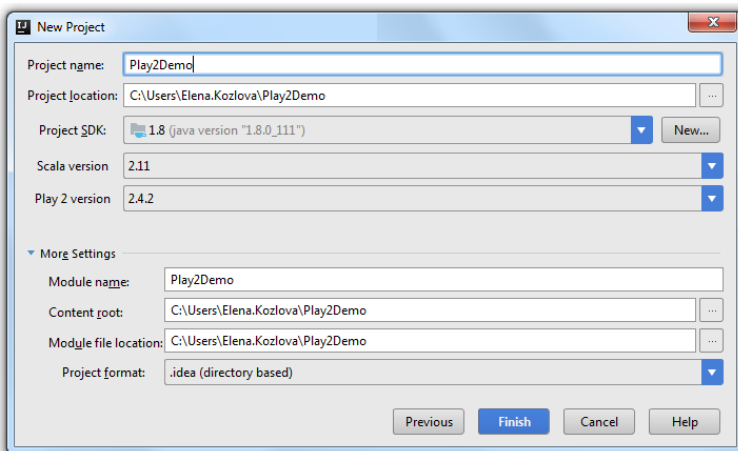

3. In the right-hand pane, select Play 2.x .

You can also select [Scala](#) for creating a project with the Scala module, [SBT](#) for creating a project with the SBT module [Activator](#) for creating a project with Typesafe Activator templates or [Dotty](#) for creating a project with the Dotty SDK.

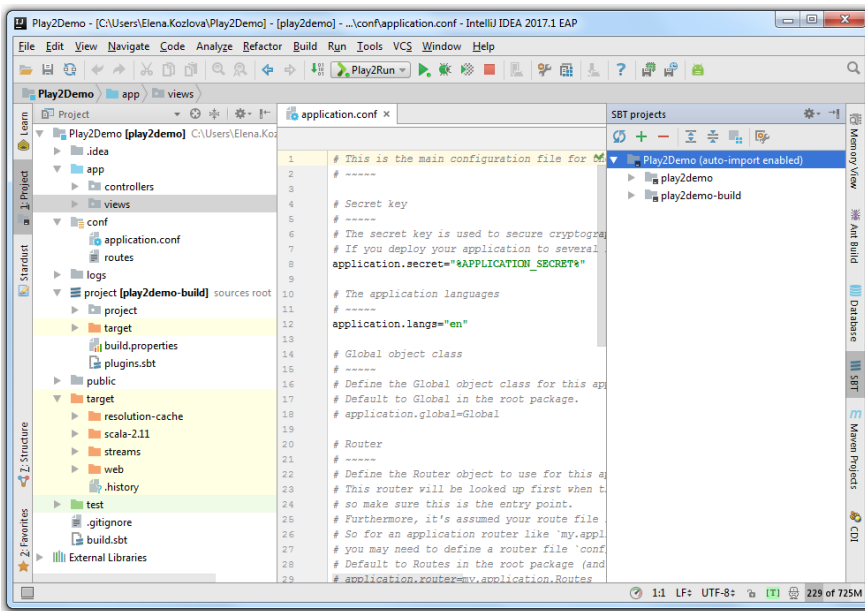

Click Next .

4. On the next page of the wizard, specify project and module location settings.

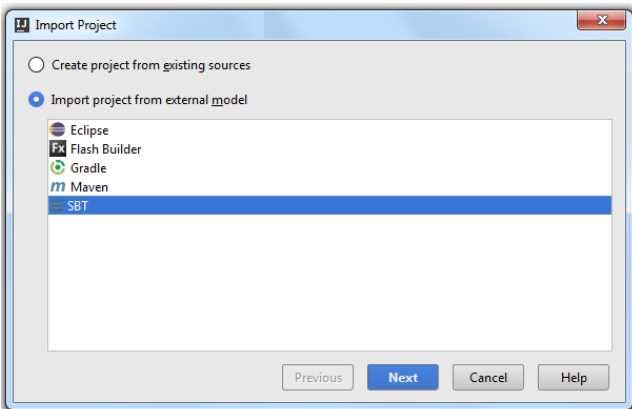

Click Finish . The IDE will create an empty application.

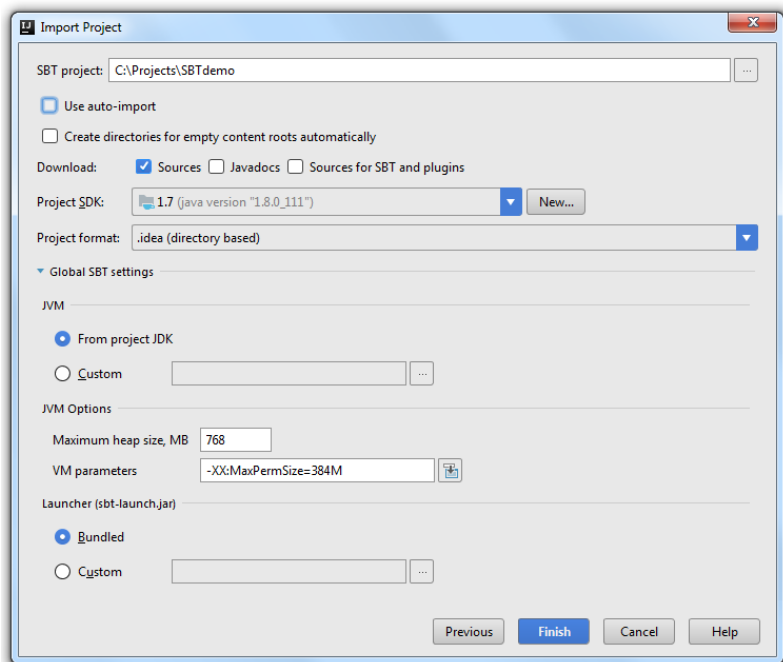

## Importing a Play 2.x project

IntelliJ IDEA lets you import an existing Play 2.x project.

1. On the main menu, select File | New | Project from Existing Sources .
2. In the window that opens, select a file that you want to import and click OK . The Import project wizard opens.
3. On the first page of the wizard, select Import project from external model option and choose SBT project from the list. Click Next .

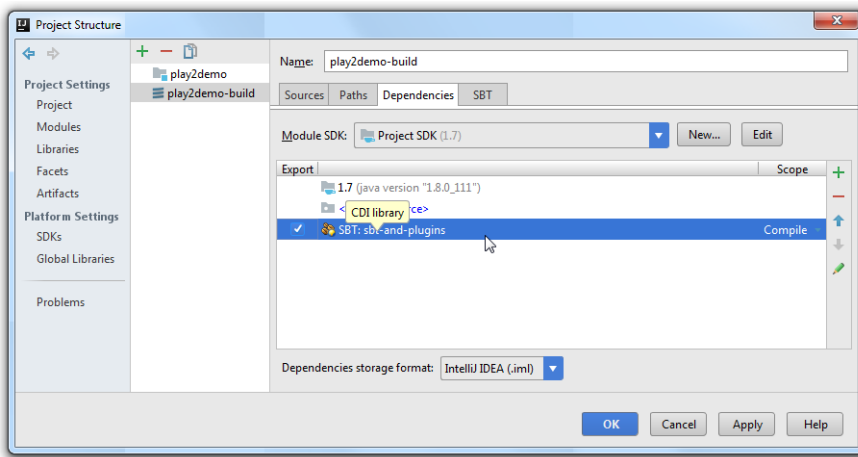

4. On the next page of the wizard, select SBT options and click Finish .

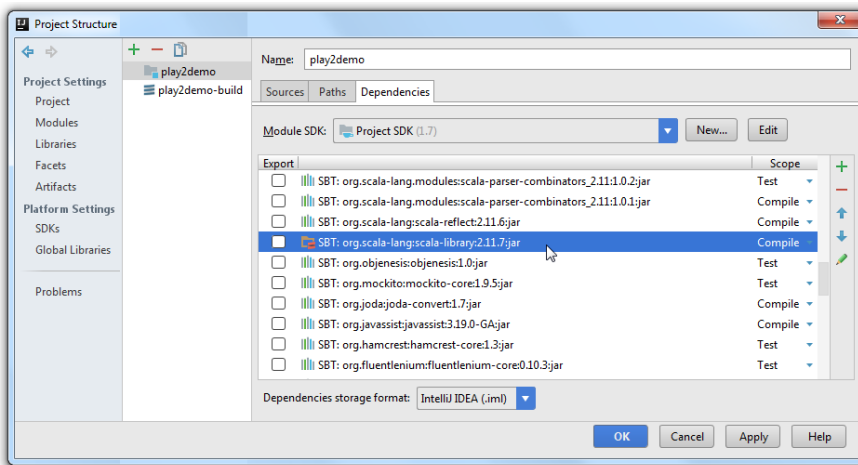

## Checking project settings

1. On the main menu, select File | Project Structure . Alternatively, use  icon on the Toolbar .
2. In the Project Structure dialog, check if module dependencies are resolved without warnings.

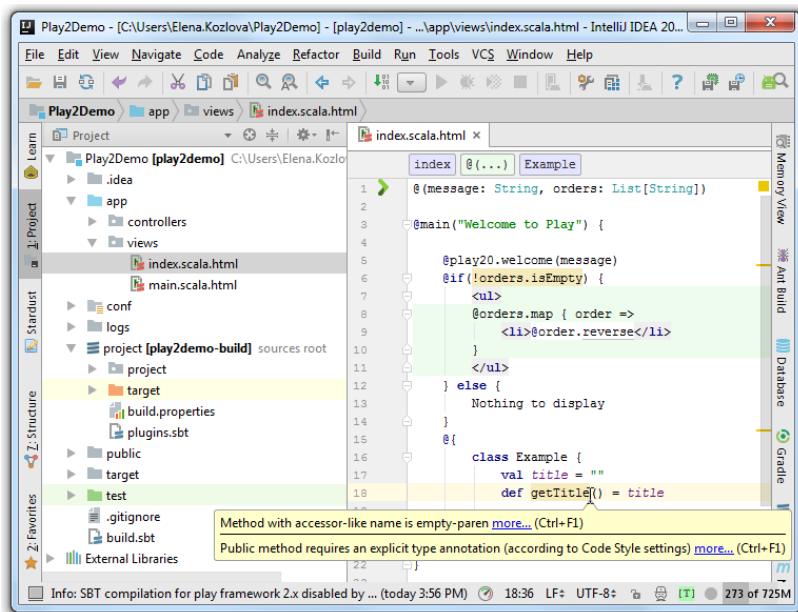

Also, ensure that the Scala compiler library is set.

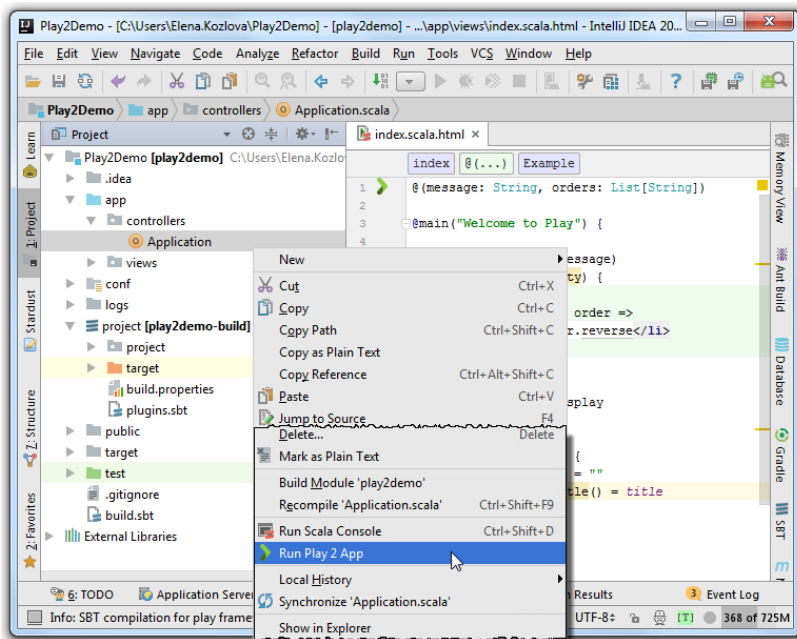

## Using code assistance

When everything is set up, you can use code completion, navigation and on-the-fly code analysis features in your Play files. IntelliJ IDEA also supports code assistance for routes files and code inspections.

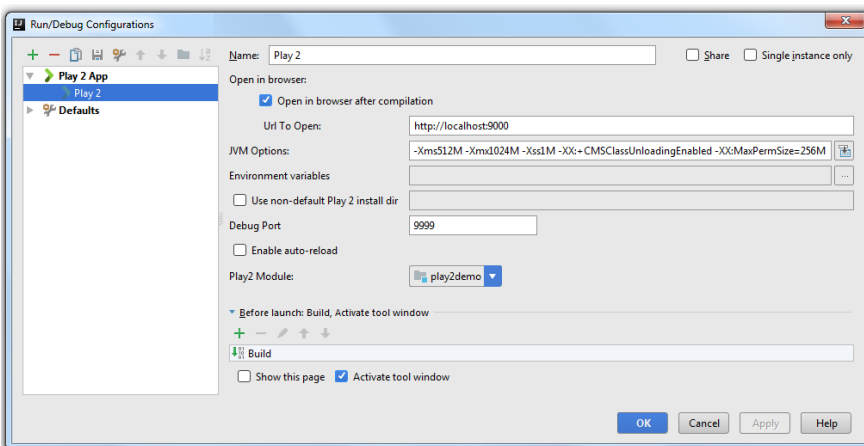

## Running a Play 2.x application

1. In the project tool window, right-click the application.
2. On the context menu, select Run Play 2 App .

## Debugging a Play 2.x application

1. On the main menu, select Run | Debug .
2. From the list that opens, select Edit Configurations .
3. In the dialog that opens, specify settings for debugging or use the default ones and press OK . IntelliJ IDEA will start a debugging session.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

On this page:

- [Introduction](#)
- [Before you start](#)
- [Importing a Scala.js project](#)

## Introduction

IntelliJ IDEA lets you import or check out from [VCS](#) an existing [Scala.js](#) project. Scala.js compiles Scala code to JavaScript and lets you write your Web application entirely in Scala.

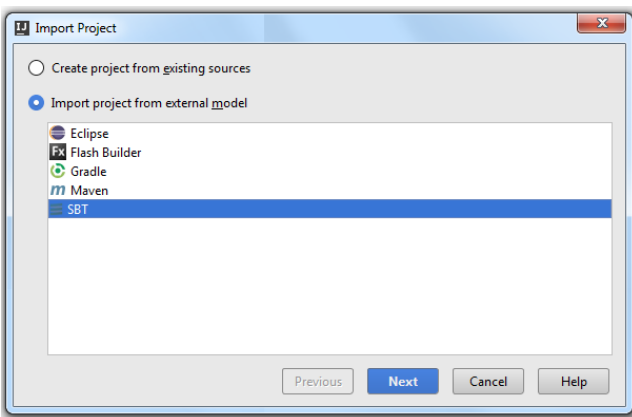

## Before you start

Before you start importing your Scala.js project, make sure that the Scala plugin is [downloaded and enabled](#) in IntelliJ IDEA.

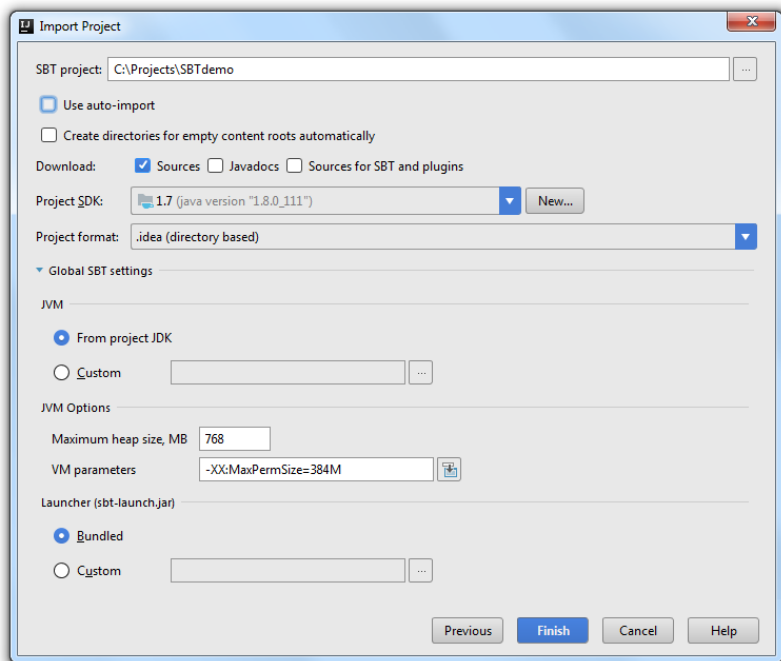

## Importing a Scala.js project

IntelliJ IDEA lets you import an existing Scala.js project.

1. On the main menu select File | New | Project from Existing Sources .
2. In the window that opens, select a file that you want to import and click OK . The Import project wizard opens.
3. On the first page of the wizard, select Import project from external model option and choose SBT project from the list.  
Click Next .

4. On the next page of the wizard, select [SBT options](#) and click Finish .

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

## – Creating a project

### Creating a project

Before you create a project make sure that the Scala plugin is [downloaded and enabled](#) in IntelliJ IDEA.

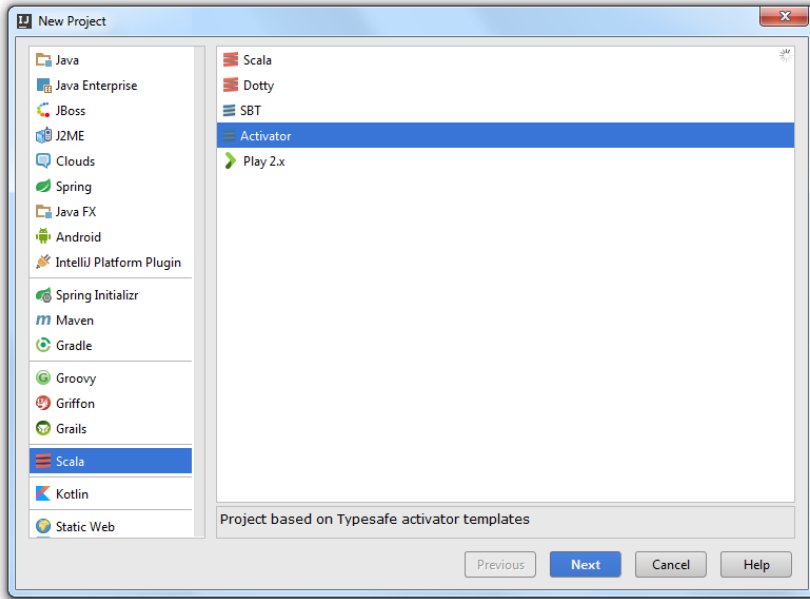

1. If no project is currently open in IntelliJ IDEA, click Create New Project on the Welcome screen. Otherwise, select File | New | Project .

As a result, the New Project wizard opens.

2. In the left-hand pane, select Scala .

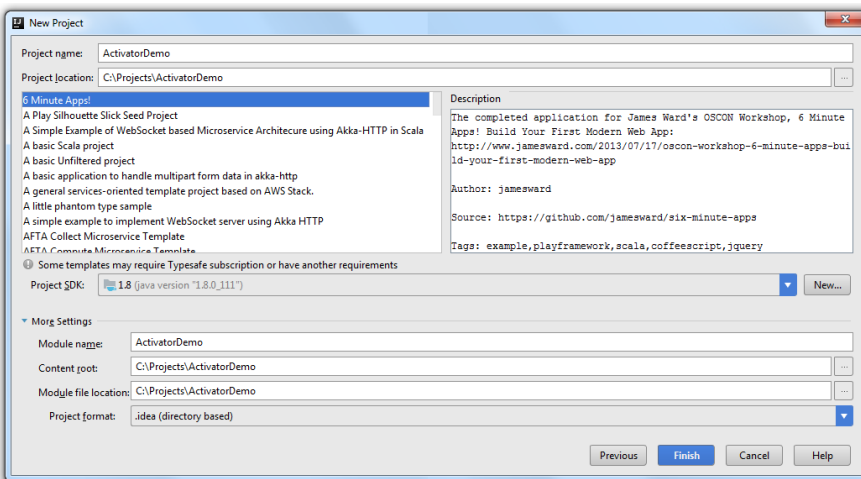

3. In the right-hand pane, select Activator .

You can also select [Scala](#) for creating a project with the Scala module, [SBT](#) for creating a project with the SBT module [Play 2.x](#) for creating a project with the Play 2.x framework or [Dotty](#) for creating a project with the Dotty SDK.

Click Next .

4. On the next page of the wizard, specify your project's information, select a template application that you want to open and click Finish .

The IntelliJ IDEA will create a project with the selected template application.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

Scala type-aware highlighting lets you get an error analysis based on the Scala type system before you start the compilation process.

- [Enabling or Disabling Type-Aware Highlighting on the Project Level](#)
- [Enabling or Disabling Type-Aware Highlighting on the File Level](#)
- [Working with Type-Aware Highlighting in Editor](#)
- [Disabling Type-Aware Highlighting Locally](#)

## Enabling or Disabling Type-Aware Highlighting on the Project Level

- Enable or disable the type-aware highlighting for your project by clicking  or  icon on the status bar. You can also use the `(Ctrl+Shift+Alt+E)` shortcut.

## Enabling or Disabling Type-Aware Highlighting on the File Level

- Open the file and on the status bar click  Hector icon. If you disable Hector, then the type-aware highlighting will also be disabled. Each time you enable or disable the type-aware highlighting, you can see the notification of the status's change in the Event log.

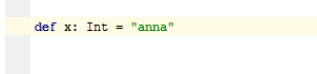

## Working with Type-Aware Highlighting in Editor

- Let's see how it works:

As you can see, the expression is wrong and the value is highlighted.

If the type-aware highlighting is disabled, the error is not highlighted and it might be quite difficult to spot:

- You can also enable the highlighting based on expression type inference.

Consider the following example:

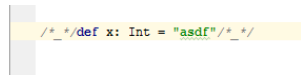

As the pop-up message suggests, the expression type is wrong and is highlighted.

## Disabling Type-Aware Highlighting Locally

- Highlight the code and on the main menu select Code | Surround With .
- When Surround With window opens, select the `/*_*/.../*_*/` option from the list.

After you've selected the appropriate option your code looks like this:

As a result, the error is not highlighted.

**Warning!** The following is only valid when Scala Plugin is installed and enabled!

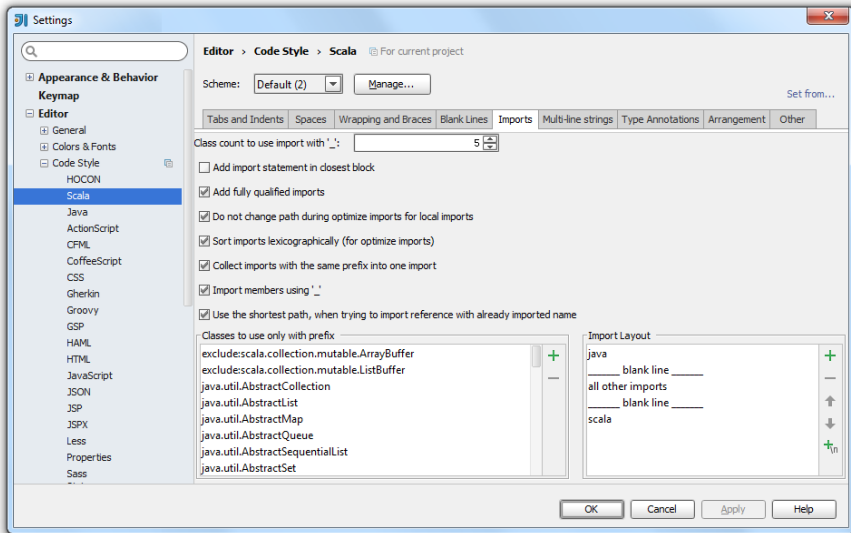

IntelliJ IDEA lets you manage your imports in Scala the same way as it does in other languages. You can configure imports in the Project Settings and in the IDE Settings. You can also optimize your imports and exclude classes from auto-import in the editor.

- [Managing Scala Imports through the Scala Settings](#)
- [Managing Scala Imports through Auto Import Settings](#)
- [Optimizing Imports](#)
- [Excluding Classes from Auto-Import](#)

## Managing Scala Imports through the Scala Settings

You can format your imports using Project Settings.

1. Select File | Settings | Code Style | Scala .
2. On the Scala page, select Imports tab.

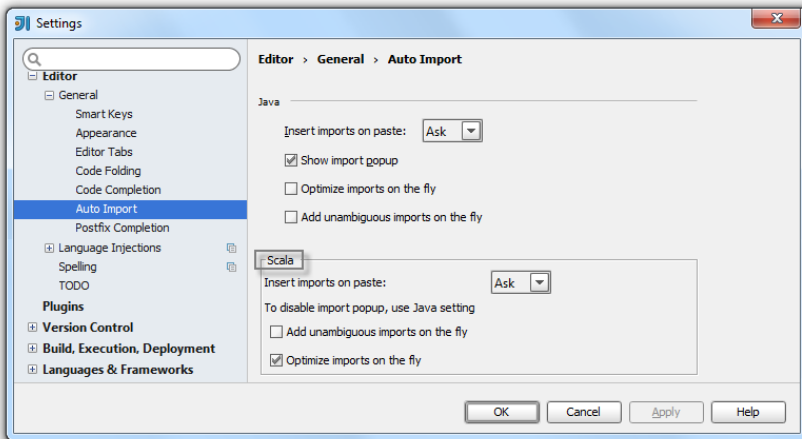

3. In the Imports tab, configure the [Importing settings](#) and press OK .

## Managing Scala Imports through Auto Import Settings

You can configure the behavior of the imports in your workspace through the Auto Import settings.

1. Select File | Settings | Editor | General | Auto Import .

2. On the Auto Import page, in the Scala section, select from the following options:
  - Insert imports on paste - use this drop-down list to define how IntelliJ IDEA will insert imports for pasted blocks of code if they contain references to classes that are not imported into the target class.

You can select from the following options:

- **All** - select this option to have IntelliJ IDEA automatically add import statements for all classes that are found in the pasted block of code and are not imported in the current class yet.
- **Ask** - if this option is selected, when pasting code blocks, IntelliJ IDEA will open a dialog box, where you can choose the desired imports.
- **None** - select this option to suppress import.

If you skip an import suggested in the **Ask** mode or choose the **None** mode, the non-imported classes will be red-

highlighted and an import pop-up window will appear to help you create import statements using the `Alt+Enter` keyboard shortcut.

- Optimize imports on the fly - select this checkbox to have the Optimize Imports operation automatically performed for your files.

If you clear this checkbox, you can manually optimize your imports selecting `Code | Optimize Imports`.

- Add unambiguous imports on the fly - select this checkbox to have IntelliJ IDEA automatically add imports that can be added without user intervention.

## Optimizing Imports

You can optimize imports on the directory selecting `Code | Optimize Imports` command. In this dialog box, specify from where you want IntelliJ IDEA to remove unused import statements, in order to optimize the import procedure.

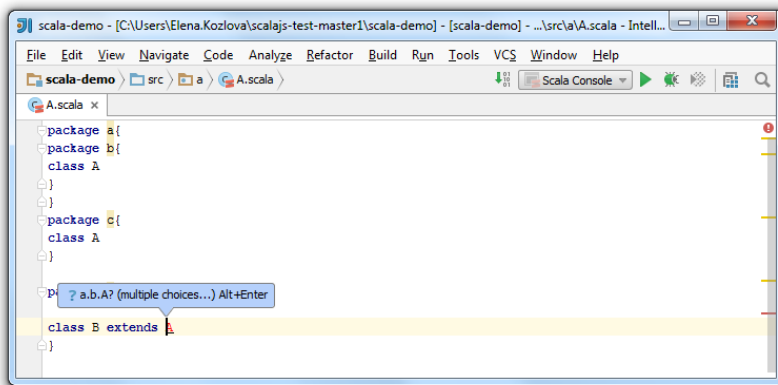

- Process only VCS changed files - if this checkbox is selected, then reformatting will apply only to the files that have been **changed locally**, but not yet checked in to the repository.

This checkbox is only available for the files under version control.

## Excluding Classes from Auto-Import

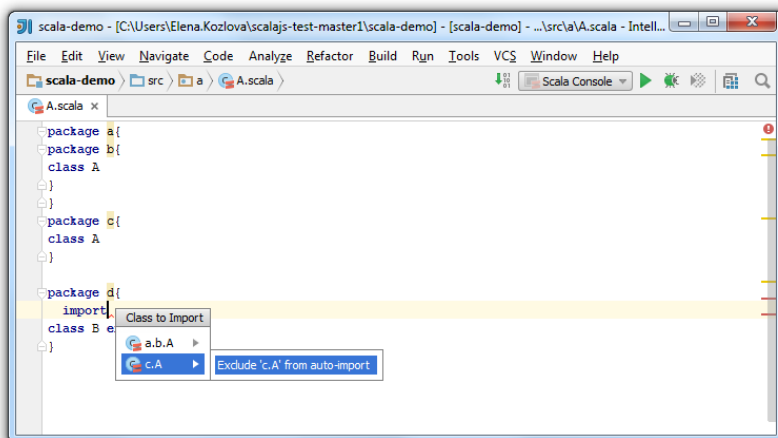

If the list of suggested imports is too wide, you can exclude unnecessary classes on the fly using intention actions.

1. Start typing a name in the editor.

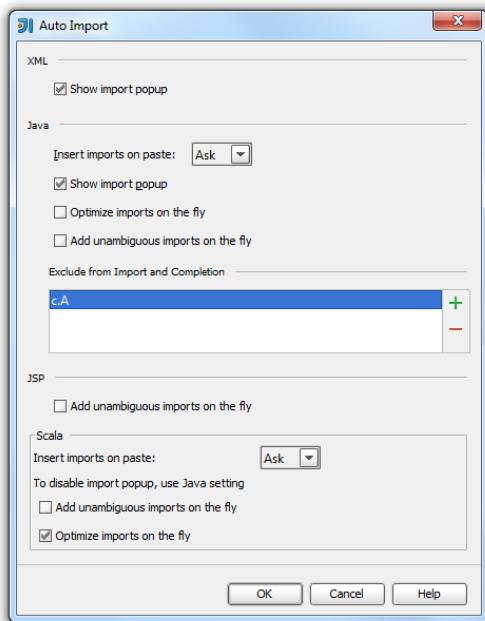

2. In the Class to Import suggestion list, click `Alt + Enter`, and click the right arrow to reveal the nested list of intention actions.

IntelliJ IDEA suggests to exclude specific class or the whole containing package.

3. In the dialog that opens perform necessary changes and click `OK`.

This feature is only supported in the Ultimate edition.

In this section:

- Seam
  - [Introduction](#)
  - [Developing applications using Jboss Seam](#)
- [Configuring Modules with Seam Support](#)
- [Defining Seam Components](#)
- [Viewing Seam Components](#)
- [Defining Seam Navigation Rules](#)
- [Defining Pageflow](#)
- [Navigating Within a Conversation](#)
- [Navigating Between an Observer and an Event](#)

## Introduction

[Seam](#) support in IntelliJ IDEA enables you to develop, run, debug and deploy applications using the facilities provided by this framework, by means of a dedicated Seam facet. Usually, Seam facet is used in modules in conjunction with the other facets required by the nature of your applications (for example, Web, EJB, JSF, Java EE, or Hibernate). Seam in IntelliJ IDEA make it easy to implement transactional models, Java Persistence API, JSF, and jPDL technologies.

Seam support involves:

- Automatic detection of Seam components.
- Detecting and visualizing Seam component dependencies.
- Possibility to detect and download the missing libraries and archives.
- Seam annotations.
- Injected expression language.
- Coding assistance (code completion, intention actions and quick fixes), which applies to the Seam annotations, components, navigation and pageflow definition files, and to injected expressions.
- Navigation, search and refactoring.

Besides the above mentioned features, IntelliJ IDEA supports business processes and pageflows provided by Seam:

- Possibility to define the page navigation rules, using the text editor, or the Navigations Graph.
- Possibility to define jPDL pageflow, using the text editor, or the Designer.

## Developing applications using Jboss Seam

### To develop an application using Jboss Seam, follow these general steps

1. [Configure Seam support](#) in your module.
2. Set up the required data sources, see [Managing data sources](#) .
3. Populate your application with the necessary classes.
4. [Define the Seam components](#) , using the `components.xml` file and Seam annotations.
5. Annotate the classes, using the other annotations (EJB, persistence etc.)
6. [Define the page navigation rules](#) .
7. [Define the pageflow](#) .

**Tip** In an application with Seam facet, you can:

- In addition to the regular means of [navigation](#) , you can jump [between the parties of a conversation](#) , or [from an observer to an event](#) .
- [Explore Seam components dependencies](#) .

This feature is only supported in the Ultimate edition.

Seam support requires a thorough approach to the module configuration. It is essential that all the necessary facets are enabled, and the libraries are defined. Thus you will be able to annotate your code, use import assistance, code completion and other productivity features of IntelliJ IDEA.

## To configure Seam support in a module

1. [Add Seam facet to the desired module](#) .
2. If you have not configured libraries for Seam in advance, the facet page displays the list of missing libraries. To resolve the problem, click the Fix button. In the Specify Libraries dialog box, specify whether you would like to use one of the existing libraries, or download the missing archive. You can control the target location where the archive will be placed, the library name, and the level on which the library will be created.
3. Edit the configuration files provided by other facets ( `web.xml` , `ejb-jar.xml` , `faces-config.xml` , hibernate configuration files etc) to include Seam-specific elements.
4. Create the necessary Seam files ( `seam.properties` , `components.xml` , `pages.xml` etc.)

This feature is only supported in the Ultimate edition.

You can define Seam components in two ways:

- By adding annotations to a class.
- By declaring a component in the `components.xml` file.

A component can be declared both with an annotation, and with an entry in the `components.xml` file. The `components.xml` file is used to specify additional properties of a component.

## To annotate a class as a Seam component

1. Open the desired class for editing.
2. Add the `@Name` Seam annotation:

```
>@Entity  
<@Name("")  
public hotel
```

**Tip** If the corresponding import statements are missing, use the import assistant prompt.

## To create the components.XML file

1. In the Project tool window, right-click the directory where you want to create the `components.xml` file, for example, `WEB-INF` directory, and choose New | Seam components.xml on the context menu.
2. Populate the file as required. Note that Seam-aware coding assistance is available.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides the possibility to view all Seam facets detected in your project in the [Seam tool window](#) . This view displays the list of all Seam components grouped by modules. The appropriate library components are also included.

For each module with a Seam facet, you can explore its structure using a dedicated dependencies graph. To open this graph, use the Show Seam Components Dependencies command available in the context menu for a module.

The read-only dependencies graph opens on a separate editor tab. You can change the way the graph is shown (zoom in and out, show or hide grid, change the layout, etc.) and perform other, basic operations.

## Viewing Seam components and dependencies

1. To open the [Seam tool window](#) , choose View | Tool Windows | Seam . The modules with a Seam facet are shown.

**Tip** You can navigate from a component to its definition in the Project view by pressing **F4** .

2. Use the toolbar buttons or the keyboard shortcuts to expand (, **Ctrl+NumPad Plus** ) or collapse (, **Ctrl+NumPad -** ) the nodes.

3. To open the dependency diagram for a module, right-click the module of interest and select Show Seam Components Dependencies from the context menu.

4. To view or edit the source code for a component, open the component in the editor. To do that, select the component of interest and press **F4** .  
To open the components which are the "leaves" of the tree (i. e. the ones at the bottom of the hierarchy), you can also use a double click.

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Creating pages.xml file](#)
- [Opening page navigation rules file](#)

## Introduction

If you have to define views for a whole application, use the global `pages.xml` file. This file contains description of the navigation rules, page actions, and exception handling. For a large application this file can grow too large, and in this case it makes sense to create a number of fine-grained `*.page.xml` files, one file per page. So doing, the global items should be still described in the `pages.xml` file.

IntelliJ IDEA provides [Navigation Graph](#) as an additional tab to the textual source of the xml file. In this view you can explore the page navigation rules in a convenient way.

The Navigation Graph tab is only available for the global `pages.xml` file. All the `*.page.xml` files detected in a module are collected and included in the common graph.

It is very important to properly configure the [Web resource directories](#) for a Web facet of your module. In particular, the directories that contain pages to be included in the navigation rules, should be added to the list of Web resources.

## Creating pages.XML file

### To create pages.XML file

1. In the Project view, right-click the `WEB-INF` directory.
2. On the context menu, choose `New | Seam pages.xml`. Stub `pages.xml` file is created.
3. Populate the file with the necessary pages, and define navigation rules. You can do it in one of the two possible ways:
  - Open the Navigation Graph tab, in the Project view select the desired pages, and drag-and-drop them to the diagram background. Draw links between the nodes.

- Open the Text tab, and type the source code for the navigation rules. Note that code completion is available for the paths to the pages, xml elements and expression language:

Note that source code of the page navigation file is fully synchronized with the Navigation Graph. Adding or removing a page or a link to/from the Navigation Graph is immediately reflected in the source code.

## Opening page navigation rules file

### To open the page navigation rules file

- In the Project view of the Project tool window, right-click the `pages.xml` file, and choose `Jump to Source`, or just press `F4`.

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Creating pageflow definition](#)
- [Actions, available in the Designer](#)

## Introduction

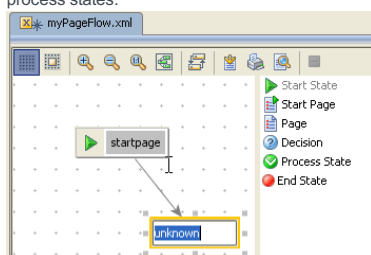

Enabling Seam facet in a module makes it possible to create pageflow definition using jPDL. IntelliJ IDEA provides a dedicated graphic Designer, completely synchronized with the source code. In the Designer, you can create a stub pageflow, which is immediately reflected in the source code of the pageflow file. To make the pageflow definition usable, you have to additionally edit the source code of the pageflow file.

It is very important to properly configure the [Web resource directories](#) for a Web facet of your module. In particular, the directories that contain pages to be included in the pageflow, should be added to the list of Web resources.

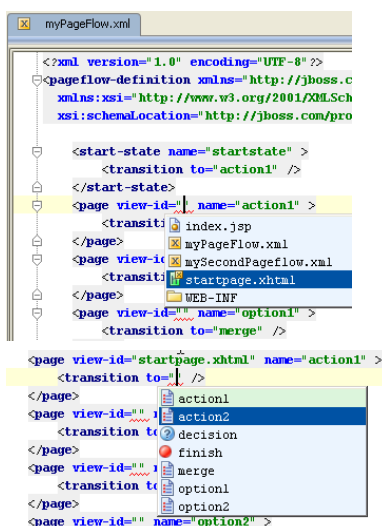

## Creating pageflow definition

### To create a pageflow definition

1. In the Project tool window, right-click the directory where you want to create the pageflow definition file, for example, `WEB-INF` directory, choose `New | Seam pageflow` on the context menu, and specify the file name. IntelliJ IDEA creates pageflow definition stub xml file, and opens it in a separate tab in the editor.
2. Click the Designer tab of the pageflow definition file.
3. Click the desired button in the toolbox of the Designer, and drag it to the Designer area. Add other nodes, and change their names as required. This way you can create start and end state, pages, decisions, and process states.

4. Draw links between nodes.
5. In the Text tab, edit the source code to associate it with specific views, add attributes and subelements (specifying action and decision expressions, transitions names, events, adding subprocesses to process states etc). Note the code completion for the attributes and values:

## Actions, available in the Designer

The following actions are available in the Designer:

- Navigation: you can jump from the visual presentation of a pageflow in the Designer to the underlying source code. To do that, right-click an element, and choose `Jump to Source` on the context menu, or press `F4`.
- Show Usages and Find Usages: select a node, and press `(Ctrl+Alt+F7)` or `(Alt+F7)`.
- Rename refactoring: select a node, press `(Shift+F6)`, and specify the new name in the Rename dialog box. So doing, the corresponding reference in the underlying xml file is also updated. Note that if you rename a node using the in-place editor, its reference in the source code is not changed, and an error is highlighted.
- Deleting nodes and links: when a node or link is deleted from the graph, the corresponding element is deleted from the

underlying xml file.

This feature is only supported in the Ultimate edition.

Seam support in IntelliJ IDEA includes support for conversations. The beginning and the end of a conversation are denoted with the `@Begin` and `@End` annotations respectively. In the source code editor, these annotations are marked with the gutter icons:

-  jump to the beginning of a conversation.
-  jump to the end of a conversation.

IntelliJ IDEA enables you navigate from the beginning of a conversation to its end, and vice versa.

## To navigate between the beginning and ending points of a conversation

- Click the gutter icon to the left from the `@Begin` annotation:

- Click the gutter icon to the left from the `@End` annotation:

If there are several possible end points of a conversation, you are prompted to select the desired one:

This feature is only supported in the Ultimate edition.

If a method is marked as an observer of a certain event type, you can jump to a method where this event is raised, using the [Show Usages](#) command.

## To navigate from an observer to an event to be observed

1. In the editor, place the caret at the event type value in the `@Observer` annotation.
2. Press `Ctrl+Alt+F7`, or choose `Edit | Find | Show Usages` on the main menu.
3. From the suggestion list, select the desired destination.

The class containing the method that raises the event in question, is opened in a separate tab, the caret resting at the event type value:

```
events.raiseTransactionSuccessEvent("bookingConfirmed");
```

**Tip** If an event is defined in the `components.xml` file, same kind of navigation is also available for it.

## Configuring Spring facet

**Warning!** Spring support is available in the Ultimate edition only.

To be able to use Spring in your project, you need to have a Spring facet that comprises libraries and UI elements for configuring Spring-specific settings.

IntelliJ IDEA can automatically detect Spring configuration in your code. It will inform you about missing configuration and will suggest necessary actions.

**Tip** If you are creating a brand new project or module, you can use the wizard to select necessary frameworks and libraries.

If for some reason IntelliJ IDEA could not detect configuration files, you can add the facet manually:

1. From the main menu, select File | Project Structure , or press `Ctrl+Shift+Alt+S` .
2. From the left-hand list, select Modules .
3. Select the necessary module and click `+` in the middle section.
4. Select Spring from the list.
5. You might need to set up a library when adding a facet. In this case, click Fix at the bottom of the window next to a warning message.

If you already have a Spring library, you can use it as is, or create a new library using JAR files on your computer. In this case, select the Use library option.

If you do not have a library, select Download .

If the Spring facet is configured correctly, you will see the gutter icons marking each component, bean, etc. To configure the gutter icons, press `Ctrl+Alt+S` and go to Editor | General | Gutter Icons .

## Creating application context

Spring application context is a way of grouping configuration files in IntelliJ IDEA. When you create a context, you let IntelliJ IDEA understand relationships between configuration files included into this context.

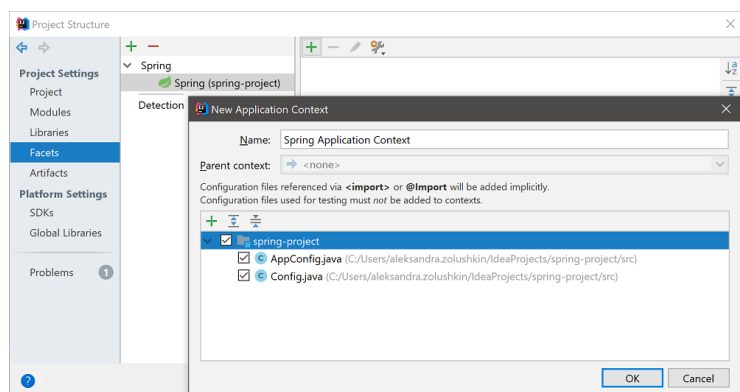

You can create as many application contexts as you need; any configuration file may be included in more than one context.

**Note** In some cases, you will not need to configure a context. For example, Spring MVC web applications have strict rules about their configuration. Spring support in IntelliJ IDEA can deduce them and create an autodetected application context for you, as well as set up the Web facet.

To create an application context:

1. Navigate to File | Project Structure | Facets .
2. Select the necessary Spring facet from the list and click `+` in the right-hand section.
3. In the New Application Context dialog, enter a name, and select files you want to include in the context.

Use the `-` and `↻` options to remove and edit contexts.

## Configuring parent context

IntelliJ IDEA allows you to configure a parent-child relationship between contexts.

Beans from a parent context are visible to beans in child contexts, but not vice versa. This way beans from child contexts can use configuration from the parent context.

For example, Spring MVC applications usually have two contexts. One context belongs to web layer beans, the other context is used for services and repositories. The web layer context will be a child context in this case, as you need to inject services into controllers, not other way around.

**Note** IntelliJ IDEA can configure parent context automatically. For example, if the IDE detects Spring Cloud context, it will make it a parent application context for Spring Boot.

To configure a parent context, use the New Application Context dialog.

The Multiple Context panel shows up on top of the editor for files included into two or more application contexts. You can use this panel to select another active context, for example, if you want to run your application with different configuration, and change highlighting. Click on the context name and select a context from the popup dialog.

To disable the panel, click , and deselect the Show Multiple Context panel checkbox.

## Navigating Spring dependencies

### Viewing Spring dependencies on diagram

The Spring dependencies diagram lets you view and analyze dependencies between beans and dependencies between configuration files in your project.

To build a diagram:

**Warning!** The UML Support plugin must be enabled to work with diagrams.

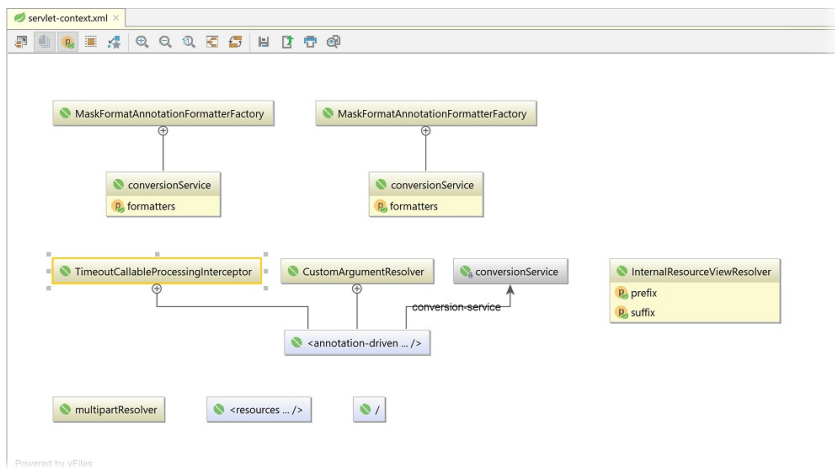

1. In the project structure, right-click a configuration file for which you want to build a diagram.
2. Select Diagrams from the menu.
3. Select Show Diagram Popup ( `Ctrl+Alt+U` ) to open a diagram in a local popup window, or Show Diagram ( `Ctrl+Shift+Alt+U` ) to open the diagram in the editor.
4. Select a diagram type. Use the Spring diagram to view beans that were defined in Spring configuration files.

The Spring Model Dependencies diagram is used for viewing relationship between configuration files.

**Tip** Bean names are considered symbols, so you can use the [navigate to symbol](#) option as well.

In Spring MVC you can also use URI request mapping to navigate to symbol. This will get you to the controller method that is mapped to the URI.

Different color edges on the diagram denote different types of connections between components ( import , component scan , etc.). Tooltips on the nodes and the edges can give you details on what each element contributes to the application context.

### Using diagrams to detect setup errors

Errors in your Spring configuration can happen at the dependencies level. For example, a circular dependency.

Circular dependencies may be hard to detect as they do not cause any obvious errors. However, some beans will be loaded multiple times possibly resulting in unexpected behaviour.

On diagrams, red arrows mark errors, such as circular dependencies, and allow you to easily spot and remove them from

your Spring configuration.

### Browsing dependencies in Spring tool window

The Spring tool window helps you navigate between Spring components and dependencies. You can view definitions for the Spring beans used in your project, and see how they are related to other beans.

To access the Spring tool window, navigate to View | Tool Windows | Spring .

**Note** For Spring MVC , the tool window lets you navigate to request mappings.

If your configuration comprises Spring Data , the Data tab of the tool window will show you the list of repositories, their queries and their projection.

The left part of the window lists all modules in your project.

Click on the necessary module to view application contexts, and then configuration files in these contexts.

For each configuration file, you can view the list of beans. By clicking on a bean, you can view its documentation and diagram showing its relation to other beans.

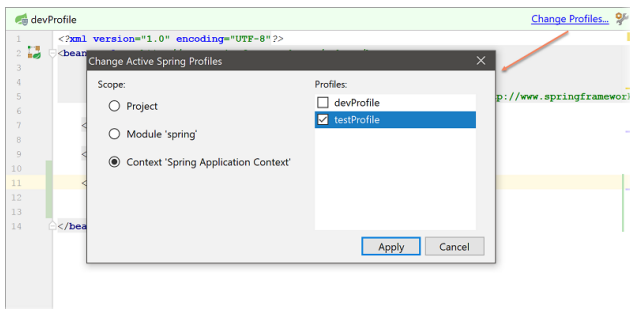

## Changing active profiles

Spring allows you to map specific contexts or beans to different profiles — for example, *test* or *production*. This way, you can activate different profiles in different environments.

If you have defined at least one profile in your project, IntelliJ IDEA will show a special panel on top of the editor. You can use this panel to view the current profile name and to change active profiles:

**Tip** You can also change active profiles in the Spring tool window. Right-click a component and select **Change Active Spring Profiles**.

1. Click **Change Profiles** on the panel.
2. Select a component to which you want to map the profile. This can be either entire project, current module or current context.
3. Select a profile to which you want to map this component.

If you want to hide the panel, click .

it. In the next dialog, deselect the **Show Profiles panel** checkbox.

## Spring Boot

### Getting started with Spring Boot

Spring Initializr is a wizard that allows you to select the necessary configuration when you are creating a project or a module. For example, you can select the necessary building tool, or add Spring Boot starters and dependencies.

To access the wizard, navigate to **File | New | Project or Module**, and select **Spring Initializr**. Follow the steps of the wizard to select technologies and dependencies you want to use.

### Configuring custom configuration files

**Note** Some custom configuration files are configured automatically. For example, profile-specific configuration files with names that match the current naming pattern will be added to the context.

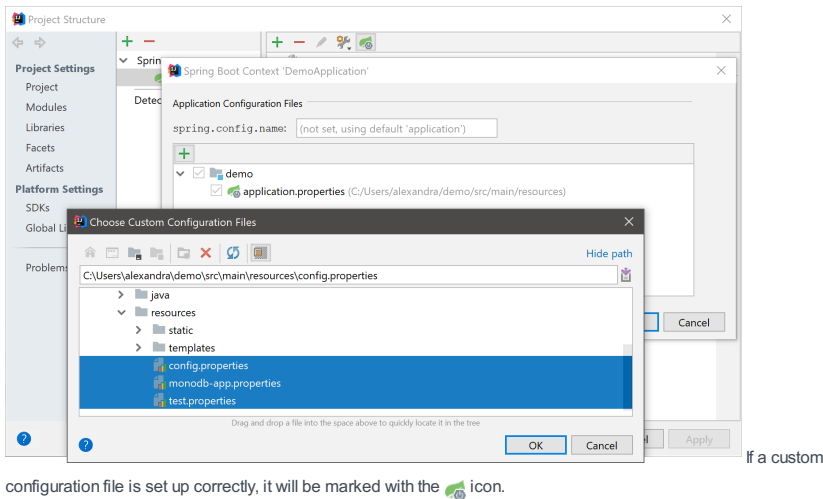

Spring Initializr creates one default configuration file that may not always be sufficient for your purposes. If you do not want to use the default configuration file, or if you want to run your code in different environments, you can use custom configuration files.

To do so, you have to let IntelliJ IDEA know which files are configuration files in your project. This will enable relevant highlighting and coding assistance.

1. Navigate to **File | Project Structure | Facets**.
2. Click  ( **Customize Spring Boot** ) in the toolbar.
3. If you want to use a custom configuration file instead of the default one, type in the name of a new custom configuration file in the search box.

If you want to use multiple configuration files, click  and select files from the project tree.

4. Click **OK** and apply the changes.

## Running and monitoring Spring Boot applications

**Note** The endpoints feature is available in Spring Boot version 1.3 and later.

Spring Boot has built-in features that allow you to get key metrics and monitor the state of your application in production environment by invoking different endpoints, such as health or bean details.

In IntelliJ IDEA, you can view endpoints on the Endpoints tab. This tab appears on the Run dashboard, or in the Run/Debug tool window, when you run an application.

To enable the Run dashboard, open the Run/Debug Configurations dialog, and select Defaults. Under the Run Dashboard Types section, click + and select Spring Boot.

To show or hide the dashboard, go to View | Tool Windows and click Run dashboard.

**Tip** The Run dashboard allows you manage your applications and monitor their state. If any errors are detected at runtime, the dashboard will display information that will help you identify and resolve them.

The Endpoints tab becomes available if the Enable JMX agent checkbox is selected in the Run/Debug Configurations dialog.

Moreover, make sure to add the `org.springframework.boot.spring-boot-starter-actuator` dependency to your module before running your application. This will let IntelliJ IDEA access and display the endpoints. For the mappings endpoint, add the `org.springframework.boot.spring-boot-starter-web` starter as well.

This feature is only supported in the Ultimate edition.

In this section:

- Struts Framework
  - [Introduction](#)
  - [Developing Web applications with Struts](#)
- [Struts Data Sources](#)
- [Preparing to Use Struts](#)
- [Managing Struts Elements](#)
- [Managing Tiles](#)
- [Managing Validators](#)
- [Using the Web Flow Diagram](#)

## Introduction

IntelliJ IDEA supports the [Struts](#) framework for creating Java EE and Web Applications.

Struts support is enabled through the dedicated Web and Struts facets. The dedicated [facets](#) that contain settings, configuration file paths, and validation rules determine the structure of the module so that IntelliJ IDEA detects how to treat the module contents.

- A Struts facet can be only created as a child of a [Web facet](#) .
- Only one Struts facet is allowed per module.

IntelliJ IDEA provides the following support of the Struts framework:

- Automatic creation of the specific module structure and the Web application deployment descriptor `web.xml` based on the dedicated Web facet.
- Downloading and adding the necessary libraries automatically and creating the Struts application configuration file `struts-config.xml` based on the dedicated [Struts facet](#) .
- Coding assistance, including code completion, syntax and error highlighting, documentation lookup, and refactoring.
- Go to Symbol and support for Actions.
- [Code inspections](#) .
- [Structure tool window](#) with native Struts application structure navigation and Struts actions.
- A [Struts Assistant tool window](#) that provides facilities to [manage Struts elements](#) .

## Developing Web applications with Struts

### To develop a Web application using Struts, follow these general steps

1. [Enable Struts support.](#)
2. [Create and edit the Struts elements and their interaction .](#)
3. [Create and edit tiles.](#)
4. [Create and edit validators.](#)
5. Populate your application with the necessary classes.
6. Deploy and run your application.

This feature is only supported in the Ultimate edition.

[Struts](#) Data Sources are managed in the Struts configuration file `struts-config.xml` .

IntelliJ IDEA provides a user-friendly visual interface for [creating](#) , [editing](#) , and [removing](#) data sources.

Data source elements are created and removed in the same way as other elements.

Editing a data source includes [editing its properties](#) and [handling its attributes](#) .

This feature is only supported in the Ultimate edition.

In this section:

- [Before you start](#)
- [Basics](#)
- [Creating a Module with a Struts Facet](#)
- [Adding a Struts Facet to a Module](#)
- [Customizing the Struts Facet](#)

## Before you start

Make sure the **Web** and **Struts1.x** bundled plugins are enabled. The plugins are activated by default. If the plugins are disabled, enable them on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Basics

Integration with **Struts** is enabled through the Web and Struts1.x facets. These **dedicated facets** contain settings, configuration file paths, and validation rules. This information determines the structure of a module so IntelliJ IDEA detects how to treat the module contents.

A Struts1.x facet can be only added as a child of a [Web facet](#). Note that only one Struts1.x facet is allowed in a module.

## Creating a Module with a Struts Facet

When you create a Struts module with the dedicated Web and Struts facets, IntelliJ IDEA configures the module, downloads and adds all the necessary libraries automatically.

1. Do one of the following:

- If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
- If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.

2. On the first page of the wizard, in the left-hand pane, select Java . In the right-hand part of the page, specify the [JDK](#) that you are going to use.

3. Under Additional Libraries and Frameworks , select the Web Application checkbox.  
Select the version of the Servlet specification to be supported from the Versions list.

If you want the deployment descriptor `web.xml` file to be created, select the Create web.xml checkbox.

4. Select the Struts checkbox.

5. Select the Struts version from the Version list.

6. You'll need a [library](#) that implements Struts. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the [Ctrl](#) key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement the selected Struts version. (The downloaded files will be arranged in a [library](#) .)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .

7. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

IntelliJ IDEA configures the new module as follows

- Creates the structure of the module with the Web and WEB-INF nodes.
- Creates a Web application deployment descriptor `web.xml` under the WEB-INF node for versions 2.2 - 2.5.
- Creates a Struts configuration file `struts-config.xml` under in the WEB-INF node.
- Configures an Action servlet in `web.xml` .
- Downloads and installs the libraries that implement Struts.

## Adding a Struts Facet to a Module

When you add a Struts facet to an existing module, IntelliJ IDEA downloads and adds the necessary libraries automatically.

A Struts facet can be added only as a child of a Web facet. If the module has no Web facet, add it first. Also note that only one Struts facet is allowed in a module.

This will change the [configuration of the module](#) .

1. Open the module settings.
2. In the Modules node, right-click the relevant module.
3. To add a Web facet, choose New from the context menu. In the drop-down list of available facets, select Web .
4. Right-click the Web node and select New on its context menu.
5. Select Struts on the context menu of available facets. The right-hand pane displays the [Facet 'Struts'](#) dialog.
6. Customize the Struts facet settings in the [Struts Features](#) and [Validation](#) tabs.
7. If some additional libraries are required, the corresponding warning message displays. Click [Fix](#) . The necessary libraries will be downloaded and added automatically.

## Customizing the Struts Facet

After you have enabled the basic Struts support, IntelliJ IDEA provides the ability to add more Struts features by customizing the Struts dedicated facet.

1. Open the settings of the Struts facet from the module in question.
2. The [Struts Features](#) tab shows a list of additional Struts components:
  - [Struts taglib](#)
  - [Struts EHtaglib](#)
  - [Tiles](#)
  - [Validator](#)
  - [Struts-Faces](#)
  - [Scripting](#)
  - [Extras](#)

To enable support of a component from the list, select the checkbox next to it.

3. In the [Validation](#) tab, specify the files to validate and the validation settings:
  - To enable validating the configuration file of a particular component, select the relevant checkbox. IntelliJ IDEA will check whether the selected component can be supported correctly using the available resources and suggest to download the missing libraries, if necessary.  
Validation can be enabled for the configuration files of the following components:
    - Struts
    - Tiles
    - Validator
  - Specify the validation settings:
    - To get informed on errors detected during validation, select the [Report errors as warnings](#) checkbox.
    - To exclude [Struts property keys](#) from validation, select the [Disable property keys validation](#) checkbox.

This feature is only supported in the Ultimate edition.

The structure of a Struts application including numerous [Struts elements and the interaction](#) between them is defined in the Struts configuration file `struts-config.xml`. The Struts configuration file is created automatically when you [enable Struts support](#) for a module.

With IntelliJ IDEA, you can edit the `struts-config.xml` in the [Struts Assistant tool window](#), which provides three synchronized views:

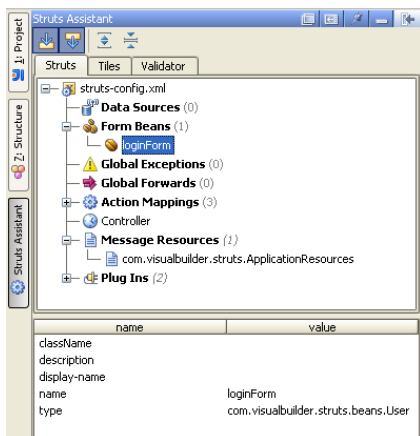

- the [Structure Tree](#)
- the [Properties Table](#)
- the [Struts Web Flow Diagram](#)

To define the structure of a Struts application, [create and edit](#) the necessary Struts elements and specify interaction among them using the [Struts Assistant tool window](#), tab [Struts](#). This dedicated tool window provides three synchronized views:

- the [Structure Tree](#) to add, edit, and remove Struts elements.

- the [Properties Table](#) to specify the values of elements and their attributes.

- the [Struts Web Flow Diagram](#) to navigate through the Struts application structure.

IntelliJ IDEA provides the facilities for managing the following Struts elements according to the [common procedure](#):

- [Data Sources](#)
- [Form Beans](#)
- Global Exceptions
- Global Forwards
- [Action Mappings](#)
- [controller](#)  
There can be only one controller element in a Web application.
- [Message Resources](#)
- [Plugins](#)

Managing [tiles](#) and [validators](#) in a friendly interface requires that you enable [support of them](#) first.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides a user-friendly visual interface for managing Struts elements which includes:

- [Creating](#) , [editing](#) , and [removing](#) elements.
- Handling [attributes](#) of elements.
- Specifying and editing elements' [properties and attributes](#) .

The [set of actions and attributes available](#) for a specific element depends on its nature.

## To create an element

All types of elements are created in the same way.

1. Open `struts-config.xml` .
2. Switch to the [Struts Assistant tool window](#) , tab Struts .
3. Right-click the corresponding element type in the Structure Tree and select the Add action from the context menu.
4. Specify the properties of the new element in the Properties Table .

Alternatively, right-click the element in the tree and select Jump to Source or press `F4` . This will bring you to `struts-config.xml` in the text view where you can specify the element's properties manually. IntelliJ IDEA displays a template for specifying the properties that are mandatory for the elements of the specific type.

## To remove an element

All types of elements are removed in the same way.

- Right-click it in the Structure Tree and select the Remove action from the context menu.

## To view or edit an element

1. Select it in the Structure Tree or on the Struts Web Flow Diagram and make the necessary changes in the Properties Table .
2. To add an attribute to the element, right-click the element in the Structure Tree and select Add in the context menu.
3. Specify the properties of the attribute in the Properties Table .
4. To remove an attribute, right-click it in the Structure Tree and select Remove in the context menu

**Warning** When you remove an attribute, its nested properties are removed as well.

This feature is only supported in the Ultimate edition.

[Tiles](#) is a templating system to create a common look and feel for a Web application.

Tiles are managed through creating, editing, and removing tile definitions, which describe tile attributes and tile elements. Tile definitions are specified in the `tiles-defs.xml` which is created when you enable tiles support.

With IntelliJ IDEA, you can edit the `tiles-defs.xml` file in the [Struts Assistant tool window](#), which provides two synchronized views: the [Structure Tree](#) and the [Properties Table](#).

Tiles are removed in the same way as other Struts elements.

Editing a tile includes [editing its properties](#) and [handling its attributes](#): forwards, exceptions, and set properties.

## To create a tile

1. [Enable tiles support](#).
2. Open `tiles-defs.xml`.
3. To add a tile definition, add the `<definition>` element to `tiles-defs.xml` manually.
4. Switch to the [Struts Assistant tool window](#), tab Tiles. A new Definition node appears in the Structure Tree.
5. Specify the attributes of the new tile in the Properties Table.  
Alternatively, right-click the tile in the tree and select Jump to Source or press `F4`. This will bring you to `tiles-defs.xml` where you can specify the tile's attributes manually. IntelliJ IDEA displays a template for specifying the mandatory attributes.

## To remove a tile

- Right-click the tile in the Structure Tree and select Remove Definition from the context menu.

## To edit a tile

1. Select it in the Structure Tree.
2. To edit the attributes of the tile, make the necessary changes in the Properties Table.
3. To manage the [elements of a tile](#), use the Structure Tree and the Properties Table.

The [elements are created, edited, and removed](#) in the same way as common Struts elements.

This feature is only supported in the Ultimate edition.

The [Validator](#) functionality within the Struts framework is intended for validating the data of forms in a Web application.

The Validator functionality uses two `xml` configuration files:

– The `validator-rules.xml` file defines the standard reusable validation routines that make the basis for configuring form-specific validations. The file is created when you enable Struts support and is supplied with a predefined set of commonly used validation rules such as Required , Minimum Length , Maximum length , Date Validation , Email Address validation and others.

The file is closed for editing.

– In the `validation.xml` file, define the validations applied to a particular form bean.

While you edit `validation.xml` , IntelliJ IDEA coordinates the code of the two files and provides you with coding assistance based on the routines defined in `validator-rules.xml` .

## To define the validations to apply to a form

1. Open `validation.xml` .
2. To add a validation definition, add the `<form-validation>` tag manually.
3. Switch to the [Struts Assistant tool window](#) , tab Validator . A new node appears in the Structure Tree .
4. Edit the attributes of the validation definition in the Properties Table .

This feature is only supported in the Ultimate edition.

Use the Web Flow Diagram for navigating through Struts configuration file `struts-config.xml` and viewing Struts actions, pages, and other elements and interactions among them. The Diagram is coordinated with the Structure Tree and Properties Table views.

### To see the Web Flow diagram

- Open your Struts configuration file `struts-config.xml` and click Diagram at the bottom of the editor window.

The layout of the diagram is common for all [diagrams](#) .

This feature is only supported in the Ultimate edition.

In this section:

- Struts 2
  - [Introduction](#)
  - [Developing Web applications with Struts 2](#)
- [Preparing to Use Struts 2](#)
- [Managing Struts 2 Elements](#)

## Introduction

IntelliJ IDEA supports integration with the [Struts 2](#) framework for creating Java EE and Web Applications.

IntelliJ IDEA provides the following support of the Struts 2 framework:

- Automatic creation of the specific module structure and the Web application deployment descriptor `web.xml` based on the dedicated Web facet.
- Downloading and adding the necessary libraries automatically and creating the Struts 2 application configuration file `struts.xml` based on the dedicated [Struts 2 facet](#).
- A [file set manager](#), library validator, and automatic detection of configuration settings.
- Coding assistance, including code completion, syntax and error highlighting, documentation lookup, and refactoring.
- Multiple [code inspections](#) that spot code issues specific for Struts 2.
- Smart navigation across Java, JSP and XML files.
- Support for in-place JavaScript and CSS code.
- Graphic view for the `struts.xml` configuration file.
- Java EE preview for JSP and JSF pages.
- [Structure tool window](#) that provides navigation across the native Struts 2 application structure and displays Struts 2 actions.

## Developing Web applications with Struts 2

### To develop a Web application using Struts 2, follow these general steps

1. Enable support of [Web](#) and [Struts 2](#) development.
2. Create and configure general [Web application elements](#): servlets, filters, and listeners.
3. Create and configure [Struts 2 specific elements](#).
4. Populate your application with the necessary classes.
5. Deploy and run your application.

On this page:

- [Before you start](#)
- [Basics](#)
- [Creating a Module with a Struts 2 Facet](#)
- [Adding a Struts 2 Facet to a Module](#)
- [Defining the Validation File Set](#)
  - [Adding a Validation File Set](#)
  - [Editing a Validation File Set](#)

## Before you start

Make sure the **Web** and **Struts2** bundled plugins are enabled. The plugins are activated by default. If the plugins are disabled, enable them on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Basics

Integration with **Struts 2** is enabled through the Web and Struts 2 facets. These dedicated facets contain settings, configuration file paths, and validation rules. This information determines the structure of a module so IntelliJ IDEA detects how to treat the module contents.

A Struts 2 facet can be only added as a child of a [Web facet](#). Note that only one Struts 2 facet is allowed in a module.

## Creating a Module with a Struts 2 Facet

When you create a Struts 2 module with the dedicated Web and Struts 2 facets, IntelliJ IDEA configures the module, downloads and adds all the necessary libraries automatically.

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project . As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module . As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java . In the right-hand part of the page, specify the [JDK](#) that you are going to use.
3. Under Additional Libraries and Frameworks , select the Web Application checkbox. Select the version of the Servlet specification to be supported from the Versions list.

If you want the deployment descriptor `web.xml` file to be created, select the Create web.xml checkbox.

4. Select the Struts 2 checkbox.
5. You'll need a [library](#) that implements Struts 2. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)
  - Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the library files that implement Struts 2. (The downloaded files will be arranged in a [library](#) .) Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .

6. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) . Click Finish .

IntelliJ IDEA configures the new module as follows:

- Creates a web node with a web application descriptor `web.xml` .
- Creates a Struts 2 configuration file `struts.xml` and adds it to the src node.
- Adds the required Struts 2 libraries.

## Adding a Struts 2 Facet to a Module

When you add a Struts 2 facet to an existing module, IntelliJ IDEA downloads and adds the necessary libraries automatically.

A Struts 2 facet can be added only as a child of a Web facet. If the module has no Web facet, add it first. Also note that only one Struts 2 facet in a module is allowed.

This will change the [configuration of the module](#) .

1. Open the module settings.
2. In the Modules node, right-click the relevant module.
3. To add a Web facet, choose New from the context menu. In the drop-down list of available facets, select Web .
4. Right-click the Web Facet node and select New on its context menu.
5. Select Struts 2 on the context menu of available facets. The right-hand pane displays the [Facet Struts 2](#) dialog.
6. In the [File Sets](#) tab, [specify the configuration files to validate](#) .
7. If some additional libraries are required, the corresponding warning message displays. Click Fix . The necessary libraries will be downloaded and added automatically.

The created Struts 2 configuration file `struts.xml` is located in the src node.

## Defining the Validation File Set

After you have enabled the Struts 2 support, IntelliJ IDEA provides the ability to define the validation list by [adding](#) , [editing](#) , and [removing file sets](#) .

## Adding a Validation File Set

1. Open the [Struts 2 Facet page](#) .
2. Switch to the [File Sets](#) tab.
3. Click  ( `Alt+Insert` ). The [Edit File Set dialog](#) opens showing the module tree.
4. In the File Set Name field, specify the name of the new file set.
5. To add a file to the set, select the checkbox next to its name.
6. To add a file that is not displayed in the tree, click Locate and select the the required files in the [Select Path dialog](#) .

## Editing a Validation File Set

1. Select the file set on the File Sets tab and click  ( `Enter` ). The Edit File Set dialog opens.
2. To add files to the file set, select the checkboxes next the required files and click OK .
3. To remove a file, select the file and click  ( `Alt+Delete` ).

To remove a validation file set, select it on the File Sets tab and click  ( `Alt+Delete` ).

[Struts 2 elements](#) like actions, results, and interceptors as well as interaction between them is defined in the `<package>` section of the `struts.xml` configuration file. The file is created automatically when you [enable Struts 2 support](#) for a module.

IntelliJ IDEA provides you with a friendly interface for editing `struts.xml` both in the text view and in [diagram](#) .

### To switch between the views

- Open `struts.xml` in the project view and click Graph in the bottom of the window.

### To create a Struts 2 application element

1. Switch to the [Project Tool Window](#) and select Project in the View as drop-down list.
2. Right-click the `struts.xml` node and select New in the context menu. Then select the relevant element type. The New... dialog box opens.
3. Specify the element data and click OK . A new element is created and displayed in the project tree. The corresponding source code is generated in the `struts.xml` .

### To remove a Struts application element, do one of the following

- In the [Project Tool Window](#) , select the element in the project tree. Then select Delete in the context menu.
- Switch to the `struts.xml` and make the necessary changes manually.

In this section:

- [Swing. Designing GUI](#)
- [GUI Designer Basics](#)
  - [GUI Designer Files](#)
  - [Bound Class](#)
  - [GUI Designer Output Options](#)
- [Customizing the Component Palette](#)
  - [Adding GUI Components and Forms to the Palette](#)
  - [Configuring Libraries of UI Components](#)
  - [Creating Groups](#)
- [Designing GUI. Major Steps](#)
  - [Binding the Form and Components to Code](#)
  - [Creating and Opening Forms](#)
  - [Localizing Forms](#)
  - [Making Forms Functional](#)
  - [Populating Your GUI Form](#)
  - [Setting Component Properties](#)
  - [Previewing Forms](#)

IntelliJ IDEA's [GUI Designer](#) enables you to [create graphical user interfaces \(GUI\)](#) for your applications, using Swing library components. The tool helps you speed up the most frequently needed tasks: creating dialogs and groups of controls to be used in a top-level container such as a JFrame. When you design a form with the GUI Designer, you create a pane rather than a frame.

Dialogs and groups of controls created with the GUI Designer, can coexist in the application with the components that you create directly with Java code.

In this part:

- [GUI Designer Files](#) .
- [Bound Class](#) .
- [GUI Designer Output Options](#) .

Using the GUI Designer is subject to the following limitations:

- GUI Designer does not support modeling of non-Swing components.
- The GUI Designer does not create a main frame for an application, nor does it create menus.

At design time, GUI information is stored in special files with a `.form` extension. These files are XML files that conform to a special schema. You can put the `.form` files into any version control system. A form can be associated with a [Java source file](#).

The GUI Designer suggests two ways of producing GUI forms: you can either create them [from scratch](#), or capture [snapshots](#) of the existing dialogs and create GUI Designer Forms from the snapshots. It doesn't matter if the dialogs were hand coded or made with another UI design tool - just capture them from the running application using the Form Snapshot feature.

A snapshot is not related to its original implementation. When you take a snapshot, you thus give up the source code used to produce the form.

**Warning!** IntelliJ IDEA does not provide the means to open the XML source of the `.form` files in the text editor, and you should not modify these files manually as text.

By default, IntelliJ IDEA automatically creates a Java class at the same time it creates a new GUI form. The new form automatically binds to the new class via the bind to class property. When components are added to the design form, a field for each component is automatically inserted into the source file of the Form's class (with some exceptions such as JPanels and JLabels which don't automatically get field names when placed on a Form). The field name appears in the relevant component's field name property, thereby binding the component to code in the class. It only remains to augment the generated code with whatever additional code is needed to implement behaviors and functionality of the form.

 Automatic binding of a component to a field is stipulated by the [Create binding field automatically](#) property of a component in the Palette.

You can opt to create a new form without a bound class. In this case you will have to [explicitly bind a form to the source code](#)

IntelliJ IDEA's GUI Designer provides two options for the output:

- Runtime classes that are generated when you compile the project to which they pertain. In this case, the intermediate step of Java source code is bypassed. Optionally, the compiled classes can be written to the compiler output directory configured for the project.
- Java source code . In that case, all code for the UI components is generated to the class to which each form is bound.

Refer to the [GUI Designer dialog](#) for the detailed description of options.

You can customize the GUI Designer's component Palette, adding groups to organize your own custom UI components and/or components from one or more third-party libraries. You can also edit the contents of any existing Palette groups to add or remove components.

### **To customize your Palette, perform the following general steps**

1. Install the desired archives of UI components in a location accessible to your computer. One of the possible locations is the `lib` folder of your IntelliJ IDEA installation.
2. [Open the Project Settings dialog](#) .
3. [Configure the archives of UI components](#) .
4. In the GUI Designer Palette, [create groups](#) and [add UI classes or forms](#) .

Adding new elements to the Palette enables you to reuse components from the libraries, or already created GUI forms that exist in your project.

For visual identification of the new components, you can use icons. Icons should not be larger than 18 x 18 pixels. If no icon is provided for a component, the Palette will default to the icon of the ancestor class if the component is derived from a Java UI class, or a default icon.

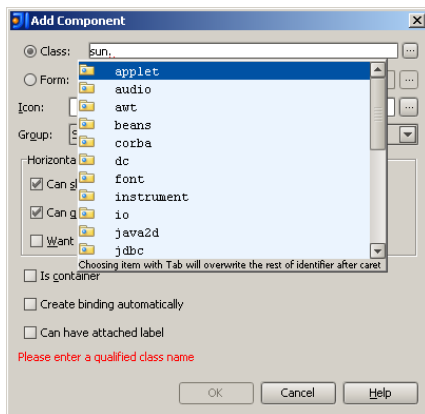

## To add a new component to the Palette

1. Right-click the target group, and choose Add Component to Palette . The **Add Component dialog** opens.

**Tip** To change an existing component, select one in the Palette, and choose Edit Component command on the context menu.

2. Click Class radio-button to add a component from a class library, or Form to add an existing GUI form.

3. Specify the fully qualified name of the component class or form, or click the ellipsis button next to the selected field, and choose the desired component class or form file in the Choose Component Class or Choose Form File dialog respectively.

**Note** If you are adding a form to the palette, make sure that the top-level component of the form is bound to a field: the field name property in the **Inspector** should not be void.

4. Optionally specify an icon for the component. Enter the fully qualified name of the icon file, or click the Browse button next to the Icon field, and choose the desired icon in the Choose Icon File dialog.
5. In the Horizontal / Vertical size policies section, define how the component should [behave when its parent container is being resized](#) .
6. Set the options [Is container](#) , [Create binding automatically](#) , and [Can have attached label](#) .
7. Click OK to add the component to the target group.

You can use UI beans from the custom libraries accessible to the module in which you want to use the components. You have to decide whether to specify each library as a single-entry, global or project level. If you will use a UI library in multiple projects, add it to the global libraries. If you have UI classes that will be used in a single project only, add the library to the project libraries for the relevant project.

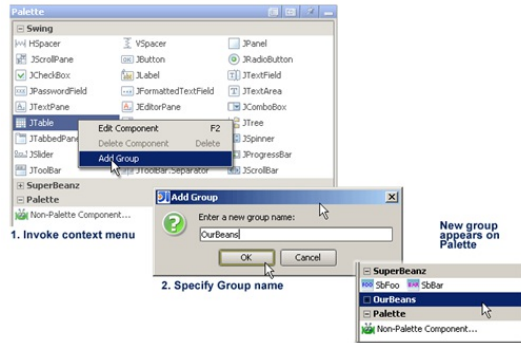

The GUI Designer's Palette tool window can contain groups which can be used as a means of organizing GUI components. Each Group can contain one or more GUI components, and can optionally display a custom icon for each component.

Initially, there are 2 default groups: Swing that contains the default `javax.swing` components, and Palette that contains one default node: Non-Palette Component. You can create other Groups for components from your libraries of GUI components and forms.

## To create a new Group

1. Right-click anywhere in the Palette tool window and choose Add Group on the context menu.
2. In the Add Group dialog, type a name for the new Group.
3. Click OK. A new group with the specified name adds to the Palette.

The process of designing a graphical user interface involves the following typical steps:

- [Creating a new form or dialog](#)
- [Placing and arranging components in the form](#)
- [Defining properties of the components](#)
- [Binding components to the source code](#)
- [Making forms functional](#)
- [Localizing forms](#)
- [Previewing Forms](#)

**Tip** You might want to review [basic concepts](#) , and take a [brief tour of the tool](#) , if you have not already done so.

If you have not created a [bound class](#) by default, when creating a new form, you do it explicitly, as described below.

There are two basic ways you can approach explicit binding depending on your situation:

- Bind a form to an [existing class](#) , and its components to the fields of this class.
- Bind a form and its components to a [class and fields that don't yet exist](#) .

When all components are cleared, or the Form node is selected in the Component Treeview, the form's properties the Inspector displays properties of the form.

## To bind a GUI form to a not-yet-existing class

1. Select the desired form in the Form Workspace or in the Components Treeview.
2. In the bind to class field, type the fully qualified name of the new class. Intention action icon appears suggesting to create the specified class.
3. Click the intention action icon, or press `Alt+Enter`. The desired class is created in the specified location.

When all components are cleared, or the Form node is selected in the Component Treeview, the form's properties the Inspector displays properties of the form.

### **To bind a GUI form to an existing class**

1. Select the desired form in the Form Workspace or in the Components Treeview.
2. Do one of the following:
  - In the bind to class field, type the fully qualified name of the bound class.
  - Click the Browse button and choose a class in the Choose Class to Bind dialog box.

When you create a [button group](#) in a form that is bound to source code, no field for the group is created. If you need to reference the group in code, you will have to explicitly bind the group to a field.

### To bind a button group to a field

1. Select the button group in the Component Treeview. The group's properties appear in the Inspector pane.
2. Make sure the value in the Name property is the name you want for the new field in the source code.
3. Check the Bind to field checkbox to generate the field declaration in the source file bound to the parent GUI form.

**Tip** You can remove the field binding by clearing the Bind to field checkbox. This removes the field in the source code file.

GUI Designer equips the developers with the possibility to create GUI forms with the desired layout and bound class, and dialogs. A form can be created as only a form file, or together with a UI class. A dialog framework consists of a class defining basic components and methods, and a GUI form with components bound to the fields of the UI class.

**Tip** As mentioned in the [GUI Designer concepts](#), GUI forms in IntelliJ IDEA are not Java classes. They are special XML files stored in your project with a `.form` extension.

Prior to creating GUI forms and dialogs, select a package where the forms will be stored. You might need to create a package first. It is recommended to store the forms and dialogs in the same package as the classes that implement their functionality.

## Creating a New GUI Form or Dialog

### To create a new GUI form

1. On the main menu, choose File | New .
2. On the pop-up menu, choose GUI Form .
3. Specify the name of the new form, and select the layout manager.
4. Check the option Create bound class , and specify the bound class name.
5. Click OK .

### To create a new dialog

1. On the main menu, choose File | New .
2. On the pop-up menu, choose Dialog .
3. Specify the name of the new dialog.
4. Specify the following options:
  - Generate `main()` method that creates and shows dialog.
  - Generate OK handler.
  - Generate Cancel handler.
5. Click OK .

## Creating a form from a File Template

You can save any form as a File Template, and thus preserve commonly needed dialogs or panes of controls for later reuse. For detailed information about creating and using File Templates, refer to the sections:

– [Creating and Editing File Templates](#)

### To create a File Template from a GUI form

1. Create a GUI form or open it in the GUI Designer.
2. On the Main menu, choose Tools | Save File as Template . The [File Templates dialog](#) displays the source code of the form. The extension of the new template is `.form`
3. Specify the template name, and click OK .

### To create a new GUI form from a File Template

1. In the Project tool window, right-click the package where you want to create the new form.
2. On the context menu choose New . The submenu contains items for all defined File Templates, including GUI forms.
3. Select the desired GUI form template on the context menu, and give it a name when prompted.

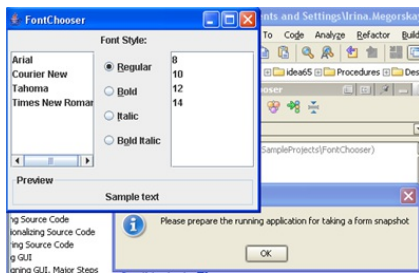

## Creating Snapshots

The Snapshot feature enables you to convert GUI forms created by some other means into IntelliJ IDEA GUI Designer Forms. All you need to do is run your application and save a part of the running application's component tree as a GUI Designer form. From then on, you can use the GUI Designer to extend or modify the form.

You can work with the layout and code in the GUI Designer just as you do with Forms originally created with the GUI Designer.

### To take a Snapshot of an existing dialog

1. Open the module that contains source code for the dialog you want to capture.
2. Select the [Application Run Configuration](#) , make sure that the option Enable capturing form snapshots is checked, and [run the application](#) .
3. In the running application, perform whatever interaction is necessary to open the dialog you want to capture.
4. In the Project tool window, right-click the target package and choose New | Form Snapshot on the context menu. If the application is not yet running, IntelliJ IDEA prompts you to run it, and then prepare the application for taking snapshot:

The Create Form Snapshot dialog box appears.

5. In the IntelliJ IDEA's Create Form Snapshot dialog, select the top-level component to be included in the snapshot, enter the form name, and click Create Snapshot button. The new form created this way is not bound to any class. You have to [bind](#) it to a class yourself.

**Note** If the selected node is not a valid container for a component, the Create Snapshot button is disabled.

## Opening Existing GUI Forms

Open form files the same way you open source code or text files for editing. Locate the file in the appropriate navigation view, select it, and do one of the following:

- Double-click.
- Choose Jump to Source on the context menu.
- Press **F4** .

Each form opens in a separate tab in the same space occupied by the Editor for source code files. You can have source code/text files and form files open simultaneously.

The GUI Designer extends [I18N Support](#) to the GUI forms, and enables you to find components that contain hardcoded strings and transfer these strings to properties files. Having produced the various locales, you can change them at design time and preview how the localized forms will look like.

In this section, you can find general recommendations for applying i18n support to GUI forms:

- [General localization procedure](#)
- [Suppressing I18nize Hard-Coded String quick fix](#)
- [Changing design-time locale](#)

## General Localization Procedure

### To localize your GUI forms, perform the following major steps

1. Make sure that Hard-Coded Strings inspection is activated. Refer to the section [Recognizing Hard-Coded String Literals](#) for details. If the inspection is activated, the appropriate tool tips for components display in the UI Designer tool window, and quick fix i18nize property<name> is displayed in the Form Workspace and UI Designer tool window.

2. Create properties files for each locale you want to provide for the GUI, and a default properties file without a postfix.

For example, for a dialog developed in English and localized to German and French, you might create the following properties files:

1. `Subscription.properties`
2. `Subscription_de.properties`
3. `Subscription_fr.properties`

3. Go through the form, and select each component that contains hardcoded strings. Click the quick fix icon, or press `Alt+Enter` to show the list of available intention actions, and select i18nize property <name> , as shown on the following image:

4. In the [I18nize Hard Coded String Literal](#) dialog box, extract hard-coded string literals to the specified properties files. Refer to the section [Extracting Hard-Coded String Literals](#) for details.

5. Edit the extracted strings in the resource bundle. Refer to the section [Editing Resource Bundle](#) for details.

## Suppressing I18nize Hard-Coded String Quick Fix

### To suppress i18nize quick fix

1. Select a component that contains hardcoded text property.

2. Click the quick fix icon, or press `Alt+Enter` to show the list of available intention actions.

3. Hover the mouse cursor over the i18nize property <name> quick fix, and click the right arrow icon `»` (or press right arrow key) to reveal the submenu, as shown on the following image:

4. Click the option Suppress for component or Suppress for all components . The list suppressed inspections appears in the GUI Designer tool window:

**Tip** To cancel suppression, select the desired inspection under the Suppressed Inspections node, and press `Delete` key.

## Changing Design-Time Locale

### To change locale at design time

1. With the GUI Designer tab having the focus, click the Change Local combo box `<default>` on the main toolbar.

2. Select the desired locale from the drop-down list.

**Note** It is assumed that you are familiar with UI programming in Java. This section covers just the basics you need to add functionality to the forms you build with the GUI Designer.

In this section:

- [Creating and Disposing of a Form's Runtime Frame](#)
- [Creating Form Initialization Code](#)
- [Creating Listeners](#)
- [Generating Accessor Methods for Fields Bound to Data](#)

To make your form work, you have to provide a runtime frame for it. The main() method for GUI forms takes care of creation and disposal of such frame.

## To create a main() method for a form

1. Open for editing the bound class of a form where you want to create the main() method.
2. Press `Alt+Insert` .
3. On the pop-up menu, click Form main() . The following method is added to the source code:

```
public static void
main(String[] args) {
    JFrame frame =
new
    JFrame("
<class name>
");
    frame.setContentPane(
new
    <class name>().
contentPane
);
    frame.setDefaultCloseOperation(JFrame.
EXIT_ON_CLOSE
);
    frame.pack();
    frame.setVisible(
true
);
}
```

When you finish [building a GUI Designer form](#) , at a minimum you should have a class that is bound to the form, and component type fields in the class bound to the various form components.

If the binary class files are specified as the output option, all runtime initialization code is generated in the class file. If your form has a bound class, you will not see the automatically generated initialization code there. In case you have selected Java source code as the output option, the bound class of your form will contain automatically generated `$$$setupUI$$$()` method.

**Warning!** Do not edit manually the GUI Initializer source code! At any compilation, IntelliJ IDEA automatically generates new code in this section, and all your changes will be lost.

Sometimes you might need to provide initialization code of your own. For example, you want a GUI component to be instantiated by a non-default constructor with certain parameters. In this case, IntelliJ IDEA will not generate instantiation of the component, and it is your responsibility to provide the call to constructor in the `createUIComponents()` method. Otherwise, a Null Pointer Exception will be reported. Follow the general technique described below.

## To create custom GUI initializer source code for a certain component, follow this general procedure

1. Select the desired component.
2. In the Inspector, check the option Custom Create .
3. With the component selected, press `F4` , or choose Jump to Source on the context menu.
4. In the text editor, locate the method `createUIComponents()` , and type the desired source code. The code in this method will not be removed on compilation.

## Example

For example, you would like to provide non-default constructors for the radio buttons 1 and 2, and have GUI Designer create a default constructor for the radio button 3:

```
...

//For the radio buttons 1 and 2, option Custom Create is set to true.

//You write custom constructors for these components

//in the method createUIComponents()

private
    JRadioButton
    radioButton1
;

private
    JRadioButton
    radioButton2
;

//For the radio button 3 the default constructor is generated automatically

//in the method $$$setupUI$$$(). The component properties

//specified in the GUI Designer

//are generated as calls to the set* methods in $$$setupUI$$$().

private
    JRadioButton
    radioButton3
;
...

private void
```

```
createUIComponents() {
```

```
radioButton1
```

```
=
```

```
new
```

```
JRadioButton(  
"Custom text 1"
```

```
);
```

```
radioButton2
```

```
=
```

```
new
```

```
JRadioButton(  
"Custom text 2"
```

```
);
```

```
}
```

```
...
```

```
private void
```

```
$$$setUpUI$$$() {
```

```
    createUIComponents();
```

```
    ...
```

```
radioButton3
```

```
=
```

```
new
```

```
JRadioButton();
```

```
radioButton3
```

```
.setText(  
"RadioButton"
```

```
);
```

```
...
```

```
}
```

GUI Designer enables you to create listeners for components. The components that have listeners, are marked with a special icon  that shows up when such component is selected. From the components in the Form Workspace and in the Components tree view, you can quickly navigate to the respective source code.

## To create a listener

1. Select component in the Form Workspace, or in the Components tree view.
2. On the context menu, choose Create Listener , or press `Ctrl+O` .
3. From the Create Listener pop-up menu, select the desired listener type.
4. In the Select Method to Override dialog box, select the desired method. Optionally, specify whether you want the JavaDoc comment for this method to be copied to the target file, and press OK . The stub method that overrides the specified method, is added to the bound class.
5. If you would like to modify the body of the stub method, edit the Overridden Method Body file template:  
In the [File Templates dialog](#) , open the Code tab, and edit the template as required.

## To navigate from a component to listener

1. Select component in the Form Workspace, or in the Components tree view.
2. On the context menu, choose Go to Listener .
3. In the Navigate to Listener pop-up menu, click the desired listener, or press `Ctrl+Alt+B` .

If you have fields in the UI class that you want bound to some data in a JavaBean class, IntelliJ IDEA provides a special [Data Binding Wizard](#). This wizard helps generate `getData` and `setData` methods for the fields in a UI class that are bound to components in a GUI form. You can create data binding to an existing bean class, or create a new bean class on the fly using the wizard.

For example, suppose you have some `JTextField` components on a GUI form that are bound to fields in a UI class, and you want the value of their text properties bound to some data in a JavaBean class. Instead of editing the UI class, creating `getData` and `setData` methods for the fields, being careful to specify the fully qualified name of the correct bean class and importing the required package, just use the Data Binding Wizard.

**Note** The GUI form must be bound to a class, and the GUI components must be bound to some fields in the class before running the Data Binding Wizard.

When you finish the wizard, the specified accessor methods are written to the form's class according to the options you specified in the wizard. Import statements are generated in the class as necessary.

Once components have been bound to data, you can invoke the Data Binding Wizard again, in which case you are presented with options to either remove the data binding, or bind to a different bean. If you choose the latter option, the wizard enables you to select or create the bean class for the data binding. The source code of the UI class (including imports) is modified according to your choices and specifications.

**Tip** If you look at the code and discover you made a mistake, you can use `Undo` to revert the code to its former state.

## To bind a component to data

1. Make sure that your form contains components that are eligible for data binding.
2. On the context menu of the form, choose `Data Binding Wizard`, or click  on the GUI Designer toolbar.
3. On the first page of the wizard, specify whether to bind to data from a new bean or an existing bean, specify the class for the option you choose, and click `Next`.
4. The second page lists the form components that are eligible for data binding, and that have been bound to a field in the form's UI class. For each component name, click the `Bean Property` field to the right, and specify the bean property that you want as the data source/target for the component.
5. Click `Finish` to complete the data binding operation.

This part explains how to place and lay out components on forms in the GUI Designer.

When you create a new GUI form, a top-level JPanel is automatically placed in the [Form Workspace](#) ready to receive the additional components that will make up the GUI you want to build. The pane's Layout Manager property is set to the default layout manager configured in the [GUI Designer Options](#) .

- The valid target areas where you can place a component, depend on the selected layout.
- [Undo and Redo](#) work for add, copy, move and delete operations in the GUI Designer.
- Use  to cancel any placement operation.

You can specify a mnemonic character for action controls by placing an ampersand (&) character in front of the desired mnemonic character in the text property. At runtime, the mnemonic character is underlined.

For components that can take mnemonics, there is an Intention Action Assign mnemonic that intelligently keeps track of already used mnemonics in the form and suggests a mnemonic for the current component based on what characters are already used.

## To delete one or more components

1. Select one or more components in the [Form Workspace](#) or in the [Components Treeview](#) .

2. Press  .

IntelliJ IDEA's GUI Designer provides several ways to create new instances of the same component on a form without returning to the Component Palette.

### To add multiple instances of a component from the Palette to a form

1. Click the desired component in the [Palette](#) .
2. Keeping the `Ctrl` button pressed, click the target locations in the form.
3. Release the `Ctrl` button when ready.

### To create a new instance of a component in a new location

1. [Select one or more components](#) in the [Form Workspace](#) or in the [Components Treeview](#) .
2. Keeping the `Ctrl` button depressed, drag the selected component to the new locations.
3. Click each target location to create a new instance of the component.
4. Release the `Ctrl` button when ready.

### To clone a component

1. Select the desired component on a form.
2. Press `Ctrl+D` .

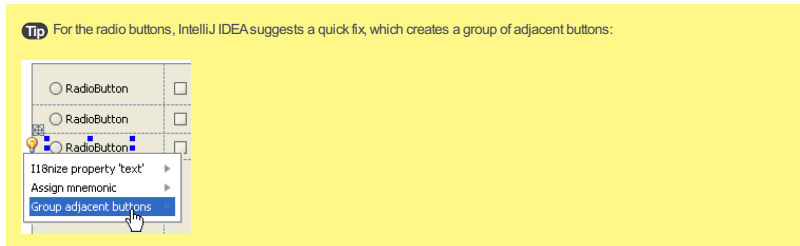

IntelliJ IDEA smartly detects components that are candidates for grouping together (for example, radio buttons). The first time you create a group, a button Groups node is added to the Component Treeview. A child node is added for each button group you add to the form.

Grouped buttons are visually indicated on the design form, when one of the buttons is selected in the Form Workspace or in the Components tree view, or when the whole button group is selected in the Button Groups node of the Components treeview:

## To create a group of components

1. In the Form Workspace, select the components to be joined into a group.
2. On the context menu of the selection, choose Group buttons .
3. In the Group Buttons dialog box, specify the name of the new button group, and click OK .

## To remove grouping

Do one of the following:

- On the design form, select any component in a group, right click, and choose Ungroup Buttons .
- In the Component Treeview, right-click the relevant button group under Button Groups node, and choose Ungroup .

Suppose you have created a JTextField component that contains some text, colors, font properties etc., and find out that you need a JFormattedTextField component with the same properties. This is when morphing comes to help.

Morphing enables you to transform selected component into a new one, while preserving all common properties.

### **To create a new component on the base of an existing one, preserving the common properties**

1. Select the desired component in the [Form Workspace](#) or in the [Components Treeview](#) .
2. On the context menu, choose Morph Component .
3. In the Choose Component to Morph Into pop-up menu, click the target component type.

Components can be repositioned on a form however you wish. The results of any move depend on the setting of the Layout Manager property of the target container.

This section describes how to move components using [drag-and-drop operation](#) , or using [navigation keys](#) on your keyboard.

## To move one or more components

1. [Select one or more components](#) in a [Form Workspace](#) .
2. A *drag handle* appears near the selected components indicating that you can drag to a new position on the form. (It is not necessary to point to the handle itself... hover anywhere over the selected components.)
3. Drag and drop the selection to the target container, or to the target area within the same container. The valid drop locations are highlighted with blue borders.

**Tip** You can also move components using the [Components Treeview](#) .

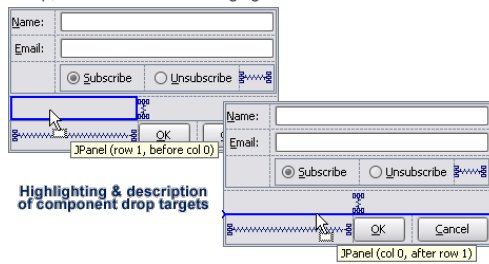

## To move a component using keyboard

1. Select the desired component on the form.
2. Press `Ctrl+Arrow` .

Use the Components Palette to populate your forms with the Swing GUI components.

## To place a component from the Palette on a form

1. Click the desired component in the [Palette tool window](#) .
2. Move your pointer over the form workspace. Valid drop location in a container highlights when the component placement pointer hovers above it, the pointer changes its shape, and the drop target is described briefly in a tooltip, as shown in the following figure:

3. Click on the form workspace at the desired valid location to place the component.
4. Check the option `Is container` , if you want the new component to be able to accommodate nested components.
5. Check the option `Create binding automatically` , if you want to generate a field for the component in the bound class.
6. Click `OK` .

In addition to the GUI components from the Component Palette, you can use GUI components and forms not registered on the Palette, but available via your project's paths configuration.

A non-palette component can be associated with a GUI form, or with a class derived from `JComponent`. Such class should be available in your project, or in the libraries. The class should be compiled, and should have a default constructor, because GUI Designer instantiates objects by calling their default constructors.

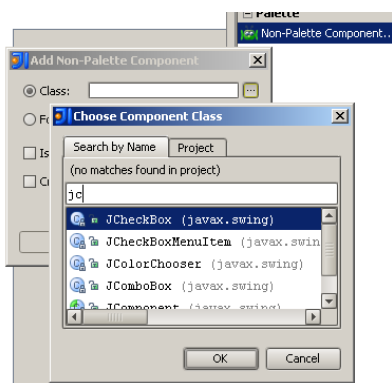

If a class does not have a default constructor, but instead has a constructor with parameters, the [Custom Create](#) property of this component is set to `true`, and `createUIComponents()` method is added to the source code, where you have to [provide the form initialization](#).

## To place non-Palette components on a GUI form

1. In the default Palette group, click the Non-Palette Component node.
2. Move your pointer over the form workspace. Valid drop location highlights when the placement pointer hovers above it, the pointer changes its shape, and the drop target is described briefly in a tooltip, as shown in the following figure:

3. Click on the form workspace at the desired location to place the component.
4. In the Add Non-Palette Component dialog box, click the Class or Form radio button, and specify the name of the class or form in the text field. Alternatively, click the corresponding ellipsis button, or press `Shift+Enter`.
5. If you have selected Class option, locate the desired class, using Search by Name tab, or Project tab:

If IntelliJ IDEA cannot locate the compiled class with the specified name and the default constructor, the component is red highlighted in the form, which means that it will not show at runtime:

Compile the class `Ctrl+Shift+F9` and press Reload Custom Components button on the toolbar .

6. If you have selected Form option, locate the desired form, using Search by Name tab, or Project tab. The form should be bound to a class.
7. Check the option `Is container`, if you want the new component to be able to accommodate nested components. In this case, the component will acquire certain properties that are specific for containers.
8. Check the option `Create binding automatically`, if you want to generate a field for the component in the bound class.
9. Click `OK`.

## To select one or more components

To select a single component, just click it. To select multiple components, do one of the following:

- In the [Components Treeview](#) , or in the [Form Workspace](#) , use `Shift+Click` to select multiple contiguous components, or `Ctrl+Click` for multiple non-contiguous components.
- Use arrow keys to move selection to the adjacent component.
- Use `Shift+Arrow keys` to select multiple contiguous components.
- Use `N/A` and `N/A` to expand or shrink selection within a container.

The **Surround With** feature is available in the GUI Designer, as well as in the editor. In the GUI Designer, you can wrap a container of your choice around one or more components, and remove wrapping.

### To wrap a container around components

1. Select one or more components in the Form Workspace, or in the Components tree view.
2. On the context menu of the selection, choose Surround with , or press `Ctrl+Alt+T` .
3. In the Surround With popup menu, click the desired container, or press the corresponding numeric key.

When reasonable, IntelliJ IDEA smartly suggests to wrap a component into a container. This is done with the help of intention action. For example, IntelliJ IDEA suggests to wrap a JList into a JScrollPane:

### To unwrap components from the surrounding container

1. Right-click container node in the Components tree view.
2. On the context menu, choose Flatten .

Whenever you select a component or an entire form in the Form Workspace, or in the Components tree view, the respective properties display in the Inspector. For the properties of different types (text, Boolean, color, etc.) the Inspector provides different editors. Besides editing in the [Inspector](#), you can edit text properties using the in-place editor.

Find the detailed description of properties in the section [Component Properties](#)

Property	Value
<b>field name</b>	<b>nameTextField</b>
Custom Create	<input type="checkbox"/>
Horizontal Size Policy	Can Grow, Want Grow
Vertical Size Policy	Fixed
Horizontal Align	Fill
Vertical Align	Center
Indent	0

GUI Designer properties

Swing properties

Show expert properties

Quick-JavaDoc Ctrl+Q  
Jump to Source F4  
Restore Default Value

To select a property in the Inspector, just click the respective property name. To activate the editor for the selected property, click the Value column. If the property requires choosing the value, the ellipsis button is revealed. Click this button to invoke one of the available property editors, or click `Shift+Enter`.

Use the following editors to modify properties in the Inspector:

- Text field : Type a value.
- Pick list : Pick a value from a drop-down list of valid choices.
- Checkbox : Set value for Boolean type properties.
- Dialog : Presents the Browse button  that opens the relevant dialog box: Edit Text, Select Color, Choose Icon File etc.

For text properties, refer to [editing text property procedure](#).

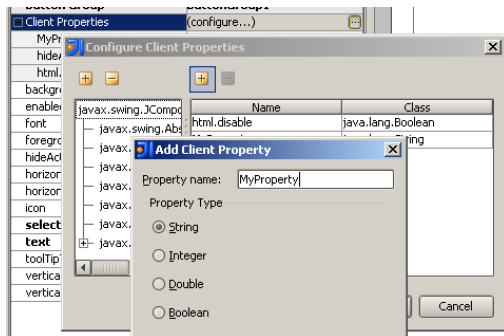

You can configure custom properties for the components of a GUI form. These are the properties listed under the Client Properties node of the [Inspector](#). This section describes how to manage custom properties of the GUI components.

## To configure a Client Property

1. Select a component in a GUI form.
2. In the [Inspector](#), click the Value column of Client Properties node to reveal the ellipsis button.
3. Click the ellipsis button in the edit field. The Configure Client Properties dialog is opened.
4. In the left-hand pane, select the class for which you want to change a Client Properties. If the class is not present in the list, click the **+** button above the list of classes and specify the name of the desired class.
5. With the class selected in the left pane, click the **+** button on the right pane. The Add Client Property dialog appears.

**Tip** To delete a client property of a component, click **-** button.

6. Enter a name for the property in the Property name field using Java naming conventions.
7. Select the option that corresponds to the new property's type and click OK.

After placing the component on the form workspace, the in-place editor for the Text property activates automatically.

To activate the in-place editor later, select the desired component and double-click it, or press **F2**. Finally, you can select a component and just start typing - in this case, the existing text will be lost.

If you need to enter a lengthy text, or take a value from a resource bundle, refer to the following procedure.

## To edit a text property

1. Click the ellipsis button. In the Edit Text dialog box, specify whether you want to edit the text as a string or resource bundle.
2. If you have selected the String option, type the desired text in the Value field, and proceed to the step 4.
3. If you have selected the Resource bundle option, specify the name of the desired [resource bundle](#), key and value.
  - Click ellipsis button next to the Bundle name field, or press **Shift+Enter**. In the Choose Properties File dialog box, find the desired resource bundle in the project tree view, or click the Search by Name tab, type the search string and select resource bundle from the suggestion list.
  - Click ellipsis button next to the Key field, or press **Shift+Enter**. In the Choose Property Key dialog box, select the desired key from the list.

Type value in the Value field.

4. If you want to enable [i18n support](#) for the property, make sure that the option Value does not need internationalization is cleared. In this case, intention action `i18nize property text` is suggested for this component. If the option is selected, the intention action is suppressed.
5. Click OK.

**Tip** When you invoke the in-place editor for a `JList` or a `JComboBox`, an editor dialog box is opened, enabling you to type the elements of the list.

The GUI Designer provides a Preview function that enables you to see how the form will look at runtime. When the form runs in Preview mode, you can click buttons, checkboxes, enter text, etc. just as at run time. Of course, there is no functionality at this point.

The Form Preview window enables you to change look and feel of the form, resize it, and exit the preview mode.

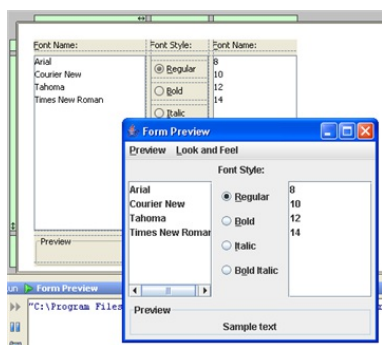

**Note** Form Preview shows only the properties specified by the GUI Designer in the `$$$setupUI$$$` method.

### To preview a GUI form, do one of the following

- Right-click a form, and choose Preview on the context menu.
- With the form having the focus, click preview button  on the main toolbar.

### To exit the preview mode, do one of the following

- On the main menu of the Preview Form window, choose Preview | Exit .
- Click  on the toolbar of the Preview Form window.

This feature is only supported in the Ultimate edition.

In this section:

- Tapestry
  - [Introduction](#)
  - [Using Tapestry in IntelliJ IDEA](#)
- [Enabling Tapestry Support](#)
- [Creating Tapestry Pages, Componenets, and Mixins](#)
- [Tapestry Tool Window](#)
- [Editing Templates](#)
- [Tapestry View](#)

## Introduction

IntelliJ IDEA comes bundled with the Tapestry plugin that provides native support for developing Web applications based on the [Tapestry](#) framework. The plugin is by default enabled. If not, enable it on the [Plugins settings](#) page of the Settings/Preferences dialog.

IntelliJ IDEA allows you to quickly setup a running Tapestry project and provides several types of assistance in developing Web applications.

## Using Tapestry in IntelliJ IDEA

### **To use Tapestry in developing a Web application, perform these general steps**

1. [Enable Tapestry support](#) .
2. [Create Tapestry-specific items](#) : pages, components, and mixins.
3. [Examine the structure of your application](#) in the Tapestry-specific terms.
4. [Edit the generated Tapestry templates](#) .

This feature is only supported in the Ultimate edition.

You can enable Tapestry support when creating a [project](#) or [module](#) , or for an existing module.

- [Enabling Tapestry support when creating a project or module](#)
- [Enabling Tapestry support for an existing module](#)

## Enabling Tapestry support when creating a project or module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java Enterprise . In the right-hand part of the page, specify the [JDK](#) to be used and select the Java EE version to be supported.
3. Under Additional Libraries and Frameworks , select the Tapestry checkbox.
4. You'll need a [library](#) that implements Tapestry. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the library files that implement Tapestry. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .
5. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click Finish .

6. Specify the [application filter](#) name and [root package](#) in the dialog that opens.

As a result, the Tapestry implementation library is added to [module dependencies](#) and a Tapestry [facet](#) is created.

## Enabling Tapestry support for an existing module

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the module of interest and select Add Framework Support .
3. In the left-hand pane of the [Add Frameworks Support dialog](#) that opens, select the Tapestry checkbox.
4. You'll need a [library](#) that implements Tapestry. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the library files that implement Tapestry. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

5. Click OK in the Add Frameworks Support dialog.

6. Specify the [application filter](#) name and [root package](#) in the dialog that opens.

As a result, the Tapestry implementation library is added to [module dependencies](#) and a Tapestry [facet](#) is created.

This feature is only supported in the Ultimate edition.

Tapestry items can be created only within the `components`, `pages`, or `mixins` dedicated packages. These packages, in their turn, should be located under the application root package.

In this topic:

- [Enabling creation of Tapestry items](#)
- [Creating a Tapestry page](#)
- [Creating a component](#)
- [Creating a mixin](#)

## To enable creation of Tapestry items in a module

1. Open the [Project](#) tool window.
2. Switch to the [Project](#) or [Package view](#) by doing one of the following:
  - Select the necessary view from the list in the left-hand part of the title bar.
  - If the views are represented by tabs, click the corresponding tab.
3. Select the application root package, and choose [New | Package](#) on the context menu.
4. In the New Package dialog box, that opens, specify the name of the dedicated package depending on the type of items to be created under it.
  - pages for Tapestry [pages](#).
  - components for Tapestry [components](#).
  - mixins for Tapestry [component mixins](#).

## To create a Tapestry page

A Tapestry page normally consists of an HTML template that implements the page appearance and a Java class that implements the page functionality and behaviour. The HTML file has the same name as the Java file and the `.tml` extension. IntelliJ IDEA generates two stubs, with the `.tml` file containing the `<header>`  
`</header>` and `<body></body>` sections.

1. Open the [Project](#) tool window.
2. Switch to the [Tapestry](#) view by choosing the Tapestry item from the list in the left-hand part of the title bar or clicking the Tapestry tab.
3. Right-click the pages node and choose [New | Tapestry | Page](#) on the context menu.
4. In the New Tapestry Page dialog box, that opens, specify the page name and the parent folders to store the generated class and template sources in.  
IntelliJ IDEA remembers the last selected directories and will automatically show them in the corresponding drop-down lists next time you create a page.
5. Customize the page generation, if necessary:
  - If you already have a page with the specified name and you want IntelliJ IDEA to overwrite it, select the [Replace existing files](#) checkbox.
  - To have only a Java class stub generated, select the [Do not create template](#) checkbox.

## To create a new component

A Tapestry component normally consists of an HTML template that implements the appearance of a piece of a page and a Java class that implements the behavior and functionality of this item. The HTML file has the same name as the Java file and the `.tml` extension. IntelliJ IDEA generates two stubs, with the `.tml` file containing a `<div></div>` section.

1. Open the [Project](#) tool window.
2. Switch to the [Tapestry](#) view by choosing the Tapestry item from the list in the left-hand part of the title bar or clicking the Tapestry tab.
3. Right-click the components node and choose [New | Tapestry | Component](#) on the context menu.
4. In the New Tapestry Component dialog box, that opens, specify the component name and the parent folders to store the generated class and template sources in.  
IntelliJ IDEA remembers the last selected directories and will automatically show them in the corresponding drop-down lists next time you create a component.
5. Customize the component generation, if necessary:
  - If you already have a component with the specified name and you want IntelliJ IDEA to overwrite it, select the [Replace existing files](#) checkbox.
  - To have only a Java class stub generated, select the [Do not create template](#) checkbox.

## To create a new mixin

1. Open the [Project](#) tool window.
2. Switch to the **Tapestry** view by choosing the Tapestry item from the list in the left-hand part of the title bar or clicking the Tapestry tab.
3. Right-click the mixins node and choose New | Tapestry | Mixin on the context menu.
4. In the New Tapestry Mixin dialog box, that opens, specify the mixin name and the parent folders to store the generated class in.  
IntelliJ IDEA remembers the last selected directory and will automatically show them in the drop-down list next time you create a mixin.
5. Customize the mixin generation, if necessary:
  - If you already have a mixin with the specified name and you want IntelliJ IDEA to overwrite it, select the Replace existing files checkbox.

This feature is only supported in the Ultimate edition.

This tool window shows contextualized information about some Tapestry element.

## Documentation

This tab shows the documentation of a Tapestry component, page or mixin.

The documentation (where applicable) is composed of:

- General description
- List of required parameters (with their name, prefix, default value and description)
- List of optional parameters (with their name, prefix, default value and description)
- List of artifacts
- Examples
- Notes

When the element selected is not a Tapestry component, page, or mixin, the documentation is composed of:

- List of Tapestry Applications
- List of Core Library components, pages and mixins

This feature is only supported in the Ultimate edition.

Loomy adds some additional features to the default HTML editor to allow faster and safer creation of Tapestry templates.

This section covers the following features:

- [Syntax Highlighting](#)
- [Error Detection](#)
- [Auto-Completion](#)
- [Navigation](#)

This feature is only supported in the Ultimate edition.

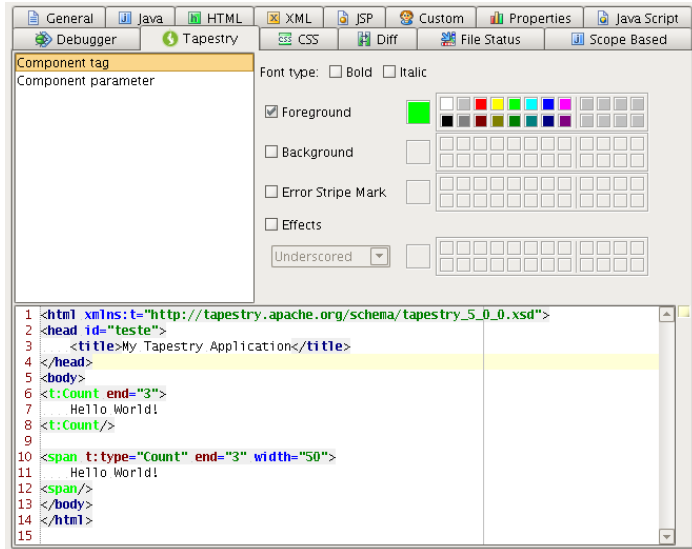

Special syntax highlighting in Tapestry templates in order to make template visual interpretation much easier.

The section covers the following features:

- [Configuration](#)
- [Component Tags Highlighting](#)

## Configuration

To configure the syntax highlighting feature you have to go to Colors & Fonts settings. In the Tapestry tab you can then choose the syntax coloring scheme that you prefer.

## Component Tags Highlighting

You can configure the plugin to highlight every Tapestry specific tag and tag parameter in your template. If you do, you will be able to easily identify in your template what are normal tags and Tapestry tags.

```
<body>
<h1>Start Page</h1>

<p> This is the start page for this application, a good place to start your modifications.
Just to prove this is live: </p>

<p> The current time is: ${currentTime}. </p>

<p>
[<a t:type="PageLink" page="Home" name="homeLink">home</a>]
[<t:pageLink page="Home" name="homeLink">refresh</t:pageLink>]
</p>
</body>
</html>
```

**Tip** If you get an inspection reporting invalid tag attributes then it's because you have an inspection that checks if your using anyHTML tag parameter that your not supposed to. When using Tapestry you will have to use special tag parameters so if you don't want to get this warning just turn off the "HTML tags and attributes conventions" inspection that you can find under "HTML Inspection".

This feature is only supported in the Ultimate edition.

There are several errors that are only found when the application is running. With Loomy it's possible to detect many of these errors without losing the time to run the application.

The plugin can detect the following errors:

Invalid component references

```
[<a t:type="pageLink" t:page="Home" href="">refresh</a>]
```

Invalid component name

Missing required parameters

```
[<a t:type="pageLink" href="">refresh</a>]
```

Missing required parameter "page"

Invalid page names

```
[<a t:type="pageLink" t:page="Home2" href="">refresh</a>]
```

Invalid page name

Invalid property

```
[<a t:type="TextField" t:value="Property1" translate=""></a>]
```

Invalid property

This feature is only supported in the Ultimate edition.

Auto-completion makes template editing much faster. Loomy extends this feature introducing lot's of Tapestry specific completions.

This section covers the following features:

- [Component Tags Auto-Completion](#)
- [Component Parameters Auto-Completion](#)
- [Parameters Values Auto-completion](#)

## Component Tags Auto-Completion

When editing your template you can take advantage of the auto-completion feature to help you insert a component using both types of possible annotations for that:

- Invisible Instrumentation

Just use the auto-completion feature on the `t:type` attribute value.

- Component Tag

Just use the auto-completion feature on the tag name where you want to insert the component.

## Component Parameters Auto-Completion

Component tags have additional parameters that don't conform to the HTML standard and so the default auto-completion won't help you. This plugin extends the auto-completion feature adding the Tapestry component parameters to the list of possible tag parameters.

## Parameters Values Auto-completion

Auto-completion of property binding is available so you can save lot's of time navigating from template to class.

- Page parameter of the PageLink component

- Boolean parameters

- Simple properties

This feature is only supported in the Ultimate edition.

Loomy allows easy navigation between several elements in your template are the related content.

You can navigate:

- [Between a template and the corresponding class.](#)
- [From a tag to the corresponding component class.](#)
- [From a property value to the associated method.](#)
- [To the component documentation.](#)

## Between template and class

Probably the most used navigation. Loomy provides an action (`Ctrl+Shift+G` by default) that allows you to navigate from a template to it's corresponding class and vice-versa.

## from tag to component class

This navigation allows you to navigate from a component tag in your template to that component class. Just press

`Ctrl+Click` on the tag itself.

## from property value to associated method

If you have bound a component parameter with a property you can now just press `Ctrl+Click` on the parameter value in your template and you will navigate to the method that corresponds to the given property.

## to component documentation

This navigation allows you to navigate from a component tag in your template to that component documentation displayed in the Tapestry ToolWindow. This action is associated by default to the key `Shift+Ctrl+D`, so just use when the cursor is on a component tag and you'll see it's documentation.

This feature is only supported in the Ultimate edition.

In this [view](#), you can browse your Tapestry application not in terms of classes and templates but in terms of pages, components, services, etc.

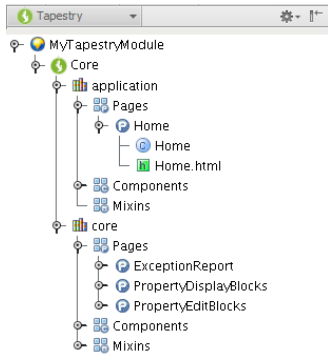

This section covers the following features:

- [Drag-and-drop](#)
- [Safe Delete](#)

## General Description

This view is available to every project that has at least one web module with Tapestry support. It can be accessed like any other project view from the View as selection box.

The view lets you browse your Tapestry modules in a tree structure that shows you all Tapestry elements like pages and components.

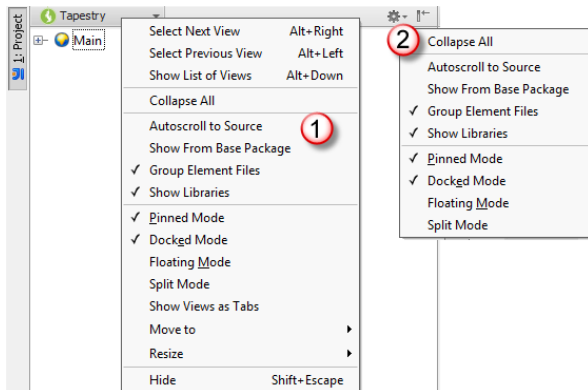

## Structured View of the Application

Each element in the Tapestry View has a different icon so that it's easy to identify the type of element:

<b>Library</b> 	<b>A Tapestry library.</b> By default you will have two library nodes, one for your application and the other of the provided core library.
<b>Page</b> 	<b>A Tapestry page.</b> You can navigate to the page class or template from here.
<b>Component</b> 	<b>A Tapestry component.</b> You can navigate to the component class or template from here.
<b>Mixin</b> 	<b>A Tapestry mixin.</b> You can navigate to the mixin class from here.

The [title bar context menu](#) (1) provides additional functionality that will also help each user customize its look&feel. Some options are also available from the list that opens when you click the  button (2).

Below is a description of menu items that are specific for Tapestry.

### ItemDescription

Show From Base Package	Only Show Content From the Application Base Package
Group Element Files	Group Element Files Like it's Class and Template in a Parent Node.

Show Libraries

Show/Hide Tapestry Libraries.

This feature is only supported in the Ultimate edition.

In order to increase development speed and prevent errors the plugin allows you to use drag&drop operations to generate simple code but that would otherwise be more error prone and take time from the task at hand.

This section covers the following features:

- [Drag&Drop Components](#)
- [Drag&Drop Pages](#)
- [Drag&Drop Mixins](#)

## Drag&Drop Components

Drop in Page or Component Template

This drop operation will result in a reference to the dropped component being inserted at the drop point with all required attributes set.

Drop in Page or Component Class

This drop operation will result in the declaration of an embedded component in the target class.

```
@Component
private ActionLink _actionLink;
```

## Drag&Drop Pages

Drop in Page or Component Template

This drop operation will result in a page link to the dropped page being inserted at the drop point.

```
<t:pageLink page="Home">Link to Home</t:pageLink>
```

Drop in Page, Component or Mixin Class

This drop operation will result in the injection of the dropped page in the target class.

```
@InjectPage
private Home _home;
```

## Drag&Drop Mixins

Drop in Component Class

This drop operation will result in the declaration of the usage of an implementation mixin.

```
@Mixin
private MyMixin _myMixin;
```

**Tip** You will only be able to use the drag&drop feature if a valid drop target is in the currently open editor.

This feature is only supported in the Ultimate edition.

If you execute the delete action from the Tapestry View you'll see that Loomy will actually figure out what Tapestry elements you're trying to delete and it will aggregate all it's file into this operation. So if for example you try to delete a page, Loomy will delete the page class, template and it's resource bundle.

IntelliJ IDEA will then look for usages of all the resulting files and you'll be able to, as usual, go through with the operation or cancel it.

This feature is only supported in the Ultimate edition.

On this page:

- [Basics](#)
- [Associating template data languages with files and folders](#)
- [Creating an extension pattern for a template data language](#)
- [Using code completion](#)
- [Fixing unresolved references](#)

## Basics

IntelliJ IDEA lets you develop templates in [Velocity](#) and [FreeMarker](#) template languages (VTL and FTL).

Coding assistance for VTL and FTL is available for files whose file name extensions match the extension patterns associated with the Velocity Template and FreeMarker Template file types. By default, those are `*.ftl`, `*.vm` and `*.vsl` for Velocity and `*.ftl` for FreeMarker.

To get coding assistance also for the languages in which the static part of the template is written (those are referred to as *template data languages*), you should do one of the following:

- Associate the template data languages with files and folders in your project. In this way you specify where in your project you need coding assistance for the corresponding template data languages.
- Add your own extension pattern for the Velocity Template or FreeMarker Template file type and associate that extension pattern with the necessary template data language.

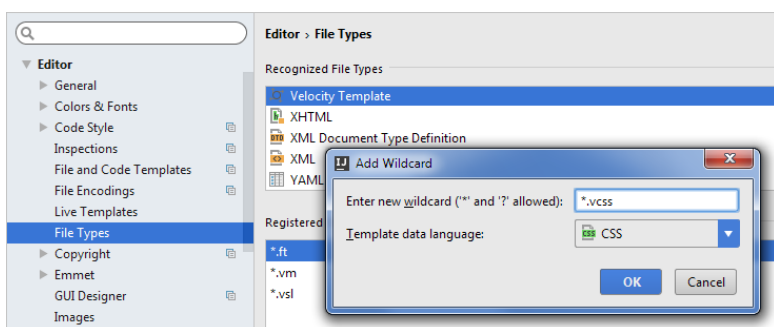

## Associating template data languages with files and folders

1. [Open the Settings / Preferences dialog](#) (e.g. `Ctrl+Alt+S`).
2. Go to the Template Data Languages page: Languages and Frameworks | Template Data Languages.
3. Click the Template data language cell to the right of the project, or the corresponding directory or file, and select the language.
4. Click OK in the Settings / Preferences dialog.

Individual template files can be assigned a template data language right in the editor. There is the Change template data language to context menu command for that.

## Creating an extension pattern for a template data language

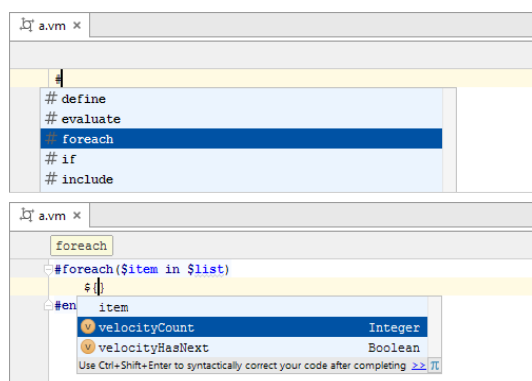

1. [Open the Settings / Preferences dialog](#) (e.g. `Ctrl+Alt+S`).
2. Go to the File Types page: Editor | File Types.
3. Under Recognized File Types, select FreeMarker Template or Velocity Template.
4. In the Registered Patterns section, click `+`.
5. In the Add Wildcard dialog that opens, specify the file name extension pattern and select the language.

6. Click OK in the Settings / Preferences dialog.

## Using code completion

IntelliJ IDEA provides [code completion](#) for the template language elements such as directives, variables, built-ins, etc.

## Fixing unresolved references

IntelliJ IDEA provides [inspections](#) for detecting unresolved references.

The unresolved references can be fixed by means of [intention actions](#). You can select to add a comment in the same file, or to create a separate file with comments. (Comments in such cases are used to provide missing info about the references.)

In the latter case, a file with the default name `velocity_implicit.vm` or `freemarker_implicit.ftl` is created. The file starts with the comment

```
## @implicitly included ##
```

To define reference types, code completion is available.

At a later time, you can rename the file, or move it to a different location within the source root, and the reference definitions will not be lost.

## Introduction

IntelliJ IDEA enables usage of the following testing frameworks:

- [JUnit](#)
- [TestNG](#)
- [GroovyJUnit](#)
  
- [FlexUnit](#)
- [MXUnit](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when PHP Plugin is installed and enabled!

- [PHPUnit](#)

**Warning!** The following is only valid when Python Plugin is installed and enabled!

- [Python unittests](#)
- [py.test](#)
- [Python nosetests](#)
- [Python doctests](#)
- [Tox](#) .
- [TwistedTrial](#)

This feature is only supported in the Ultimate edition.

- BDD frameworks:
  - [Behave](#) .
  - [Lettuce](#) .
  - [Cucumber](#) .

Refer to the section [BDD Testing Framework](#) for details.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

- [Test::Unit](#) is intended for unit testing and comes bundled with Ruby.
- [Shoulda](#) is intended for unit testing, and becomes available in Ruby projects on attaching the `shoulda` gem. So doing, the Shoulda tests are added on to the Test::Unit framework.
- [RSpec](#) . This testing tool supports [BDD](#) . RSpec becomes available in Ruby projects on attaching the `rspec` gem. For the Rails applications, `rspec-rails` gem is also required.
- MiniTest becomes available on attaching the [minitest-reporters](#) gem. The minitests are added to the Test::Unit framework.
- [Cucumber](#) . This testing tool supports [BDD](#) , and enables using features and scenarios written in a human-readable language, either English or any other language specified in the `# language:` comment. Cucumber becomes available in project upon installing and activating the `cucumber` gem.

## Testing frameworks support

For each of the supported testing frameworks, IntelliJ IDEA provides:

- [Code completion](#) , aware of the specific testing framework.
- [Run/debug configurations](#) .
- Ability to [create tests](#) .
- Ability to [navigate between tests and test subjects](#) .
- Ability to run tests from within the IDE , and view test results in the test runner UI . The test results are shown on the [Test Runner tab](#) of the [Run tool window](#) .
- Ability to run all tests or features in a directory, specific test classes, test cases or features, individual test methods or examples.
- Code inspections.

Refer to the section [Testing](#) for the detailed description of the common testing procedures.

For framework-specific usage guidelines, refer to:

- [Testing ActionScript and Flex Applications](#) (FlexUnit)
- [Testing PHP Applications](#) (PHPUnit)
- [Testing JavaScript](#)
- [Creating TestNG Test Classes](#)
- [Cucumber](#)

To create a TestNG test class, you can use the [Create Test intention action](#) .

You can also create a new class for your TestNG test and then add the necessary code to that class. This way of creating a TestNG class is described on this page.

## Creating a TestNG test class

1. In the [Project Tool Window](#) , right click the directory where you want to create a new test class.
2. Select New | Java Class from the context menu.
3. In the Create New Class dialog, specify the class name and click OK .
4. In the editor, write the code for your test class. Use the TestNG annotations where necessary. For example, you may want to annotate the whole class or individual methods:

```
@Test()
public class testetsng {
    @DataProvider
    public Object[][] data() {
        return new String[][] {new String[] {"data1"}, new String[] {"data2"}};
    }

    @Test(dataProvider = "data")
    public void test(String d) {
        Assert.assertEquals("First Line>\nSecond Line", "Third Line\nFourth Line");
    }
}
```

If the annotation you add lacks the import statement, the corresponding intention action will suggest you to create one:

**Warning!** The following is only valid when Python Plugin is installed and enabled!

## Prerequisites

Before you start working with tox, make sure that Python plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Python SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Python](#)
- [Django](#)

## Using Tox integration

To make use of the Tox integration, follow these steps:

1. [Create a project](#) and the required files.
2. Right-click the file `tox.ini` and choose Run . So doing, the dedicated [Tox run/debug configuration](#) is launched.

The results show up in the [test runner tab of the Run tool window](#) :

Right-click any test result in the Test Runner to execute Tox in a particular environment:

**Tip** The test tree view shows only those runners that IntelliJ IDEA is aware of. If IntelliJ IDEA doesn't understand the test runner, then the interpreter name only is written.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Using the supported testing frameworks requires the respective gems to be installed and activated in your project. Without the required gems, the corresponding context menu commands and code completion will not be available.

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

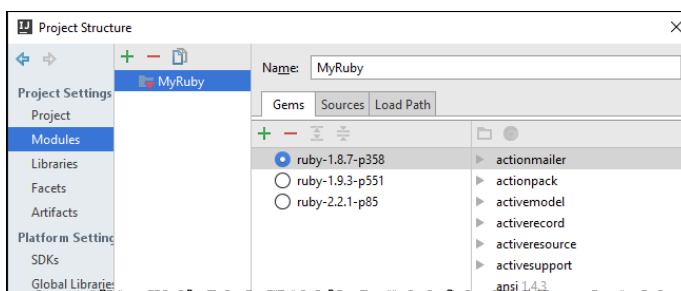

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

## Installing gems for testing

### To install Ruby gems for testing, follow these steps:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ), and click the node Modules .
2. Choose the desired Ruby module.
3. In the Gems tab, view the list of installed gems.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

This section describes how to use Test::Unit and the Test::Unit-based framework, both in the plain Ruby projects, and in Rails applications. In this section:

- Test::Unit and Related Frameworks
  - [Prerequisites](#)
- [Test::Unit Special Notes](#)
- [Collecting Code Coverage with Rake Task](#)
- [Shoulda](#)
- [Minitest](#)

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

[Test::Unit](#) comes bundled with Ruby 1.8.x, and in general requires no additional tuning. If you are working in IntelliJ IDEA with Rails 3.x, or with Rails 2.3.x and without the `test-unit` gem, you can use this framework "out-of-the-box".

However, there are certain situations when IntelliJ IDEA will be unable to plug the test runner UI to the test engine:

- [Ruby 1.9.x with a limited version of Test::Unit](#)
- [Rails 2.3.x and test-unit gem](#)

## Ruby 1.9.x with a limited version of Test::Unit

Use the complete version, which is distributed by means of the `test-unit` gem. If this gem is missing, the test results will be shown in the console, and the test runner UI will only show the error message "No tests were found".

If you want the test runner UI show the tree view of test results, include `test-unit` gem in your Gemfile.

## Rails 2.3.x and test-unit gem

The problem affects all Test::Unit-based testing frameworks. To fix this problem, you have to manually enable the Test::Unit custom reporter, as described below.

### To enable Test::Unit custom reporter for your test

1. Open for editing the `config/environment.rb` file, and disable `test-unit` gem autoload. To do that, modify the `environment.rb` as follows:

```
Rails::Initializer.run do |config|
  ...
  config.gem 'test-unit', :lib => false
  ...
end
```

2. Open for editing the `test_helper.rb` file, and enable the IntelliJ IDEA formatter manually. To do that, modify the source code as shown below.

It is important to enable it after `environment.rb` has been required, but before the `require 'test/unit'` call.

```
# test/test_helper.rb
ENV["RAILS_ENV"] = "test"
require File.expand_path(File.dirname(__FILE__) + "../config/environment")

# RubyMine
if ENV["RUBYMINE_TESTUNIT_REPORTER"]
  $:.unshift(ENV["RUBYMINE_TESTUNIT_REPORTER"])
  $!.uniq!
end

require 'test_help' # !!! test_helper script loads 'test/unit'
...
```

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

If a test is launched via a Rake task, it is the user's responsibility to provide code coverage measurement.

## To enable rcov for Test::Unit run/debug configuration

It is supposed that you have a special Rake task that collects code coverage information via rcov.

1. Open for editing your `*.rake` file, and add the following code:

```
require 'rcov/rcovtask'

ovTask.new do |t|
  s << "test"
  t_files = FileList ['test/**/*.rb']
  base = true
```

2. Create run/debug configuration for the task 'rcov' and run it with coverage.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA helps you write Shoulda tests on attaching the `shoulda` gem.

IntelliJ IDEA provides Shoulda-specific code completion, if one of the following conditions is observed:

- The Bundler is used.
- For Rails 2.\*, Shoulda is specified in `environment.rb`
- For the Ruby projects, `require 'shoulda'` is mandatory.

Refer to [Shoulda installation](#) page to learn about using Shoulda in Rails applications.

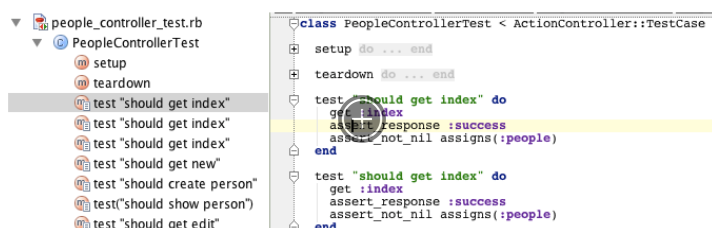

Having enabled Shoulda support in your project, you can:

- Use Shoulda-aware code completion for the contexts and should blocks:

- Run and debug Shoulda tests using the [Test:Unit run/debug configuration](#), or a user-defined [Rake task](#). In both cases, IntelliJ IDEA will run tests in the test runner UI. So doing, you can launch test cases, should blocks, or all test cases in a directory.

- View Shoulda tests in the File Structure view:

- In the Rails applications, view Shoulda tests in the Test:Unit/Shoulda node of the [Rails view](#):

## To enable Shoulda support, follow these general steps

1. Install `shoulda` gem to your project.
2. Mark as test roots the directories with the Shoulda tests.

## Example

Consider creating a Shoulda test in a Ruby project. Note that you can also create a plain Ruby script. In this case, make sure that its name ends with `_test.rb`.

In an empty Ruby project, add the following statements to the Test:Unit test cases with Shoulda tests:

```
require
```

```
"test/unit"
```

```
require
```

```
"rubygems"
```

```
gem
```

```
"shoulda"
```

```
require
```

```
"shoulda"
```

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

On this page:

- [Overview](#)
- [Prerequisites](#)
- [Important note](#)
- [Naming](#)

## Overview

IntelliJ IDEA helps you write tests using the MiniTest testing framework. MiniTest comes bundled with Ruby 1.9.x, but we suggest to use [minitest](#), as a more up-to-date version.

## Prerequisites

Before you start, make sure that:

- [minitest](#) is downloaded and installed on your computer.  
IntelliJ IDEA supports `minitest` versions higher than 3.1.0
- [minitest-reporters](#), version 0.5.0 or higher, is downloaded and installed on your computer. This gem is required for integration with IntelliJ IDEA test runner.  
For `minitest` `>= 5.0.0`, `minitest-reporters` gem is not required.
- For Windows, [win32Console](#), version '1.3.0' is downloaded and installed.
- The gems should be properly attached to your project. For example, if you use the [Bundler](#) for managing gems, the required gems should be added to the `Gemfile` of your project.  
For example, the `Gemfile` can contain the following code:

```
group :test do
  if RUBY_PLATFORM =~ /(win32|w32)/
    gem "win32console", '1.3.0'
  end
  gem "minitest"
  gem 'minitest-reporters', '>= 0.5.0'
  gem 'cucumber-rails'
end
```

- Depending on the version of `minitest-reporters` gem, one of the following code fragments is added to your tests (if you are working with a Rails application, it is better accomplished with `test/test-helper.rb` file):
  - Version 0.8.0 and higher

```
require 'minitest/reporters'

MiniTest::Reporters.use!
```

- Older versions

```
require 'minitest/reporters'

MiniTest::Unit.runner = MiniTest::SuiteRunner.new
if ENV["RM_INFO"] || ENV["TEAMCITY_VERSION"]
  MiniTest::Unit.runner.reporters << MiniTest::Reporters::RubyMineReporter.new
elsif ENV['TM_PID']
  MiniTest::Unit.runner.reporters << MiniTest::Reporters::RubyMateReporter.new
else
  MiniTest::Unit.runner.reporters << MiniTest::Reporters::ProgressReporter.new
end
```

The above code enables specific results reporter, which depends on the environment where tests have been launched: IntelliJ IDEA, TeamCity CI server, or TextMate text editor/ terminal. This approach is helpful, when you work in a mixed team that uses different IDEs, or text editors.

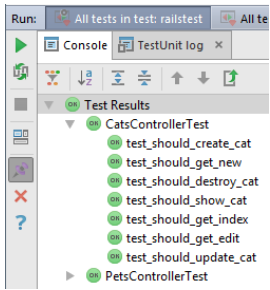

It is important to execute this code at the test initialization, before running the tests.

## Important note

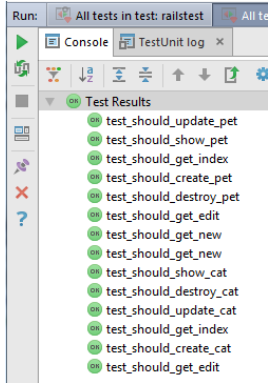

**Tip** You can jump to a test body directly from the test tree, using the context menu command Jump to Test

As mentioned before, `minitest-reporters` gem is required for integration with IntelliJ IDEA for `minitest` version lower than 5.0.0.

However, this gem is still essential for the higher versions of `minitest`, if you want to see the test results in a tree view:

rather than as plain list:

## Naming

It's important that the names of the `minitest` files match the following patterns:

```
*_test`.rb  
test_`*.rb
```

The test case classes should have suffix `Test` :

```
FooTest < AcceptanceTest
```

This limitation is not related to `MiniTest` , but rather is imposed by IntelliJ IDEA's code insight.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

IntelliJ IDEA supports RSpec up to version 3.0.x. This section describes how to use RSpec in plain Ruby projects, and in Rails applications:

- RSpec
  - [Prerequisites](#)
  - [RSpec 2.x Note](#)
  - [Zeus Note](#)
- [Using RSpec in Ruby Projects](#)
- [Using RSpec in Rails Applications](#)

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

## RSpec 2.x Note

For RSpec 2.x , special configuration is required for the coverage options. The Rake task that launches RSpec 2.x tests with the code coverage enabled, need `RCOV_OPTS` environment variable, and should be modified as shown below:

```
# rspec 2.x
require "rake"
require "rspec/core/rake_task"

desc "Run all specs with rcov"
RSpec::Core::RakeTask.new("test_cov") do |t|
  t.rcov = true
  t.rcov_opts = ENV["RCOV_OPTS"]
end
```

## Zeus Note

If you are going to [run RSpec tests under Zeus server](#) , make sure to use Zeus version 0.13.4.pre2, or higher.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

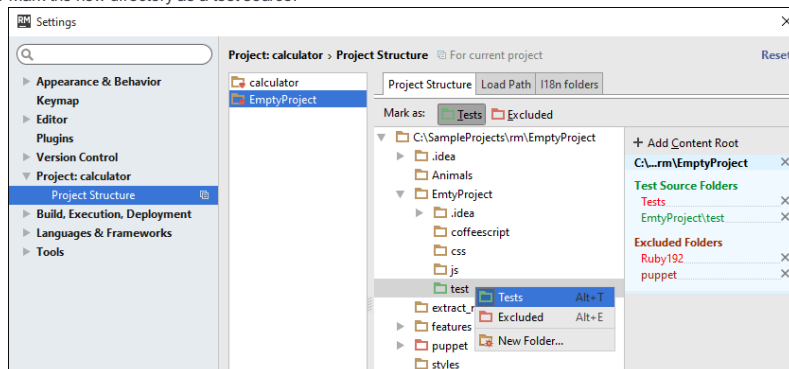

Though IntelliJ IDEA provides RSpec test template by default, the complete RSpec support only becomes available, when `rspec` gem is attached to your Ruby project. IntelliJ IDEA's RSpec support, in particular, includes:

- The possibility to run and debug individual examples.
- Use RSpec-specific code completion:

## To enable RSpec support in a Ruby project, perform these general steps:

1. Create a directory, for example, `test`, that will be used for testing purposes.
2. Mark the new directory as a test source.

3. Make sure that `rspec` gem is added to your project.
  4. In the directory you've created for testing, generate test templates.
  5. Run or debug your spec.
- If you are using the bundler, make sure that in the [RSpec run/debug configuration](#) the checkbox Run the script in context of the bundle is selected.

Note that you can execute all tests in a folder, specific test script, or individual examples in a script.

- To execute all tests in a folder, in the Project tool window right-click the folder that contains specs, and choose Run: All specs in <folder name> on the context menu.
- To execute a test script, right-click the spec in the Project tool window, or open this spec in the editor and right-click somewhere outside individual examples. Then choose Run <spec name> . on the context menu.
- To execute an individual example, open the desired spec in the editor, right-click the example to be executed, and choose Run <Spec name><example name> .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

Using RSpec in Rails application requires `rspec-rails` gem to be added to your project. So doing the dependent `rspec` gem is added to the project automatically. When the `rspec-rails` gem is added, the corresponding generator `rspec:install` appears in the list of available generators.

IntelliJ IDEA supports `rspec-rails` gem version 2.12.0 and higher.

When RSpec support is enabled in a Rails application, IntelliJ IDEA provides:

- Generation of RSpec testing infrastructure.
- RSpec-specific code completion:

- [Usage of Zeus server](#) .
- [RSpec run/debug configuration](#)

Depending on your particular version of Rails, different workflows are possible. If you are using Rails 3.0 and higher, it is recommended to use the [bundler](#) and specify `rspec-rails` gem in the Gemfile. Thus, IntelliJ IDEA suggests the following workflow:

## To use RSpec, follow these general steps

1. Make sure that the required gems are installed.
2. In the Gemfile, add the following line:

```
gem 'rspec-rails'
```

3. Generate the RSpec testing infrastructure. To do that, press `Alt+Insert` , choose Run Rails Generator on the pop-up menu, start typing the `rspec` generator name, and choose `rspec:install` from the list:

In the Setup RSpec Support dialog box, specify the generator options. The respective script is executed, and displays its output in the console tab of the Run tool window.

4. Generate the test templates same way as the other [Rails application elements](#).
5. Run or debug your spec.  
If you are using the bundler, make sure that in the [RSpec run/debug configuration](#) the checkbox Run the script in context of the bundle is selected.

Note that you can execute all tests in a folder, specific test script, or individual examples in a script.

- To execute all tests in a folder, in the Project tool window right-click the folder that contains specs, and choose Run: All specs in <folder name> on the context menu.
- To execute a test script, right-click the spec in the Project tool window, or open this spec in the editor and right-click somewhere outside individual examples. Then choose Run <spec name> . on the context menu.
- To execute an individual example, open the desired spec in the editor, right-click the example to be executed, and choose Run <Spec name><example name> .

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Basics](#)
- [Prerequisites](#)
- [Managing Spork DRb server](#)
- [Tips and tricks](#)

## Basics

Running test suits sometimes involves overheads, because every time a test suit is executed, the whole environment (for example, the entire environment for applications) should be reloaded. You can avoid it using the [Spork DRb server](#), which loads the environment only once.

With the Spork DRb server running in the background, you have a choice to execute any testing script [using the Spork DRb server](#), or locally.

## Prerequisites

- Prior to launching Spork DRb server, make sure [spork](#) gem, and the corresponding testing gems (`rspec-rails`, `cucumber`, `cucumber-rails`, etc.) are used in your application.
- [spork](#) gem is added to the Gemfile.

Before you start working with , make sure that plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

### To launch Spork DRb server

1. On the main menu, choose Tools | Run Spork DRb server... .
2. In the Spork DRb Launch Options dialog box, select the desired testing framework, and click Run .  
If you are going to use `spork` for the first time in your project, launch the action with the Perform bootstrap checkbox selected. Thus Spork will patch the testing scripts.

The Spork DRb server starts in a separate tab of the Run tool window.

### To run a test script using the Spork DRb server

1. Make sure that Spork DRb server is launched using IntelliJ IDEA and is running in the background.
2. **Run** a test script, or one of its examples. Note that the option Spork DRb is automatically selected in the corresponding run configuration. If you want to run this test locally, you have to select the option None .

### To debug tests, when using Spork DRb, follow these general steps

1. Make sure the breakpoints are set in the test script you want to debug.
2. On the main toolbar, click the run/debug configuration selector, and choose Edit Configurations .
3. In the [Run/Debug Configurations Dialog](#) dialog box, create run/debug configuration for Spork DRb server.  
Refer to the section [Creating and Editing Run/Debug Configurations](#) for detailed description of the procedure.
4. Launch Spork DRb in the debug mode. To do that, with the Spork DRb run/debug configuration selected, click , or press `Shift+F9` .
5. With the Spork DRb server running in the debug mode, run the desired test script.

**Note** Note that if you debug a test script, it will be executed without Spork DRb server.

## Managing Spork DRb server

Refer to the description of the [Run tool window](#) . In particular, use the following buttons:

-  - stop the Spork DRb server without closing its tab in the Run tool window.
-  - close the Spork DRb server tab.
-  - rerun Spork DRb server in the same tab.

## Tips and tricks

- IntelliJ IDEA creates a temporary run/debug configuration for Spork DRb server. Later you can change this run/debug configuration as required, save it as permanent, and use it to launch the server.
- If you are using [TeamCity](#), avoid overhead by adding the following statement into `Spork.preload` :

```
require
```

```
'teamcity/spec/runner/formatter/teamcity/formatter'
```

- Spork DRb server doesn't work with Ruby 2.0.
- If both Zeus and Spork DRb servers are running simultaneously, it is Zeus that gets priority.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Ruby Plugin is installed and enabled!

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

In this section:

- [Basics](#)
- [Tips and tricks](#)

## Basics

Running test suits sometimes involves overheads, because every time a test suit is executed, the whole environment (for example, the entire environment for applications) should be reloaded. You can avoid it using the [Zeus server](#) , which loads the environment only once.

With the Zeus server running in the background, you have a choice to execute any testing script [using the Zeus server](#) , or locally.

### To run a test script using the Zeus server

1. Make sure that Zeus server is launched using IntelliJ IDEA and is running in the background.
2. [Run](#) a test script, or one of its examples. Note that the option Zeus is automatically selected in the corresponding run configuration. If you want to run this test locally, you have to select the option None .

### To debug tests, when using Zeus, follow these general steps

1. Make sure the breakpoints are set in the test script you want to debug.
2. On the main toolbar, click the run/debug configuration selector, and choose Edit Configurations .
3. In the [Run/Debug Configurations Dialog](#) dialog box, create run/debug configuration for Zeus server. Refer to the section [Creating and Editing Run/Debug Configurations](#) for detailed description of the procedure.
4. Launch Zeus in the debug mode. To do that, with the Zeus run/debug configuration selected, click  , or press `Shift+F9` .
5. With the Zeus server running in the debug mode, run the desired test script.

**Note** Note that if you debug a test script, it will be executed without Zeus server.

## Tips and tricks

- IntelliJ IDEA creates a temporary run/debug configuration for Zeus server. Later you can change this run/debug configuration as required, save it as permanent, and use it to launch the server.
- If both Zeus and Spork DRb servers are running simultaneously, it is Zeus that gets priority.
- If you are going to run RSpec tests under Zeus server, make sure to use Zeus version 0.13.4.pre2, or higher.

## Overview

[Behavior-driven development](#) , or BDD , makes it possible to write tests in a human-readable language.

## Running a feature file

IntelliJ IDEA provides the ability to run a specific feature file, or all feature files in a folder, which is specified in the corresponding run/debug configurations for [Cucumber](#) , [Cucumber for Java](#) , .

The procedure of running tests is the same as for the other testing frameworks:

1. Open the desired feature file in the editor, or select it in the Project tool window.
2. Do one of the following:
  - Right-click the selected file or folder, and choose Run <feature file name> on the context menu of the selection.
  - [Create run/debug configuration](#) for one of the BDD frameworks , and specify the desired file or folder there.

## Renaming steps

When renaming Gherkin steps, mind the following limitations:

- Step definitions should not contain regular expressions
- Step names should contain alphanumeric characters only.
- A step definition should be only one in various frameworks.
- There should be a "one-to-one" mapping between a step and a step definition.

Refer to the section [Renaming](#) for details.

[Cucumber](#) supports [BDD](#) , and enables using features and scenarios written in a human-readable language.

In this section:

- [Cucumber](#)
  - [Prerequisites](#)
  - [Cucumber support](#)
- [Enabling Cucumber Support in Project](#)
- [Creating .feature Files](#)
- [Creating Examples Table in Scenario Outline](#)
- [Creating Step Definition](#)
- [Navigating from .feature File to Step Definition](#)
- [Supporting Regular Expressions in Step Definitions](#)
- [Running Cucumber Tests](#)

## Prerequisites

Cucumber becomes available in IntelliJ IDEA, provided that the following prerequisites are met:

- Cucumber for Java:

**Warning!** The following is only valid when Cucumber for Java Plugin is installed and enabled!

- Cucumber for Java bundled plugin is enabled.
- `cucumber-java` version 1.xx is specified as a dependency.

- Cucumber for Groovy:

**Warning!** The following is only valid when Cucumber for Groovy Plugin is installed and enabled!

- Cucumber for Groovy bundled plugin is enabled.
- `cucumber-groovy` version 1.xx is specified as a dependency.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

- `cucumber` gem (for Ruby projects), or `cucumber` and `cucumber-rails` (for Rails applications) is [installed and activated](#).

## Cucumber support

IntelliJ IDEA supports:

- Cucumber for Java, Cucumber for Groovy

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Cucumber.js and Gherkin plugins are installed and enabled!

- [Cucumber.js](#)

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

- [Cucumber](#) both in plain Ruby projects, and in Rails applications.

Cucumber feature files are marked with  icon.

Cucumber support includes:

- Syntax and error highlighting.
- Quick fix to [create step definitions](#) .
- [Navigation between step definitions and steps](#) .
- Ability to describe steps in English or any other language specified in the `# language:` comment.
- Run/debug configurations: [Cucumber](#) , [Cucumber for Java](#), [Cucumber.js](#) .
- Ability to run all features in a directory, a feature, or a single step within a feature.

## Prerequisite

Make sure that Cucumber for Java and/or Cucumber for Groovy bundled plugins are enabled. The choice of plugin depends on the type of step definitions to be generated.

## Two ways of creating Cucumber dependencies

Cucumber dependencies can be defined in two different ways:

- Using Maven dependencies
- Using libraries

## Using Maven dependencies

### To enable Cucumber in a Maven project, follow these general steps

1. Create a project [from scratch](#) , and select module type Maven . Alternatively, just [add a Maven module](#) .  
Do not create a Maven module from archetype!
2. Open for editing `pom.xml` file of the new project or module.
3. In the `pom.xml` , create and expand the section `dependencies` , and add the following code:

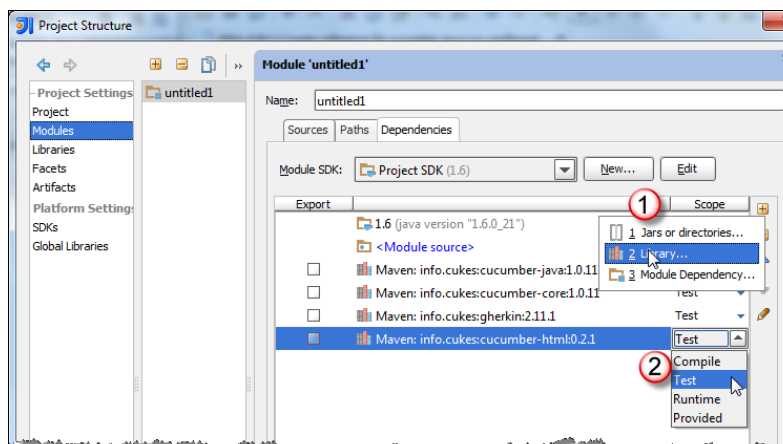

```
<dependency>
<groupId>info.cukes</groupId>
<artifactId>cucumber-java</artifactId>
<scope>test</scope>
<version>1.0.11</version>
</dependency>
<dependency>
<groupId>info.cukes</groupId>
<artifactId>cucumber-jvm</artifactId>
<version>1.0.11</version>
<type>pom</type>
</dependency>
```

4. Run the phase `package` to include all dependencies.

## Using libraries

### To enable Cucumber support via libraries, follow these general steps

1. In a project where Cucumber tests should be created, click  . [Project Structure](#) dialog box opens.
2. In the [Modules page](#) , click [Dependencies](#) tab, and add the required Maven dependencies:
  1. Click  , and choose Libraries from the submenu.  
If the libraries already exists locally, then in the Choose Libraries dialog box, select the desired version of the library `cucumber-java` (for Java) or `cucumber-groovy` (for groovy), and click the button Add Selected .  
  
If the library does not yet exist locally, click New Library , and select library type From Maven . Then, in the Download Library from Maven Repository dialog box, specify the Maven coordinates (if known), or a keyword, select the target for downloading, and click OK .  
  
Configure the new library as required (for example, attach documentation URL or sources).
2. In the Scopes column, click the arrow to reveal the drop-down list, and select Tests .

3. Apply changes and close the [Project Structure](#) dialog box.

## Prerequisite

Cucumber for Java should be downloaded and installed on your computer!

Once Cucumber for Java support is [enabled](#) , you can create feature files .

## Creating feature files

### To create a feature file

1. In the Project tool window, right-click a directory, where feature files should be created.
2. On the context menu of the target directory, choose New | File , and in the New File dialog box, type `<name>.feature` .
3. In the feature file, type your scenario. Since there are no step definitions, the steps will be highlighted as unresolved.
4. [Create step definitions](#) .

## Introduction

IntelliJ IDEA provides support for scenario outlines, enabling you to describe multiple scenarios by means of templates with placeholders. This support includes:

- Code completion (`Ctrl+Space`) for keywords.
- Syntax highlighting for keywords, placeholders, and attributes.
- Code inspection to detect missing examples, and a quick fix for generating Examples table stub.

## Creating Examples table

### To create Examples table for a scenario outline, follow these general steps

1. Having created a feature file, type the desired scenario outline. Use angle brackets to enclose placeholders. Note that initially the placeholders are not syntactically highlighted. If the steps are not defined, [create step definitions](#). Since the Examples section is missing, IntelliJ IDEA marks Scenario Outline name as an error.
2. Press `Alt+Enter` to show the suggested intention action, and press `Enter` :

The header row of the Examples table is created; so doing, the placeholders are highlighted both in the table header, and in the scenario outline steps.

3. Add the desired rows to the Examples table:

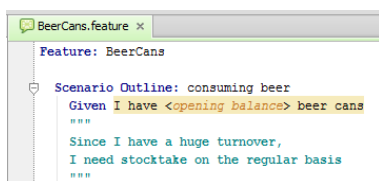

As you add rows, the columns in the Examples section are aligned automatically.

Note highlighting of the placeholders, and the values in the Examples table, which will be substituted on running examples.

## Tips and tricks

- If a colon is missing after the keyword Examples, it is recognized and marked as a syntax error, and a quick fix suggests to create colon.
- You can add textual notes to the steps of a scenario outline. Such notes should be enclosed in triple quotes; in this case, IntelliJ IDEA perceives the text inside as a string, and displays it when running the scenario step:

## Overview

If a `.feature` file refers to a non-existent step, IntelliJ IDEA's code inspection recognizes and highlights such step, and provides an intention action that helps create missing step definition.

## Creating step definition

### To create a missing step definition

1. While editing the `.feature` file, type a reference to a step definition. IntelliJ IDEA highlights step as undefined, and gives detailed information at the tooltip:

2. Press `Alt+Enter` to show the Create Step Definition intention action:

3. Select the target step definition file from the pop-up list:

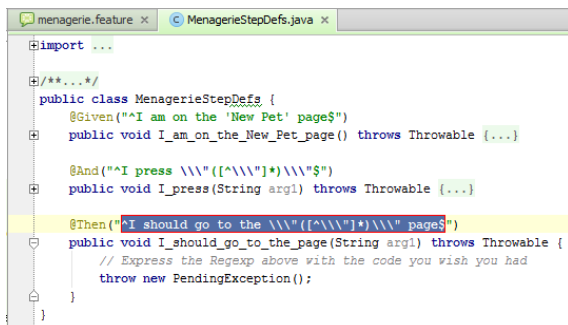

You can either select one of the existing step definition files from the suggestion list, or create a new one.

If you opt to create a new step definition file, specify its name, type (Java or Groovy), and the parent directory.

IntelliJ IDEA creates a step definition stub in the specified location.

4. In the selected step definition file that opens in the editor, enter the desired code.

Note that the editor turns into the template editing mode and displays the first input field highlighted with the red frame.

Type step definition in this frame and press `Enter` or `Tab` to complete input and pass to the next input field, where you have to enter your source code. After completing input, the caret moves to the end of the suggested step definition, and the editor returns to the regular mode of operation.

## Tips and tricks

- While typing, use code completion `Ctrl+Space` after keywords. Note that you can narrow down the suggestion list by typing characters contained anywhere within a description. On top of the suggestion list there will be the variants that contain specified characters as prefixes, followed by the variants with the arbitrary occurrences of characters:
- You can find usages of a step definition. To do that, place the caret at the desired definition, and press `Alt+F7`. Refer to the section [Finding Usages in Project](#) for details.
- IntelliJ IDEA keeps an eye on the uniqueness of the step definitions. Step definitions with the same names are highlighted.

## To navigate from a .feature file to step definition

1. Open the desired `.feature` file in the editor.
2. Do one of the following:
  - Keeping the `Ctrl` button pressed, hover your mouse pointer over a step. The step turns to a hyperlink, and its reference information is displayed at the tooltip:

Click the hyperlink. The step definition file opens in the editor, with the caret resting at the desired step definition.

- On the main menu, choose `Navigate | Declaration`.
- Press `Ctrl+B`.

**Warning!** You cannot navigate to a step definition file, if it resides outside a package under the test root.

IntelliJ IDEA supports regular expressions of Java flavor. As such, it uses the Java's `re` module.

When editing source code in a step definition file, note that it is possible to specify data in a step definition as constants, or as regular expressions.

To make IntelliJ IDEA perceive the entered code as a regular expression, ensure the following line is added to the source code of a step definition:

```
use_step_matcher("re")
```

So doing, the expressions used in step definitions are perceived as regular expressions:

```
use_step_matcher("re")
@when("I have (?P<number>[0-9]+) pets")
def step_impl(context, number):
    """ """
    pass
```

If the matcher is not used, then the expressions in quotes are perceived as strings:

```
# use_step_matcher("re")
@given("I have (?P<amount>[0-9]+) dollars")
```

The Cucumber feature files [are run same way](#) as the other executables, with certain run/debug configuration settings.

Prior to running a test, you have to set up run/debug configuration for a particular feature file or scenario, or for the whole bunch of features within a directory. Creating a run/debug configuration is described in the section [Creating and Editing Run/Debug Configurations](#) .

**Warning!** Do not forget to specify the package where [step definitions](#) are stored. To do that, in the Glue field of the [Edit Run/Debug Configuration](#) dialog box, specify the name of the package in question, or click the browse button to locate it on project.

However, there is always the possibility to run Cucumber tests with the default settings, which is described below.

Results of tests execution are displayed in the [Test Runner](#) tab of the [Run tool window](#) .

### **To run all feature files in a directory**

1. In the [Project Tool Window](#) , right-click the directory where the feature files are stored.
2. On the context menu of the directory, choose Run all features in <directory name> .

### **To run a feature**

1. In the [Project Tool Window](#) , right-click the desired feature file, or open it in the editor.
2. On the context menu of the feature file, choose Run Feature <name> .

### **To run a scenario**

1. In the [Project Tool Window](#) , right-click the desired feature file, or open it in the editor.
2. On the context menu of the desired scenario, point to Run, and then choose Run Scenario <name> .

In this section:

- [TextMate](#)
- [Prerequisites](#)
- [TextMate support](#)
- [Importing TextMate Bundles](#)
- [Editing Files Using TextMate Bundles](#)

## Prerequisites

Before you start working with TextMate, make sure that TextMate bundle support plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also, make sure that the TextMate bundles are **downloaded** to your computer.

## TextMate support

TextMate files are marked with  .

TextMate support in IntelliJ IDEA includes:

- Possibility to [import bundles](#) .
- Possibility to establish mappings between the color schemes of IntelliJ IDEA and TextMate.
- [Syntax and error highlighting](#) .
- Code completion in `*.markdown` files.

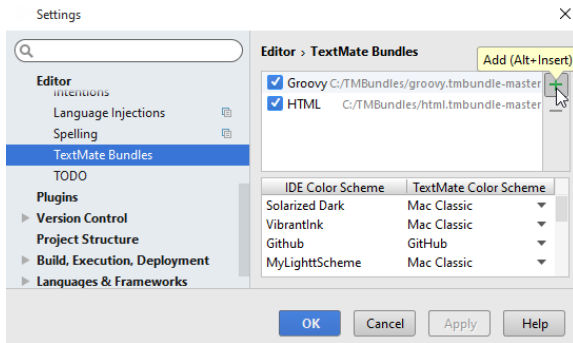

TextMate bundles become available to IntelliJ IDEA when they are **downloaded** to your computer.

## To import a TextMate bundle, follow these general steps

1. Make sure that TextMate bundles you want to import to IntelliJ IDEA, are already downloaded. For example, you can find the desired TextMate bundles on [GitHub](#).

**Note** It is important to note that IntelliJ IDEA cannot read the binary bundles. Use only bundle sources instead. You can find them on [GitHub](#).

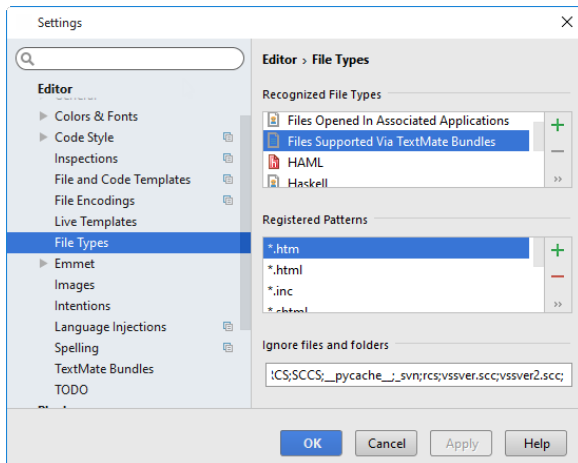

2. Open **Settings/Preferences dialog**, and click **TextMate Bundles**.
3. In the **TextMate Bundles** page, click **+**:

4. In the **Select Path** dialog box that opens, locate the desired bundle in the file system, and click **OK**. Repeat this step as required.
5. Apply changes.
6. If necessary, add the desired file type to the to the imported TM bundle.  
For example, if you want Ruby files with `.rb` extension to be supported by the IntelliJ IDEA's TextMate integration, you have to open for editing the file `Ruby.tmbundle\Syntaxes\Ruby.plist`, locate the section `fileTypes`, and under `array` add `rb`.

Then restart IntelliJ IDEA.

7. Just to make sure that the desired file type will be opened via the TextMate bundles, open **File Types** page of the **Settings/Preferences dialog**, among the recognized file types find **Files supported via TextMate bundles**, and see the list of extensions:

1. [Create a file](#) with the extension `*.markdown` .

**Note** A file with the extension `*.markdown` should be associated with the type Files supported via TextMate Bundles , as described in the section [Creating and Registering File Types](#) .

2. [Open](#) file for editing, and enter the desired text. The lines are highlighted according to the imported bundles.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports the [Thymeleaf](#) latest release version.

On this page:

- [Overview of Thymeleaf support](#)
- [Enabling the Thymeleaf plugin](#)
- [Thymeleaf support for projects and modules](#)
- [Adding Thymeleaf support when creating a project or module](#)
- [Adding Thymeleaf support for an existing project or module](#)

## Overview of Thymeleaf support

Thymeleaf support in IntelliJ IDEA includes:

- [Code completion](#) for expressions and `th:*` attributes.

- The [Navigate to Declaration](#) feature ( `Navigate | Declaration` or `Ctrl+B` ) that lets you jump from a reference in a template to the corresponding getter method, message in a `.properties` file or other appropriate code fragment.

- The [Navigate to Type Declaration](#) feature ( `Navigate | Type Declaration` or `Ctrl+Shift+B` ) for switching to corresponding type definitions.

- The [Rename refactoring](#) ( `Refactor | Rename` or `Shift+F6` ) for referenced properties (and getter methods), iteration and status variables, etc.

- [Code inspections](#) that find unresolved references and errors in expression syntax.

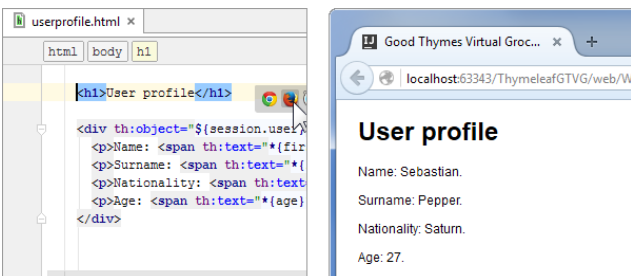

- Various [Find](#) functions e.g. [Find Usages](#) ( `Edit | Find | Find Usages` or `Alt+F7` ).

- [Intention actions](#) such as [Create property](#) for unresolved message references or [Import class](#) for adding the `import` statements for `org.thymeleaf.*` classes.

- [Preview](#) in a web browser for your prototypes (the static part of your templates) that can be accessed right from the editor.

## Enabling the Thymeleaf plugin

To be able to use the Thymeleaf support in IntelliJ IDEA, make sure that the Thymeleaf [plugin](#) is enabled. (This plugin is bundled with the IDE and enabled by default.)

See [Enabling and Disabling Plugins](#) .

## Thymeleaf support for projects and modules

You can add Thymeleaf support when creating a [project](#) or [module](#) , or for an existing project or module. In all such cases, IntelliJ IDEA downloads the Thymeleaf library files (you can select which of the library files are necessary and which aren't) and adds them to the [dependencies](#) of the corresponding module.

You can also create a "Thymeleaf project" by opening an appropriate `pom.xml` file. In that case, the dependencies in your project will be managed by Maven. For more info, see [Maven](#) .

## Adding Thymeleaf support when creating a project or module

1. Do one of the following:
  - If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select Java . In the right-hand part of the page, specify the [JDK](#) that you are going to use.
3. Under Additional Libraries and Frameworks , select the Thymeleaf checkbox.  
In the lower part of the page, click Configure and select the library files that you want to download in the [dialog that opens](#) .
4. You may also want to enable web app development support by selecting the Web Application checkbox. (For more info, see e.g. [Enabling Web Application Support](#) .)  
Click Next .
5. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .  
Click Finish .

## Adding Thymeleaf support for an existing project or module

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the project or the module folder and select Add Framework Support .
3. In the left-hand pane of the [Add Frameworks Support dialog](#) that opens, select the Thymeleaf checkbox.
4. In the right-hand part of the dialog, click Configure and select the library files that you want to download in the [dialog that opens](#) .
5. You may also want to enable web app development support by selecting the Web Application checkbox. (For more info, see e.g. [Enabling Web Application Support](#) .)
6. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

On this page:

- [Plugins](#)
- [Libraries](#)
- [Overview of Tiles 3 support](#)

## Plugins

To be able to use [Apache Tiles 3](#) support in IntelliJ IDEA, make sure that the following [plugins](#) are enabled:

- Struts 1.x
- Struts 2 (if you want to use the [OGNL](#) support).

(These plugins are bundled with the IDE and enabled by default.)

See [Enabling and Disabling Plugins](#) .

## Libraries

To get the [library](#) files for your Tiles 3 development, use the [Apache Tiles Downloads page](#) .

Don't forget to add your libraries to the [dependencies](#) of corresponding [modules](#) .

## Overview of Tiles 3 support

Tiles 3 support in IntelliJ IDEA includes code completion, and syntax and error highlighting for:

- Tiles definition files
- Expression languages (EL): Unified EL and Object-Graph Navigation Language (OGNL)
- Tiles - JSP support tag library

This feature is only supported in the Ultimate edition.

IntelliJ IDEA supports developing and running [TypeScript](#) source code. IntelliJ IDEA recognizes `*.ts` files and provides full range of coding assistance for editing them without any additional steps from your side. TypeScript files are marked with the  icon.

### Before you start

1. Make sure the **JavaScript Support** plugin is enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .
2. Make sure the **Node.js** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

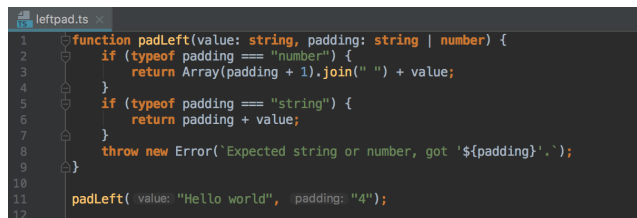

## TypeScript-aware coding assistance

**Tip** IntelliJ IDEA provides code completion, error and syntax highlighting, code verification and compilation mainly based on the data from the [TypeScript Language Service](#) .

- [Code completion](#) for keywords, labels, variables, parameters, and functions.
- Error and syntax highlighting.
- Code [formatting](#) and [folding](#) .
- Numerous code [inspections](#) and [quick-fixes](#) .
- On-the-fly code verification and compilation into JavaScript.

## Parameter hints

**Parameter hints** show the names of parameters in methods and functions to make your code easier to read. By default parameter hints are shown only for values that are literals or function expressions but not for named objects.

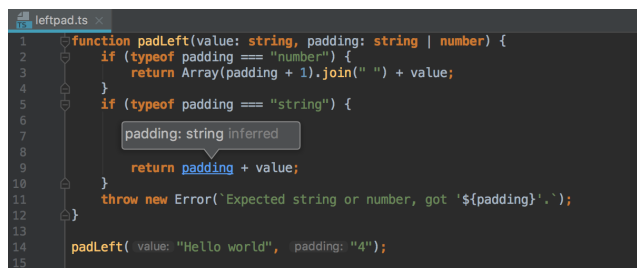

```
1 function padLeft(value: string, padding: string | number) {
2   if (typeof padding === "number") {
3     return Array(padding + 1).join(" ") + value;
4   }
5   if (typeof padding === "string") {
6     return padding + value;
7   }
8   throw new Error(`Expected string or number, got '${padding}'.`);
9 }
10
11 padLeft( value: "Hello world", padding: "4");
12
```

To show parameter hints for all arguments

1. In the Settings/Preferences dialog box ( [Ctrl+Alt+S](#) ), choose General under Editor , then choose Appearance . The [Appearance page](#) opens.
2. Click Configure next to the Show parameter name hint checkbox (the checkbox is selected by default).
3. In the Configure Parameter Name Hints dialog that opens, select the Show name for all arguments checkbox in the Options area.

## Inferred type information

To see the [inferred type](#) of an object, hold [⌘](#) on macOS or [Ctrl](#) on Windows and Linux and hover the mouse pointer over it:

```
1 function padLeft(value: string, padding: string | number) {
2   if (typeof padding === "number") {
3     return Array(padding + 1).join(" ") + value;
4   }
5   if (typeof padding === "string") {
6     padding: string inferred
7     return padding + value;
8   }
9   throw new Error(`Expected string or number, got '${padding}'.`);
10 }
11
12 padLeft( value: "Hello world", padding: "4");
13
14
15
```

## TypeScript code verification and compilation into JavaScript

**Tip** By default, integration with the [TypeScript Language Service](#) is turned on.

**Tip** The default compilation scope is entire project. To change this default settings, choose the relevant scope from the Compile scope list on the [TypeScript page](#).

IntelliJ IDEA verifies TypeScript code mainly based on the data from the [TypeScript Language Service](#) which also compiles TypeScript into JavaScript. All the detected syntax and compilation errors are reported in the Errors and Compile errors tabs of the [TypeScript Tool Window](#) . For each error, IntelliJ IDEA provides a brief description and information about the number of the line where it occurred.

The Console tab shows the log of the [TypeScript Language Service](#) since the tool window was opened.

To configure integration with the TypeScript Language Service

1. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click TypeScript under Languages and Frameworks . The [TypeScript page](#) opens.
2. Select the Use TypeScript Service checkbox.
3. Use the controls below to configure the behaviour of the TypeScript compiler and enable or disable integration with the [Angular language service](#) .
4. In the Options field, specify the command line options to be passed to the TypeScript Language Service when the `tsconfig.json` file is not found. See the list of acceptable options at [TSC arguments](#) . Note that the `-w` or `--watch` ( [Watch input files](#) ) option is irrelevant.

To monitor syntax errors

Open the TypeScript tool window ( View | Tool Windows | TypeScript ) and switch to the Errors tab. The tab lists the discrepancies in the code detected by the TypeScript Language Service. The list is updated dynamically as you change your code.

- By default, the list contains only the errors from the file in the active editor tab and the full path to this file is displayed at the top. To show the errors across the entire project, press the Show project errors toggle button  on the toolbar. The tab shows error messages grouped by files in which they were detected.
- To navigate to the code in question, select the corresponding error message and choose Jump to Source on the context menu.

To monitor compilation errors

Open the TypeScript tool window ( View | Tool Windows | TypeScript ) and switch to the Compile errors tab. The tab lists the errors that occurred during compilation.

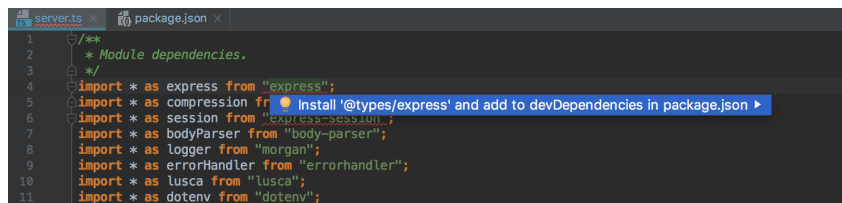

- By default, the list is updated dynamically as you edit your code. To change this setting, clear the Recompile on changes checkbox on the [TypeScript](#) page.
- By default, the list contains only the errors from the file in the active editor tab. To view the compilation errors across the entire compilation scope, click  on the toolbar and choose Compile All from the list. The error messages are shown grouped by files in which they were detected.
- To navigate to the code in question, select the corresponding error message and choose Jump to Source on the context menu.

## Using JavaScript libraries in TypeScript

When working with JavaScript libraries in TypeScript, you need to [install type declarations](#) for them. IntelliJ IDEA reminds you to install them via `npm` and updates your `package.json` file accordingly.

To install the type declarations

1. Position the cursor at the warning and press `Alt+Enter` .
2. Select the suggestion and press `Enter` .

```
1  /**
2  * Module dependencies.
3  */
4  import * as express from "express";
5  import * as compression from "compression";
6  import * as session from "session";
7  import * as bodyParser from "body-parser";
8  import * as logger from "morgan";
9  import * as errorHandler from "errorhandler";
10 import * as lusca from "lusca";
11 import * as dotenv from "dotenv";
```

## Common and TypeScript-specific refactoring

**Tip** See also [Refactoring JavaScript](#).

- Common refactoring procedures, such as `rename/move` , etc. See [Rename Refactorings](#) and [Move Refactorings](#) for details.
- TypeScript-specific refactoring procedures, such as `change signature` , `extract parameter` , `extract variable` . See for details.

## Code generation

- Generating code stubs based on [file templates](#) during file creation.
- Ability to create [line and block comments](#) ( `Ctrl+Slash` / `Ctrl+Shift+Slash` ).
- Generating `import` statements for modules, classes, and any other symbols that can be exported and called as a type. See [Importing TypeScript Symbols](#) .
- Configuring automatic insertion or skipping the `public` access modifier in generated code.

Learn more from [Generating Code](#) .

This feature is only supported in the Ultimate edition.

[Refactoring](#) means updating the structure of the source code without changing the behaviour of the application. Refactoring helps you keep your code solid, [dry](#), and easy to maintain.

## Move refactorings

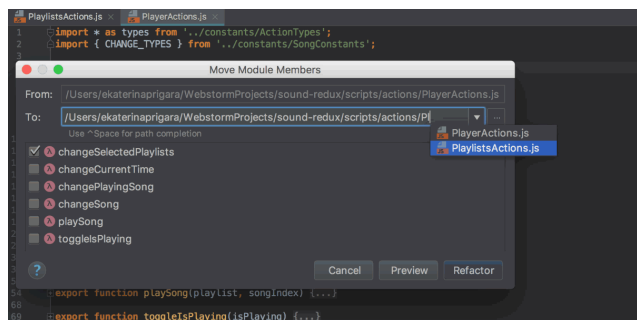

Besides [moving files and folders](#), IntelliJ IDEA lets you move TypeScript top-level symbols. The **Move Symbol Refactoring** works for classes, functions, and variables in ES6 modules.

To move a class, a function, or a variable

1. Select the symbol to move.
2. Press **F6** or choose Refactor | Move on the main menu or on the context menu of the selection.
3. In the dialog box that opens, specify the destination file.

**Tip** Alternatively, choose Refactor | Refactor This or press **Ctrl+Shift+Alt+T**, then choose Move from the list.

In the example below, the function `changeSelectedPlaylists` is moved from the `PlayerActions.js` file to the `PlaylistsActions.js` file. Note that an import statement for the types that `changeSelectedPlaylists` requires is added to `PlaylistsActions.js`. Also all the imports of `changeSelectedPlaylists` in the other files are updated.

## Pull Class Members Up refactoring

The **Pull Class Members Up** refactoring moves class methods upwards in the class hierarchy – from the current class to a superclass or to the interface which it implements.

Suppose you have a class `AccountingDepartment` that extends an abstract class `Department` and implements an interface `ReportingDepartment`.

```
abstract class Department {
  constructor(public name: string) {
  }
  printName(): void {
    console.log("Department name: " + this.name);
  }
}

interface ReportingDepartment {
  generateReports(): void
}

class AccountingDepartment extends Department implements ReportingDepartment {
  constructor() {
    super("Accounting and Auditing");
  }
  printMeeting(): void {
    console.log("The Accounting Department meets each Monday at 10 a.m");
  }
  generateReports(): void {
    console.log("Generating accounting reports...");
  }
}
```

### Example 1: Moving a class method to a superclass

In this example, the `printMeeting()` method is moved from `AccountingDepartment` to `Department`.

```

abstract class Department {
    constructor(public name: string) {
    }
    printName(): void {
        console.log("Department name: " + this.name);
    }
    printMeeting(): void {
        console.log("The Accounting Department meets each Monday at 10 a.m");
    }
}

interface ReportingDepartment {
    generateReports(): void
}

class AccountingDepartment extends Department implements ReportingDepartment {
    constructor() {
        super("Accounting and Auditing");
    }
    generateReports(): void {
        console.log("Generating accounting reports...");
    }
}

```

### Example 2: Moving a class method to the interface

In this example, the `PrintMeeting()` method is copied from the `AccountingDepartment` class to the `ReportingDepartment` interface.

```

abstract class Department {
    constructor(public name: string) {
    }
    printName(): void {
        console.log("Department name: " + this.name);
    }
}

interface ReportingDepartment {
    generateReports(): void
    printMeeting(): void
}

class AccountingDepartment extends Department implements ReportingDepartment {
    constructor() {
        super("Accounting and Auditing");
    }
    printMeeting(): void {
        console.log("The Accounting Department meets each Monday at 10 a.m");
    }
    generateReports(): void {
        console.log("Generating accounting reports...");
    }
}

```

### To move the methods of a class to a superclass or the interface

1. Place the cursor anywhere inside the class from which you want to pull the members up.
2. Choose Refactor | Pull Members Up on the main menu or on the context menu. The Pull Members Up dialog opens.
3. From the drop-down list, choose the superclass or the interface where you want to move the methods.
4. To pull a method up, select the checkbox next to it in the Members to be pulled up list. If applicable, select the Make

abstract checkbox next to the method to move.

## Rename refactorings

Besides [Renaming files and folders](#) , which is available in the context of any language, you can also rename classes, functions, variables, and parameters. IntelliJ IDEA changes the name of the symbol in its declaration and by default all its usages in the current project.

### To rename a function, a class, or a variable

1. In the editor, select the symbol to rename and press `Shift+F6` or choose Refactor | Rename on the context menu or on the main menu.
2. In the [Rename dialog](#) that opens, type the new name of the symbol.
3. Optionally:
  - Select the Search in comments and strings and Search for text occurrences checkboxes to rename the usages of the function or the class in comments, string literals, documentation, HTML, and other files included in the project.
  - Select the Search JavaScript References checkbox to rename the usages of the function or the class in generated JavaScript code.
4. If necessary, [preview and apply the changes](#) .

### To rename a parameter

1. Select the parameter in the editor and press `Shift+F6` or choose Refactor | Rename on the context menu or on the main menu.
2. In the text box with red canvas around the selected parameter, type the new parameter name.
3. Press `Enter` to run the refactoring.

## Extract refactorings

IntelliJ IDEA provides various **Extract** refactorings to introduce parameters, variables, constants, fields, methods, and functions. To run any of these refactorings, select the expression to refactor and choose Refactor | Extract | <target> . You can select an entire expression or place the cursor anywhere inside it and IntelliJ IDEA will help you with the selection.

### Extract Parameter

Use the **Extract Parameter** refactoring to replace an expression in the calls of a function with a parameter. IntelliJ IDEA will update the declaration and the calls of the function accordingly. The default value of the new parameter can be initialized inside the function body or passed through function calls.

Suppose you have a piece of code with a hardcoded `"Hello, "` in the function `greeter()` .

```
function greeter(firstName : String, lastName : String) {  
    return "Hello, " + firstName + " " + lastName;  
}  
  
document.body.innerHTML = greeter("Jane","User");
```

With the Extract Parameter refactoring, you can replace this hardcoded `"Hello, "` with a `greeting` parameter. The new `greeting` parameter can be extracted as **optional** or as **required** .

#### Example 1: Extracting an optional parameter

A new parameter `greeting` is extracted as an optional parameter. The new parameter is added to the definition of `greeter()` using the function default parameter syntax. The call of `greeter()` is not changed.

```
function greeter(firstName : String, lastName : String, greeting = "Hello, ") {  
    return greeting + firstName + " " + lastName;  
}  
  
document.body.innerHTML = greeter("Jane","User");
```

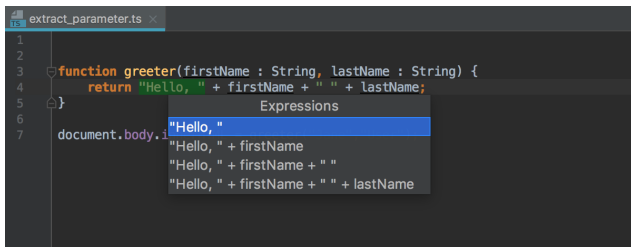

#### Example 2: Extracting a required parameter

In this example, a new parameter `greeting` is extracted as a required parameter. So the corresponding function call (`document.body.innerHTML = greeter(user);`) is changed accordingly.

```
function greeter(firstName : String, lastName : String, greeting: string) {  
    return greeting + firstName + " " + lastName;  
}  
  
document.body.innerHTML = greeter("Jane", "User", "Hello, ");
```

### To extract a parameter

1. In the editor, place the cursor within the expression that you want to convert into a parameter and press `Ctrl+Alt+P` or choose Refactor | Extract | Parameter on the context menu or on the main menu.
2. If several expressions are detected in the current cursor location, select the required one in the Expressions list.

3. If more than one occurrence of the selected expression is found, choose Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu. Finally, the pop-up window for configuring the refactoring appears.

4. Select the Generate JSDoc to have a JSDoc comment block generated. This may be helpful if you need to specify a custom default parameter value. Learn more from the [JSDoc Official website](#).
5. Choose where the new parameter will be initialized and specify its default value, if applicable:
  - If the Optional parameter checkbox is selected, the parameter will be initialized with the default value in the function body.
  - If the Optional parameter checkbox is cleared, the default parameter value will be passed through the existing function calls. All the function calls will change according to the new function signature and a parameter initialization will be added to the function body.

Initially, IntelliJ IDEA accepts the expression where the refactoring is invoked as the default value. In most cases you do not need to change it. If it is still necessary, specify another default value in the JSDoc comment in the format `@param <parameter name> - <default value>`.

6. Accept one of the suggested parameter names by double-clicking it in the pop-up list or specify a custom name in the text box with red canvas. Press `Enter` when ready.

### Choosing the refactoring mode

You can extract a parameter right in the editor (in the in-place mode) [as described above](#) or use the Extract Parameter dialog. These two approaches are rather similar, the difference is as follows:

- [Previewing the results of the refactoring](#).

In the dialog box, you can click Preview and examine the expected changes in the dedicated tab of the Find tool window. In the in-place mode, this functionality is not available.

- [Specifying the default parameter value](#).

In the dialog box, IntelliJ IDEA suggests the default parameter value in the Value field where you can accept the suggestion or specify another value. In the in-place mode, IntelliJ IDEA treats the expression where the refactoring is invoked as the default parameter value. To specify another value, you have to use a JSDoc comment block.

### Extract Variable

Use the **Extract Variable** refactoring to replace an expression with a [function-scoped variable \(var\)](#), a [block-scoped variable \(let\)](#), or a [block-scoped constant \(const\)](#). This refactoring makes your source code easier to read and maintain. It also helps you avoid using hardcoded constants without any explanations about their values or purposes.

```
function Multiplication(a : number, b : number) {
  let d = (a + b) * (a + b);
  return d;
}

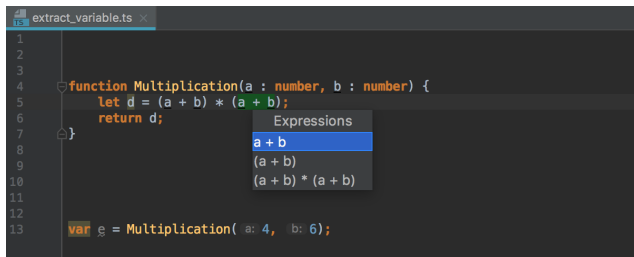

var e = Multiplication(4, 6);
```

```
function Multiplication(a : number, b : number) {
  let c = a + b;
  let d = (c) * (c);
  return d;
}

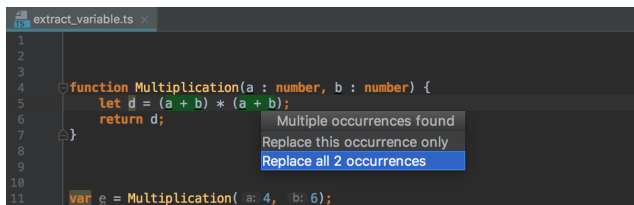

var e = Multiplication(4, 6);
```

1. In the editor, select the expression to convert into a variable and press `Ctrl+Alt+V` or choose Refactor | Extract | Variable on the context menu or on the main menu.

2. If several expressions are detected in the current cursor location, select the required one in the Expressions list.

3. If more than one occurrence of the selected expression is found, choose Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu.

Finally, the pop-up window for configuring the refactoring appears.

4. In the pop-up menu, choose the statement to use in the declaration of the new variable:

- Choose var to introduce a [function-scoped variable](#) . This variable can be declared in the enclosing function or outside any function.
- Choose let to introduce a [block-scoped variable](#) .
- Choose const to introduce a [block-scoped constant](#) .

5. Accept one of the suggested variable names by double-clicking it in the pop-up list or specify a custom name in the text box. Press `Enter` when ready.

### Choosing the refactoring mode

You can extract a variable right in the editor (in the in-place mode) [as described above](#) or use the Extract Variable dialog . By default, IntelliJ IDEA runs the Extract Variable refactoring in the in-place mode. To use the Extract Variable dialog box, open the Settings/Preferences dialog (`Ctrl+Alt+S`) and click Editor | General . On the [General page](#) that opens, clear the Enable in-place mode checkbox in the Refactorings area.

### Extract Field

The **Extract Field** refactoring declares a new field and initializes it with the selected expression. The original expression is replaced with the usage of the field.

Suppose you have the following code:

```

class Rectangle {
    constructor(public height: number, public width: number) {
        this.height = height;
        this.width = width;
    }

    get area() {
        return this.calcArea();
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

In all the three examples below, the same field, `_calcArea` is extracted. The examples illustrate three different ways to initialize the extracted field.

Example 1: The extracted field `_calcArea` is initialized in the enclosing method `get Area()`

```

class Rectangle {
    constructor(public height: number, public width: number) {
        this.height = height;
        this.width = width;
    }

    private _calcArea: number;

    get area() {
        this._calcArea = this.calcArea();
        return this._calcArea;
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

Example 2: The extracted field `_calcArea` is initialized in its declaration

```

class Rectangle {
    constructor(public height: number, public width: number) {
        this.height = height;
        this.width = width;
    }

    private _calcArea = this.calcArea();

    get area() {
        return this._calcArea;
    }

    calcArea() {
        return this.height * this.width;
    }
}

```

Example 3: The extracted field `_calcArea` is initialized in the constructor of the class

```

class Rectangle {
  constructor(public height: number, public width: number) {
    this._calcArea = this.calcArea();
    this.height = height;
    this.width = width;
  }

  private _calcArea: number;

  get area() {
    return this._calcArea;
  }

  calcArea() {
    return this.height * this.width;
  }
}

```

### To extract a field

1. In the editor, select the expression to convert into a field and press `Ctrl+Alt+F` or choose Refactor | Extract | Field on the context menu or on the main menu.
2. In the [Extract Field Dialog](#) that opens:
  - Specify the field name and [type](#).
  - Choose where the new field will be initialized, the available options are:
    - Current method, see [Example 1](#).
    - Field declaration, see [Example 2](#).
    - Class constructor, see [Example 3](#).
  - Choose the field visibility, the available options are Public, Private, and Protected. Learn about field visibility modifiers from the [TypeScript Official website](#).

## Extract Method

**Tip** The selected code fragment does not necessarily have to be a set of statements. It may also be an expression used somewhere in the code.

The **Extract Method** refactoring lets you create a named method or function with the extracted code. When the **Extract Method** refactoring is invoked, IntelliJ IDEA detects the variables that are the input for the selected code fragment and the variable that is the output for it. The detected output variable is used as the return value for the extracted method or function.

### Example 1: Extracting a global method from an expression inside another method

In this example, a globally scoped method `NewMethod()` is extracted from the `let c = a + b;` expression. The parameters for the extracted method are retrieved from the `let c = a + b;` expression.

#### Example 1.1: A function declaration is generated

```

function MyFunction(a : number, b : number) {
  let c = a + b;
  let d = c * c;
  return d;
}

```

```

function NewMethod(a: number, b: number) {
  let c = a + b;
  return c;
}

function MyFunction(a : number, b : number) {
  let c = NewMethod(a, b);
  let d = c * c;
  return d;
}

```

### Example 1.2: The extracted function is declared inside an expression

```
function MyFunction(a : number, b : number) {
  let c = a + b;
  let d = c * c;
  return d;
}

let NewMethod = function (a : number, b : number) {
  let c = a + b;
  return c;
};

function MyFunction(a : number, b : number) {
  let c = NewMethod(a, b);
  let d = c * c;
  return d;
}
```

### Example 2: Extracting a method with declaration inside the enclosing method

In this example, a method `NewMethod()` is extracted from the `let c = a + b;` expression. The destination scope `function MyFunction` is chosen.

```
function MyFunction(a : number, b : number) {
  let c = a + b;
  let d = c * c;
  return d;
}

function MyFunction(a : number, b : number) {
  let NewMethod = function () {
    let c = a + b;
    return c;
  };
  let c = NewMethod();
  let d = c * c;
  return d;
}
```

### Example 3: Extracting a method from an expression outside any method

A method `NewMethod()` is extracted from the `var e = MyFunction(4, 6);` expression that is outside any method. The extracted method is globally scoped.

```
var e = MyFunction(4, 6);

let NewMethod = function () {
  var e = MyFunction(4, 6);
};

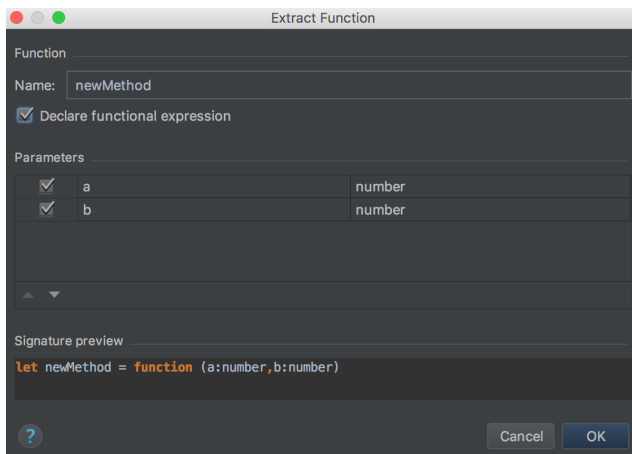

NewMethod();
```

### To extract a function

1. In the editor, select a code fragment to convert into a function and press `Ctrl+Alt+M` or choose Refactor | Extract | Method on the context menu or on the main menu.
2. If the selected expression is inside another function, choose the destination scope from the pop-up list:

- If you choose global, the extracted function will be declared outside any function, see [Example 1](#) above.
  - To declare the extracted function inside the current enclosing function, choose function <current enclosing function name>, see [Example 2](#) above.
3. In the [Extract Function](#) dialog box that opens, specify the name of the new function.
  4. Choose how the function will be declared. By default, the Declare functional expression checkbox is cleared and IntelliJ IDEA generates a [function declaration](#), see [Example 1.1](#) above.  
  
[To declare the extracted function inside an expression](#), select the Declare functional expression checkbox, see [Example 1.2](#) above.
  5. When extracting a [globally scoped function](#), configure the set of variables to be passed as parameters. By default, all the variables from the specified scope are listed in the Parameters area.
    - To have a variable included in the parameter set, select the checkbox next to it.
    - To change the order of parameters, use the Move Up and Move Down buttons.

6. In the Signature preview read-only area, check the declaration of the new function.

## Extract Type Alias

Use this refactoring to convert a type declaration expression into a [type alias](#) and replace all the occurrences of this expressions with this alias.

```
function createSquare(config): {color: string; area: number} {
  let newSquare = {color: "white", area: 100};
  if (config.color) {...}
  if (config.width) {...}
  return newSquare;
}

let mySquare = createSquare( config: {color: "black"});
```

Suppose you have the following fragment of code with a `{ z : number }` type declaration:

```
function returnsObj(): { x : number, y : { z : number } } {
  return null
}

function anotherObjectReturned(): {x : number, y : {z : number} } {
  return null
}
```

In the example below, a type alias `MyNewAlias` is extracted from the `{ z : number }` type declaration:

```
type MyNewAlias = { z : number };

function returnsObj(): { x : number, y : MyNewAlias } {
  return null
}

function anotherObjectReturned(): { x : number, y : MyNewAlias } {
  return null
}
```

### To extract a type alias

1. In the editor, place the cursor within the expression that you want to replace with a type alias and choose Refactor | Extract | Type Alias on the context menu or on the main menu.
2. If several expressions are detected in the current cursor location, select the required one in the Expressions list.

3. If more than one occurrence of the selected expression is found, choose Replace this occurrence only or Replace all occurrences in the Multiple occurrences found pop-up menu.

```

1 function returnsObj(): { x : number, y : { z : number } } {
2   return null
3 }
4
5 function anotherObjectReturned(): { x : number,
6   return null
7 }

```

4. In the text box, type the name of the type alias and press `Enter` when ready.

```

1 type MyNewAlias = { z : number };
2
3 function returnsObj(): { x : number, y: MyNewAlias } {
4   return null
5 }
6
7 function anotherObjectReturned(): { x : number, y: MyNewAlias } {
8   return null
9 }

```

## Extract Superclass

The **Extract Superclass** refactoring creates a new abstract class based on the members of the current class. The created abstract class is extended automatically.

Suppose you have a class `AccountingDepartment` and you expect that the `printName()` method from it will be re-used.

```

class AccountingDepartment {
  name: string;
  printName(): void {
    console.log("Department name: " + this.name);
  }
  printMeeting(): void {
    console.log("The Accounting Department meets each Monday at 10 a.m.");
  }
  generateReports(): void {
    console.log("Generating accounting reports...");
  }
}

```

You can extract a superclass `Department` and include the `printName` and the `Name` field in it.

```

class Department {
  name: string;

  printName(): void {
    console.log("Department name: " + this.name);
  }
}

class AccountingDepartment extends Department {
  printMeeting(): void {
    console.log("The Accounting Department meets each Monday at 10 a.m.");
  }
  generateReports(): void {
    console.log("Generating accounting reports...");
  }
}

```

### To extract a superclass

1. Place the cursor anywhere inside the class from which you want to extract a superclass.
2. Choose Refactor | Extract | Superclass on the main menu or on the context menu. The Extract Superclass dialog opens.
3. Specify the name of the new superclass and select the checkboxes next to the class members you want to include in it.
4. In the Destination file field, specify the location of the file where the new class will be. By default, the field shows the path to the current file where the refactoring was invoked.
5. Choose Extract Superclass . IntelliJ IDEA creates a new class and marks the source class with `extends` .

To create a superclass and replace the references to the source class with references to the superclass in parameters of methods, choose Extract superclass and use it where possible . IntelliJ IDEA shows the proposed changes in the Refactoring Preview pane of the Find tool window.

## Extract Interface

The Extract Interface refactoring creates a new interface based on the members of the current class. The created interface will be implemented automatically.

Suppose you have a class `AccountingDepartment` and you expect that the `generateReports()` method from it will have other implementations.

```

abstract class Department {
    constructor(public name: string) {
    }
    printName(): void {
        console.log("Department name: " + this.name);
    }
}

class AccountingDepartment extends Department {
    constructor() {
        super("Accounting and Auditing");
    }
    printMeeting(): void {
        console.log("The Accounting Department meets each Monday at 10 a.m");
    }
    generateReports(): void {
        console.log("Generating accounting reports...");
    }
}

```

You can extract a `DepartmentInterface` interface and include the `generateReports()` in it.

```

abstract class Department {
    constructor(public name: string) {
    }
    printName(): void {
        console.log("Department name: " + this.name);
    }
}

interface DepartmentInterface {
    generateReports(): void;
}

class AccountingDepartment extends Department implements DepartmentInterface {
    constructor() {
        super("Accounting and Auditing");
    }
    printMeeting(): void {
        console.log("The Accounting Department meets each Monday at 10 a.m");
    }
    generateReports(): void {
        console.log("Generating accounting reports...");
    }
}

```

#### To extract an interface

1. Place the cursor anywhere inside the class from which you want to extract an interface.
2. Choose Refactor | Extract | Interface on the main menu or on the context menu. The Extract Interface dialog opens.
3. Specify the name of the new interface and select the checkboxes next to the class members you want to include in it.
4. In the Destination file field, specify the location of the file where the new interface will be. By default, the field shows the path to the current file where the refactoring was invoked.
5. Choose Extract Interface . IntelliJ IDEA creates a new interface and marks the source class as its implementation.

To create an interface and replace the references to the source class with references to the interface in parameters of methods, choose Extract interface and use it where possible . IntelliJ IDEA shows the proposed changes in the Refactoring Preview pane of the Find tool window. Note that if an instance references a method or a field that is not defined in the interface, IntelliJ IDEA will not suggest replacing it.

## Inline refactorings

Inline refactorings are opposite to [Extract refactorings](#) .

### Example 1: Inline Variable

The **Inline Variable** refactoring replaces a redundant usage of a variable or a constant with its initializer. This type of refactoring is available only for block-scoped and function-scoped variables.

```
function Multiplication(a : number, b : number) {
  let c = a + b;
  let d = (c) * (c);
  return d;
}
```

```
function Multiplication(a : number, b : number) {
  let d = ((a + b)) * ((a + b));
  return d;
}
```

The **Inline Method / Inline Function** refactoring results in placing the body of a method or a function into the body of its caller(s); the method/function itself is deleted.

In the example below, the body of `Sum()` is placed in the body of `Multiplication()`.

```
function Sum(a: number, b: number) {
  return a + b;
}

function Multiplication(a: number, b: number) {
  let d = Sum(a, b) * Sum(a, b);
  return d;
}

var e = Multiplication(4, 6);
```

```
function Multiplication(a : number, b : number) {
  let d = (a + b) * (a + b);
  return d;
}

var e = Multiplication(4, 6);
```

To run an **Inline** refactoring:

1. In the editor, place the cursor at the symbol to be inlined and press `Ctrl+Alt+N` or choose Refactor | Inline on the context menu or on the main menu.

## Change Signature refactoring

**Tip** You can also add a parameter using the [Extract Parameter](#) refactoring.

**Tip** To perform the refactoring right away, click Refactor.

**Tip** Configuring the visibility is applicable only to functions defined within classes.

**Tip** If necessary, [propagate the new parameter](#) to the functions that call the current function.

Use the **Change Signature** refactoring to change the name of a function, its visibility, and return type, to add, remove, reorder, and rename parameters, and to propagate new parameters through the hierarchy of calls.

In the example below, the function `eat()` is renamed to `feed()` and a new `boolean` parameter `isMammal` is introduced.

```
class Animal {
  constructor(age: number, name: string){
  }

  eat(food: string[]): void {
  }
}

let Max = new Animal(23, 'Max');
Max.eat(['Apple', 'Parsley']);
let Daisy = new Animal(12, 'Daisy');
Daisy.eat(['Pork', 'Fish']);
```

```
class Animal {
  constructor(age: number, name: string){
  }

  feed(food: string[], isMammal: boolean = true): void {
  }
}

let Max = new Animal(23, 'Max');
Max.feed(['Apple', 'Parsley'], false);
let Daisy = new Animal(12, 'Daisy');
Daisy.feed(['Pork', 'Fish'], false);
```

To invoke **Change Signature**

In the editor, place the cursor within the name of the function to refactor and press `Ctrl+F6` or choose Refactor | Change Signature on the context menu or on the main menu. The **Change Signature dialog** opens.

To rename a function

In the Change Signature dialog (`Ctrl+F6`), edit the Name field.

To change the return type of a function

In the Return type field, specify the type of the value that the function returns. If the field is empty, the return type is treated as `void`. Learn more about the return type from the [TypeScript Official website](#).

To change the visibility of a function

From the Visibility drop-down list, choose a [function modifier](#), the available options are [public \(default\)](#), [private](#), and [protected](#),

### To manage the function parameters

In the Change Signature dialog ( `Ctrl+F6` ), use the table of parameters and the buttons to the right of it:

- To add a parameter, click `+` ( `Alt+Insert` ) and specify the name of the new parameter and its type. Specify the default value of the parameter or the value to be passed through function calls.
- To remove a parameter, click any of the cells in the corresponding row and click `-` ( `Alt+Delete` ).
- To reorder the parameters, so required parameters are listed before optional ones, use `↑` ( `Alt+Up` ) and `↓` ( `Alt+Down` ). Learn more about required and optional parameters from the [TypeScript Official website](#) .
- To rename a parameter, edit the Name field.

### To propagate a parameter along the hierarchy of calls

1. In the Change Signature dialog ( `Ctrl+F6` ), select the parameter and click `⌵`. The Select Methods to Propagate New Parameters dialog opens. The left-hand pane shows the hierarchy of function calls. When you select a function, the right-hand pane shows its code and the code of the function it calls in the Caller Method and Callee Method fields respectively.
2. In the left-hand pane, select the checkboxes next to the functions where you want to propagate the parameter and click OK .

### To preview the changes and complete the refactoring

1. In the Change Signature dialog ( `Ctrl+F6` ), click Preview .
2. In the Refactoring Preview tab of the [Find tool window](#) , [view the expected changes](#) , make the necessary adjustments, and click Do Refactor when ready.

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Running a file with injected TypeScript from IntelliJ IDEA](#)

## Introduction

TypeScript code is not processed by browsers that work with JavaScript code. Therefore to be executed, TypeScript code has to be translated into JavaScript. This operation is referred to as **compilation** and the tools that perform it are called **compilers**.

## Running a file with injected TypeScript from IntelliJ IDEA

Note that no run configuration is required for launching applications with injected TypeScript from IntelliJ IDEA.

1. [Compile the TypeScript code into Javascript](#).
2. In the editor, open the HTML file with the TypeScript reference. This HTML file does not necessarily have to be the one that implements the starting page of the application.
3. Do one of the following:
  - Choose View | Open in Browser on the main menu or press `Alt+F2`. Then select the desired browser from the pop-up menu.
  - Hover your mouse pointer over the code to show the browser icons bar:  Click the icon that indicates the desired browser.

This feature is only supported in the Ultimate edition.

## Introduction

Before debugging, you need to compile your code into JavaScript.

IntelliJ IDEA needs [source maps](#) to recognize breakpoints you set in the TypeScript code. To have source maps generated during compilation, open the `tsconfig.json` file and make sure the `sourceMap` property is set to `true`.

Before you start, configure the built-in debugger as described in [Configuring JavaScript Debugger](#). To use the **Live Edit** functionality that shows the changes in your HTML and CSS in the browser on the fly, install the [JetBrains IDE Support](#) Chrome extension. Find more about that in [Live Edit in HTML, CSS, and JavaScript](#).

## Debugging client-side TypeScript

Most often, you may want to debug a client-side application running on an external development web server, e.g. powered by Node.js.

1. [Configure and set breakpoints](#) in the TypeScript code.
2. Compile the TypeScript code into JavaScript.
3. Run the application in the **development mode**. Often you need to run `npm start` for that. When the development server is ready, copy the URL address at which the application is running in the browser - you will need to specify this URL address in the run/debug configuration.
4. Create a debug configuration of the type **JavaScript Debug**:

Choose Run | Edit Configuration on the main menu, click **+** on the toolbar and select JavaScript Debug from the pop-up list.

5. In the **Run/Debug Configuration: JavaScript Debug** dialog box that opens, specify the URL address at which the application is running.

This URL can be copied from the address bar of your browser as described in Step 3 above. Click OK to save the configuration settings.

6. Choose the newly created configuration in the Select run/debug configuration drop-down list on the toolbar and click the Debug toolbar button . The URL address specified in the run configuration opens in the chosen browser and the **Debug tool window** appears.
7. In the Debug tool window, proceed as usual: [step through the program](#), [stop and resume](#) the program execution, [examine it when suspended](#), [view actual HTML DOM](#), etc.

If your TypeScript code is running on the built-in IntelliJ IDEA server, you can also debug it same ways as when [debugging JavaScript running on the built-in server](#).

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides facilities to run TypeScript-specific code quality inspections through integration with the **TSLint** code verification tool. This tool registers itself as an IntelliJ IDEA code inspection: it checks TypeScript code for most common mistakes and discrepancies without running the application. When the tool is activated, it launches automatically on the edited **TypeScript** file. Discrepancies are highlighted and reported in pop-up information windows, a pop-up window appears when you hover the mouse pointer over a stripe in the Validation sidebar. You can also press `Alt+Enter` to examine errors and apply suggested quick fixes. Learn more about inspections and intention actions at [Code Inspection](#) and [Intention Actions](#).

## Before you start

1. Download and install the [Node.js runtime environment](#) and configure it as a Node.js interpreter as described in [Configuring Node.js Interpreters](#).
2. Install and enable the **NodeJS** repository plugin as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

## Installing TSLint

Open the IntelliJ IDEA built-in Terminal (View | Tool Windows | Terminal or `Alt+F12`) and type `npm install tslint typescript --save-dev`. See [TSLint](#) for more information.

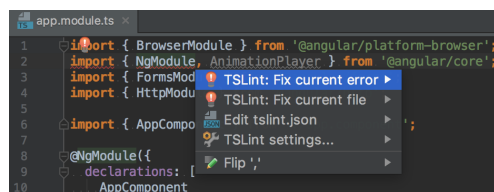

## Activating and configuring the TSLint tool

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), choose TypeScript under Languages and Frameworks, then choose TSLint. The **TSLint** page opens.
2. Select the Enable checkbox. After that all the controls in the page become available.
3. Specify the location of the **Node.js** executable file and the path to the **TSLint** package.
4. In the Configuration File area, appoint the configuration to use. By default, IntelliJ IDEA first looks for a `tslint.json` configuration file. IntelliJ IDEA starts the search from the folder where the file to be checked is stored, then searches in the parent folder, and so on until reaches the project root. If no `tslint.json` file is found, **TSLint** uses its default embedded configuration file. Accordingly, you have to define the configuration to apply either in a `tslint.json` configuration file, or in a custom **JSON** configuration file, or rely on the default embedded configuration.
  - To have IntelliJ IDEA look for a `tslint.json` file, choose the Search for tslint.json option. If no `tslint.json` file is found, the default embedded configuration file will be used.
  - To use a custom file, choose the Configuration File option and specify the location for the file in the Path field. Choose the path from the drop-down list, or type it manually, or click the `...` button and select the relevant file from the dialog box that opens.
5. If necessary, in the Additional Rules Directory field, specify the location of the files with additional code verification rules. These rules will be applied after the rules from `tslint.json` or the above specified custom configuration file and accordingly will override them.

## TSLint quick-fixes

With IntelliJ IDEA, you can fix some of the issues reported by **TSLint** automatically.

- To fix a specific error, place the cursor at the highlighted code, press `Alt+Enter`, and then choose TSLint: fix current error from the pop-up menu.
- To fix all the issues detected in the file, choose TSLint: fix current file.

```
app.module.ts
1 import { BrowserModule } from '@angular/platform-browser';
2 import { NgModule, AnimationPlayer } from '@angular/core';
3 import { FormsMod
4 import { HttpModu
5
6 import { AppCompo
7
8 @NgModule({
9   declarations: [
10     AppComponent
```

The screenshot shows a code editor with a TypeScript file named 'app.module.ts'. The code includes imports for 'BrowserModule', 'NgModule', 'AnimationPlayer', 'FormsMod', and 'HttpModu'. A TSLint error is highlighted on line 3, and a context menu is open over it, showing options like 'TSLint: Fix current error', 'TSLint: Fix current file', 'Edit tslint.json', 'TSLint settings...', and 'Flip ''

This feature is only supported in the Ultimate edition.

In this part:

[Getting Started with Vaadin](#)

[Getting Started with Vaadin-Maven Project](#)

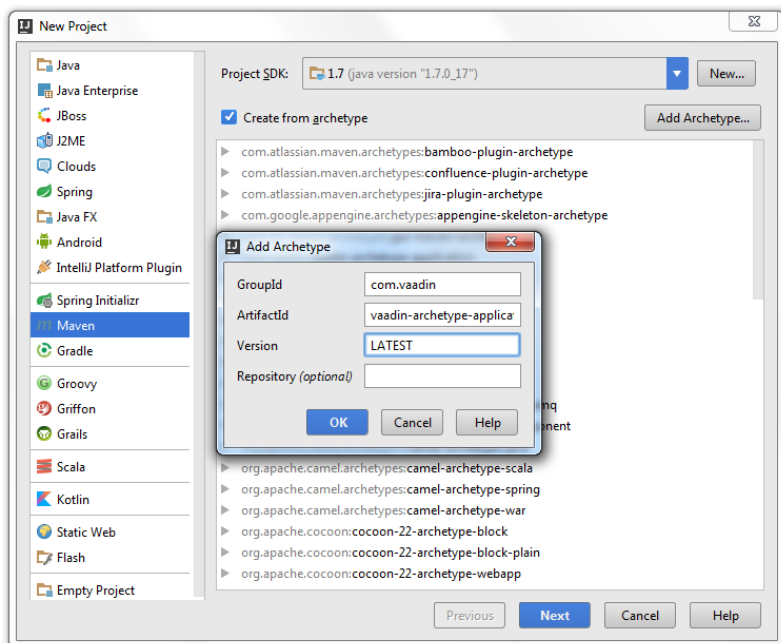

This feature is only supported in the Ultimate edition.

IntelliJ IDEA lets you create and manage a Maven project with Vaadin archetype.

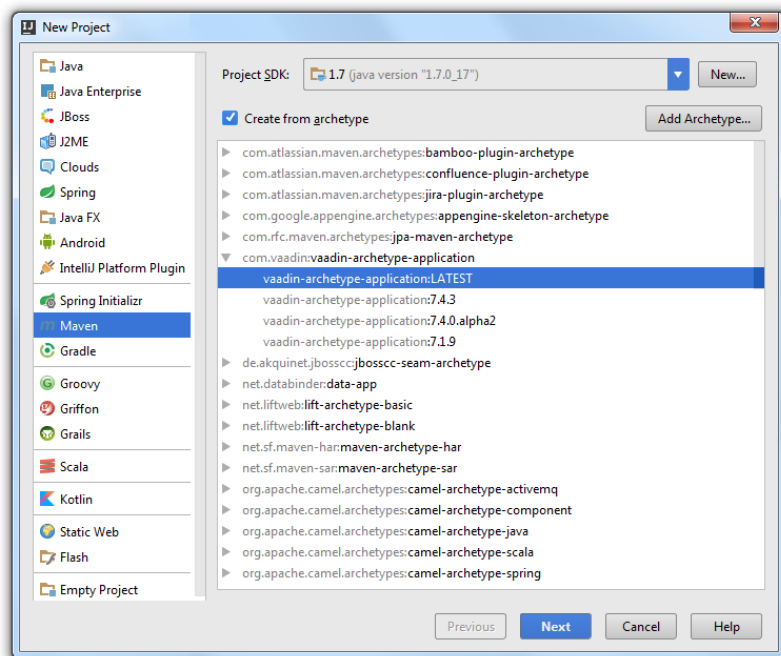

- [Creating Maven project with Vaadin archetype](#)
- [Import an external Vaadin project with Maven](#)
- [Configure run/debug settings and run application](#)

## Creating Maven project with Vaadin archetype

1. Open Project Wizard, under Maven , select Create from archetype checkbox and click Add archetype .
2. In the dialog that opens, enter maven GroupId, ArtifactId and Version.

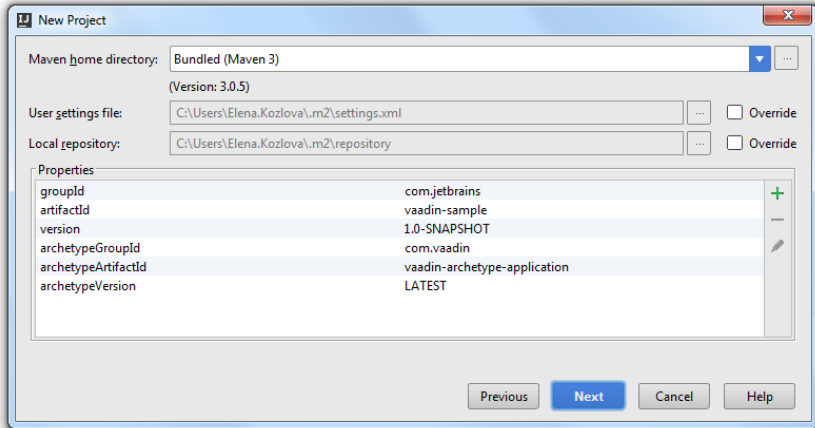

3. After you click OK , the Vaadin archetype is added to the list of available archetypes. Click Next .

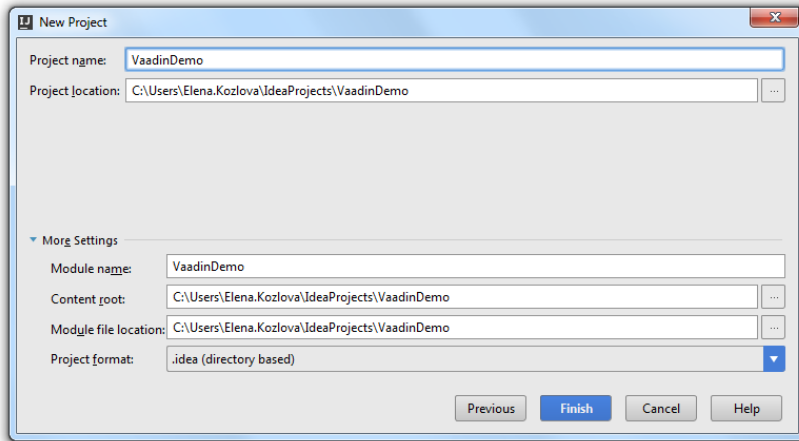

4. On the next page of the wizard, enter maven information for your project and click Next .

5. On the next page of the wizard, enter maven settings for your project and click Next .

6. On the next page of the wizard, enter your project's information and click Finish .

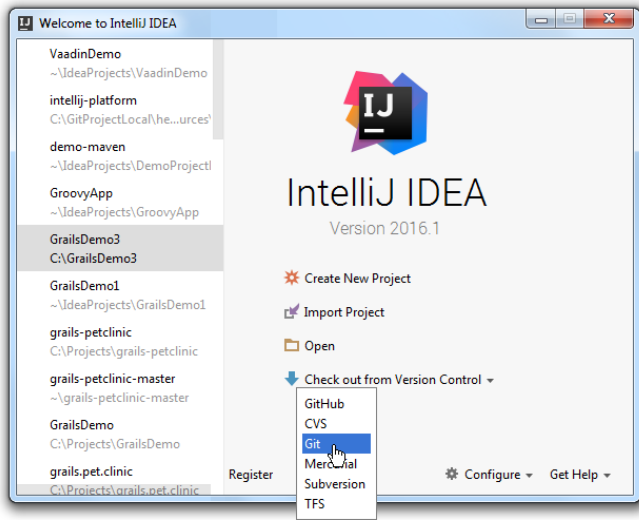

IntelliJ IDEA creates a maven project with pom.xml. IntelliJ IDEA also recognizes that this is a Web application and creates a webapp in your source directory.

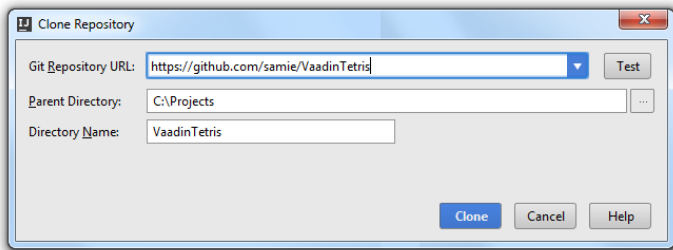

## Import an external Vaadin project with Maven

You can import external Vaadin project using VCS and check out your project from, for example, Git. In this case IntelliJ IDEA automatically converts your project structure, detects necessary frameworks and downloads appropriate dependencies.

1. In the Project Wizard, click Check out from Version Control and from the drop-down list, select Git .

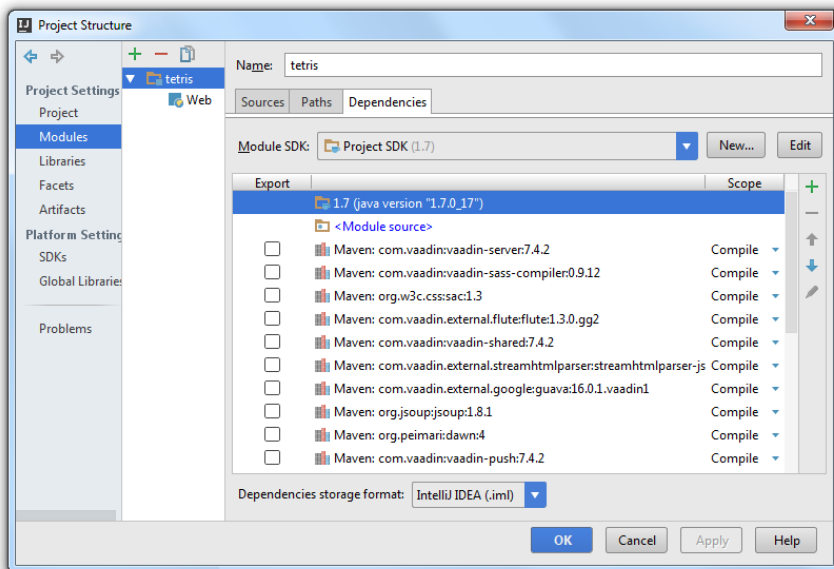

2. Specify Git Repository from which you want to clone your project, a Parent Directory location and the name of the parent directory. Click Clone .

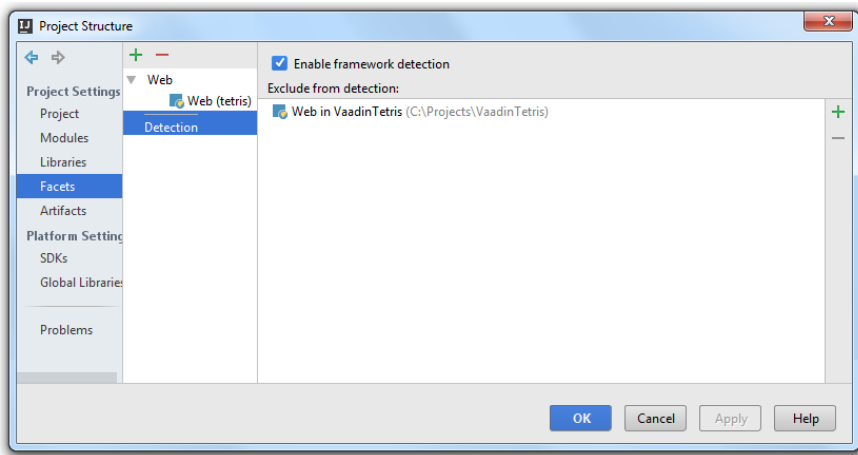

IntelliJ IDEA copies git project to your local directory, recognizes POM file, meaning it recognizes that this is a Maven project with Vaadin framework and imports the project with all the necessary configurations.

3. Check project structure to make sure that all necessary dependencies are downloaded.

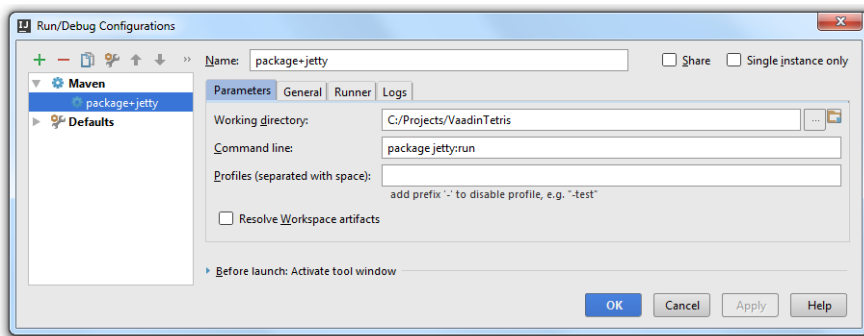

The frameworks are configured automatically, so you can exclude the detected ones.

## Configure run/debug settings and run application

IntelliJ IDEA lets you quickly configure Run/Debug settings for your project.

1. On the main menu, select Run | Edit Configurations .
2. Click **+** to add a new configuration from the list, specify the appropriate parameters for your configuration and press OK .

3. On the main menu press **R** to run the application.

You can view the output in the default browser <http://localhost:8080/> .

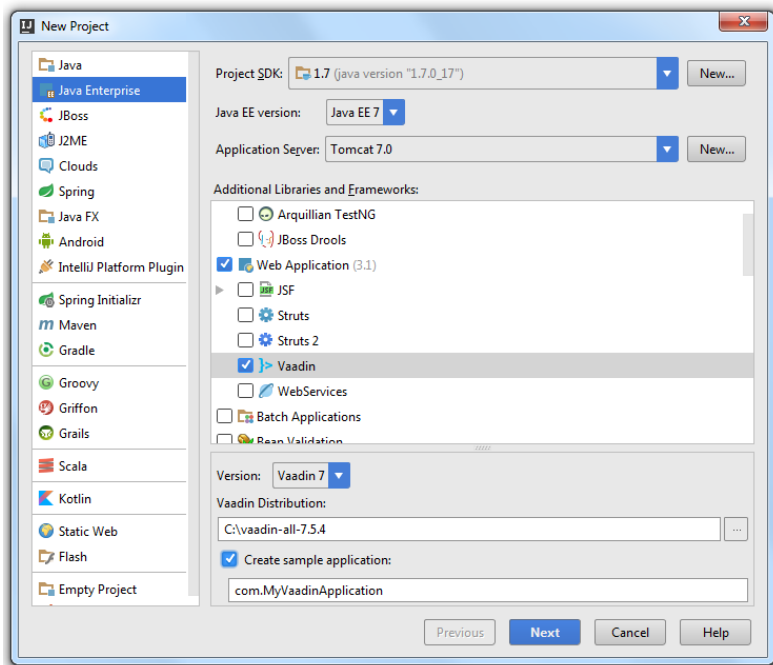

This feature is only supported in the Ultimate edition.

IntelliJ IDEA lets you create and manage projects using [Vaadin framework](#) that optimizes your Web application development. Note that before you start creating your project you need to make sure that [Vaadin SDK](#) is downloaded on your computer and Vaadin plugin is [enabled](#) in IntelliJ IDEA.

- [Creating Vaadin project with Project Wizard](#)
- [Running Vaadin application](#)
- [Debugging Vaadin application](#)

## Creating Vaadin project with Project Wizard

1. Open Project Wizard, under Java Enterprise select Vaadin framework.

2. Specify the following settings:

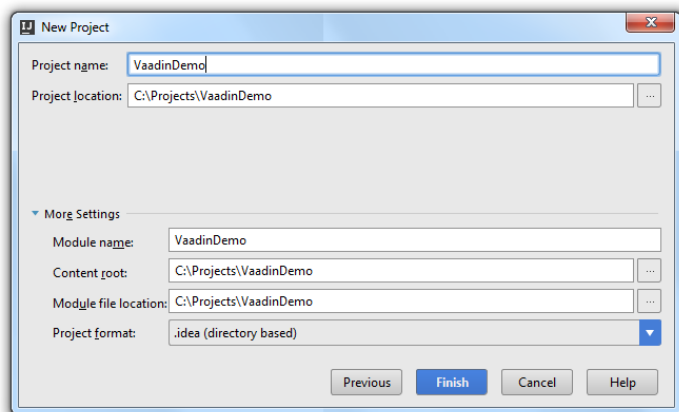

- Project SDK - specify your project SDK.
- JavaEE version - specify the version of JavaEE or use the default option.
- Application Server - specify the application server or use the default server. IntelliJ IDEA creates a run configuration for your Vaadin application.
- Version - for IntelliJ IDEA 13 and later, you can choose either Vaadin 6 or 7 version.
- Vaadin distribution - enter the location of Vaadin installation on your machine.

If Vaadin is not installed, then the warning message with the appropriate link appears. Click the link, download "All-in-One Archive" ZIP file and unpack it to the desired location.

- Create sample application - select this checkbox to either enter the name of the sample application or use the default name.

3. Click Next .

4. Specify your project information and click Finish .

IntelliJ IDEA creates a project with Web application and all necessary configurations.

## Running Vaadin application

Since the application server is specified you can run your application and view the output in the default browser

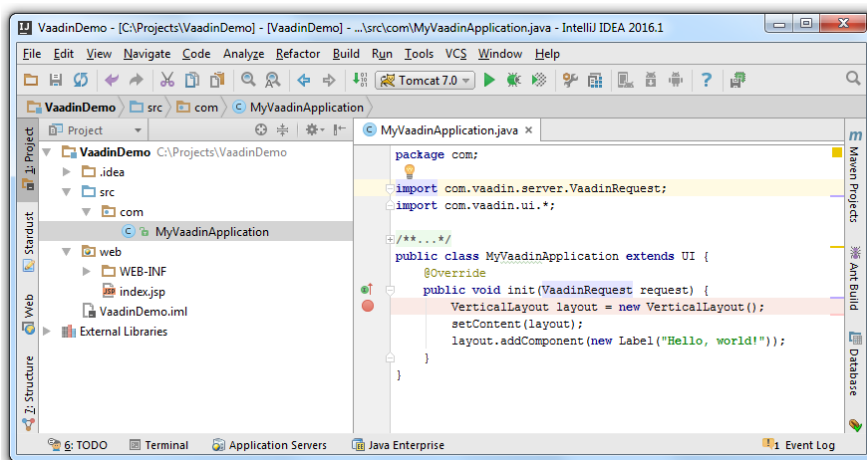

<http://localhost:8080/> .

## Debugging Vaadin application

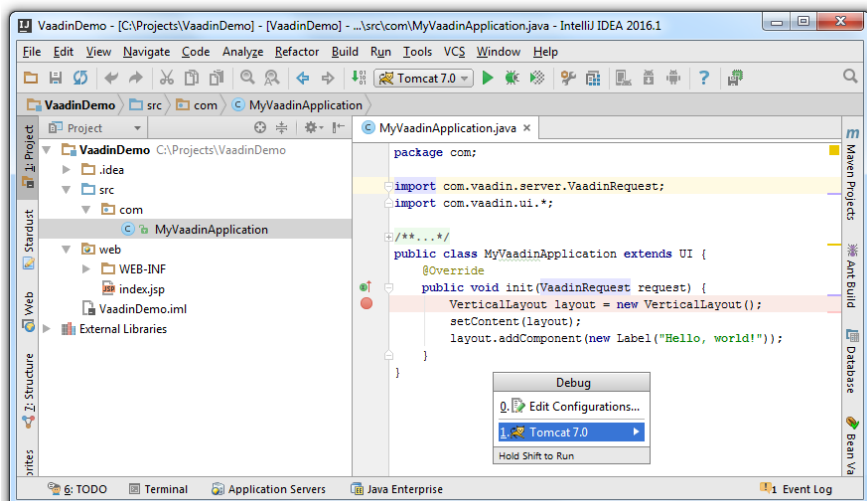

IntelliJ IDEA lets you easily start a debugging session for your project.

Let's choose one of the debugging actions, for example, **Toggle Line Breakpoint** .

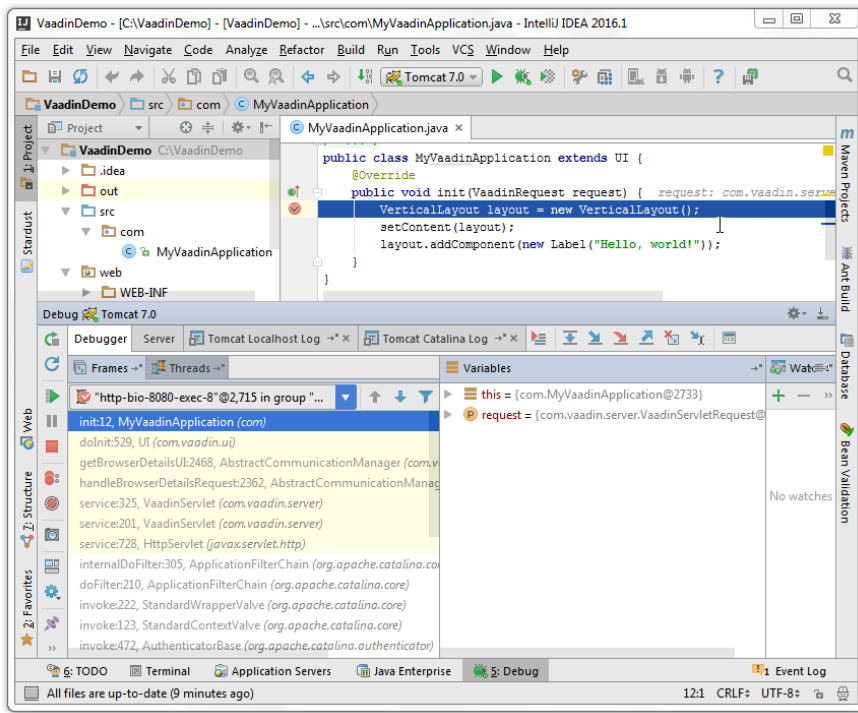

1. Place the caret on the desired line of the source code. Press **Ctrl+F8** or from the main menu select **Run | Toggle Line Breakpoint** .

2. Press **Shift+Alt+F9** to start a debugging session.

3. View results in the Debugger console.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Vagrant Plugin is installed and enabled!

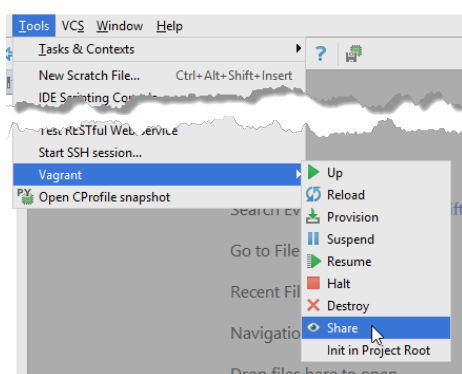

Integration with [Vagrant](#) helps you create reproducible development environments defined by [VagrantFile](#) configuration files. To have the same environment set up on the machines of all the team members you only need to put the [VagrantFile](#) under your team version control. Any team member can set up the required environment by running the `vagrant up` command with the relevant [VagrantFile](#). Vagrant support in IntelliJ IDEA is provided through the [Vagrant](#) plugin.

Integration with Vagrant in IntelliJ IDEA lets you:

- [Create new virtual boxes, and delete](#) the unnecessary ones.
- [Initialize Vagrant boxes](#), and execute other Vagrant commands without leaving the IDE.
- Choose the desired virtual box when performing the [vagrant up](#) command (Multiple Vagrant configuration).

Vagrant support in IntelliJ IDEA brings the following changes to the UI:

- A [Vagrant page](#) is added to the Settings dialog.
- A Vagrant node is added to the Tools menu. The node contains the commands that correspond to the standard Vagrant actions.

## Prerequisites

Install and enable the Vagrant plugin as described in the sections [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

Besides that, make sure that the following prerequisites are met (outside of IntelliJ IDEA):

- [Oracle's VirtualBox](#) is installed on your computer.
- [Vagrant](#) is installed on your computer, and all the necessary infrastructure is created.
- The parent folders of the following executable files are added to the system `PATH` variable:
  - `vagrant.bat` or `vagrant` from your Vagrant installation. This should be done automatically by the installer.
  - `VBoxManage.exe` or `VBoxManage` from your Oracle's VirtualBox installation.
- The required virtual boxes are created.

## Basics

In the context of IntelliJ IDEA, the following terms are used to denote Vagrant-specific notions:

- A [Vagrant box](#) in the IntelliJ IDEA user interface or [Vagrant base box](#) in the current documentation is a [box](#) in the native Vagrant terminology. It denotes a pure image, a skeleton, on the base of which a specific environment is customized, provisioned, and deployed on your machine.
- An [instance](#) is a [virtual machine](#). In other words, it is a specific environment customized, provisioned, and deployed on your machine on the base of a [Vagrant base box](#) and in accordance with a [VagrantFile](#). In other similar products and documentation, an [instance](#) can be referred to as [virtual machine](#).
- An [instance folder](#) is the folder where the relevant [VagrantFile](#) is stored after initialization and where IntelliJ IDEA will look for it. By default, it is the project root folder.

## Preparing to work with Vagrant

1. In the Settings/Preferences dialog (`Ctrl+Alt+S`), click Vagrant under Tools. The [Vagrant page](#) page opens.
2. Specify the [Vagrant](#) executable file. Because the parent folder of the executable file has been already added to the system `PATH` variable, type just the name of the executable.
3. In the Instance Folder field, specify the fully qualified path to the directory where the [VagrantFile](#) is initialized and stored. A [VagrantFile](#) is a configuration file that defines the [instance \(virtual machine\)](#) you need. The file contains the virtual IP address, port mappings, and the memory size to assign. The file can specify which folders are shared and which third-party software should be installed. According to the [VagrantFile](#) your [instance \(virtual machine\)](#) is configured, provisioned against the relevant [Vagrant base box](#), and deployed on your computer. A [VagrantFile](#) is created through the `vagrant init` command.

When creation of an [instance \(virtual machine\)](#) is invoked either through the `vagrant up` command or through the Tools | Vagrant | Up menu option, IntelliJ IDEA looks for the [VagrantFile](#) in the directory specified in the Instance folder field.

For more information, see <http://docs.vagrantup.com/v2/vagrantfile/>.

You can create a `VagrantFile` in any directory and appoint it as **instance folder**. If the field is empty, IntelliJ IDEA will treat the **project root** as the **instance folder** and look for a `VagrantFile` in it.

- In the Vagrant Boxes area, configure a list of the predefined **Vagrant base boxes** available in IntelliJ IDEA. Each item presents a **Vagrant base box** on which Vagrant configures and launches its **instances (virtual machines)**. The entries of this list correspond to the output of the command `vagrant box list`.
  - To download a new **base box**, click the Add button **+**. In the dialog box that opens, specify the URL address to access the **base box** and the name to refer to it in IntelliJ IDEA. By default, IntelliJ IDEA suggests the URL to the **lucid32** box. This command corresponds to `vagrant box add <name> <URL>`. As a result, the specified **base box** is downloaded to your machine.
  - To remove a **base box**, select it in the list and click the Remove button **-**. The **base box** and the nested files are physically deleted from the disk. This command corresponds to `vagrant box remove <name>`.

## Initializing the Vagrantfile

A `VagrantFile` is a configuration file that defines the **instance (virtual machine)** you need. The file contains the virtual IP address, port mappings, and the memory size to assign. The file can specify which folders are shared and which third-party software should be installed. According to the `VagrantFile` your **instance (virtual machine)** is configured, provisioned against the relevant **Vagrant base box**, and deployed on your computer. A `VagrantFile` is created through the `vagrant init` command.

You can initialize the `Vagrantfile` in any folder, just keep in mind that this folder should be specified as the **instance folder** on the Vagrant page of the Settings dialog box. Otherwise IntelliJ IDEA will be unable to find the relevant `VagrantFile` during the **instance (virtual machine)** creation.

To initialize the `VagrantFile`, do one of the following:

### To initialize the Vagrantfile

- To have the `Vagrantfile` created in the project root, choose Tools | Vagrant | Init on Project Root on the main menu and select the target project root from the pop-up list that opens. The output of the `init` command is displayed in the Run tool window.
- To have the `Vagrantfile` created in a specific folder, open the embedded Terminal (View | Tool Windows | Terminal) and then type the following commands at the prompt:

```
cd <directory to initialize the VagrantFile in>
vagrant init <base box name> <base box url>
```

Once the `VagrantFile` initialization is successfully completed, you are ready to import the **base box**, provision and deploy it according to the `VagrantFile`, thus creating your own **instance (virtual machine)**.

## Creating and launching an instance (virtual machine)

Creating an **instance (virtual machine)** means importing and provisioning a **base box** according to the `VagrantFile` located in the **instance folder**.

### To create an instance, follow these steps:

- Do one of the following:
  - To have the instance created in the project root, choose Tools | Vagrant | Up.
  - Open the embedded Terminal (View | Tool Windows | Terminal) and then type the following commands at the command prompt:

```
cd <instance folder>
vagrant up
```

- Select the desired virtual machine configuration from the suggestion list:

## Stopping, suspending, resuming, reloading, and destroying an instance (virtual machine)

### To reload an instance

- If you have made some changes to the `VagrantFile` and want a running virtual machine updated in accordance to them, choose Tools | Vagrant | Reload on the main menu or run the following command in the embedded Terminal:

```
vagrant reload
```

For details, see <http://docs.vagrantup.com/v2/cli/reload.html>.

## To suspend an instance

- To temporarily stop the operating system on a running virtual machine ( **guest machine** ) and save the exact state of the environment as it is at this moment so it can be resumed exactly from this point, choose Tools | Vagrant | Suspend on the main menu or run the following command in the embedded Terminal :

```
vagrant suspend
```

For details, see <http://docs.vagrantup.com/v2/cli/suspend.html>.

## To resume an instance

- To resume a previously suspended operating system on a virtual machine ( **guest machine** ) and have it run from the state saved at the suspension moment, choose Tools | Vagrant | Resume on the main menu or run the following command in the embedded Terminal :

```
vagrant resume
```

For details, see <http://docs.vagrantup.com/v2/cli/resume.html>.

## To shut an instance down

- To shut down the operating system on a virtual machine ( **guest machine** ), choose Tools | Vagrant | Halt on the main menu or run the following command in the embedded Terminal :

```
vagrant halt
```

For details, see <http://docs.vagrantup.com/v2/cli/halt.html>.

- To shut down the operating system on a virtual machine ( **guest machine** ), stop the virtual machine itself, and remove the resources provisioned on it during the creation ( `vagrant up` ), choose Tools | Vagrant | Destroy on the main menu or run the following command in the embedded Terminal :

```
vagrant destroy
```

For details, see <http://docs.vagrantup.com/v2/cli/destroy.html>.

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [Creating a Vagrant box](#)
- [Deleting a Vagrant box](#)

## Introduction

It is possible to work with multiple virtual boxes, created in Vagrant. With IntelliJ IDEA, you can [add new boxes](#) without leaving the IDE.

The unnecessary boxes can be easily [deleted](#) .

## Creating a Vagrant box

1. [Open the Settings dialog box](#) .
2. Under the Project Settings , click [Vagrant](#) .
3. Click [+](#) button, located next to the Vagrant Boxes table.
4. In the Add Vagrant Box dialog box, specify the name of the new box, and its URL. Then click OK .  
The new box is added to the list of available boxes.

## Deleting a Vagrant box

1. In the [Vagrant](#) page of the project settings, under the Vagrant Boxes table, select the box to be deleted.
2. Click [-](#) , and confirm deletion.

The selected box is removed from the list.

This feature is only supported in the Ultimate edition.

On this page:

- [Basics](#)
- [Initializing a virtual box](#)
- [Activating a virtual box](#)

## Basics

IntelliJ IDEA makes it possible to execute the `init` procedure on a project root. After performing `init` on a project root, the Vagrant configuration file named `Vagrantfile` is created there. This file can be used for [creating a remote interpreter](#).

### Initializing a virtual box

1. On the main menu, choose Tools | Vagrant | Init in Project Root.
2. In the Select Vagrant Folder pop-up menu, select the project root to be used:

3. Since it is possible to have multiple virtual boxes, specify the particular box you want to work with:

The `vagrant init` command is launched, and shows its output messages in the Run tool window.

If the Vagrant executable is not specified in the [Vagrant](#) page, you can still initialize a Vagrant box. However, in this situation, IntelliJ IDEA pops up a file browser, enabling you to select Vagrant executable.

### Activating a virtual box

Once `init` is successfully completed, you are ready to perform the `vagrant up` command and import to the root the box used at initialization.

To activate a virtual box by executing the `vagrant up` command, choose Tools | Vagrant | Up on the main menu. The `vagrant up` command is launched, and shows its output messages in the Run tool window.

This feature is only supported in the Ultimate edition.

In this section:

- Web Applications
  - [Introduction](#)
  - [Developing Web applications](#)
- [Enabling Web Application Support](#)
- [Populating Web Module](#)
- [Configuring Web Application Deployment](#)

## Introduction

The term Web application is usually applied to a hierarchical set of folders with HTML, JSP, JavaScript, etc. files and resources, that represent the user interface, and Java classes that implement the application functionality. These folders are arranged according to the standard specified for the server where the application is deployed and executed. To ensure successful deployment and accessibility of your Web application, you need to set up its structure in accordance with the target server standard already at the development stage.

Next, most likely you will need to configure Web application elements, set initialization parameters, and define interaction with EJB, WebServices, etc. You will need various libraries to configure these components and relations and an application descriptor that contains definitions of these components, settings, and constraints.

With IntelliJ IDEA, you can have the basic application structure automatically set up according to the required standard and get extensive coding assistance at all the stages of Web application development.

## Developing Web applications

### **To develop a Web application in IntelliJ IDEA, perform the following general steps:**

1. [Enable Web application development support](#) to get the necessary libraries, the basic folder hierarchy, and the application descriptor.
2. [Populate the Web module](#) : create the required Java classes, configure servlets, filters, listeners, and references.
3. [Configure the required static Web content resources](#) .
4. [Configure Web application deployment](#) .
5. Deploy and run the application.

This feature is only supported in the Ultimate edition.

This topic discusses the features that become available when you turn on the Web Application option.

- [Prerequisites](#)
- [Overview of the features](#)
- [Turning on the Web Application option](#)
- [Managing deployment descriptors, web resource directories and Java web source roots](#)
- [Managing application artifacts](#)

## Prerequisites

For the Web Application option and associated features to be available:

- You should be using the ULTIMATE Edition of IntelliJ IDEA. (The corresponding functionality is not available in the Community Edition.)
- The Java EE: EJB, JPA, Servlets [plugin](#) must be enabled. (This plugin is bundled with the IDE and enabled by default.)

## Overview of the features

When you turn on the Web Application option, IntelliJ IDEA:

- Creates a web resource directory `web` with `index.jsp` intended as a starting page of your app and, optionally, a web app [deployment descriptor](#) `WEB-INF/web.xml`.
- Creates a [Web facet](#) that lets you manage your deployment descriptors, web resource directories and your Java web [source roots](#).
- Creates an Exploded [WAR artifact](#) configuration.
- Makes the [Web tool window](#) available.

If you turn on the Web Application option when creating a project or module and specify an application server, IntelliJ IDEA also creates a [run/debug configuration for that server](#).

## Turning on the Web Application option

You can turn on the Web Application option:

- When creating a project or module ( `File | New | Project` or `File | New | Module` ). On the first page of the New Project or the New Module wizard, select Java Enterprise , and then select the Web Application checkbox under Additional Libraries and Frameworks .
- For an existing module. In the Project tool window ( `View | Tool Windows | Project` ), right-click the module folder and select `Add Framework Support` . Then select the Web Application checkbox in the dialog that opens.

## Managing deployment descriptors, web resource directories and Java web source roots

You can manage your web app [deployment descriptors](#) , web resource directories and Java web [source roots](#) in the Project Structure dialog:

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. In the leftmost pane, select Modules or Facets .
3. In the pane to the right, select Web or Web (<ModuleName> ) .
4. On the page that opens in the right-hand part of the dialog:
  - Deployment Descriptors. Form the list of deployment descriptors for your web app.

Web Resource Directories. Specify the directories that contain your web app resources such as web pages, images, etc.

Source Roots. Select the source roots that contain your web application Java classes (servlets, filters, managed beans, etc.).

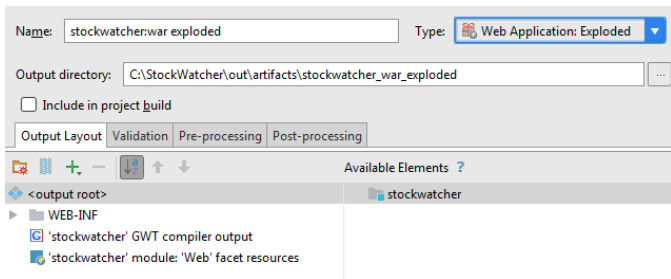

For more info, see [Web facet page](#) .

## Managing application artifacts

To deploy your application to a server, you need an application [artifact](#) . For Java web applications, IntelliJ IDEA provides the following artifact formats:

- Web Application: Exploded. This is a decompressed Web application archive ([WAR](#) ), a directory structure that is ready for deployment onto a web server.
- Web Application: Archive. This is, obviously, a WAR file.

To manage your artifact configurations, use the Project Structure dialog ( `File | Project Structure | Artifacts` ).

See also, [Working with Artifacts](#) .

This feature is only supported in the Ultimate edition.

After you [enable Web development support](#) in a module, IntelliJ IDEA sets up the basic module structure as follows:

- Creates a `web` folder with the `index.jsp` stub file. By default, the `web` folder will be the root of your application after deployment and the `index.jsp` file will be its home page.
- Creates a `WEB-INF` subfolder that contains the `web.xml` descriptor with an `Action` servlet configured.
- Creates an `src` folder if you specified so when creating your project.

**To populate the Web module, perform the following general steps:**

- Below the `src` folder, create the Java class files that implement the functionality of your application.
- [Configure the static Web content resources](#) that represent the user interface.
- [Configure the application elements](#) .
- [Specify the assembly descriptor references](#) .

This feature is only supported in the Ultimate edition.

Configuring static Web resources involves:

1. [Specifying location of the static Web contents on the server](#) .

After deployment, all the static content resources that implement the user interface should be located below the [Web application root directory](#) . By default, IntelliJ IDEA maps the target Web application root directory to the `web` folder which is created after you [enable Web development support](#) . The default application home page is mapped to the `index.jsp` stub file which is also created automatically.

You can arrange your static content resources in a module in two ways:

- Store the required resources and directories below the `<project root>\web` folder. After deployment, the entire folder hierarchy of these resources will be copied to the server below the application root.
- Store the required resources locally wherever you may find suitable and [map them to folders](#) on the server.

2. [Including static Web contents in the artifact to be deployed](#) .

## To configure static Web content resources

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Click Modules on the left-hand pane and expand the desired module.
3. Click the Web facet. The right-hand pane of the dialog box displays all the available settings.
4. In the Web Resource Directories area, manage the list of mappings between the local folders with resources you need and the target directories on the server to deploy the resources to. The default mapping between the `<project root>\web` folder and the application root directory is already on the list:

- To configure a mapping, click the New button. In the [Web Resource Directory Path](#) dialog box that opens specify the desired local folder and the target location relative to the application root folder. By default, IntelliJ IDEA maps the `<project root>\web` folder to the root folder of the application after deployment. For example, if you type a forward slash `/` , the files from the Web resource directory will be copied into the deployment root directory.

- To edit a mapping, select it in the list, click the Edit button, and update the mapping in the [Web Resource Directory Path](#) dialog box that opens.
- To discard a mapping, select in the list and click the Remove button.

This feature is only supported in the Ultimate edition.

The elements and deployment settings of a Web application are defined in the Web module deployment descriptor `web.xml`, which is created automatically when you [enable Web application support](#) for a module.

For the sake of consistency with the User Interface, the module deployment descriptors are also referred to as Assembly Descriptors .

You can use the editor and edit the source code using the IntelliJ IDEA coding assistance.

Web modules are populated with elements similarly, according to the [common basic procedure](#) . For element-specific details, refer to the relevant topics in this part:

- [Creating and Deleting Web Application Elements - General Steps](#)
- [Servlets](#)
- [Listeners](#)

This feature is only supported in the Ultimate edition.

This topic describes general procedures for elements in a Web module.

### **To add an element to a Web module**

1. Open the [Web](#) tool window by choosing View | Tool Windows | Web . The tool window displays all the modules with Web facets.
2. Right-click the desired Web module node and choose New | Servlet/Filter/Listener on the context menu.
3. In the New Servlet/Filter/Listener dialog box that opens, type the name of the element.
4. Specify the package where the element will be created.
5. Specify the class that implements the element.
6. Click OK . A new class is created and opened in the editor.
7. Proceed as described in the relevant element-specific topic.

### **To remove an element from a Web application**

1. In the [Web](#) tool window, select the element to be removed.
2. On the context menu, choose Delete and click Yes in the confirmation dialog box.

This feature is only supported in the Ultimate edition.

[Servlets](#) as a part of a Web application are created and configured through the `<servlet>` and `<servlet-name>` elements in the `web.xml` Web Application deployment descriptor.

In this part:

- [Defining the Servlet Element](#)
- [Specifying the Servlet Initialization Parameters](#)
- [Specifying the Servlet Name and the Target Package](#)

This feature is only supported in the Ultimate edition.

On this page:

- [Introduction](#)
- [General steps](#)
- [Defining a servlet](#)
- [Removing a servlet](#)

## Introduction

The Servlet element defines the name of the servlet and specifies the compiled class that implements it. Alternatively, instead of specifying a servlet class, you can specify a JSP.

The Servlet element also contains definitions of [initialization attributes](#) .

IntelliJ IDEA provides the facilities to [configure](#) , [remove](#) , and edit Servlet elements using the IntelliJ IDEA editor.

Note that you can map URL pattern that associates the servlet with the set of URLs that call the servlet using annotations in the editor.

## General steps

Defining the Servlet element includes:

- [Specifying](#) the servlet name and the name of the package where the servlet will be created.
- [Customizing](#) the initialization process by specifying the initialization attributes of the servlet.

## Defining a servlet

### To define a servlet

1. Configure a [new servlet](#) .
2. Click OK in the [New Servlet](#) dialog box. The new servlet is added to the list in the Servlets Configured pane.
3. Specify the servlet [initialization parameters](#) .

## Removing a servlet

### To remove a servlet

- Select the servlet in the Servlets Configured pane and click  or select Remove in the context menu.

This feature is only supported in the Ultimate edition.

You can customize the servlet initialization by specifying initialization parameters of the servlet. This allows the servlet to perform various one-time activities by overriding the `init` method of the Servlet interface. An initialization attribute is defined through the Name and Value parameters. In the Web application deployment descriptor `web.xml`, these parameters are presented as `<param-name>` and `<param-value>` elements.

This feature is only supported in the Ultimate edition.

## To define the servlet name and the target package where the servlet will be created

1. Open the [New Servlet](#) dialog box from the [Project Tool Window](#) .
2. In the <servlet-name> text box, specify the root part of the new servlet name.
3. In the Package text box, specify the name of the target package where the new servlet will be generated. If necessary, use the  button. The [Choose Servlet Package](#) dialog box opens.
4. Select the relevant package or create a new one by clicking  . Click OK. You return to the New Servlet dialog box.
5. In the Servlet Class text box, type the name of the class that implements the new servlet. If necessary, use the  button. The Choose Servlet Class dialog box opens.
6. Select the relevant class and click OK . You return to the New Servlet dialog box.
7. Click OK .

This feature is only supported in the Ultimate edition.

A listener receives notifications on any events related to the Web application, such as deployment/undeployment of the Web application, activation/deactivation of an HTTP session, as well as on adding, removing, and replacing attributes of the application/session.

Listeners, as a part of a Web application, are configured in the Web module deployment descriptor `web.xml`.

## To define a listener element

1. [Configure a new listener](#).
2. Switch to the Text view and specify the necessary settings in the Web application deployment descriptor.

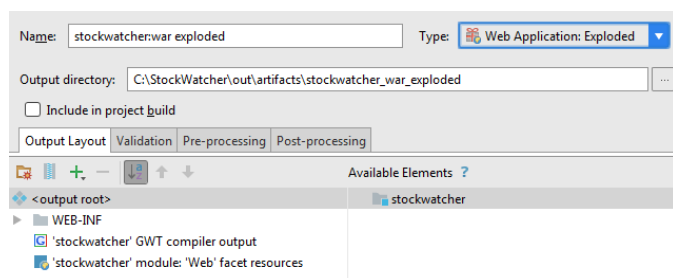

This feature is only supported in the Ultimate edition.

Assembly descriptor references define interaction of Web applications with EJB, WebServices, etc. The assembly descriptor references are specified in the deployment descriptor file `web.xml`.

This feature is only supported in the Ultimate edition.

A Web application can be deployed to the server as an exploded directory where files and folders are presented in the file system as separate items or as a Web archive ( `WAR` file) which contains all the required files. Therefore you need to configure the layout of your project output so it can be deployed to the server in one of these forms. In IntelliJ IDEA, the layout of a project output is defined through [artifacts](#) .

When you [enable Web development](#) in a module, IntelliJ IDEA configures an [artifact](#) of the type exploded with the following basic structure:

You can [use this pre-defined artifact](#) , possibly with necessary customization, or [configure a new artifact](#) .

Configuring an artifact to deploy involves:

1. Specifying the [artifact type, name, and output directory](#) .
2. [Adding static Web content resources](#) .

The suggested deployment configuration procedure reflects the basic workflow which can be flexibly customized depending on your preferences and the requirements to a specific Web application.

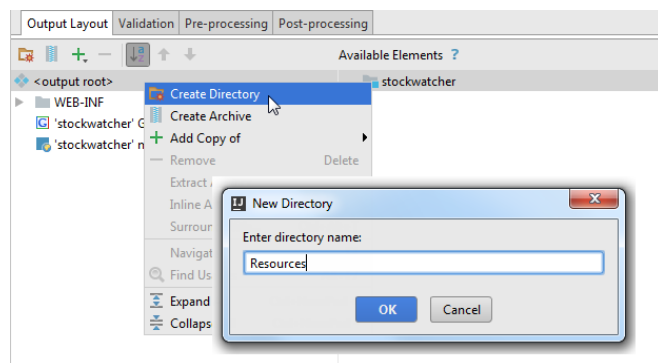

## To configure the basic artifact settings

1. Open the Project Structure dialog (e.g. `Ctrl+Shift+Alt+S` ).
2. Click Artifacts to open the [Artifacts page](#) .
3. Do one of the following:
  - To use a pre-defined exploded directory artifact, select the `<module name>:war:exploded` artifact from the list on the left-hand pane. If necessary, change the name and output directory of the artifact in the corresponding fields on the right-hand pane.
  - To create a new artifact, click the New toolbar button `+` on the left-hand pane and choose the artifact type from the New drop-down list.
  - To have the application deployed as a directory, choose `Web Application: Exploded` .
  - To have the application deployed in the packed form, choose `Web Application: Archive` .

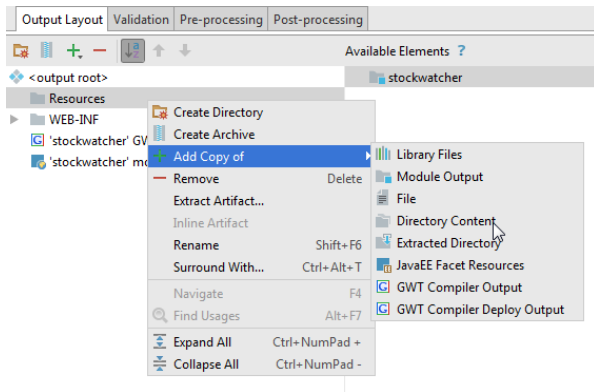

On the right-hand pane, specify the [general settings of the artifact](#) , such as name and output directory, in the corresponding fields.

## To add static Web content resources

1. Open the desired artifact and switch to the right-hand pane, the Output Layout tab.
2. With the select the output root node selected, choose the Create Directory item on the context menu or click the Create Directory toolbar button `+` . In the dialog that opens specify the name of the new folder, for example Resources :

3. With the new folder selected, choose the Add Copy of item on the context menu or click the Add Copy of toolbar button `+` .
4. On the context menu, choose the Directory Content item on the context menu. In the [dialog that opens](#) , choose the directory where the required Web content resources are stored.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA integrates with the [webpack](#) module bundler. This support improves coding assistance in JavaScript files by taking into account [webpack module resolution](#) and [resolve aliases](#) . For webpack version 2 and higher, IntelliJ IDEA provides code completion and quick documentation look-up for options in webpack configuration files.

## Before you start

1. Download, install, and configure [Node.js](#) .
2. Make sure the [NodeJS](#) plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

## Configuring webpack in IntelliJ IDEA

1. Make sure webpack is added to package.json

Webpack should be listed in the `dependencies` or `devDependencies` object of `package.json` .

If webpack is missing, install it

Open the built-in IntelliJ IDEA Terminal ( `Alt+F12` ) and type `npm install --save-dev webpack` at the command prompt.

For details, see [Getting Started on the webpack Official website](#) .

2. Create a webpack configuration file

Create a configuration file in the project root or elsewhere ( `New | JavaScript file` ). Learn more on the [webpack Official website](#) .

3. Specify the webpack configuration file to use

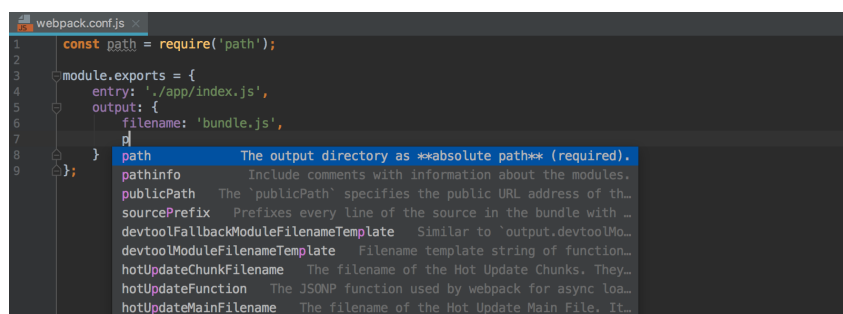

By default, IntelliJ IDEA analyses the webpack configuration file in the root of the project. To use another webpack configuration file, specify the path to it on the Webpack page ( `File | Settings | Languages and Frameworks | JavaScript | Webpack for Windows and Linux or IntelliJ IDEA | Preferences | Languages and Frameworks | JavaScript | Webpack for macOS` ).

**Tip** Based on the analysis of a webpack configuration file, IntelliJ IDEA understands the webpack configuration and provides coding assistance in JavaScript files, see [Resolving modules](#) below.

## Editing a webpack configuration file

For webpack version 2 and higher, IntelliJ IDEA provides code completion and documentation look-up in the configuration object of `webpack.config.js` . Code completion is provided on the fly. To view documentation for a symbol, press

`Ctrl+Q` .

```
webpack.config.js
1  const path = require('path');
2
3  module.exports = {
4    entry: './app/index.js',
5    output: {
6      filename: 'bundle.js',
7      path: ''
8    }
9  };
10
```

**Tip** IntelliJ IDEA provides coding assistance in a webpack configuration file only if its name contains the `webpack` character string and webpack is listed in `package.json` .

## Resolving modules

When you open a project or edit your `webpack.config.js` , IntelliJ IDEA analyses the configuration in the background and, based on the received information, properly understands the project [resolve roots](#) and [resolve aliases](#) . Thanks to this understanding of the project configuration, IntelliJ IDEA provides more precise code completion for imports and exported symbols in JavaScript files. As a result, everything works fine without any steps from your side.

The image below illustrates module resolution in a project where `react-color` is an alias for the path `./src/index.js` . IntelliJ IDEA properly resolves the import from `react-color` , provides navigation to it and completion for the exported symbols:

```
webpack.config.js
35 resolve: {
36   alias: {
37     'react-color': path.resolve(__dirname, './src/index.js'),
38     'react': path.resolve(__dirname, './node_modules/react'),
39     'remarkable': path.resolve(__dirname, './modules/remarkable'),
40     'highlight.js': path.resolve(__dirname, './modules/highlight.js'),
41     'tinycolor2': path.resolve(__dirname, './modules/tinycolor2'),
42   },
  },
  module.exports > module > loaders

Button.js
1 'use strict'
2 //Users/ekaterinaprigara/WebstormProjects/react-color/src/index.js
3 import React from 'react'
4 import { ChromePicker } from 'react-color'
5
6 class ButtonExample extends React.Component {
7   state = {
```

## Debugging applications that use webpack

You can debug applications that use webpack same way as you debug any JavaScript client-side application, see [Debugging React apps created with Create React App](#) and [Debugging Angular apps created with Angular CLI](#).

This feature is only supported in the Ultimate edition.

In this section:

- Web Service Clients
  - [Introduction](#)
  - [Developing Web services client applications](#)
- [Enabling Web Service Client Development Support](#)
- [Monitoring SOAP Messages](#)
- [Generating Call to Web Service](#)
- [Generating Client-Side XML-Java Binding](#)

## Introduction

With IntelliJ IDEA, you can develop the client side for Web services of the following most common types:

- GlassFish/JAXWS2.X RI/Netro 1.X/JWSDP2.0 for developing JAX-WS Web services clients.
- Apache Axis for developing Apache Axis Web services clients.
- JAX-RS for developing RESTful Web Services clients.

You can also enable and manually configure support of the following [additional WS engines](#) :

- [Apache Axis2](#)
- <https://jax-rpc.dev.java.net/>
- [XFire 1.X /CXF](#)
- [JBossWS](#)
- [WebSphere 6.X](#)

## Developing Web services client applications

### **To develop a Web services client application, follow these general steps:**

1. [Create a Java module](#) and [enable support](#) of the desired Web services client in it.
2. [Generate the client-side XML-Java binding](#) .
3. Modify the generated code to have the client properly initialized.
4. To enable data exchange with the Web service, do one of the following:
  - Declare the variables that will contain the request to the service and the service response.
  - Have IntelliJ IDEA [generate the Web service invocation](#) .
5. Populate the module with the necessary classes and methods to implement the user's interface.
6. Run the application.

This feature is only supported in the Ultimate edition.

To develop a Web service client in IntelliJ IDEA, the corresponding module must be relevantly configured and supplied with all the required libraries. This section describes the most common ways to meet these requirements.

**To enable Web service client development support, do one of the following:**

- [Use the dedicated facet](#). This fast and efficient approach is available for most frequently used WS engines. IntelliJ IDEA will download the predefined WS engine implementation version.
- Enable support of an [extra WS engine](#) for which the dedicated facet functionality is not provided. This approach is also applicable when you need to use a specific WS engine implementation version.
- [Add the relevant libraries](#) to an existing module manually.

This feature is only supported in the Ultimate edition.

This approach is applicable if you are going to develop the client side for a Web service of one of the following types:

- GlassFish/JAXWS2.X RI/Netro 1.X/JWSDP2.0 .
- Apache Axis .
- RESTful Web Service .

IntelliJ IDEA creates the relevant Web services client module structure and identifies all the necessary libraries automatically through the dedicated Web Services Client [facet](#) . Besides, IntelliJ IDEA either locates the previously downloaded required libraries or suggests to download them to the location of your choice.

A Web Services Client facet can be added to the module directly without a parent Web facet.

## To enable Web Service Client development support through a dedicated facet, do one of the following

- [Create a Java module](#) with the dedicated Web Services Client facet. Besides setting up the relevant module structure and providing all the necessary libraries automatically, IntelliJ IDEA will create a sample package with a `HelloWorldClient` class, which you can use as an example or populate it as necessary to develop your application.
- [Add the dedicated facet](#) to an existing module.

In either case, IntelliJ IDEA will download the predefined WS engine implementation version.

## To create a module for a Web service client application

1. Do one of the following:

- If you are going to create a new project: click Create New Project on the [Welcome screen](#) or select File | New | Project .  
As a result, the [New Project wizard](#) opens.
- If you are going to add a module to an existing project: open the project you want to add a module to, and select File | New | Module .  
As a result, the [New Module wizard](#) opens.

2. On the first page of the wizard, in the left-hand pane, select Java . In the right-hand part of the page, specify the [JDK](#) that you are going to use.

3. Under Additional Libraries and Frameworks , select the WebServices Client checkbox.

4. Select the desired WS engine implementation from the Version list.

5. You'll need a [library](#) that implements the selected WS engine. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the WS engine implementation. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

Click Next .

6. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#) .

Click Finish .

## To add the dedicated facets to an existing module

1. Open the Project tool window (e.g. View | Tool Windows | Project ).
2. Right-click the module of interest and select Add Framework Support .
3. In the left-hand pane of the [Add Frameworks Support dialog](#) that opens, select the WebServices Client checkbox.

4. If you want sample client code to be generated, select the corresponding checkbox.
5. Select the desired WS engine implementation from the Version list.
6. You'll need a [library](#) that implements the selected WS engine. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).

Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
  - Download. Select this option to download the WS engine implementation. (The downloaded files will be arranged in a [library](#) .)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
  - Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.
7. Click OK in the Add Frameworks Support dialog.

This feature is only supported in the Ultimate edition.

This approach is applicable if the necessary libraries have been previously downloaded.

### To add the necessary libraries to an existing module

1. Open the Module Settings dialog box.
2. With the desired module selected, click the Dependencies tab.
3. Click the Add button again, then select Single-Entry Module Library from the context menu. In the [dialog that opens](#) , select the `javaee.jar` library and the required Web service-specific libraries.
  1. The location of the `javaee.jar` library is defined during the installation of IntelliJ IDEA.
  2. The location of the Web-service specific libraries is defined during their download.
4. Click OK when ready.

This feature is only supported in the Ultimate edition.

Besides most common WS engines, support of which is enabled through dedicated facets, with IntelliJ IDEA you can also use the following ones:

- [Apache Axis2](#)
- [XFire 1.X /CXF](#)
- [JBossWS](#)
- [WebSphere 6.X](#)

Moreover, you can use any desired WS engine implementation version instead of restricting yourself to the predefined one.

### **To enable support of an extra WS engine or a specific implementation version**

1. Download the desired WS engine implementation.
2. In the Settings/Preferences dialog ([Ctrl+Alt+S](#)), click Tools | Web Services in the left pane and specify the path to external web service engines, server name and port, etc. (for details, see [Web Services](#)).

This feature is only supported in the Ultimate edition.

While testing the client side of an Apache Axis Web service, it may be helpful to view related SOAP messages which provide procedure details.

**Warning!** Make sure the target Web service application is running.

### To enable monitoring SOAP messages

1. On the main menu, choose Tools | Web Services | Axis | Monitor SOAP Messages .
2. In the [Monitor SOAP Messages](#) dialog box that opens specify the Web context of the target application and the port to listen to.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides coding assistance in developing client calls to Web services, both [strictly typed and loosely typed](#) . Coding assistance for [calls to strongly typed](#) Web services is Web service interface- and data type- specific and is based on the [XML-Java binding generated](#) from the WSDL descriptor.

IntelliJ IDEA will also help you generate [calls to loosely typed](#) Apache Axis or XFire Web services. In this case, the basic Web service client coding assistance is provided through the dedicated [facet](#) .

## To have a call to a strongly typed Web service generated

1. Open the client code in the editor and position the cursor where the call should be generated.
2. Choose Tools | WebServices | WebServices Client Code on the main menu or WebServices | WebServices Client Code on the context menu.
3. From the context menu that opens select the relevant option depending on the type of the target Web service. The available options are:
  - Generate WS Call for Axis
  - Generate WS Call for Axis2
  - Generate WS Call for JAX-WS RI/GlassFish/JWSDP
  - Generate WS Call for XFire
  - Generate WS Call for JAXRPC
  - Generate WS Call for WebSphere
4. Complete the generated invocation code stub by providing the relevant data in the template input fields, using [suggestion lists](#) and intention actions, where applicable. The active input field is highlighted with a red frame. The contents of the suggestion lists are determined by the Java classes generated from the WSDL descriptor.

## To have a call to a loosely typed Web service generated

1. Open the client code in the editor and position the cursor where the call should be generated.
2. Choose Tools | WebServices | WebServices Client Code on the main menu or WebServices | WebServices Client Code on the context menu.
3. From the context menu that opens select the relevant option depending on the type of the target Web service. The available options are:
  - Generate WS Untyped Call for Axis
  - Generate WS Untyped Call for XFire
4. Complete the generated invocation code stub by providing the relevant data in the template input fields, using [suggestion lists](#) and intention actions, where applicable. The active input field is highlighted with a red frame. The contents of the suggestion lists are determined by the libraries provided through the dedicated [facet](#) .

This feature is only supported in the Ultimate edition.

To develop well-formed and valid requests from your client to the target Web service, you need to know the available methods of the Web service, the data types it uses, the interface to the service, the acceptable format of requests, the format of generated responses, etc. All this data is presented in the [WSDL descriptor](#) of the target Web service.

IntelliJ IDEA can generate the necessary client-side XML-Java bindings based on the desired WSDL descriptor, thus providing you with efficient coding assistance in developing client requests. You only need to specify the URL address of the WSDL descriptor, IntelliJ IDEA will retrieve the necessary data and generate Java classes.

Java code generation is configured in the [Generate Java Code from Wsdl or Wadl](#) dialog box, that primarily opens upon enabling the Web service client development support.

## To configure generation of the client-side XML-Java binding

1. Open the [Generate Java Code from Wsdl or Wadl](#) dialog box by doing one of the following:
  - Create a module and [enable support](#) of the Web Services client in it.
  - At any time during the development, select the desired client module in the Project view and choose WebServices | Generate Java Code from Wsdl or Wadl on the context menu.
2. In the Web Service WSDL URL field, specify the URL address of the desired Web service WSDL descriptor.

**Tip** If the Status read only field informs you about a WSDL URL connection exception, make sure the target Web service is running and the URL address of its WSDL descriptor is correct.

3. From the Output Path drop-down list, select the directory to place the generated files in.
4. In the Package Prefix drop-down list, specify the package to place the compiled Java classes in.
5. For the client side of an Apache Axis Web service, specify additional configuration options for the code generation process using the following fields:
  - Type Mapping Version
  - Generate TestCase
  - Generate Classes for Schema Arrays
  - Generate Unreferenced Elements
  - Support Wrapped Document/Literal Style

This feature is only supported in the Ultimate edition.

In this section:

- Web Services
  - [Introduction](#)
  - [Developing Web services](#)
- [Preparing to Develop a Web Service](#)
- [Exposing Code as Web Service](#)
- [Managing Deployed Web Services](#)
- [Generating WSDL Document from Java Code](#)

## Introduction

IntelliJ IDEA supports efficient development, packaging, and deployment of [Web services](#).

The supported standards are:

- [Java API for XML Web Services \(JAX-WS\)](#)
- [Apache Axis](#)
- [JAX-RS](#)

You can also enable and manually configure support of the following [additional WS engines](#) :

- [Apache Axis2](#)
- [XFire 1.X /CXF](#) (version 2.7 is supported)
- [JBossWS](#)
- [WebSphere 6.X](#)

IntelliJ IDEA provides the following development and packaging facilities:

- Setting up the relevant module structure and downloading all the necessary resources based on the dedicated Web services [facet](#) you specify.
- Generating the necessary deployment descriptors, mapping and manifest files "on-the-fly".
- Packaging the Web service files, with the EAR file structure following the rules defined by the Enterprise Web Services 1.1 specification.

**Tip** The Web service development functionality is provided via the Web Services bundled plugin, which is by default enabled. If not, enable it using the [Plugins settings](#) page of the Settings/Preferences dialog box.

## Developing Web services

### To develop a Web service, follow these general steps:

1. In a [Java module](#), [enable support](#) of the relevant Web service.
2. Populate the module with the necessary classes and methods.
3. [Compile](#) the developed classes and [expose](#) them as a Web service.

**Tip** To enable developing the client side of the Web service before the Web service itself is deployed, generate a [WSDL document](#).

4. Configure the [artifacts](#) to deploy.

**Warning!** Do not forget to include the Web and Web Services facet resources in the artifact.

5. [Create a run configuration](#). On the Deployment tab, create a list of artifacts to be deployed. Specify the application contexts for each of them.
6. Run the application.
7. [View and manage deployed Web services](#) in the [Deployment Console](#) of the [Run](#) tool window.

This feature is only supported in the Ultimate edition.

On this page:

- [Before you start](#)
- [Basics](#)
- [Enabling Web Services Development Support through a Dedicated Facet](#)
- [Adding the Necessary Libraries to an Existing Modules](#)
- [Enabling an Extra WS Engine](#)

## Before you start

Make sure the **Web** and **JavaEE: WebServices (JAX-WS)** bundled plugins are enabled. The plugins are activated by default. If the plugins are disabled, enable them on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

## Basics

To develop a Web service in IntelliJ IDEA, the corresponding module must be relevantly configured and supplied with all the required libraries and servlet references. This section describes the most common ways to meet these requirements.

## Enabling Web Services Development Support through a Dedicated Facet

This approach is applicable if you are going to develop a Web service of the type **GlassFish/JAXWS2.X RI/Netro**

**1.X/JWSDP2.0** or **Apache Axis**.

Integration with **Struts** is enabled through the **Web** and **Web Services** facets. These **dedicated facets** contain settings, configuration file paths, and validation rules. This information determines the structure of a module so IntelliJ IDEA detects how to treat the module contents.

A **Web Services** facet can be only added as a child of a **Web facet**. Note that only one **Web Services** facet is allowed in a module.

You can create a new module with the dedicated facets or add the facets to an existing module. In either case, IntelliJ IDEA downloads the predefined WS engine implementation version.

To create a module with a **Web Services** facet:

1. Do one of the following:
  - If you are going to create a new project: click **Create New Project** on the [Welcome screen](#) or select **File | New | Project**. As a result, the [New Project wizard](#) opens.
  - If you are going to add a module to an existing project: open the project you want to add a module to, and select **File | New | Module**. As a result, the [New Module wizard](#) opens.
2. On the first page of the wizard, in the left-hand pane, select **Java**. In the right-hand part of the page, specify the **JDK** that you are going to use.
3. Under **Additional Libraries and Frameworks**, select the **Web Application** checkbox. Select the version of the **Servlet** specification to be supported from the **Versions** list.

If you want the deployment descriptor `web.xml` file to be created, select the **Create web.xml** checkbox.

4. Select the **WebServices** checkbox.
5. Select the desired WS engine implementation from the **Version** list.
6. You'll need a **library** that implements the selected WS engine. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.
  - **Use library.** Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a **library** and use that new library. To do that, click **Create** and select the necessary files in the [dialog that opens](#). (Use the `Ctrl` key for multiple selections.)

Optionally, click **Configure** to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#).)

- **Download.** Select this option to download the WS engine implementation. (The downloaded files will be arranged in a [library](#).)  
Optionally, click **Configure** to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- **Set up library later.** Select this option to postpone setting up the library until a later time.

**Configure.** Click this button to edit the settings for the library selected next to **Use library** or the one that is about to be downloaded.

Click **Next**.

7. Specify the name and location settings. For more information, see [Project Name and Location](#) or [Module Name and Location](#).

Click **Finish**.

To add a **Web Services** facet to an existing module:

## Adding the Necessary Libraries to an Existing Modules

This approach is applicable if the necessary libraries have been previously downloaded.

1. Open the module settings.
2. With the desired module selected, click the Dependencies tab.
3. To enable Web development, click the Add button and select Single-Entry Module Library from the context menu. In the [dialog that opens](#) , select the `javaee.jar` library and click OK .
4. Click the Add button again, then select Single-Entry Module Library from the context menu. In the [dialog that opens](#) , select the `javaee.jar` library and the required Web service-specific libraries.
  - The location of the `javaee.jar` library is defined during the installation of IntelliJ IDEA.
  - The location of the Web-service specific libraries is defined during their download.
5. Click OK when ready.

## Enabling an Extra WS Engine

Besides most common WS engines, support of which is enabled through dedicated facets, with IntelliJ IDEA you can also use the following ones:

- [Apache Axis2](#)
- [XFire 1.X /CXF](#)
- [JBossWS](#)
- [WebSphere 6.X](#)

Moreover, you can use any desired WS engine implementation version instead of restricting yourself to the predefined one.

To use a custom WS engine:

1. Download the desired WS engine implementation.
2. In the Settings/Preferences dialog ( `Ctrl+Alt+S` ), click Tools | Web Services in the left pane and specify the path to external web service engines, server name and port, etc. (for details, see [Web Services](#) ).

This feature is only supported in the Ultimate edition.

Suppose, you have a piece of code that implements a certain functionality and you want this functionality to be available on the Web through a specific protocol. In this case you need to [transform existing code into a Web service](#) and deploy. The action updates the Web service descriptors and generates additional deployment code if needed. This action is required every time any Web service method signature is changed or a new method is added or removed.

## To expose a class

1. Position the cursor at the class name in the editor and press `Alt+Enter` or click the yellow bulb icon .
2. From the suggestion list, choose Expose Class as Web Service .
3. In the [Expose Class As Web Service](#) dialog box that opens, specify the following:
  - The name and URL address of the Web service.
  - The protocol and encoding style used when accessing the public operations of the Web service.
  - The type information, including name, operations, parameters and data comprising the interface of the Web service.

IntelliJ IDEA automatically adds the service description to the `server-config.wsdd` file.

This feature is only supported in the Ultimate edition.

IntelliJ IDEA provides the possibility to [view which Web services are currently deployed](#) as well as to [re-deploy and undeploy Web services](#) without re-starting the application server.

These operations are enabled only when the corresponding server is running.

### To get a list of currently deployed Web services, do one of the following

- On the main menu, choose Tools | Web Services | Show Deployed Web Services . The Web services deployed under various application contexts are listed in the browser.
- Open the [Deployment Console](#) of the [Run](#) tool window. The console shows which of the deployment artifacts are successfully deployed and which are not. Find the artifacts that constitute the Web services in question.

### To manage the list of deployed Web services, perform these general steps

- Open the [Deployment Console](#) of the [Run](#) tool window. The console shows which of the [marked for deployment artifacts](#) are successfully deployed and which are not. Find the artifacts that constitute the Web services in question.
- To set the deployment statuses up-to-date, click the Refresh Deployment Status button .
- To undeploy a Web service, select the relevant artifacts in the list and click the Undeploy button .
- To have IntelliJ IDEA deploy all the artifacts marked for deployment, click the Deploy All button .

This feature is only supported in the Ultimate edition.

The available functionality of a Web service, the ports to access them, the acceptable format of requests, the format of generated responses, etc. are reflected in the Web service [WSDL descriptor](#) , which is normally generated on the server during the Web service deployment. A major part of Web service client development is implementing generation of requests to the service and parsing responses from it in compliance with the WSDL descriptor settings.

Suppose you have developed a Web service and want its client side development start before the Web service itself is deployed, that is, before the WSDL descriptor is generated on the server. With IntelliJ IDEA, you can have it generated before deployment.

### **To create a WSDL descriptor from Java code**

1. Select the desired class name in the editor.
2. Choose Tools | Web Services | Generate WSDL From Java Code on the main menu or choose Web Services | Generate WSDL From Java Code from the context menu.
3. In the [Generate WSDL From Java](#) dialog box that opens specify the following:
  - The name and URL address of the Web service.
  - The protocol and encoding style used when accessing the public operations of the Web service.
  - The type information, including name, operations, parameters and data comprising the interface of the Web service.

Click OK , when ready.

This feature is only supported in the Ultimate edition.

In this section:

- XPath and XSLT Support
  - [Overview](#)
  - [Changes to the UI](#)
- [XPath Expression Evaluation](#)
- [XPath Search](#)
- [XPath Expression Generation](#)
- [Plugin Settings](#)
- [XSLT Support](#)

**Tip** IntelliJ IDEA implements the XSLT functionality with a bundled plugin, which can be completely disabled by clearing the XPath View+XSLT Support check box on the the Plugins page of IntelliJ IDEASettings ( [Ctrl+Alt+S](#) ).

- XSLT support is available in all XML files that declare the XSLT-Namespace `http://www.w3.org/1999/XSL/Transform` on their root element.
- IntelliJ IDEA supports XSLT versions 1.0 and 2.0, XPath versions 1.0 and 2.0.
- An XSLT 2.0-capable processor (e.g. Saxon 9-HE) should be added to the classpath of a module that is used to run a stylesheet, and placed in front of JDK. See [Configuring projects](#) .

## Overview

The plugin lets you do the following:

- Evaluate expressions against the currently focused document, including support for the `document()` function to make cross-document queries
- Evaluate an expression against multiple XML documents in a *Find in Path* style way by the new [Find by XPath](#) action.

The Expression Evaluation dialog allows you to highlight matching expressions in the current editor or to open the [Find](#) tool window to display a list of matching lines. Editing XPath expressions is enhanced by on-the-fly error-checking including a set of customizable [XPath Inspections](#) and a wide range of code completion suggestions.

The plugin also offers a way to display a unique XPath expression for a selected element in an editor. This is available via [View | Unique XPath](#) in the Main Menu .

XSLT support is not limited to XPath expressions, it also supports a wide range of XSLT constructs, like checking the existence of templates that are called via `xsl:call-template` and their parameters, refactoring and navigation enhancements. Find out more about this in the [XSLT Support](#) section.

## Changes to the UI

- [XPath viewer](#) settings
- [XSLT](#) settings
- [XSLT run/debug configuration](#)

This feature is only supported in the Ultimate edition.

On this page:

- [Overview](#)
- [Simple mode](#)
- [Advanced mode](#)
- [Options](#)

## Overview

Evaluating XPath expressions in IntelliJ IDEA has two main purposes: testing XPath expressions that are to be used in program code or XSLT scripts, and making structured queries against XML documents. The **Evaluate XPath** action can be invoked either from the editor context menu or from the main menu ( `Edit | Find | Evaluate XPath` ). In either case, the Evaluate XPath Expression dialog box opens.

The **Expression Evaluation** has two different modes:

- The **Simple** mode that allows you to enter simple one-line expressions and doesn't allow you to configure Context settings.
- The **Advanced** mode is intended for more convenient editing of long expressions in a multi-line style way. The **Advanced** mode is configured in the dialog box also has a button to edit some context settings, such as namespaces and their prefixes, and variables to use for the evaluation.

To toggle the mode, click the Advanced / Simple button.

In either mode, the dialog box features a history of the recently evaluated expressions, completion, syntax-checking and highlighting, as well as some semantic error checking of the entered expression. Semantic checks include validation of used namespace prefixes, useless XPath expressions (e.g. `@comment()` ) and node tests for element/attribute names that don't occur in the context document and would not be successfully matched.

Some error checks and XPath inspections also provide Quick Fixes for detected problems, e.g. the possibility to map an unresolved namespace-prefix to a URI by intention.

## Simple mode

The simple mode comes with an input field that can be used to enter simple one-line expressions that don't require any customization of namespace prefixes or make use of predefined variables. The last recently used expressions can be selected from the drop-down list.

## Advanced Mode

The advanced mode adds the possibility to edit expressions in a multiline editor and has another button to edit the [XPath Context](#) . The expression history can be browsed by the Up- and Down arrays on the right of the dialog or the keyboard shortcuts for the previous/next history element (usually `Ctrl-Alt-Up` , `Ctrl-Alt-Down` ).

## XPath Context

This dialog allows you to assign custom prefixes to the namespace URIs that are used in the context document. This can be useful to assign a shorter prefix, resolve prefix clashes or to actually define a prefix for the default namespace. This can be essential because XPath does not automatically match elements in the default namespace without specifying a prefix for the element to be matched.

The XPath Context also includes the possibility to define custom XPath variables that can be used in queries for repeating expressions. Each variable in the table can be assigned an expression that will be evaluated once when the query is executed. The resulting value is then available for multiple use at no additional computational cost.

## Options

- **Highlight results:** This option highlights the matched nodes in the current editor. Matched nodes that don't belong to the current editor (may happen by using the `document()` function) are not highlighted. It's recommended to display such cross-document results in the Find Usages toolwindow.
- **Show results in Usage View:** this option shows all matched nodes in the Find Usages toolwindow. Check `Open in new tab` to open the result in a new tab instead of reusing the last one.

This feature is only supported in the Ultimate edition.

This new feature is the XML-aware counterpart to IntelliJ IDEA built-in functions [Find in Path](#) and [Search Structurally](#) . It allows you to find occurrences of certain XPath expressions in all XML files in a specific scope. It is available through [Edit | Find | Find by XPath...](#) on the main menu.

The scope that can be chosen is either the full project scope, a specific module or a simple directory. There's also the ability to use *custom* scopes, but this is somewhat limited as it will only scan XML files inside source-folders.

This dialog provides the same functionality regarding completion, error checking, and intentions as described in [Evaluate Expression](#) .

This feature is only supported in the Ultimate edition.

This action computes a unique XPath expression that matches the currently selected node in the document. The action is available from the View-Menu ( Unique Path ) and the Editor-Context Menu ( Show Unique XPath ). The action is only enabled when the caret is placed on an element that a useful expression can be generated for.

**Tip** The generated expression in the pop-up can be selected and copied into the clipboard for further use.

If a simple XPath expression like `/root/something/else` doesn't produce a unique result, the action has two strategies to make it unique:

– If the non-unique node is an element, the action looks for attributes with the name 'id', 'name' and attributes that are of ID-type, as defined by the document's DTD or XML Schema.

Example : `/root/something[<annotation>@id="foo"</annotation>]/else`

– For nodes other than elements (comments, processing instructions), or if the above rule doesn't produce a unique result, the index of the node inside its parent is appended.

Example : `/root/something/else[<annotation>2</annotation>]`

This feature is only supported in the Ultimate edition.

XPathView plugin settings are configured on the [XPath Viewer](#) page of the [Settings/Preferences](#) dialog.

---

**ItemDescription**

---

Scroll first hit into visible area	Select this checkbox to have the editor automatically scroll to the first XPath match.
Use node at cursor as context node	Select this checkbox to have the entered XPath expression use the currently selected node (tag/attribute/pi, etc.) as its context node and evaluate the expression relatively to this node.
Highlight only start tag instead of whole tag content	Do one of the following: <ul style="list-style-type: none"><li>- Select this checkbox to have only the name of a matching tag highlighted.</li><li>- Clear this checkbox to have the entire content of a matching tag highlighted.</li></ul>
Add error stripe markers for each result	Select this checkbox to have each match supplied with an error stripe marker which can be quickly navigated to. The tooltip of each marker shows the matched content.
Show actions in Toolbar	Select this checkbox to have buttons that invoke XPath -related actions displayed on the <a href="#">Main Toolbar</a> .
Show actions in Main Menu	When this checkbox is selected, XPath -related actions are available from the main menu.
Colors	In this area, configure color indication during execution of XPath expressions. Clicking on the color box will open the <a href="#">Select Color</a> dialog in which you can modify the current color indication. <ul style="list-style-type: none"><li>- Highlight Color - in this area, select the color to indicate XPath matches in the editor.</li><li>- Context Node Color - in this area, select the color to indicate the current context node.</li></ul>

This feature is only supported in the Ultimate edition.

- [Completion](#)
- [Refactoring](#)
- [Error Highlighting](#)
- [Navigation](#)
- [Documentation](#)
- [Run Configurations](#)
- [File Associations](#)
- [Intentions](#)

This feature is only supported in the Ultimate edition.

On this page:

- [Overview](#)
- [Completion in XPath expressions](#)
- [Completion for template names in xsl:call-template](#)
- [Completion for template parameters](#)

## Overview

With Code Completion being one of the key features of IntelliJ IDEA, the plugin provides several possibilities to complete keywords, predefined functions, variables and parameters used in XPath expressions, template names and names of parameters that can be passed to a template invocation.

## Completion in XPath Expressions

It's possible to complete all parameters/variables in scope inside an XPath expression in a normal expression attribute or inside an [attribute value template](#)

```
<xsl:message>
  <xsl:value-of select="concat('Param: ', $my-)" />
</xsl:message>
```

Also, all predefined functions and keywords are available for completion, including function signatures.

```
<xsl:value-of select="st" />
```

The [Quick Documentation Lookup](#) also works in completion lookup lists.

## Completion for Template Names in Xsl:Call-Template

The template's name that is to be called can be completed from a list of all named templates in the current document and included stylesheets

```
<xsl:call-template name="my-template">
  <xsl:with-param name="my-template" />
  <xsl:with-param name="my-template2" />
</xsl:call-template>
```

## Completion for Template Parameters

There's a special completion for parameters that should be passed to a template in a `xsl:call-template` invocation. The completion lists all parameters that are declared by the template and are not yet present in the *argument list* of the invocation, i.e. there's no `xsl:with-param` yet.

```
<xsl:call-template name="my-template">
  <xsl:with-param name="my-param1" select="123" />
  <xsl:with-param name="my-" />
  <xsl:with-param name="my-param2" select="" />
</xsl:call-template>
```

**Tip** That's especially useful when also using completion to create the `xsl:with-param` tag, because this will automatically trigger the completion for the parameter's name which is required according to the schema; e.g.

```
<xsl:with-p <ctrl-space>
=>
<xsl:with-param name=" [lookup list]
```

This feature is only supported in the Ultimate edition.

In the XSLT context, some the IntelliJ IDEA built-in refactorings are available:

- **Rename** and **Safe Delete** for XSLT items such as templates, variables and parameters.
- **Introduce Variable** for creating XSLT variables from selected XPath expressions.
- **Inline** for variables.

On this page:

- [Renaming templates](#)
- [Rename variables and parameters](#)
- [Safe delete](#)
- [Introduce variable](#)
- [Introduce parameter](#)
- [Inline variable](#)

## Renaming templates

Refactor | Rename

Named templates can be renamed in IntelliJ IDEA just like any other symbol. All `xsl:call-template` invocations that refer to this template will be updated accordingly.

## Rename variables and parameters

Refactor | Rename

Just as named templates, it is possible to rename XSLT variables and template parameters, either at a point of their use or at their declaration.

## Safe delete

Refactor | Safe Delete

Named templates, parameters and variables can be deleted using IntelliJ IDEA Safe Delete feature, i.e. the item will be removed if there aren't any references left to it in other stylesheets across the project.

This is especially useful if the stylesheet may be included in other ones via `xsl:include` or `xsl:import` to make sure that nothing will be deleted that is still used somewhere else.

## Introduce variable

Refactor | Extract

It is possible to extract XPath-Expressions and turn them into an `xsl:variable` declaration. Check the `Replace all occurrences` checkbox to replace all other occurrences of the same expression.

## Introduce parameter

Refactor | Extract

This is similar to `Introduce Variable`, but it creates a new parameter instead of a variable. It also has an additional option `Create with default value` that determines if the selected expression should be added as the introduced parameter's default value or if all calls to the template should be updated to pass the selected expression. That option is only available when introducing parameters to named templates.

## Inline variable

Refactor | Inline

This is just the opposite of `Introduce Variable`, it replaces all usages of a variable with the expression that is specified in the variable's `select`-attribute. Variables that don't have such an attribute cannot be inlined. Inlining variable references that resolve to parameters is not possible as well.

This feature is only supported in the Ultimate edition.

The XSLT support can detect a range of errors in XSLT constructs, such as misspelled template names, missing template parameters, bad match-patterns, references to undeclared variables, wrong or useless embedded XPath expressions, etc. and also offers Quick Fixes to automatically fix some of those errors.

- [Syntax highlighting](#)
- [XPath syntax checks](#)
- [XPath type checking](#)
- [Pattern validation](#)
- [Unresolved references](#)
- [Duplicate declarations](#)
- [Other checks](#)
  - [Shadowed variables](#)
  - [Missing template arguments](#)
  - [Superfluous template arguments](#)
  - [XPath inspections](#)

## Syntax highlighting

Where allowed, XPath function-calls, Axis names, Numbers, Strings, etc. are highlighted according to the currently active color scheme. By default, the plugin uses the colors that are defined for the corresponding Java types, such as number- and string literals, etc. If a different coloring is desired, those colors can be configured in the tab on the [Color Scheme](#) page of the [Settings / Preferences Dialog](#).

## XPath syntax checks

Just like the interactive XPath Expression Evaluation, the XSLT support catches any syntax error in XPath expressions used inside a stylesheet.

```
<xsl:value-of select="foo/bar/"/>
```

location step expected

## XPath type checking

In XPath, almost all types are assignable to each other with certain well-defined conversion semantics. However, the conversion to NODESET isn't defined for any type and there's also no (portable) conversion function available. Such type-conversions are highlighted as an error.

```
<xsl:value-of select="name(12345)" />
```

Expected type 'nodeset', got 'number'

## Pattern validation

A special form of XPath expression are patterns in XSLT. They are e.g. used as the value of the *match*-attribute in `xsl:template` elements. Only a certain subset of XPath expressions is allowed here, which the XSLT support checks for.

```
<!-- Pattern validation -->
<xsl:template match="string()" />
```

Bad pattern

## Unresolved references

References to variables that have not been declared or are not accessible from the current scope are detected and highlighted as an error. There are Quick Fixes available to create a variable or parameter declaration for such unresolved variables references.

```
<!-- undefined variable check -->
<xsl:message>
  <xsl:value-of select="concat('Variable: ', $my-variable)" />
</xsl:message>
```

Unresolved variable 'my-variable'

Quick-fixes:

```
<xsl:message>
  <xsl:value-of select="concat('Variable: ', $my-variable)" />
</xsl:message>
```

Create Variable 'my-variable'  
Create Parameter 'my-variable'

## Duplicate declarations

In XSLT there must not be more than one variable or parameter declared on the same scope level. It's also not allowed that there is more than one template with the same name. The plugin will identify such duplicate declarations and highlight them in the editor.

## Other checks

- [Function call arguments](#)

## Shadowed variables

Even though is possible to have identically named variables or parameters in different nesting levels, this can be confusing

and is likely to cause programming mistakes. The plugin can identify shadowed declarations and offers Quick-Fixes to either rename the local or the outer variable.

## Missing template arguments

Another check that the XSLT support performs is whether all required parameters are specified with a `<xsl:call-template>`. A parameter is considered required if there is no default value, i.e. if there's no `select` attribute and the parameter's declaring element has an empty body.

```
<xsl:call-template name="my-template">
  Missing template parameter: my-param2
```

Quick-Fixes:

```
<xsl:call-template name="my-template">
  Add Argument for 'my-param2'
```

## Superfluous template arguments

There's also a supplemental check that flags arguments that are not declared as template parameters. There are Quick Fixes available to either remove the argument from the template-call or to add a corresponding parameter to the called template.

```
<xsl:with-param name="my-undeclared-param" select="" />
/xsl:call-template> Superfluous template parameter: my-undeclared-param
```

Quick-fixes:

```
<xsl:with-param name="my-undeclared-param" select="" />
  Add Parameter 'my-undeclared-param' to Template 'my-template'
  Remove Argument 'my-undeclared-param'
```

## Function call arguments

The XSLT support does, just like the interactive XPath Expression Evaluation, check whether the number and types of function arguments match their declaration for built-in functions of XPath and XSLT.

```
<!-- missing function parameter check -->
<xsl:message select="concat($my-param2)" />
  Function 'concat' requires 2 arguments
```

## XPath inspections

All [XPath Inspections](#) are supported for editing XSLT documents. Those inspections can also be suppressed in a way that is similar to the standard suppression-mechanism IntelliJ IDEA uses for Java code by using `noinspection` XML comments. The suppression is possible on different levels, either on instruction level, template-level (if applicable) or stylesheet level.

The XPath language implementation provides a few built-in inspections that can check for common coding mistakes when writing XPath expressions both in the interactive mode and when writing XSLT scripts. Those inspections also provide a number of configuration options which can be configured on the [Inspections](#) page of the [Settings](#) dialog box.

Due to the way how these inspections are implemented and integrated, they only work for the on-the-fly editor highlighting and *not* if the inspections are run via Analyse | Inspect Code .

## XPath Type Checking

There are two inspections that deal with type-conversion in XPath expressions: Implicit Type Conversion and Redundant Type Conversion .

### Implicit Type Conversion

This inspection checks for any implicit conversions between the predefined XPath-types STRING, NUMBER, BOOLEAN and NODESET. While this is usually not a problem as the conversions are well-defined by the standard, this inspection can help to write XSLT scripts that are more expressive about types and can even help to avoid subtle bugs:

```
<xsl:if test=" foo " /> is not the same as <xsl:if test=" string(foo) " />
```

The first test checks whether the element *foo* exists ( `count(foo) > 0` ), the latter one however is only true if the element actually contains any text ( `string-length(foo) > 0` ). The plugin will then offer to make the type-conversion more explicit.

There are several options to adjust the inspection to personal preferences by offering the possibility to individually enable it for implicit conversions between certain types.

The plugin can also be told to always flag explicit conversions that do not result in the actually expected type, such as

```
<xsl:if test="number(foo)" /> and provides a special option to ignore the conversion from NODESET to BOOLEAN by using the string() function as a shortcut for writing string-length() > 0 .
```

### Redundant Type Conversion

This inspection checks whether any type-conversion with the functions `string()` , `number()` or `boolean()` is redundant, i.e. whether the type of argument is the same as the functions return type or if the expected type of the expression is of type *any* . While such an explicit conversion may sometimes be intentional to emphasize the type, this can usually be safely removed.

## Expression validity checks

Those inspections check whether an expressions contains any potential semantic mistakes, such as referencing element/attribute names that don't occur in instance documents or using predicates that don't potentially match anything.

### Check Node Test

This inspection checks whether any element/attribute names that are used in XPath-expressions are actually part of an associated XML file or are defined in a referenced schema. This helps to avoid problems caused by typos in XPath-expressions that would otherwise occur when running the script and may even then not be recognized immediately.

Example:

```
<xsl:template match="<keyword>h:txtarea</keyword>" />
```

If the prefix *h* is bound to the XHTML namespace, the inspection will flag this part of the match-expression as an unknown element name because the correct name of the element is *textarea* .

### Index Zero Usage

This inspection checks for any accidental use of zero in a predicate index or in a comparison with the function `position()` . Such is almost always a bug because in XPath, the index starts at one, *not* at zero.

Example:

```
//someelement[ position() = 0 ] or //something[ 0 ]
```

## Developing custom XPath inspections

The XPath inspections make use of the normal inspections API of IntelliJ IDEA. However, due to the way the XPath Language-Support is integrated, this is a bit more complicated and it's at the moment not readily possible to develop full-blown 3rd-party XPath inspections. While it's theoretically possible to develop custom inspections that make use of the XPath-PSI API and are derived from `org.intellij.lang.xpath.validation.inspections.XPathInspection` , this is not recommended and not supported.

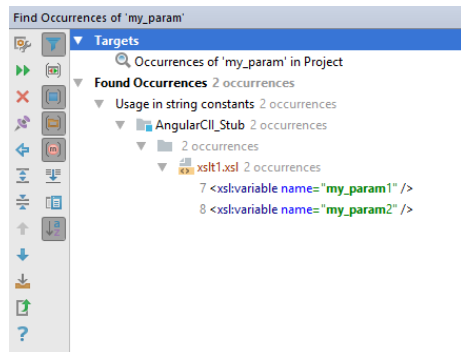

Please contact me if there's a need for a special inspection or there is significant interest that would justify the effort to make this more pluggable.

Basically all possibilities for code-navigation are supported for named templates, variables and parameters. For example: Goto Declaration, Find Usages, Highlight Usages in File, Quick Definition Lookup, etc.

```
<xsl:variable name="var" select="123" />  
<xsl:value-of select="$var + $var" />
```

## Find Usages

Find Usages works for Variables and Parameters as well as named XSLT Templates. It finds all places of a certain template in all XSLT Stylesheets that are contained in the specified scope.

## Goto Symbol

The plugin also supports IntelliJ IDEA Goto Symbol action. The names of templates, top-level variables and parameters are offered for that action to be able to quickly navigate to them by their name.

On this page:

- [Documentation for XSLT-elements and predefined XPath-functions](#)
- [Custom documentation](#)

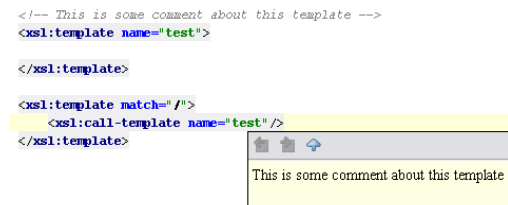

## Documentation for XSLT-elements and predefined XPath-functions

The plugin comes with bundled documentation for XSLT elements and functions that is accessible via the Quick Documentation Lookup ( Ctrl-Q ) action. This documentation is extracted from the respective sections in the official W3C XSLT and XPath documents.

## Custom documentation

It's also possible to annotate elements in an XSLT stylesheet with some documentation fragments. This can be looked up by the Quick Documentation Lookup function for variables, parameters and templates

Running XSLT Scripts is as easy as opening the Editor Context Menu and either creating a permanent Run Configuration or simply choosing Run to instantly run the selected XSLT script.

## Creating Run Configurations

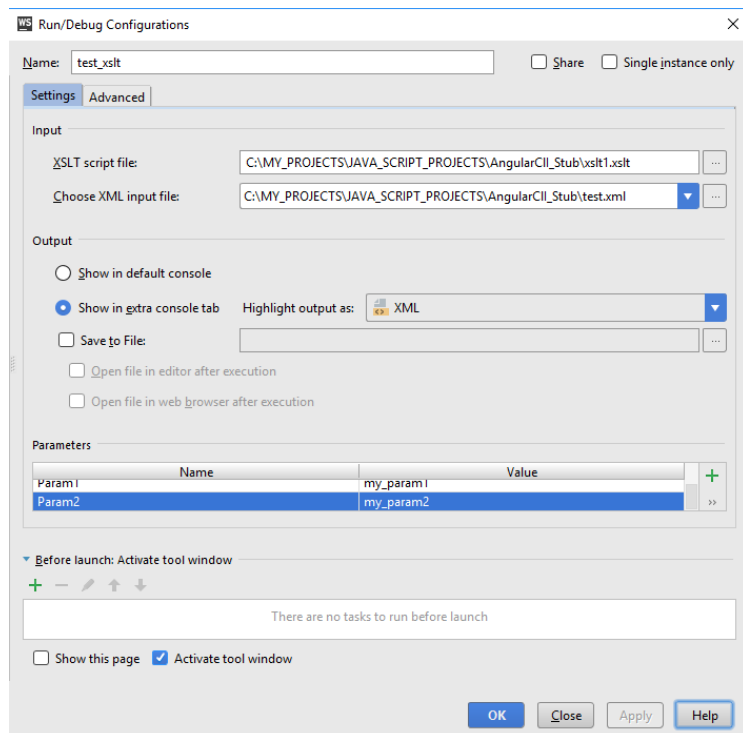

Permanent Run Configurations can be created through Run | Edit Configurations on the main menu. You'll find an additional tab named XSLT to add Run Configurations for XSLT scripts.

A Run Configuration can also be created by the Create "<name>" action from the context menu.

In that case, the name of the configuration will be taken from the stylesheet's file name and its path will already be filled into the XSLT script file text field. If the stylesheet defines parameters, those will be filled into the [Parameters](#) table with empty values. Parameters that are highlighted in blue don't have a value assigned yet and will not be passed to the stylesheet during execution, so it's not required to delete those automatically created parameter values if nothing should be passed to the stylesheet.

## Run Configuration Settings

### Input

An XSLT Run Configuration has various settings that can be adjusted. The most important ones are the location of the XSLT script file and the XML input file that should be transformed. Those are mandatory and the specified files must exist, otherwise the configuration cannot be executed.

The XML input file combobox lists all XML files that have been associated with the chosen stylesheet via the File Associations functionality.

### Output

There are three different choices about how the output of the script should be handled. The first is Show in default console . When this is selected, the output will appear in the normal run console, together with any warnings and error messages from the XSLT transformer, as well as messages generated by the script, e.g. by `xs1:message` .

By default selected is the option Show in extra console tab which will show the output in an extra tab named *XSLT Output* . This option has the ability to highlight the produced output according to different file types that are available in IntelliJ IDEA. However this is kind of an experimental feature, so it can be turned off completely by selecting the Disabled option. The output will then be written into a temp file that is displayed by the normal Log Viewer .

The last option, Save to file can be used to directly write the output to a file. The textfield must not be empty and can refer to any existing or non-existing file. Check the option Open file in editor after execution to open the file in IntelliJ IDEA after the script ends normally. The option Open file in web browser can be checked to open the generated file in the configured web browser after execution has finished.

**Warning!** The specified output file will be overwritten without confirmation.

## Parameters

The Parameters table is used to specify the parameter names and their values that should be passed to the script. Press the Add and Remove buttons to modify the list. A newly added parameter will not have any value assigned by default, and thus will not be passed to the script if the value isn't edited.

## Advanced Options

This tab allows you to control some options that are not needed for usual run configurations.

### Smart error handling

Clear this checkbox to see full error messages including their complete stack traces when an error occurs during execution. When the checkbox is selected, those stack traces will be suppressed and only the relevant information about errors will be displayed in the console.

### VM Arguments

Allows you to pass arbitrary VM arguments to the VM that is used for running the XSLT script.

### Working Directory

The working directory to use. When left empty, the working directory will be the directory the XSLT script file is located in.

### Classpath and JDK

Allows you to choose the environment to run the script under. The default setting is the Module the XSLT script file belongs to. The option From module will also include the full classpath of the chosen module. This can be needed if the script makes use of custom XSLT Extension Functions .

The option Use JDK allows you to select the JDK without including anything module- or project-related into the classpath. It can be useful to explicitly choose a specific JDK to test the script with.

On this page:

- [Overview](#)
- [Managing associations from the editor](#)
- [Removing an association](#)

## Overview

File Associations are used to associate an XSLT file with other XML files. This is currently used for three purposes:

- Enhanced completion for element- and attribute names in XSLT node-selections. The completion will offer all element- and tag names that are found in the associated documents.
- Enhanced error highlighting for XSLT node-selections. If an XSLT script has been associated with one or more XML files, any references to element- and attribute names that are not part of the associated files will be flagged with the warning message: " Tag name '...' is not part of the document ".
- File Associations are also used for creating Run Configurations . The XML input file to use for the transformation can be conveniently chosen from the list of associated files.

XSLT File Associations are defined per project and managed in the [XSLT File Associations](#) settings page.

## Managing associations from the editor

Associations can also be created by invoking the Add... action from the File Associations group in the Editor Context Menu. A file-selection dialog opens that can be used to select one or more X(HT)ML files to associate the XSLT file with.

## Removing an association

An Association can be removed by clicking on the corresponding file name in the File Associations group. The file names are displayed with a path that is relative from the current file. If the associated file is part of any module, the module name is included in square brackets.

It's also possible to invoke the associations configuration dialog through the Configure... action. This opens the associations configuration dialog and preselects the file that's currently opened in the editor.

The XSLT Support comes with a few intentions that can be useful for XSLT development.

### Intention to convert xsl:if to xsl:choose

This is useful if it turns out that a simple if-branch isn't enough in a certain situation and an else-branch is required. When positioning the caret on the start tag of the `xsl:if`, the intention shows up and converts the code fragment into an `xsl:choose`, preserving the original `xsl:if` as an `xsl:when` block and adding an `xsl:otherwise` block.

#### Before

```
<xsl:if test="true()">
  </xsl:if>
```

#### After

```
<xsl:choose>
  <xsl:when test="true()">
  </xsl:when>
  <xsl:otherwise>
  </xsl:otherwise>
</xsl:choose>
```

### Intention to add optional parameters

This intention can be used to pass a value for an optional parameter in a template-call. It will insert the appropriate `xsl:with-param` tag and show a lookup list for all parameters that aren't already passed to the template.

#### Before

```
<xsl:template match="/">
  <xsl:call-template name="test" />
</xsl:template>
```

#### After

```
<xsl:template match="/">
  <xsl:call-template name="test" >
    <xsl:with-param name="select" />
  </xsl:call-template>
</xsl:template>
```

- Note** Before you start configuring a connection to your tracker, note that IntelliJ IDEA:
- Supports only services with REST API.
  - Supports either [Basic HTTP authentication](#) or sending preliminary requests to the server.
  - Supports GET and POST requests.
  - Does not support pagination in server responses.

IntelliJ IDEA supports integration with many task trackers out of the box. However, if you use a tracker that IntelliJ IDEA does not support yet, you can still integrate it configuring a so called generic server.

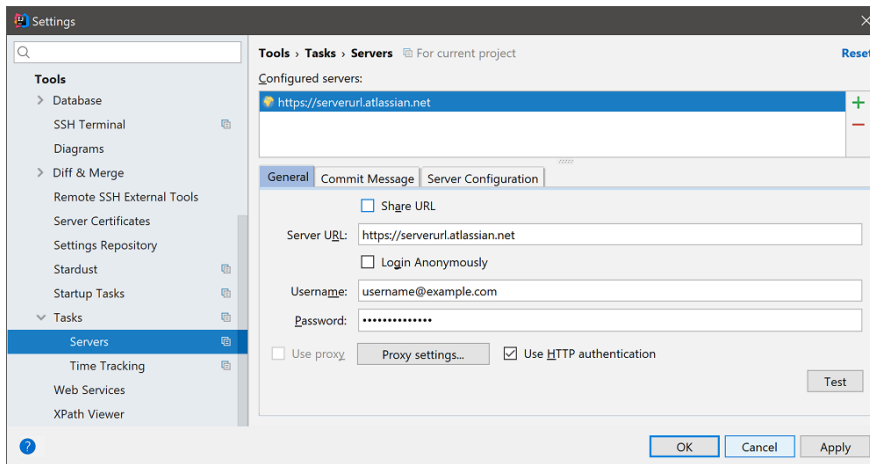

This tutorial describes how to:

- Connect to JIRA Cloud as a generic server
- Obtain the list of issues assigned to you
- For each issue, get its ID, title, description, date and time when the issue was created and updated

## 1. Specify server URL and credentials

**Tip** If you work on MacOS, navigate to IntelliJ IDEA | Preferences | Tools | Tasks | Servers .

1. Navigate to File | Settings | Tools | Tasks | Servers .
2. Click **+** and select Generic .
3. On the General tab, specify the URL of your task tracker, connection credentials and select the Use HTTP authentication checkbox.

## 2. Configure server settings

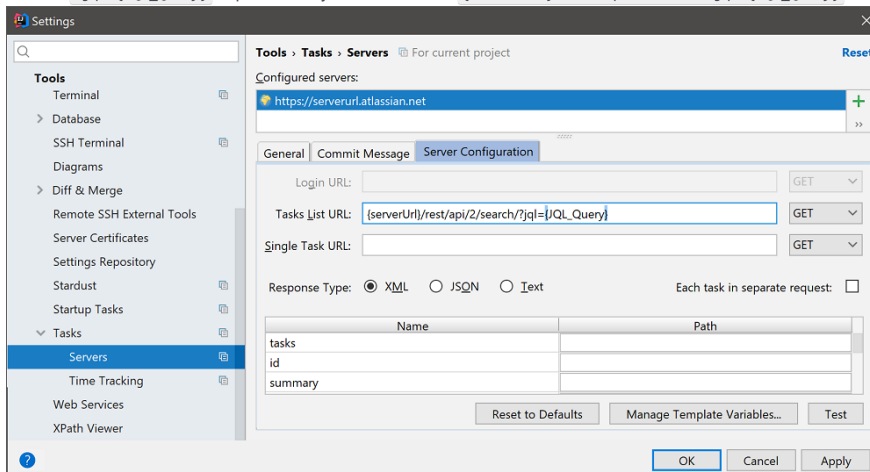

**Tip** You can use code completion in the Login URL , Tasks List URL and Single Task URL fields.

**Note** The `{serverUrl}` is a variable that stands for the URL you have specified on the General tab.

1. Switch to the Server Configuration tab.
2. In the Tasks List URL , enter the URL for obtaining issues from the server. You can use variables or enter the full URL:

`{serverUrl}/rest/api/2/search` or `https://serverurl.atlassian.net/rest/api/2/search`

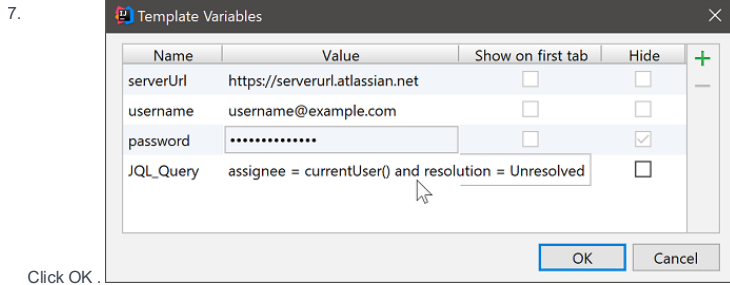

3. Add the `?jql={JQL_Query}` expression to your task list URL: `{serverUrl}/rest/api/2/search?jql={JQL_Query}` .

4. Click Manage Template Variables at the bottom of the window to configure the `JQL_Query` variable.
5. Click **+** in the top right-hand corner.
6. In the new filed, specify variable name (`JQL_Query` ), and add its value (`assignee = currentUser()` and `resolution =`

Unresolved ).

This will let you obtain unresolved issues assigned to you.

Click OK .

**Note** Note that the Login URL field will be disabled, as you are using HTTP authentication.

### 3. Configure response type and specify selectors

**Note** Selectors help you retrieve specific information about tasks. First three selectors are mandatory.

tasks : path to tasks in the server response (root element).

id : relative path to a task ID in the server response.

summary : relative path to a task title in the server response.

1. In the Server Configuration window, select the JSON response type.

2. Specify selectors in the table to get IDs and titles of issues, and to obtain their description and time when issues were created and updated:

- tasks: `$.issues`

- id: `key`

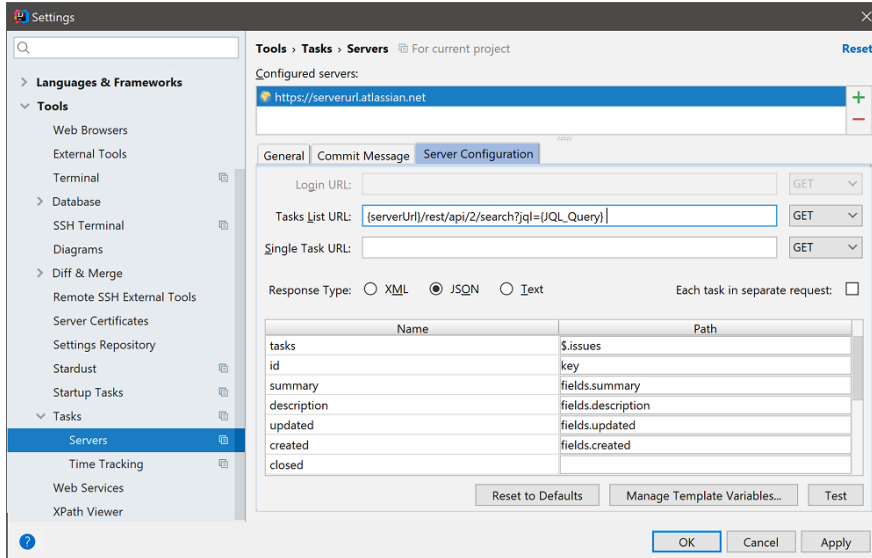

- summary: `field.summary`

- description: `field.description`

- updated: `field.updated`

- created: `field.created`

3. Click Test to make sure all parameters are configured correctly.

**Tip** For JIRA you can check the server responses in real time. Replace placeholders with actual values and open the link in a browser:

<http://<server URL>:<port>/rest/api/2/search>

### 4. Upload issues from server

1. Click the tasks combo and select Open Task . IntelliJ IDEA will load from the server all issues that match your

configuration.

2. Select the necessary issue from the list.

3. Press **Ctrl+Q** to open issue description and make sure all required details are obtained.

Enter task name:  Include closed tasks (Alt+Shift+N) 

Create New Task 'configure'

PROJ-6: Configure generic tracker

...

Press SHIFT to merge with current context  
Pressing Ctrl+Q would show task description and comments

Documentation for PROJ-6: Configure generic tracker 

**Summary:** Configure generic tracker  
**Id:** PROJ-6  
**Created at:** Tue Aug 01 16:26:02 MSK 2017  
**Updated at:** Tue Aug 01 16:26:02 MSK 2017  
**Description:**

Configure a generic tracker. Describe configuration in a tutorial. Post online.

## What this tutorial is about

This tutorial aims to walk you step-by-step through debugging a Java application with Chronon, a recorder and a "time-travelling" debugger.

Chronon records changes are made by your application while it is executing. The recordings are saved to files. You can later play these recordings back and share them among the team members.

## Before you start...

First of all, it is essential to understand that Chronon is not literally a debugger - it only helps you record the execution progress and then play it back, like a videotape.

Second, make sure that:

- Your IntelliJ IDEA version is 13.1 or later. This tutorial is made for the version 14.1.
- The Chronon plugin is [downloaded and installed](#) .

Third, note that keyboard shortcuts on different keymaps may differ. This tutorial is made with the default keymap.

## Preliminary steps

### Preparing an example

Let's see how Chronon works on a simple example of a two-thread class. One thread performs quick sorting, while the second thread performs bubble sorting.

First, create a project as described in the page [Creating, Running and Packaging Your First Java Application](#) .

Next, [create a package](#) with the name `demo` , and, finally, add Java classes to this package. The first class is called `ChrononDemo.java` and it performs two-threaded array sorting:

```

package demo;

import org.jetbrains.annotations.NotNull;

import java.util.AbstractMap;
import java.util.Arrays;
import java.util.Random;

public class ChrononDemo {

    public static final int SIZE = 1000;
    public static final Random GENERATOR = new Random();

    public static void main(String[] args) throws InterruptedException {
        final int[] array = new int[SIZE];
        for (int i = 0; i < SIZE; i++) {
            array[i] = GENERATOR.nextInt();
        }
        final Thread quickSortThread = new Thread(new Runnable() {
            @Override
            public void run() {
                QuickSort.sort(Arrays.copyOf(array, array.length));
            }
        }, "Quick sort");

        final Thread bubbleThread = new Thread(new Runnable() {
            @Override
            public void run() {
                BubbleSort.sort(Arrays.copyOf(array, array.length));
            }
        }, "Bubble sort");

        quickSortThread.start();
        bubbleThread.start();

        quickSortThread.join();
        bubbleThread.join();
    }
}

```

The second is the class `QuickSort.java` that performs quick sorting:

```

package demo;

class QuickSort {
    private static int partition(int arr[], int left, int right) {
        int i = left, j = right;
        int tmp;
        int pivot = arr[(left + right) / 2];

        while (i <= j) {
            while (arr[i] < pivot)
                i++;
            while (arr[j] > pivot)
                j--;
            if (i <= j) {
                tmp = arr[i];
                arr[i] = arr[j];
                arr[j] = tmp;
                i++;
                j--;
            }
        }

        return i;
    }

    public static void sort(int arr[], int left, int right) {
        int index = partition(arr, left, right);
        if (left < index - 1)
            sort(arr, left, index - 1);
        if (index < right)
            sort(arr, index, right);
    }

    public static void sort(int arr[]) {
        sort(arr, 0, arr.length - 1);
    }
}

```

And, finally, the third one is the class `BubbleSort.java` that performs bubble sorting:

```

package demo;

public class BubbleSort {
    public static void sort(int[] arr) {
        boolean swapped = true;
        int j = 0;
        int tmp;
        while (swapped) {
            swapped = false;
            j++;
            for (int i = 0; i < arr.length - j; i++) {
                if (arr[i] > arr[i + 1]) {
                    tmp = arr[i];
                    arr[i] = arr[i + 1];
                    arr[i + 1] = tmp;
                    swapped = true;
                }
            }
        }
    }
}

```

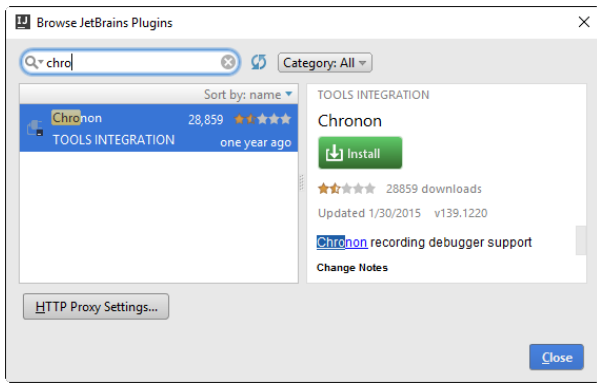

By the way, it is recommended to type the code manually, to see the magic IntelliJ IDEA's [code completion](#) in action.

## Installing plugin

Open the Settings/Preferences dialog. To do that, click  on the main toolbar, or press `Ctrl+Alt+S`.

Then click the page [Plugins settings](#).

In this page, click the button `Install JetBrains plugin...` to download and install plugins from the JetBrains repository. In the `Browse JetBrains Plugins` dialog box, find the `Chronon` plugin - you can type the search string in the filter area:

Install the plugin and restart IntelliJ IDEA for the changes to take effect.

## Changes to the UI

After restart, pay attention to the following changes:

- Dedicated Run with Chronon icon appears on the main toolbar. By now, this icon is disabled .

It will become enabled  as soon as the corresponding run/debug configuration appears.

- Chronon tool window (which becomes available on launching a run/debug configuration with Chronon, or on opening a Chronon record).
- Chronon tab appears in the run/debug configuration of the Application type (and some other types as well):

- Run menu is extended with two commands:

- Run <run/debug configuration name> with Chronon
- Open Chronon recording

## Creating run/debug configuration

To launch our application, we need a [run/debug configuration](#). Let's [create one](#).

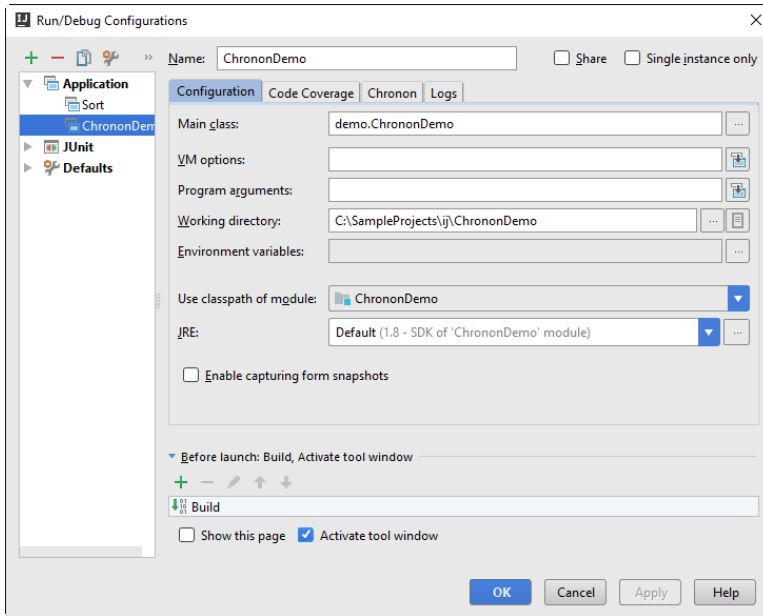

On the main menu, choose Run | Edit Configuration, and in the Run/Debug Configurations dialog box, click . We are going to create a new run/debug configuration of the [Application](#) type, so select this type:

The new run/debug configuration based on the Application type appears. So far, it is unnamed and lacks reference to the class with the main method. Let's specify the missing information.

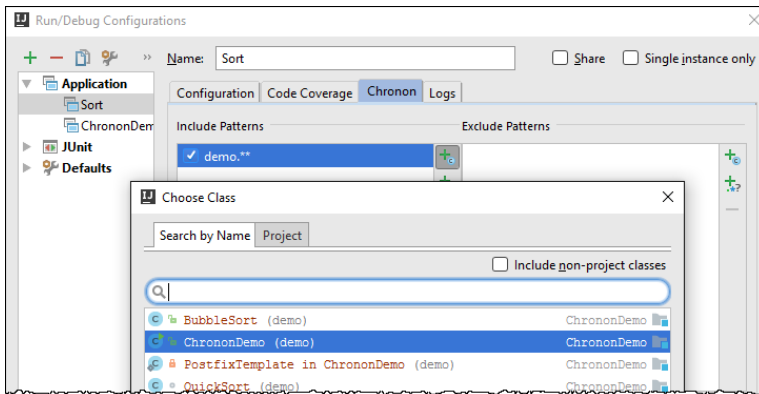

First, give this run/debug configuration a name. Let it be `ChrononDemo`. Next, press `Shift+Enter` and find the class named `ChrononDemo.java` that contains the main method. This class resides in the package `demo`:

## Defining include/exclude patterns

Next, return to the Chronon tab. In this tab, you have to specify which classes IntelliJ IDEA should look at. This is done by Include / Exclude Patterns. In the Include Patterns area, click :

Now apply changes and close the dialog. The preliminary steps are done.

## Running with Chronon

OK, it's time to launch our application. To do that, either click the Chronon button on the main toolbar, or choose Run | Run ChrononDemo with Chronon on the main menu.

Let's choose the first way:

IntelliJ IDEA shows the progress bar, and then the [Run tool window](#), where you can see the Chronon messages:

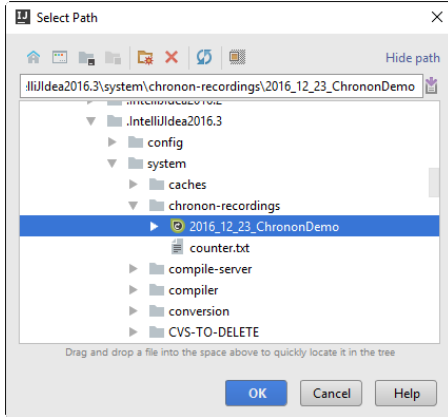

It is important to note that a Chronon record is NOT created, when you terminate your application by clicking . If it is necessary to stop an application and still have a Chronon record, click the Exit button on the toolbar of the Run tool window.

Then the Chronon tool window appears. It looks very much like the [Debug tool window](#). In this tool window you see a record created by Chronon; so doing, each record shows in its own tab:

## Opening an existing record

By the way, if you want to open one of the previous records, use Run | Open Chronon recording on the main menu, and then choose the desired record:

## What can you do with a record?

In the Chronon tool window, you can:

### Switch between threads

This is most easy - just switch to the Threads tab, and double-click the thread you are interested in. The selected thread is shown in boldface in the list of threads; besides that, the information about the currently selected thread appears in the upper-right part of the Chronon tool window:

### Step through the application

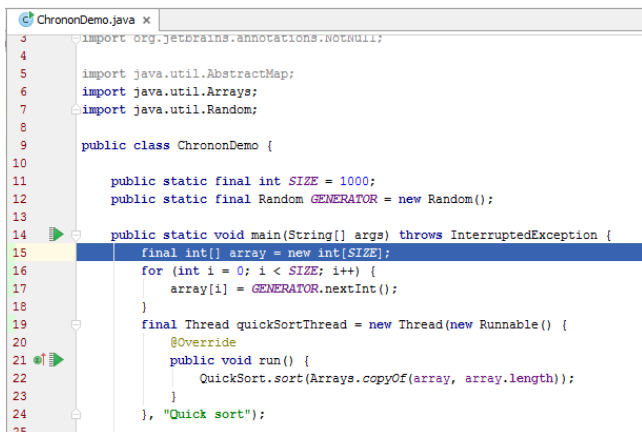

Actually, you can use either the stepping commands of the Run menu, or the stepping buttons of the Chronon tool window. Unlike the debugger that allows only stepping forward, Chronon makes it possible to step through the applications in the reverse direction also:

So, besides the traditional stepping buttons, there is Step Backwards button  and Run Backwards to Cursor button .

### Use bookmarks

Suppose you've stopped at a certain line, for example, in the main method of the class ChrononDemo.java :

You want to memorize this place with its event number, to be able to return to it from any other location. This is where the

Bookmarks tab becomes helpful. Switch to this tab, and click . A bookmark for the current event, thread and method is created:

So doing, the bookmark memorizes the event number, thread and method name. Next, when you are in a different place of the code, clicking this bookmark in the Bookmarks tab will return you to this particular place.

## Explore methods

If you look at the editor, you notice the icons in the left gutter next to the method declarations. Hovering the mouse pointer over such an icon shows a tooltip with the number of the recorded calls.

However, if you want to see a particular call event, then select the desired thread in the Threads tab (remember - the selected thread is shown in upper right part of the Chronon tool window), switch to the Method History tab, and track the execution history of a method:

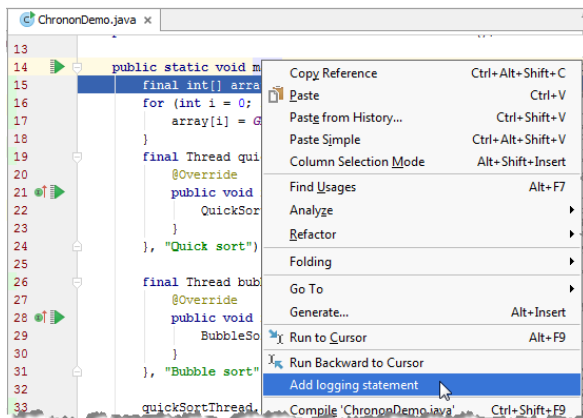

Thus you can explore the method execution, with the input and output data, which makes it easy to see how and where a method has been invoked.

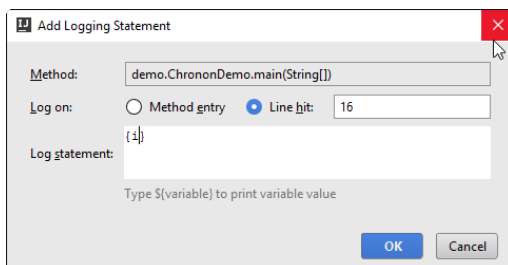

## Log values

What is the Logging tab for? By default, it is empty. However, using this tab makes it possible to define custom logging statements and track their output during application run.

This is how logging works. In the editor, right-click the statement of interest, and choose Add logging statement on the context menu:

Then, in the dialog box that opens, specify the variable you want to watch in the following format:

Next, to make use of this logging statement, click in the toolbar of the Logging tab. In the right-hand side of the Logging tab, the output of the logged statement is displayed:

Note that such logging is equivalent to adding an output statement to your application; you could have added

```
System.out.println(<variable name>);
```

However, this would require application rebuild and rerun. With Chronon's logging facility, such complications are avoided.

## Explore exceptions

Suppose you want to find out how and when an exception has occurred. The Exceptions tab shows all the exceptions that took place during an application execution:

If you double click an exception, IntelliJ IDEA will bring you directly to the place of the exception occurrence:

## Summary

You've learned how to:

- Download and install Chronon plugin for IntelliJ IDEA
- Launch an application with Chronon recording.
- Open existing Chronon recordings.
- Work with the Chronon tool window. By the way, refer to the [Hide/Restore Toolbar](#) section of the Debug tool window reference to learn how to show/hide tabs.

This tutorial is over - congrats!

## What this tutorial is about

This tutorial aims to take you step-by-step through configuring an managing deployment of your code to remote hosts, using IntelliJ IDEA.

## Before you start

Make sure that:

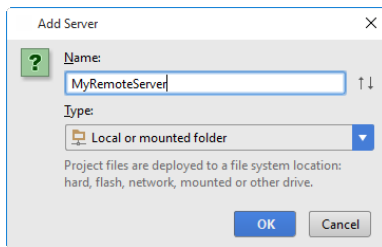

- You are working with IntelliJ IDEA version 15.0 or higher. This tutorial is prepared with IntelliJ IDEA 2016.1.
- You have access right to a remote host you want your code to be deployed on.

Also note that this tutorial is created on Windows 10 and makes use of the default keyboard shortcuts scheme. If you are working on a different platform, or use another keyboard scheme, the keyboard shortcuts will be different.

## Configuring a deployment server

On the main toolbar, click  to open the Settings/Preferences dialog, and choose the page [Deployment](#) (actually, you can access the same page by choosing Tools | Deployment | Configuration on the main menu).

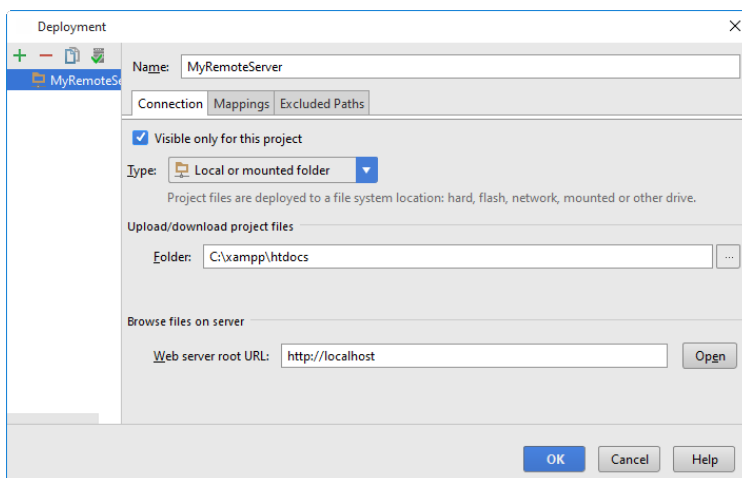

Click , then in the Add Server dialog box, type your server name (`MyRemoteServer`) and select its type (in our case, this is Local or mounted folder):

OK, the new server is added, but it is still void... It only shows the Web server root URL `http://localhost`, where you will actually browse your uploaded files.

## What is specified in the Connection tab?

Select the directory where the project files will be uploaded. In our case, this is the local folder `C:\xampp\htdocs` (You can either type this path manually, or press `Shift+Enter` to open the [Select Path dialog](#).)

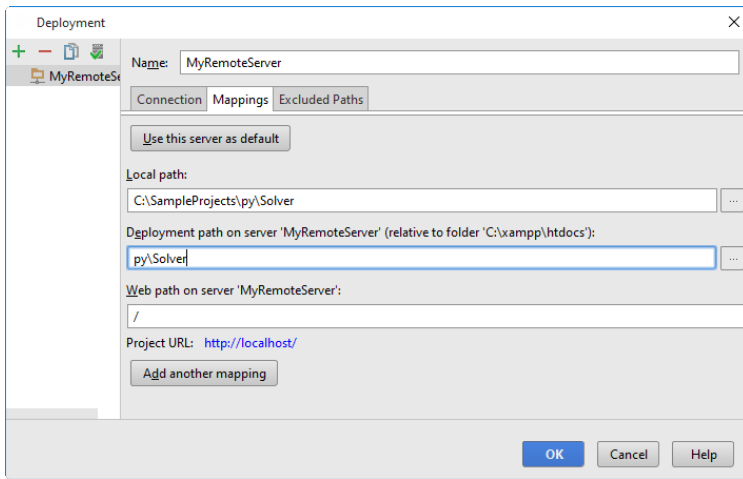

## What is specified in the Mapping tab?

Next, choose the [Mappings tab](#). By default, the Local path field contains the project root. However, you can select any other directory within your project tree. Let's assume the default value.

In the Deployment path field (which is by default empty), you have to specify the folder on your server, where IntelliJ IDEA will upload data from the folder, specified in the Local path (in this example, it's `ij\MetersToInchesConverter`). This path is specified relative to the folder `C:\xampp\htdocs` !

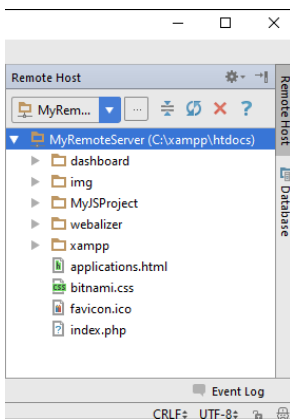

And, finally, let's accept the default value for Web path on server 'MyRemoteServer' :

OK, apply changes, and the server is ready to use.

## Browsing remote hosts

You can easily make sure your server is up and running. Just choose the command **Tools | Deployment | Browse Remote Hosts** on the main menu, and the **Remote Hosts tool window** appears at the right edge of the IntelliJ IDEA's frame:

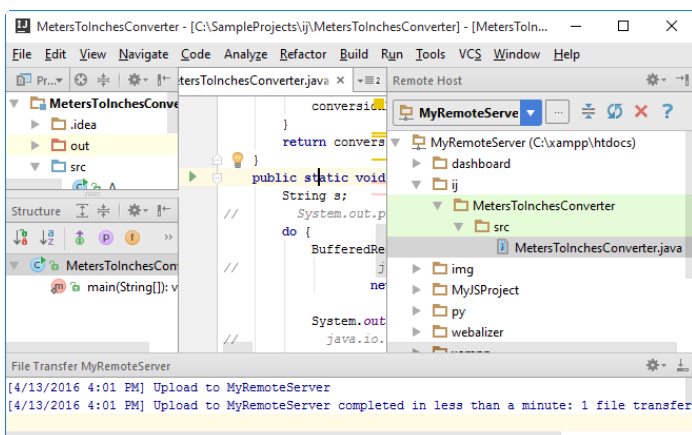

## Deployment tools

Next, let's perform some actions, and see what happens.

## Uploading

First, let's upload one of the files to the remote server. This how it's done...

In the **Project Tool Window**, right-click a file you want to upload. In our case, let it be the file `MetersToInchesConverter`. On the context menu, choose **Upload to MyRemoteServer**, and see the upload results!

You can also upload contents of each directory within your project. For example, right-click the parent directory of the `MetersToInchesConverter`, namely, `src`, choose **Upload to MyRemoteServer** on the context menu. Wow! We have the entire directory uploaded to the server:

## Comparing remote and local versions

There is a local and a remote copy of the file `MetersToInchesConverter`, and they are identical. Let's change the local

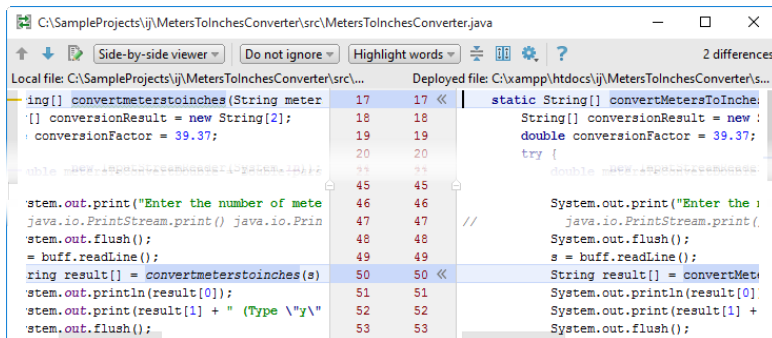

version.

To do that, place the caret at the method declaration, and press `Ctrl+Shift+Alt+T` (or choose Refactor | Refactor This on the main menu). The popup menu shows all refactorings, available in the current context. Let's choose Rename refactoring, and [rename a method](#) :

Perform refactoring and see the method name and its usage changed.

OK, now we've changed the local version. Let's make sure IntelliJ IDEA knows about these changes. To do that, again go to the [Remote Host Tool Window](#) tool window, and right-click `MetersToInchesConverter` . On the context menu, choose Compare with Local Version . IntelliJ IDEA opens the differences viewer, where you can accept changes or reject them, using the buttons `>>`, `<<`, `>`, `<`, `⌂`, `×` :

## Downloading

In the [Remote Host Tool Window](#) tool window, right-click the file `MetersToInchesConverter` , and choose Tools | Deployment | Download from here on the main menu. IntelliJ IDEA immediately shows a warning:

Do not be afraid, and click Continue :

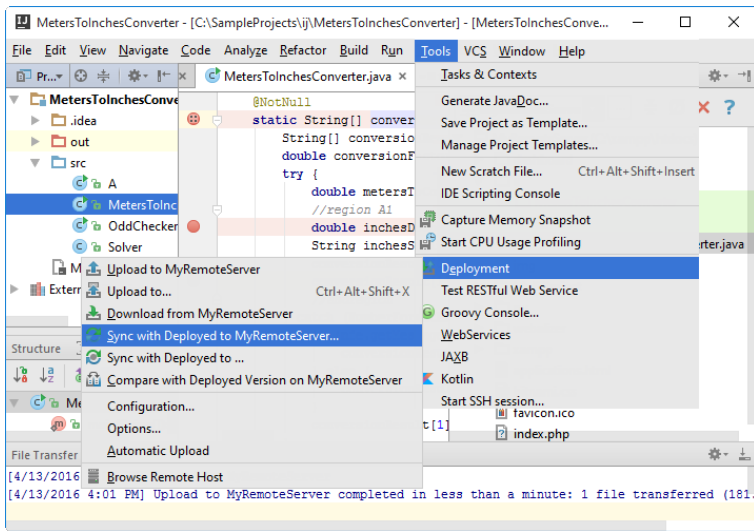

You can also download an entire directory, if it has been previously uploaded to the server. For example, if you click the parent directory `src` and choose the same command, all nested files will be downloaded from the server.

## Synchronizing changes

Make a preliminary step - roll the changes to the `MetersToInchesConverter` file back (`Ctrl+Z` ). You again see the class `MetersToInchesConverter` with the renamed method.

Next, click `MetersToInchesConverter` , and on the main menu choose Deployment | Sync with Deployed to MyRemoteServer :

IntelliJ IDEA shows differences viewer, where you can accept individual changes or reject them, using the buttons » , « , ↵ , ↲ , ↳ , × .

## Automatic upload to the default server

When a user needs to have the exact same files on the server as in a IntelliJ IDEA project, automatic upload can be of help. Automatic upload means that whenever a change is saved in the IDE, it will be deployed to the default deployment server.

## Defining a server as default

A deployment server is considered default, if its settings apply by default during automatic upload of changed files. To define a deployment server as the default one, follow these steps:

1. Choose the desired server in the [Deployment page](#) (in our case, `MyRemoteServer` ). You can open this page it two possible ways: either Settings/Preferences | Build, Execution, Deployment | Deployment , or Tools | Deployment | Configuration on the main menu.
2. Click  .

## Enabling automatic upload

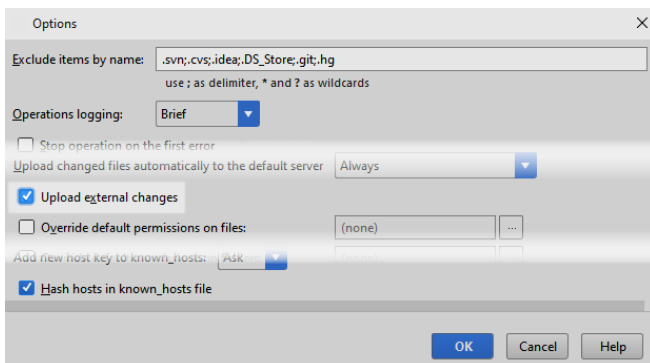

As soon as the default server is set, you can make upload to this server automatic. This can be done in the following two ways:

- First, open the deployment [Options](#) ( Settings/Preferences | Deployment | Options or Tools | Deployment | Options on the main menu), and in the field Upload files automatically to the default server choose Always , or On explicit save action . The difference between these two choices is explained in the [field description](#) .
- Second, on the main menu, select the check command Tools | Deployment | Automatic upload . Note that automatic upload in this case is performed in the Always mode.

It is worth mentioning that the option Always is not recommended for deployment to production: incomplete code can be uploaded while developing, potentially breaking the production application.

## Uploading external changes

By default, IntelliJ IDEA uploads only the files changed by itself. If the files are changed by some other process, such as a [VCS branch change](#) , [compilation of SASS or LESS](#) or a [File Watcher](#) , they are not automatically uploaded. To change this behavior and autoupload these changes as well, enable the Upload external changes option:

## Summary

Congrats! You've passed this very basic tutorial. What you've done?

- Created and configured a server of your own.
- Uploaded and downloaded files and folders.
- Compared local and remote versions.
- Configured the server as default.

- Enabled automatic upload of external changes.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Node.js Plugin is installed and enabled!

## What this tutorial is about

This tutorial aims to walk you step by step through using file watchers in IntelliJ IDEA.

The basics of file watchers, in particular, usage of LESS and CoffeeScript, are out of scope of this tutorial.

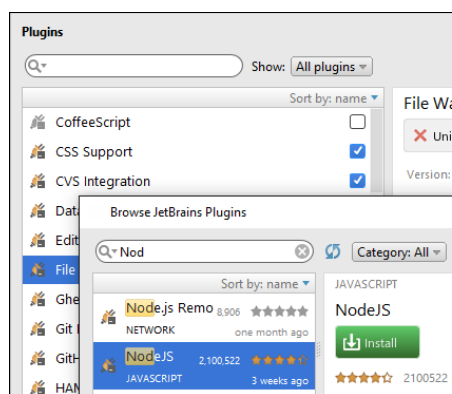

## Prerequisites

Make sure that:

- You are working with IntelliJ IDEA .
- [Node.js](#) is downloaded and installed. It is advisable, depending on your particular operating system, to add the path to Node.js executable to the Path environment variable.
- Before you start working with file watchers, make sure that the File Watchers plugin is enabled. The plugin is bundled with IntelliJ IDEA and is activated by default. If the plugin is not activated, enable it on the [Plugins settings](#) page of the [Settings / Preferences Dialog](#) as described in [Enabling and Disabling Plugins](#) .
- It is advisable to familiarize yourself with the matter in advance. Please read the section [Using File Watchers](#) .
- In this tutorial, we'll work with [Less](#) and [CoffeeScript](#) files. So, before you start your workout, perform some preliminary steps.

## Installing Node.js plugin

First, download and install Node.js plugin. It is not bundled; so to have it installed, open the [Plugins settings](#) page (click  on the main toolbar, remember ?) and look for this plugin in the JetBrains repository:

For the changes to take effect, restart IntelliJ IDEA. After restart, you will notice a new page under the Languages and Frameworks node in the Settings/Preferences dialog - [Node.js and NPM](#) .

## Installing LESS and CoffeeScript compilers

Open Settings/Preferences() and open then the page [Node.js and NPM](#) . On this page, specify the Node interpreter (its version is determined automatically), and then click  - one time to install less , and the other time to install coffee-script .

As you've noticed already, LESS and CoffeeScript are installed locally, so the corresponding compiler files are written under the project root:

These files will be required a little bit later. Now, it's time to start!

## Configuring file watchers

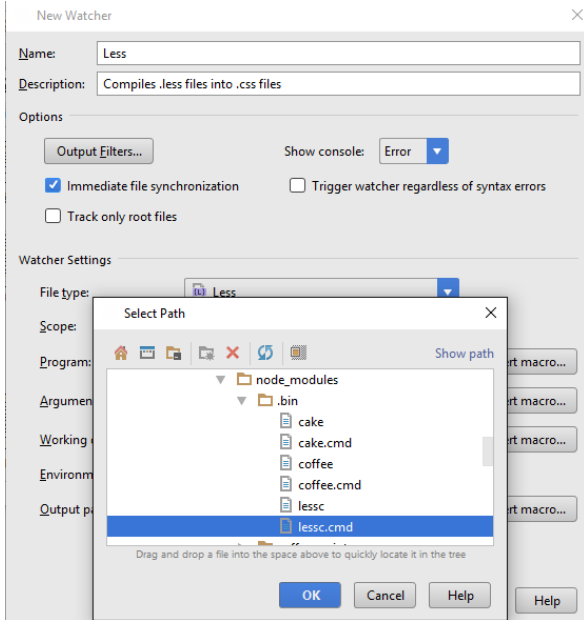

When IntelliJ IDEA detects that you are working with a file it can "watch," it prompts to set up a File Watcher.

## Configuring file watcher for LESS files

For example, when you open for editing a LESS file, IntelliJ IDEA shows a notification banner:

```
my.less x
File watcher 'Less' is available for this file. Description: 'Compiles .less files into .css files' Add watcher Dismiss
.h1
@myColor: #7fe599;
@myFontSize: 25px;
@myBorderColor: #1f7eff;
.h1 {
  color: saturate(@myColor, 5%);
  border-color: @myBorderColor;
  font-size: @myFontSize;
}
```

Click the link Add watcher. IntelliJ IDEA shows the following dialog box, where you have to specify your file watcher type (Less here), executable (`lessc.cmd` here), and select the option to generate output from stdout:

Looking at this configuration, you can easily figure out what the file watcher actually does:

- Watches for changes on all Less files within your project.
- Compiles files with the extension `.less` into the files with the extension `.css`, using the compiler `lessc.cmd`, specified in the field Program.

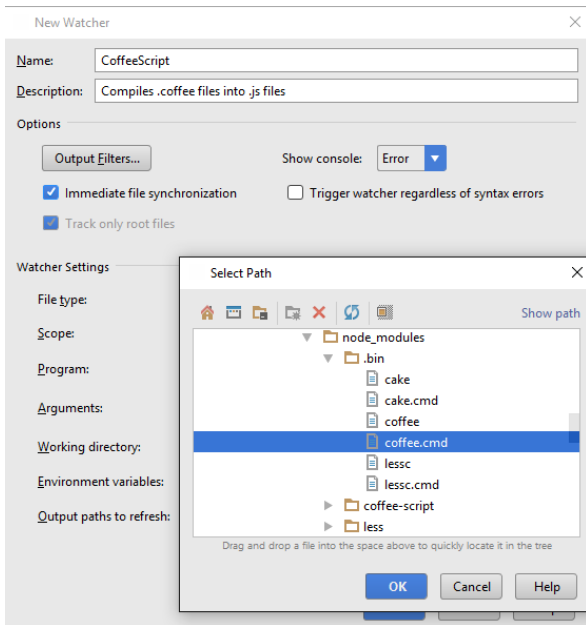

### Configuring file watcher for CoffeeScript

Next, open for editing a CoffeeScript file. IntelliJ IDEA immediately prompts you to configure a file watcher for it:

```
my.coffee x
File watcher 'CoffeeScript' is available for this file. Description: 'Compiles .coffee files into .js files' Add watcher Dismiss
# Assignment:
number = 42
opposite = true

# Conditions:
number = -42 if opposite
```

Again, click Add watcher and specify the file watcher settings, in particular, the CoffeeScript executable:

What does this file watcher do?

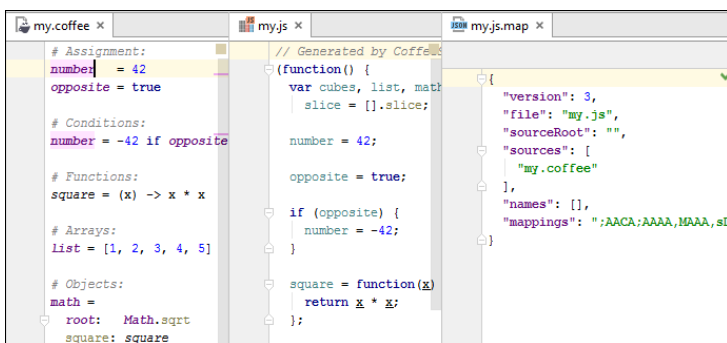

- It also tracks changes in all CoffeeScript files in your project.
- It compiles files with the extension `.coffee` into the files with the extension `.js`, using the compiler `coffee.cmd`, specified in the field Program.
- It compiles files with the extension `.coffee` into the files with the extension `.map`, using the compiler `coffee.cmd`, specified in the field Program.

## Editing file watchers

OK, here we are. Open for editing the file `my.less`, and change something, for example, rename the variable `@myColor` to `@Color`, and change its value. The file watcher immediately processes the changed source file, and produces an output file with the extension `.css`:

Next, open for editing a CoffeeScript file and change something there. The configured file watcher generates a JavaScript file and a source mapping file:

Note that in either case IntelliJ IDEA shows generated files in the [Project Tool Window](#) under the source files.

## Troubleshooting, or if an error occurs?

If a command line tool executed by the File Watcher fails, IntelliJ IDEA shows its output in the [Run tool window](#):

```
my.less x
.h1
@Color: #7fe599;
@myFontSize: 25px;
@myBorderColor: #1f7eff;
.h1 {
  color: @MyColor;
  border-color: @myBorderColor;
  font-size: @myFontSize;
}
Run Output
C:\Program Files (x86)\Microsoft Visual Studio\2019\Community\MSBuild\Tools\less.exe /D /C: C:\SampleProjects\SampleProjects\py\MyColor\
NameError: variable @MyColor is undefined in C:\SampleProjects\Sa
5 .h1 {
6   color: @MyColor;
7   border-color: @myBorderColor;
```

Helpful for troubleshooting, isn't it?

## Example code

Consider the following XML code fragment:

```
<new product="ij" category="105" title="Multiline search and replace in the current file" />
<new product="ij" category="105" title="Improved search and replace in the current file" />
<new product="ij" category="105" title="Regexp shows replacement preview" />
...
```

## Finding and replacing a string using regular expression

Suppose you want to replace an attribute within an element ( `title` ) with an expanded tag `<title></title>` , which contains some arbitrary string in double-quotes within.

This is how it's done.

1. With the XML file in question opened in the editor, press `Ctrl+R` . The Replace pane appears on top of the editor.
2. Since you want to replace all the `title` attributes, regardless of the actual strings contained therein, use regular expressions. Make sure that the checkbox `Regex` is selected. Thus everything you type in the Search and Replace fields will be perceived as the regular expressions.
3. In the Search field, start typing regular expression that describes all `title` attributes. Note that though the regular expression `\stitle=".*?"\s*(/>)*` matches contents of the `title` attribute, it is recommended to capture the groups for referencing them in the Replace field:

```
\stitle="(.*?)"\s*(/>)*
```

Note that for the regular expressions replacement preview is shown at the tooltip:

4. Then, in the Replace field, type the following regular expression:

```
$2<title>$1</title>
```

5. Click `Replace` , or `Replace All` .

As you see, the second capture group ( `/>` ) is moved ahead to close the `<new>` element, while the first capture group `<` , which matches any string in double quotes, is moved to the element `<title>` .

## Changing case of the characters

Suppose now that you want to change characters of the search strings. Again make sure that `Regex` checkbox is selected.

In the Search field, type the search expression:

```
\stitle="(.*?)"\s*(/>)*
```

Next, fill in the Replace field with the following expression:

```
\U$1
```

The found occurrences are replaced with the upper-case characters:

Next, let's make the strings all lower-case. To replace occurrences with the lower-case characters, type the following replacement string:

```
\L$1
```

Then the suggested replacement will be:

And finally, if you want change the case of the first letter only, type the following replacement string:

```
\l$1
```

IntelliJ IDEA suggests the following replacement:

On this page:

- [Introduction](#)
- [Renaming](#)
- [Extracting](#)
- [Deleting](#)
- [Conclusion](#)

## Introduction

IntelliJ IDEA offers a lot of [automatic refactoring capabilities](#), but as developers it's not enough to know how to perform them, we need to understand what these refactorings are, when we would want to apply them, and any possible downsides or things to consider before using them.

[Refactoring, as defined by Martin Fowler](#), "...is a disciplined technique for restructuring an existing body of code, altering its internal structure without changing its external behavior". Hence it's important before performing any refactoring in production code to have comprehensive [test coverage](#) to prove that you haven't inadvertently changed the behaviour.

The goal of this tutorial is to introduce those who may be new to the idea of refactoring, particularly automatic refactoring, to IntelliJ IDEA's capabilities and show when you might want to apply three of the basic types of refactoring: [Renaming](#), [Extracting](#) and [Deleting](#).

## Renaming

[Renaming](#) may seem like a trivial refactoring, but renaming via a simple find-and-replace often means unrelated items with the same name are unintentionally changed. Using IntelliJ IDEA's [rename refactorings](#) minimises these errors.

### Why Rename?

Renaming is one of the simplest things you can do to improve the readability of the code. When a class, method or variable name doesn't match what it appears to do, it can cause a lot of confusion. Some reasons why you might want to rename something:

1. The name is not descriptive enough
2. The class/method/variable name doesn't match the what it really is
3. Something new has been introduced, requiring existing code to have more specific name

### Renaming as you code

Imagine you come across the following code as you're implementing some feature or fixing some bug

```
server = new Server(path, port, endpoint);
server.init();
server.run();
```

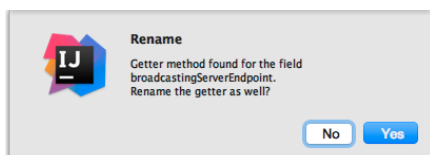

Let's assume that we want to:

- Rename `endpoint`, a field, to describe what sort of endpoint it is.
  - Rename `init()`, a method on `Server`, to something that more accurately describes that method.
  - Rename `Server`, a class, to something more specific.
1. To rename the `endpoint` field, place your cursor on the word endpoint and press `Shift+F6`. IntelliJ IDEA will pop up a list of suggestions, based on the class name and other aspects. In this case, the name of the parameter this field is used in is also suggested.

```
@Override
public void run() {
    try {
        server = new Server(path, port, endpoint);
        server.init();
        server.run();
    } catch (Exception e) {
        LOGGER.severe(e.getMessage());
    }
}
```

Select one of these options or type your own. If the field has a getter, IntelliJ IDEA will ask if you want to rename this as well.

You'll notice that all uses of this field are changed to the new name, and if you've chosen to rename the getter, other classes in your project will be updated to use the new name. See the next step for more information on method renaming.

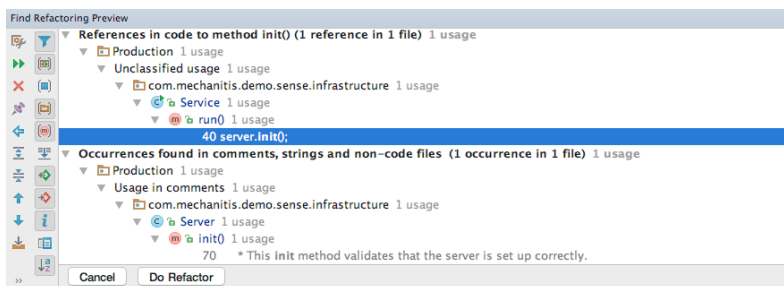

2. To rename the method, the process is the same: place your cursor on `init` and press `Shift+F6`. Here you'll have fewer suggestions, so type the new name:

```
@Override
public void run() {
    try {
        server = new Server(path, port, broadcastingServerEndpoint);
        server.validate();
    } catch (Exception e) {
        LOGGER.severe(e.getMessage());
    }
}
```

As well as renaming the method, this renames all calls of the method and all overridden/implemented methods in subclasses. IntelliJ IDEA can also rename non-code uses of the name too, which is useful if you have XML configuration or other non-Java files which refer to classes or methods. You can configure what gets renamed if you press `Shift+F6` a second time to bring up the rename dialog

If the rename will apply to more than just code, IntelliJ IDEA will preview the refactoring for you, so you can select which changes you want to make. Often in these cases you may choose not to rename occurrences in comments, especially if the original method name was a common word like `name`.

If you don't want to make some of these changes, press `Backspace` on the usages you do not want to change.

3. Renaming a class is similar, but can also be performed via the [Project Tool Window](#). In this case, because we've discovered we want to rename the class where we use it, we're going to use `Shift+F6` on the class name in the code.

```
@Override
public void run() {
    try {
        server = new WebSocketServer(path, port, broadcastingServerEndpoint);
        server.valid
        server.run()
    } catch (Exception e) {
        LOGGER.severe(e.getMessage());
    }
}
```

Of course, any code that uses this class will also be renamed, but you also have the option of renaming variables, inheritors and other parts of the code so they're aligned with the new name. Again, these options can be set by pressing `Shift+F6` a second time.

## Impact of renaming

Renaming local variables or private methods can be done fairly safely on-the-fly. For example, while you're working on a piece of functionality that touches this area of code, you can perform this refactoring knowing the impact is limited in scope.

Renaming classes or public methods could potentially impact a lot of files. If this is the case, this sort of refactoring should, at the very least, be in its own separate commit so the changes are clearly separated from any changed or additional functionality that you may have been working on at the time.

## Extracting

IntelliJ IDEA's [extract refactorings](#) give developers the power to reshape their code when it becomes clear the current design, whether on a small or large scale, is no longer fit for purpose.

### Extract variable

[Extract variable](#) is a low impact change to make your code [code self-documenting](#). It can also be used to reduce code duplication.

Imagine you come across the following code

```

static String getUsernameFromMessage(String message) {
    return message.substring(message.indexOf("\"screen_name\": \"") + 15,
        message.indexOf("\"", message.indexOf("\"screen_name\": \"") + 15));
}

```

We can use extract variable to improve the readability of this code by:

- Removing the duplication of `message.indexOf("\"screen_name\": \"") + 15)`
- Introducing variables to describe what each of the `indexOf` calls represent
- Removing the magic number 15

1. First, let's reduce the duplication and introduce a variable that describes what this operation is doing. Place your cursor anywhere in the expression `message.indexOf("\"screen_name\": \"") + 15)` and press `(Ctrl+Alt+V)`. IntelliJ IDEA will suggest a context for this refactoring, and you want to choose the one that encapsulates this expression:

```

static String getUsernameFromMessage(String message) {
    return message.substring(message.indexOf("\"screen_name\": \"") + 15,
        message.indexOf("\"", message.indexOf("\"screen_name\": \"") + 15));
}

```

Next, if IntelliJ IDEA has detected this expression occurs more than once, you have the option to replace all the occurrences or just the one you selected.

```

static String getUsernameFromMessage(String message) {
    return message.substring(message.indexOf("\"screen_name\": \"") + 15,
        message.indexOf("\"", message.indexOf("\"screen_name\": \"") + 15));
}

```

Once the variable is extracted, IntelliJ IDEA suggests possible names based on things like the parameter the expression was used in.

```

static String getUsernameFromMessage(String message) {
    final int beginIndex = message.indexOf("\"screen_name\": \"") + 15;
    return message.substring(beginIndex,
        message.indexOf("\"", beginIndex));
}

```

We're going to use our own name, `indexOfFieldValue`, to describe what this really represents. Note that you can decide whether or not you wish this variable to be final.

2. Next we're going to introduce a variable for the String value. There's two reasons for this: firstly, to document what the String value represents, and secondly because it will help us to remove the magic number.

Place your cursor somewhere on `screen_name` and press `(Ctrl+Alt+V)`.

```

static String getUsernameFromMessage(String message) {
    final int indexOfFieldValue = message.indexOf("\"screen_name\": \"") + 15;
    return message.substring(indexOfFieldValue,
        message.indexOf("\"", indexOfFieldValue));
}

```

We're going to give this a more meaningful name, `fieldName`.

```

static String getUsernameFromMessage(String message) {
    final String fieldName = "\"screen_name\": \"";
    final int indexOfFieldValue = message.indexOf(fieldName) + 15;
    return message.substring(indexOfFieldValue,
        message.indexOf("\"", indexOfFieldValue));
}

```

3. Now, we're going to create a variable for the other expression used as a parameter to `substring()`, using the same process, and we'll call this `indexOfEndOfFieldValue`.

```

static String getUsernameFromMessage(String message) {
    final String fieldName = "\"screen_name\": \"";
    final int indexOfFieldValue = message.indexOf(fieldName) + 15;
    final int indexOfEndOfFieldValue = message.indexOf("\"", indexOfFieldValue);
    return message.substring(indexOfFieldValue,
        indexOfEndOfFieldValue);
}

```

4. Finally, we can remove the magic number, as this is just the length of the field name. The final code looks like:

```

static String getUsernameFromMessage(String message) {
    final String fieldName = "\"screen_name\": \"";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\"", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

```

It's longer than the original, but it's much more descriptive, which is particularly important in code like this where it's not clear what each expression represents. The choice of applying `final` or not is up to you, and depends upon your coding standards.

## Extract parameter

[Extracting](#) or [adding a parameter](#) allows a developer to change a method so that it's easier to use. You may want to change the parameters, for example by passing in some values from an Object rather than the object itself, or you may want to introduce a value from the method body as a parameter to allow the method to be used in more places. We're going to look at an example of the latter.

For this example, we're going to use the same code as the last example, after it has been refactored, and extend it slightly to show another method in the same class:

```
static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

static String getUsernameFromMessage(String message) {
    final String fieldName = "\\screen_name\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

Our goal is to remove the duplication of code that we see in these two methods. To do that, we're going to:

- Change `fieldName` into a parameter so that we can make the `getUsernameFromMessage` method apply to any field.
- Rename `getUsernameFromMessage` to something which represents its more general nature
- Remove the duplication of code in `getTextFromMessage`.

1. Place your cursor on `fieldName` and press `Ctrl+Alt+P`

As with the other refactorings, you can type a new name for the parameter if you wish. IntelliJ IDEA also previews the updated method signature. Press `Enter` to approve the changes.

This particular issue tells us the method is being used as a method reference, and this change will result in the method reference being converted into a lambda expression. This message could be a sign that this is not the refactoring you wish to perform. If this is the case, the next example shows an approach we could take using Extract Method. However, for this example we'll assume we're happy with the consequences of introducing a new parameter, so we'll just select Continue.

Next, IntelliJ IDEA will detect any code which can now be replaced with a call to the new method signature.

```

static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf(";", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

static String getUsernameFromMessage(String message, String fieldName) {
    final int indexOfField... Process Method getUsernameFromMessage Duplica... length();
    final int indexOfEndOf... value);
    return message.substri
}

```

If you select Replace in this case, all the duplicate code will be replaced, and IntelliJ IDEA will select the appropriate value to pass in for the new parameter.

- At this point, the original method `getUsernameFromMessage` is more general than it was, so we should rename it. We put our cursor on the name and use `Shift+F6`, as shown in the previous section.

```

static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:";
    return getValueForField(message, fieldName);
}

static String getValueForField(String message, String fieldName) {
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf(";", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

```

- We can simplify the code further. `Inline` is the inverse of `extract`, and in the code we have here it may be appropriate to [inline our temporary variable](#), as the variable name gives us little more than having the value passed directly into the method. Or, given that `getTextFromMessage` really is a simple delegation to `getValueForField`, we can use `inline` to remove this method completely.

To inline, place your cursor on the `getTextFromMessage` variable and press `Ctrl+Alt+N`

```

static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:";
    return getValueForField(message, fieldName);
}

```

- Now our final code looks like:

```

static String getValueForField(String message, String fieldName) {
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf(";", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

```

Our code that was calling the original `getUsernameFromMessage` method was:

```
Parser::getUsernameFromMessage
```

and is now

```
(message) -> Parser.getValueForField(message, "\\screen_name\\:")
```

Our code that was calling the original `getTextFromMessage` method was:

```
String[] wordsInMessage = Parser.getTextFromMessage(message).split("\\s");
```

and is now

```
String[] wordsInMessage = Parser.getValueForField(message, "\\text\\:").split("\\s");
```

Note that the way we applied this refactoring forces all callers to pass in the field name and a) spreads the use of a String value around your code and b) may introduce duplication of one or more of these String values. This may be appropriate for your code, especially if the String duplication is dealt with, or the method is not frequently used. However, if this is not a trade off you wish to make for reducing the duplication of code, see the next chapter for an alternative approach.

Extract parameter can be very powerful, so it's worth reading the [more detailed help page](#).

## Extract method

One way to aid code readability is to have it in small, understandable sections. [Extract method](#) allows a developer to do just that, moving segments of code into their own, descriptively-named, method when appropriate.

Some developers may find themselves writing long methods that perform the operation they have in mind, and when they've completed (and tested) the functionality, look at the code to see where it can be refactored and

simplified and break up these longer methods. Or, as a developer comes across code when they're implementing a new feature, they realise extracting some code into its own method lets them reuse existing functionality.

**Tip** When IntelliJ IDEA detects duplicate code this is a very good candidate for creating a new method that can be called by all of the places that has the duplicate code.

We're going to look at the same example as in the previous section, but take a slightly different approach to before.

```
static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

static String getUsernameFromMessage(String message) {
    final String fieldName = "\\screen_name\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

As we saw earlier, the previous refactoring had some trade-offs: a method reference needed to be converted to a lambda expression, and all calling code needed to know the field name that was required. We may choose to remove the code duplication between the two methods in a different way:

– Extracting the common code into its own method.

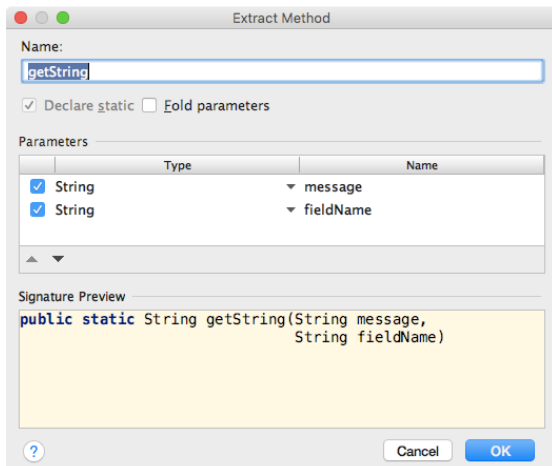

– Inlining variables to simplify the remaining code.

1. First, highlight the code that's common between the two methods:

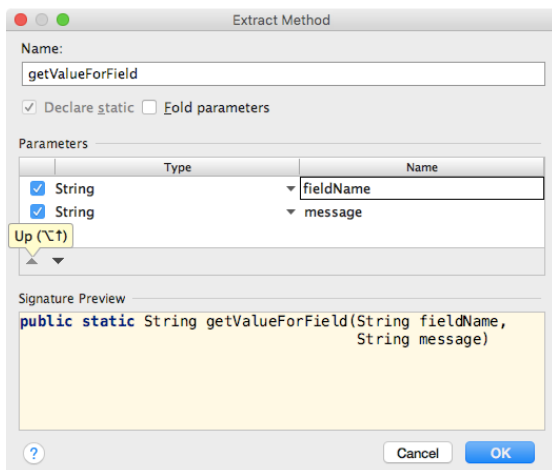

```
static String getTextFromMessage(String message) {
    final String fieldName = "\\text\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}

static String getUsernameFromMessage(String message) {
    final String fieldName = "\\screen_name\\:\\\\";
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("\\", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

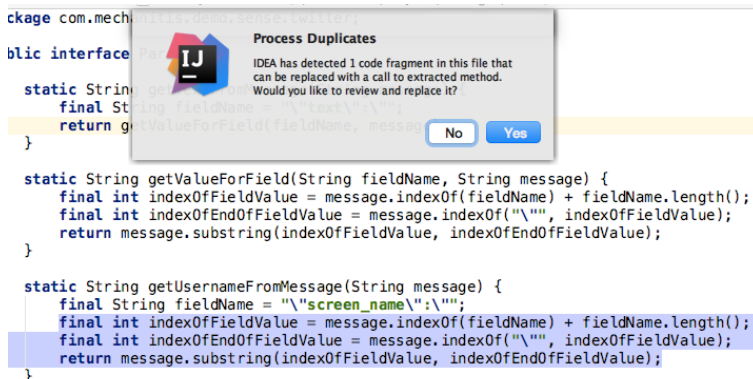

Pressing `Ctrl+Alt+M` will bring up the [Extract Method Dialog](#).

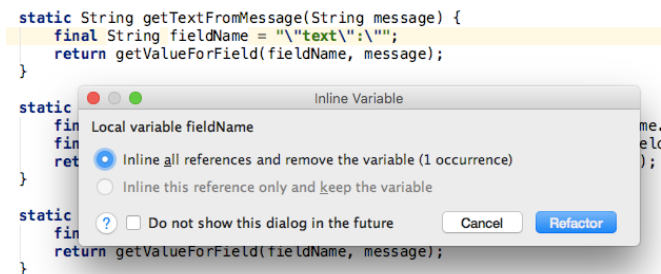

Type the name of the new method, `getValueForField`, and check the parameter names and order. In this case, we're going to swap the order of the parameters because we prefer the `fieldName` parameter to be closer to the name of the method. This will depend upon your code style and team preferences, you might like to read the name and parameters aloud to see if it makes sense as a statement in natural language.

When you press OK, IntelliJ IDEA will detect code that can be replaced with a call to this new method, and will offer to refactor that too. We're going to select Yes.

- At this point, our `getTextFromMessage` and `getUsernameFromMessage` methods are two lines of simple code, and here it makes sense to `inline` the `fieldName` variable, as the method name is descriptive enough to remove the `temporary variable`. Press `Ctrl+Alt+N` on `fieldName` and select Refactor.

- As a last touch, you may want all similar methods grouped together. Depending upon your settings, IntelliJ IDEA may have placed the new method directly under the method you were in when you chose to extract the method, as in our case here. To put the helper methods next to each other, put your cursor on the `getValueForField` method name and press `Ctrl+Shift+Down`. This will place your new method, `getValueForField`, under the existing `getUsernameFromMessage` method.

Our final code looks like:

Now we have two very specific helper methods which get the message body and the username, and a more general method that can be used to get the value of any field from the message. Additional helper methods can be added when there are other fields which are frequently needed.

Note that the Extract Parameter and Extract Method examples start with the same code, but end with code that

looks very different. This is not just because we used a different refactoring, but because we made different decisions - in the first example, we chose to remove duplication completely, and move some of the decision-making into the caller of the method. In the second example, we chose to provide an API which hid the details of the the field name behind small helper methods but still provide the more general method as well. We also could have mixed and matched the approaches, the refactoring we chose to begin with may have lead us in a particular direction but we can dictate our final destination. We should remember the goal of our refactoring (in this case, reduce duplication) and understand the trade offs we're making when we choose one direction over another, for example deciding whether we want calling code to know which field name they're asking for.

## Impact of extracting

The good news is that you can undo an extract fairly easily. Not only by selecting `Ctrl+Z`, of course, but by [inlining](#) the created method so that the code is back where it used to be.

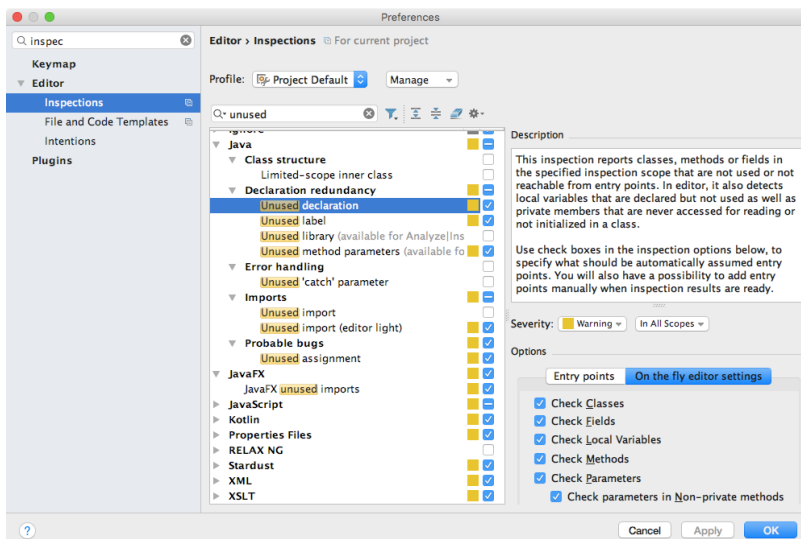

The [extract refactorings](#) we've mentioned here are used regularly by experienced developers to shape the code as it evolves, and it would not be uncommon to use them to some greater or lesser extent every time the code is touched. Some of the ones that were not covered, like [extract interface](#) and [extract superclass](#), may have a wider impact on the overall design, and more care should be taken with them.

## Deleting

Sometimes when you've refactored code in several steps, you can end up with code that is no longer used, or ideally should not be used. As the goal of refactoring is simplification, you should always aim to remove unused code where you can - regardless of any impact (or not) unused code has on the performance of your application, unused code definitely takes a toll on developers working with and trying to understand the application.

## Safe delete

IntelliJ IDEA lets you [safe delete](#) unused code fragments or whole files, informing you if it's safe to delete the code, and giving you the option to preview the changes before you make them. The fastest way to identify and deal with unused code is to make sure the relevant inspections are enabled, which they usually are by default:

Let's continue the example of our previous refactoring. Assuming we ended up with this code:

```
static String getUsernameFromMessage(String message) {
    return getValueForField("\screen_name\":"", message);
}

static String getValueForField(String fieldName, String message) {
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

It's possible that some time later, when we come back to this code, the `getUsernameFromMessage` method is no longer used - maybe it's no longer required, or maybe people are comfortable calling `getValueForField` with the relevant parameter. So assuming we're comfortable with these reasons, we can go ahead and remove this method.

1. If the unused declaration inspection is turned on, the method name will be in grey to represent that it is unused.

```
static String getUsernameFromMessage(String message) {
    return getValueForField("\screen_name\":"", message);
}

static String getValueForField(String fieldName, String message) {
    final int indexOfFieldValue = message.indexOf(fieldName) + fieldName.length();
    final int indexOfEndOfFieldValue = message.indexOf("", indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

- Place the cursor in `getMessageFromMessage` and press `Alt+Enter`. This will give you the option to delete this method.

```
static String getMessageFromMessage(String message) {
    return getValueForField("username", message);
}

static String getValueForField(String fieldName, String message) {
    final int indexOfFieldValue = message.indexOf(fieldName);
    final int indexOfEndOfFieldValue = message.indexOf(fieldName, indexOfFieldValue);
    return message.substring(indexOfFieldValue, indexOfEndOfFieldValue);
}
```

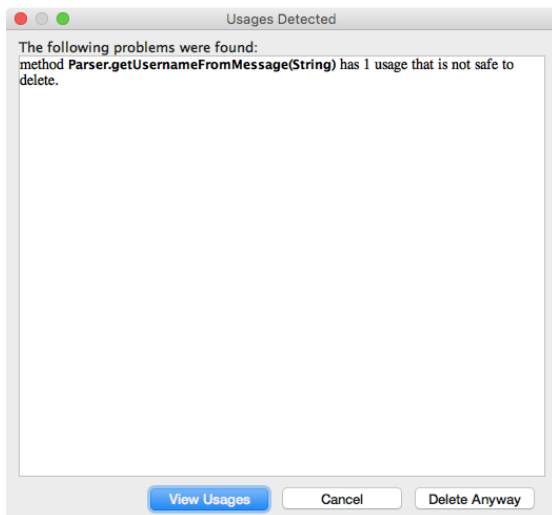

- Selecting safe delete will pop up the safe delete dialog, allowing you to search for usages of this method.

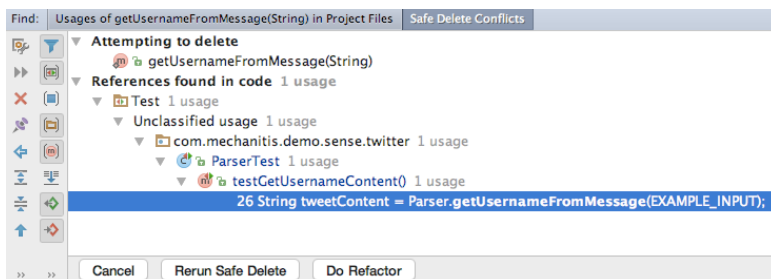

Press OK to go ahead and do the search. In our case, it was completely safe to delete, so the method is removed.

- It's possible that our "unused" method is not flagged as unused, as it may be covered by a test. But if we still know that it's unused, or have checked it via `Alt+F7`, we can still safely delete it.

Place the cursor on the method name and press `Alt+Delete`. This will pop up the safe delete dialog as before, and this time when you press OK IntelliJ IDEA will warn you that this method has usages

Press View Usages to check what these are

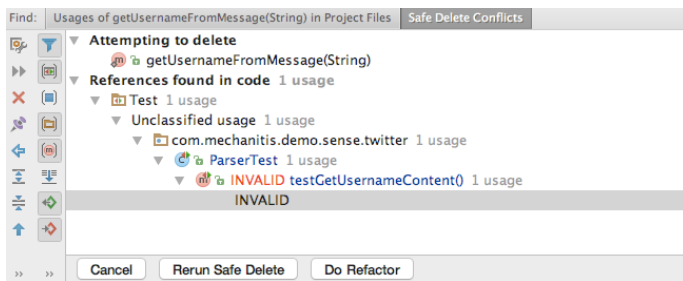

- Use the results panel to navigate to the usages by double-clicking on each usage. In our case, we see there's a test that calls the method we want to delete.

```
@Test
@DisplayName("should return the username from the full JSON")
void testGetUsernameContent() {
    String tweetContent = Parser.getMessageFromMessage(EXAMPLE_INPUT);
    assertEquals(MESSAGE_BODY, tweetContent);
}
```

Since this test is there to ensure the correctness of a method we no longer want, we can delete this test too. In the editor window, press `Alt+Delete` on the test method name and say OK in the Safe Delete dialog. The test method will be removed.

- Now we'll see in our Safe Delete Conflicts window that this code is no longer valid.

Since this was our only usage of the method we originally wanted to delete, we can select the Rerun Safe Delete button. This time when you press OK on the Safe Delete dialog, the `getMessageFromMessage` method will have been removed.

## Impact of deleting

**Tip** If you find a public method that appears to be unused but does form part of a public API, it should be covered by tests. The "unused" warning may not mean you should delete the method, it's telling you this method should be tested.

IntelliJ's inspections can show you code that is unused, but if your code is going to be packaged as a library for others to use, or exposes a public API in some other way, it's possible that some public symbols may be marked as unused when in actual fact they are used by code that you do not control. If public symbols appear to be unused, you should check if these are used by other systems in some way.

Unused parameters, local variables, and private fields are good candidates for deletion as it should be easy to see that deleting them does not impact any functionality.

Using safe delete to remove symbols, whether they were unused or not, lets you check before you perform the refactoring that the areas impacted are the ones you expect, and gives you control over the changes you wish to apply. However, still be aware of the caveat that public symbols may be used by systems out of your control, so always exercise caution when deleting these.

## Conclusion

IntelliJ IDEA has a number of automatic refactorings available, all of which aim to let you, the developer, reshape your code in as low-impact way as possible. The aim is to make small, incremental changes, all the time keeping the code in a state that compiles. The power of the refactoring capabilities lies in chaining smaller changes together to move the code in the direction of some goal that you have in mind: reducing duplication, removing unnecessary code, striving for simplicity, improving readability, or some larger re-shaping of the design.

Small, simple changes are possible, even desirable, while working on new features or bug fixing, but remember that larger changes may need to be applied separately to differentiate between refactoring that should not impact existing functionality and functional changes.

When you have a method with lots of conditional logic (i.e., if statements), you're asking for trouble. Conditional logic is notoriously difficult to manage, and may cause you to create an entire state machine inside a single method.

- [Analyzing the sample application](#)
- [Creating and running test](#)
- [Extracting methods](#)
- [Using Extract Delegate refactoring](#)
- [Fine tuning](#)
- [Implementing the abstract class](#)
- [Happy end](#)

## Analyzing the sample application

Here's a short example. Let's say, there is a method that calculates insurance costs based on a person's income:

```
package ifs;

public class IfElseDemo {

    public double calculateInsurance(double income) {
        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            return (income-60000)*0.02+105600;
        }
    }
}
```

Let's analyze this example. Here we see the four "income bands widths", separated into four calculation strategies. In general, they conform to the following formula:

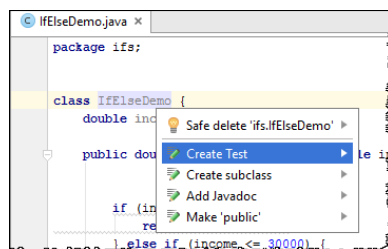

$$(income - adjustment) * weight + constant$$

Our goal is to provide separate classes to calculate each strategy, and transform the original class to make it more transparent.

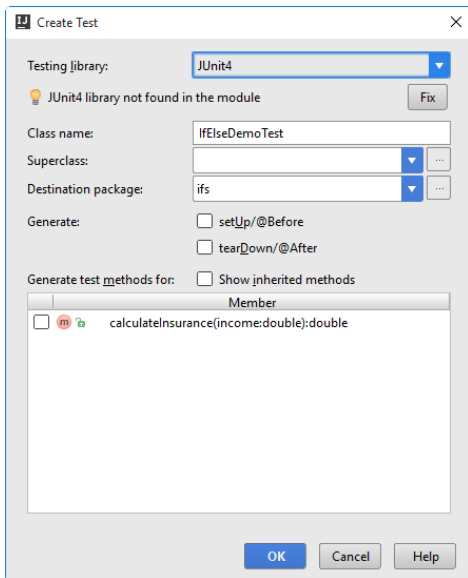

## Creating and running test

First of all, let's make sure that the class works. To do that, create a test class, using the [JUnit4](#) testing framework.

Place the caret at the class name, and then press `Alt+Enter` (or click ). From the list of suggested intention actions, choose Create Test:

In the [Create Test](#) dialog, choose JUnit4 from the Testing library drop-down list, click Fix, if you do not have JUnit library, and then click OK:

The stub test class is created. However, you have to provide some meaningful code, using the provided quick fix (🔧) to create import statement:

```
import org.junit.Test;

import static org.junit.Assert.*;

public class IfElseDemoTest {
    @Test
    public void low() {
        assertEquals(1825, insuranceFor(5000), 0.01);
    }

    @Test
    public void medium() {
        assertEquals(38600, insuranceFor(25000), 0.01);
    }

    @Test
    public void high() {
        assertEquals(78500, insuranceFor(50000), 0.01);
    }

    @Test
    public void veryHigh() {
        assertEquals(106400, insuranceFor(100_000), 0.01);
    }

    private double insuranceFor(double income) {
        return new IfElseDemo().calculateInsurance(income);
    }
}
```

Now let's run this test by clicking the run button ▶ in the left gutter, or by pressing `Ctrl+Shift+F10` :

All 4 tests pass:

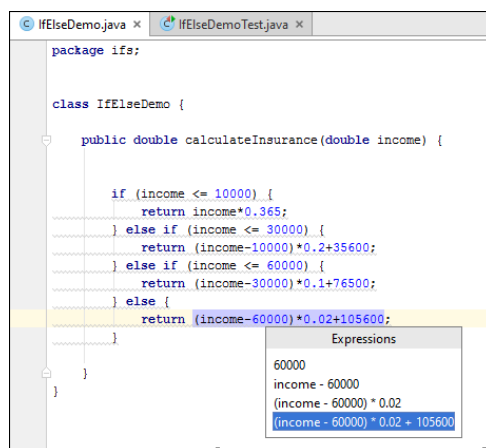

Extracting methods

Next, bring forward the original class, place the caret at the expression

```
(income-60000)*0.02+105600
```

and invoke **Extract Method Dialog** dialog (**Ctrl+Alt+M**):

You get the following code:

```
package ifs;

class IfElseDemo {

    public double calculateInsurance(double income) {
        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            return calculateInsuranceVeryHigh(income);
        }
    }

    public double calculateInsuranceVeryHigh(double income) {
        return (income-60000)*0.02+105600;
    }
}
```

Next, use the same Extract Method refactoring for for 60000, 0.02 and 105600 fragments, and create the methods

`getAdjustment` , `getWeight` and `getConstant` :

```

package ifs;

class IfElseDemo {

    public double calculateInsurance(double income) {
        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            return calculateInsuranceVeryHigh(income);
        }
    }

    public double calculateInsuranceVeryHigh(double income) {
        return (income- getAdjustment())* getWeight() + getConstant();
    }

    public int getConstant() {
        return 105600;
    }

    public double getWeight() {
        return 0.02;
    }

    public int getAdjustment() {
        return 60000;
    }
}

```

## Using Extract Delegate refactoring

Next, select all the methods created in the previous chapter, and invoke the [Extract Delegate](#) refactoring:

The newly created class has the name `InsuranceStrategyVeryHigh`.

Then delete all the selected methods from the class `IfElseDemo`. Thus you get the following two classes:

```

package ifs;

class IfElseDemo {

    private final InsuranceStrategyVeryHigh insuranceStrategyVeryHigh = new InsuranceStrategyVeryHigh();

    public double calculateInsurance(double income) {

        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            return insuranceStrategyVeryHigh.calculateInsuranceVeryHigh(income);
        }
    }
}

```

and

```

package ifs;

public class InsuranceStrategyVeryHigh {
    public InsuranceStrategyVeryHigh() {
    }

    public double calculateInsuranceVeryHigh(double income) {
        return (income - getAdjustment()) * getWeight() + getConstant();
    }

    public int getConstant() {
        return 105600;
    }

    public double getWeight() {
        return 0.02;
    }

    public int getAdjustment() {
        return 60000;
    }
}

```

## Fine tuning

This code requires some modifications. First, let's change the class `IfElseDemo` :

- Rename ( `Shift+F6` ) the field `insuranceStrategyVeryHigh` to `strategy`
- Make this field not final.
- Using the intention action, split it into declaration and initialization:

```

package ifs;

class IfElseDemo {
    private InsuranceStrategyVeryHigh insuranceStrategyVeryHigh = new InsuranceStrategyVeryHigh();

    public double calculateInsurance(double income) {
        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            return strategy.calculateInsuranceVeryHigh(income);
        }
    }
}

```

- Move the initialization down to the corresponding `if-else` branch.

Get the following code:

```

package ifs;

class IfElseDemo {

    private InsuranceStrategyVeryHigh strategy;

    public double calculateInsurance(double income) {

        if (income <= 10000) {
            return income*0.365;
        } else if (income <= 30000) {
            return (income-10000)*0.2+35600;
        } else if (income <= 60000) {
            return (income-30000)*0.1+76500;
        } else {
            strategy = new InsuranceStrategyVeryHigh();
            return strategy.calculateInsuranceVeryHigh(income);
        }
    }
}

```

Next, let's modify the class `InsuranceStrategyVeryHigh` - invoke the [Extract Superclass](#) refactoring for it.

Mind the settings in the [Extract Superclass Dialog](#) dialog:

- The name of the superclass to be generated is `InsuranceStrategy` .
- All the methods of the class `InsuranceStrategyVeryHigh` are checked - it means that they will be included in the superclass.
- The method `calculateInsuranceStrategyVeryHigh` remains non-abstract; all the other methods are made abstract by selecting the Make Abstract checkboxes.

Agree to replace the usage of `InsuranceStrategyVeryHigh` class (in `IfElseDemo` class) with the superclass, and get the following `InsuranceStrategy` class:

```

package ifs;

public abstract class InsuranceStrategy {
    public double calculateInsuranceVeryHigh(double income) {
        return (income - getAdjustment()) * getWeight() + getConstant();
    }

    public abstract int getConstant();

    public abstract double getWeight();

    public abstract int getAdjustment();
}

```

## Implementing the abstract class

Next, for this abstract class, use Implement Abstract Class intention to create implementations for all strategies:

Name the new implementation classes `InsuranceStrategyLow`, `InsuranceStrategyMedium` and `InsuranceStrategyHigh`.

For all new implementations provide correct `return` statements for the methods `getAdjustment()`, `getWeight()` and `getConstant()`.

Thus all implementation classes should look similar to the class `InsuranceStrategyVeryHigh`, but with strategy-specific adjustment, weight and constant. For example:

```

package ifs;

public class InsuranceStrategyMedium extends InsuranceStrategy {
    @Override
    public int getConstant() {
        return 35600;
    }

    @Override
    public double getWeight() {
        return 0.2;
    }

    @Override
    public int getAdjustment() {
        return 10000;
    }
}

```

Note that in all newly created implementation classes the class names are grey - they are not used so far.

Next, bring forward the class `IfElseDemo`, and modify all the branch bodies so that they initialize the `strategy` field, like in the last branch:

```

package ifs;

class IfElseDemo {

    private InsuranceStrategy strategy;

    public double calculateInsurance(double income) {

        if (income <= 10000) {
            strategy = new InsuranceStrategyLow();
            return strategy.calculateInsuranceVeryHigh(income);
        } else if (income <= 30000) {
            strategy = new InsuranceStrategyMedium();
            return strategy.calculateInsuranceVeryHigh(income);
        } else if (income <= 60000) {
            strategy = new InsuranceStrategyHigh();
            return strategy.calculateInsuranceVeryHigh(income);
        } else {
            strategy = new InsuranceStrategyVeryHigh();
            return strategy.calculateInsuranceVeryHigh(income);
        }
    }
}

```

Finally, rename the method `calculateInsuranceVeryHigh` : bring forward the class `InsuranceStrategy` , place the caret at the method name and press `Shift+F6` . The new name should be `calculate` .

## Happy end

And finally enjoy the code:

```

package ifs;

class IfElseDemo {

    private InsuranceStrategy strategy;

    public double calculateInsurance(double income) {
        if (income <= 10000) {
            strategy = new InsuranceStrategyLow();
            return strategy.calculate(income);
        } else if (income <= 30000) {
            strategy = new InsuranceStrategyMedium();
            return strategy.calculate(income);
        } else if (income <= 60000) {
            strategy = new InsuranceStrategyHigh();
            return strategy.calculate(income);
        } else {
            strategy = new InsuranceStrategyVeryHigh();
            return strategy.calculate(income);
        }
    }
}

```

Next, let's run the test class again. All tests should pass – we have refactored the code, but it still produces the same results.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when RubyPlugin is installed and enabled!

In this section:

- [Introduction](#)
- [Prerequisites](#)
- [Opening from the Welcome Screen](#)
- [Configuring Ruby SDK](#)
- [Importing a module and configuring a separate SDK for it](#)

## Introduction

In this tutorial we'll learn how to open already existing Rails project in IntelliJ IDEA for the first time (next time you'll be able to open it in a normal manner) and configure Ruby SDK for it.

## Prerequisites

Before you start working with Ruby on Rails, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

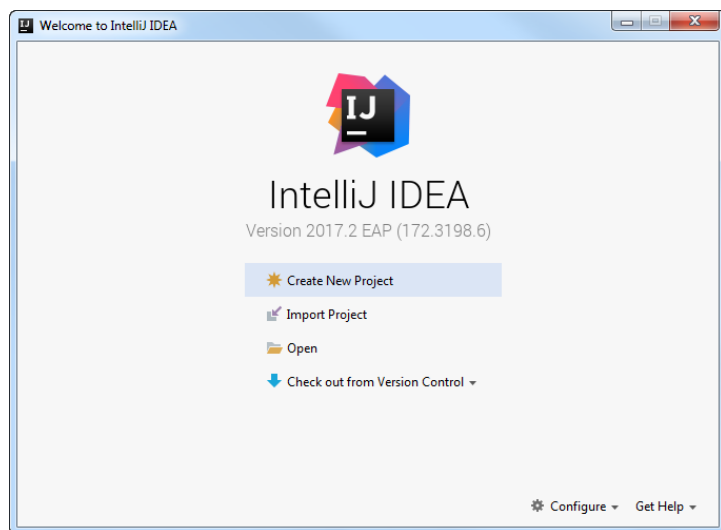

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

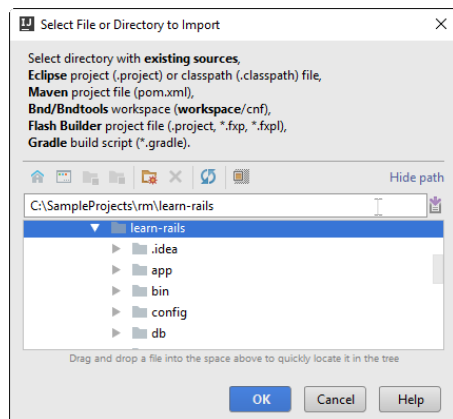

- [Ruby](#)
- [Ruby on Rails](#)

## Opening from the Welcome Screen

Open IntelliJ IDEA and choose Import Project from the [Welcome Screen](#) :

Select the directory of your project:

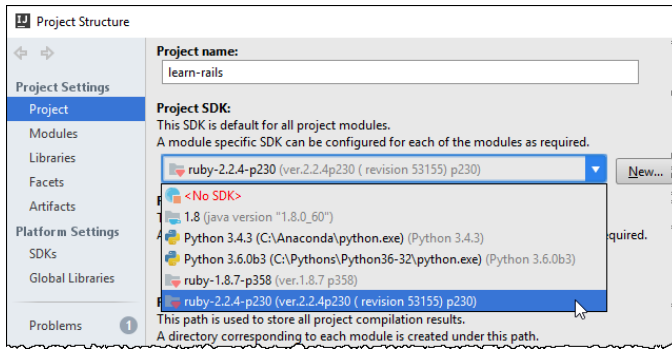

Then follow the steps of the wizard.

**Note** IntelliJ IDEA will offer the same steps when opening a project from the main menu ( File | New | Project from Existing Sources ).

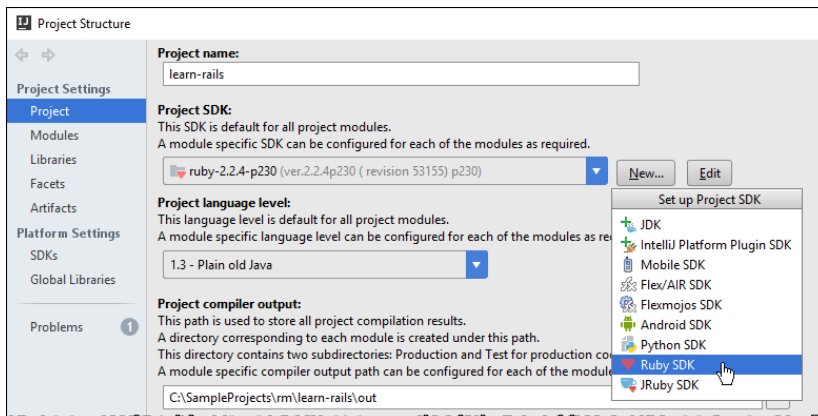

## Configuring Ruby SDK

Once you've imported your Rails application, you need to configure a Ruby SDK. To do that, choose Project Structure... on the File menu (or click  on the main toolbar).

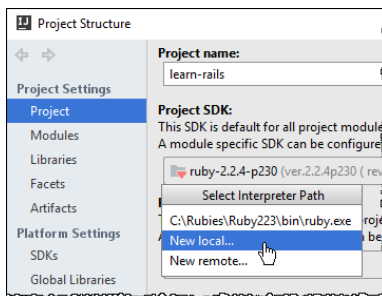

Then, under the section Project Settings , click Project and specify Ruby SDK to be used:

If the desired SDK is not present in list of the available SDKs, click New , and select Ruby SDK or JRuby SDK :

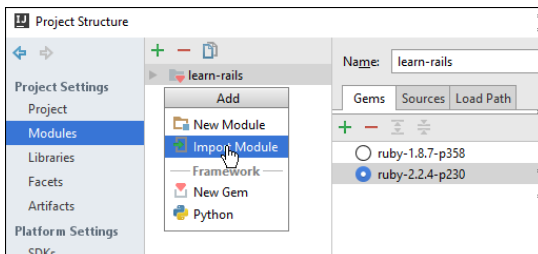

Then, from the pop-up window, choose the type of SDK to be configured (local, remote or an existing one):

## Importing a module and configuring a separate SDK for it

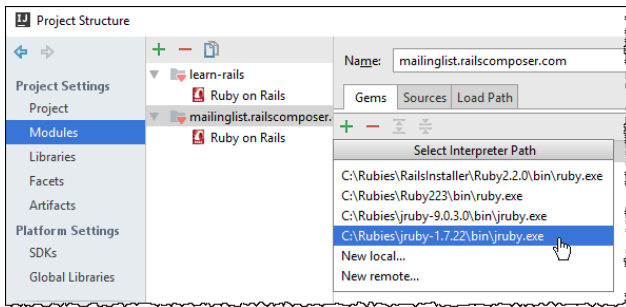

IntelliJ IDEA enables you to import an existing module. This is how it's done:

1. In the **Modules** of the Project Structure dialog, click .
2. Choose Import Module from the pop-up menu:

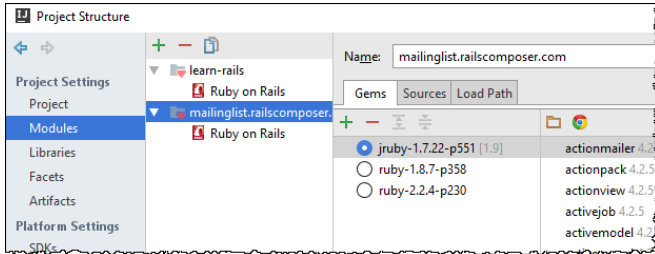

3. Specify the directory of the module to be imported, and follow the steps of the wizard.

IntelliJ IDEA enables you to specify an SDK other than the project SDK. To do that, select the imported module, in the **Gems** tab click , and then select the desired interpreter from the pop-up menu:

You see that the imported module has a different SDK:

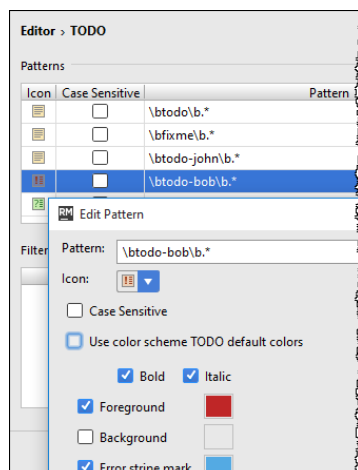

Note also that IntelliJ IDEA has correctly detected the Ruby on Rails framework.

Consider the following example: creating and viewing TODO items for each of the team members.

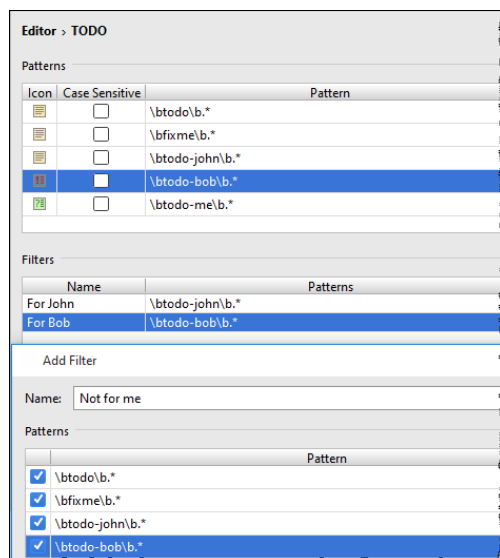

## Creating patterns for TODO items

On the **TODO** page of the Settings dialog, click **+** in the Patterns section, and **create additional TODO patterns**, for example, `todo-John`, `todo-Bob` and `todo-me`, with new icons, and custom color schemes:

## Creating filters

Next, create several filters, which you will use to show the TODO items, say, for each of the developers, and not for your good self. For this purpose, in the Filters section, click **+**, and specify the filter names, for example, `For John`, `For Bob`, and `not for me`. Associate these filters with the patterns:

## Creating TODO items in source code

Now, in the source code, create TODO items: in the line of code, where you want to add a note, press `Ctrl+Slash`, or `Ctrl+Shift+Slash`, and type `TODO` that matches one of the patterns, followed by some meaningful description:

```
//TODO-bob region Description
mach = {
  root: Math.sqrt,
  square: square,
  cube: function(x) {
    return x * square(x);
  }
};
race = function() {
  var runners, winner;
// todo-me have a break
  //endregion
//TODO-john fix
  winner = arguments[0], runners = 2
```

## Viewing TODO items

Having produced a number of TODO items across the whole project, review them in the TODO tool window: click the **TODO** button on the tool window bar to show the tool window. By default, all the encountered TODO items are displayed.

Let's now show the TODO items for Bob and John, and hide the other items: click the filter icon **▼** on the toolbar of the TODO tool window, and select `Not for me` in the menu:

TODO:	Project	Current File	Scope Based
↑	Found 2 TODO items in 1 file		
↓	JavaScript (2 items in 1 file)		
?	numbers.js		
		(16, 3) //todo-bob comment	
		(74, 4) //todo-john review	
	✓ Show All		
	myFilter		
	For John		
	For Bob		
	For me		
	Not for me		

## Overview

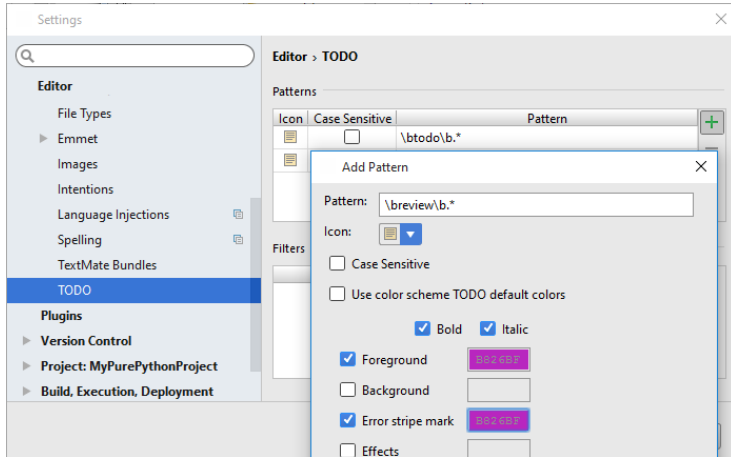

Let's explore an advanced IntelliJ IDEA's facility to create a [live template](#) for the TODO items' text. Why do we need it at all? For example, you want your team mates to create unified TODO items, with the user name automatically filled in, followed by some arbitrary text.

This is how it's done.

## Creating TODO pattern and filter

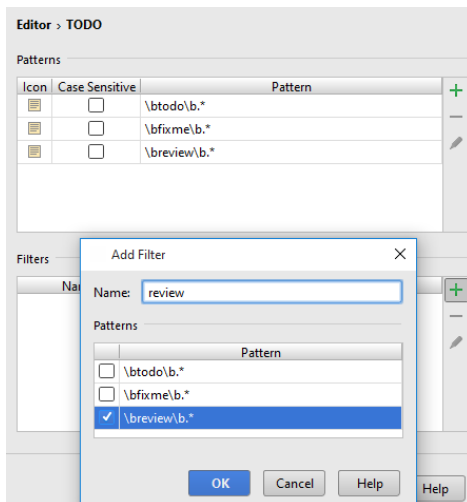

Open the Settings/Preferences dialog, and under the Editor section, click [TODO](#).

[Create pattern](#) `review`. To do that, click [+](#) in the Patterns section:

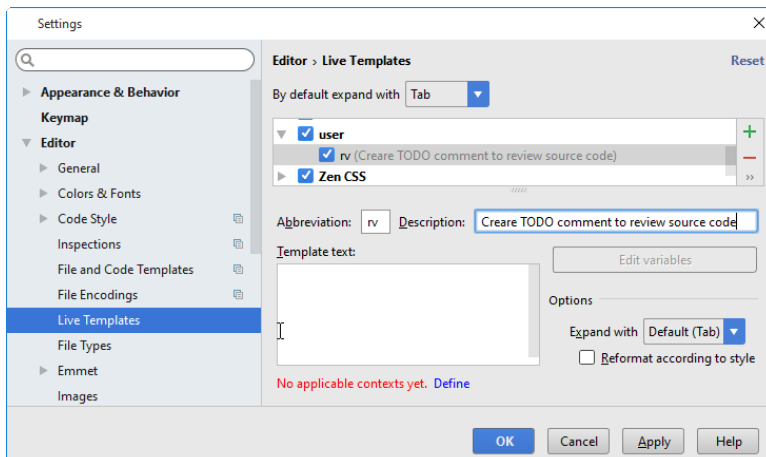

Define color in the Color Picker - in this case, it's pink.

Next, let's [create a filter](#). To do that, click [+](#) in the Filters section, and define the filter:

## Creating live template and variables

Next, back in the Settings/Preferences dialog, under the Editor section, click [Live Templates](#).

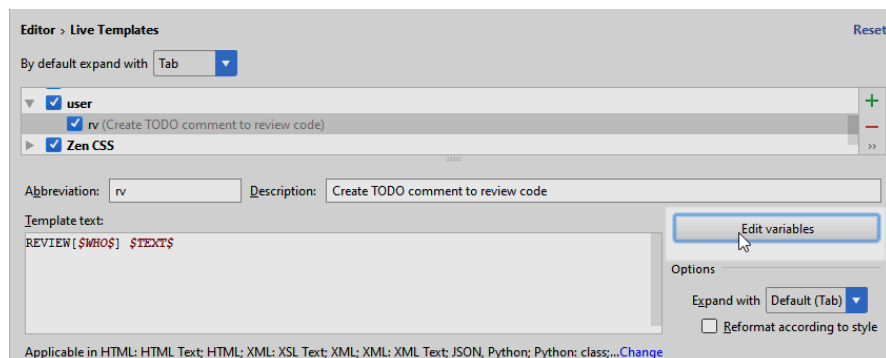

Note that the new template is added to the automatically created group `user`.

Next, pay attention to the red note at the bottom. It says that the new template lacks context, where it should apply. So let's click the link [Define](#), and allow all possible contexts. And finally, let's define the body of the template itself: in the area

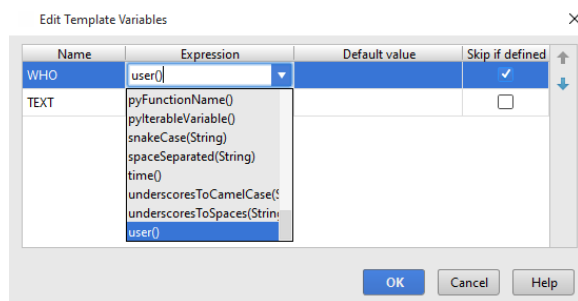

Template text , type the following:

```
REVIEW[$WHO$] $TEXT$
```

We have two undefined variables here: `$WHO$` and `$TEXT$` . The variable `$TEXT$` will be used just as an input field, while the variable `$WHO$` should be filled in automatically. To define this variable, click the button Edit variables :

Next, in the [Edit Template Variables](#) dialog box, select an expression for the variable `$WHO$` :

## Using the REVIEW items

Now let's make sure it works. Back in the editor, create a line comment ( `Ctrl+Slash` ), type `rv` , and press `TAB` :

```
# REVIEW[wombat] REVIEW[wombat]
```

Note that a right-gutter stripe next to the TODO comment is also added to the editor. As you see, the live template `rv` has automatically populated the user name, leaving us with the task of just entering some meaningful comment:

```
# REVIEW[wombat] please make sure that everything works
```

Now, when you opt to show REVIEW comments only, use the filter. To do that, click  and select the filter review to show those TODO comments only, that have the keyword REVIEW .

**Warning!** The following is only valid when TextMate Bundles Support Plugin is installed and enabled!

## What this tutorial is about

Projects can contain file types unknown to IntelliJ IDEA. While IntelliJ IDEA comes with the built-in support for many programming and scripting languages, you might want to have syntax highlighting for the project-specific languages. For example, a project can contain a shell script, or Perl; a configuration file can exist in a project for the infrastructure automation purposes. If you want to have syntax highlighting for these cases, use the powerful IntelliJ IDEA's integration with the text editor [TextMate](#).

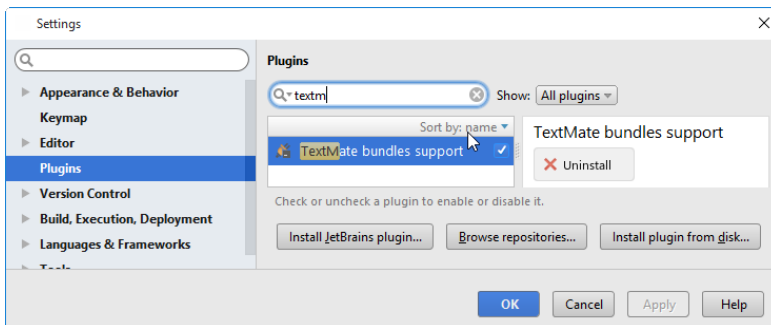

This tutorial aims to walk you step by step through configuring IntelliJ IDEA to use the TextMate Bundles, and editing files with the registered extensions.

Learning TextMate is out of scope of this tutorial. For information about TextMate, refer to the [product documentation](#).

## Prerequisites

Make sure that:

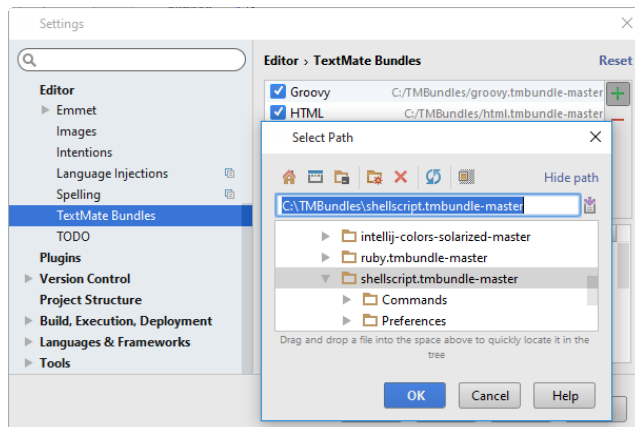

- You have already downloaded bundles you want to use. You can, for example, find the bundles you want to install on [GitHub](#) or [Subversion](#).
- You are working with IntelliJ IDEA 13.0 (where TextMate Bundles has been supported) or higher. In this tutorial, IntelliJ IDEA 2016.1 is used.
- Before you start working with TextMate Bundles, make sure that TextMate bundle support plugin is [installed and enabled](#). The plugin is not bundled with IntelliJ IDEA.

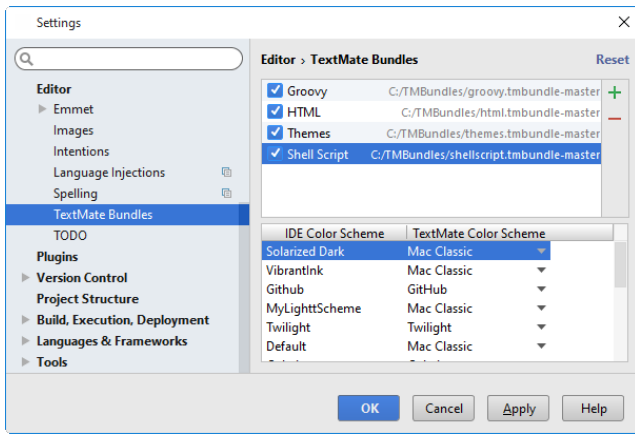

## Importing bundles

Suppose you want IntelliJ IDEA to highlight syntax of the Shell Script files. For this purpose, you have already downloaded the [Shell Script TextMate Bundle](#). It now resides on your hard disk, and you only have to import this bundle into IntelliJ IDEA.

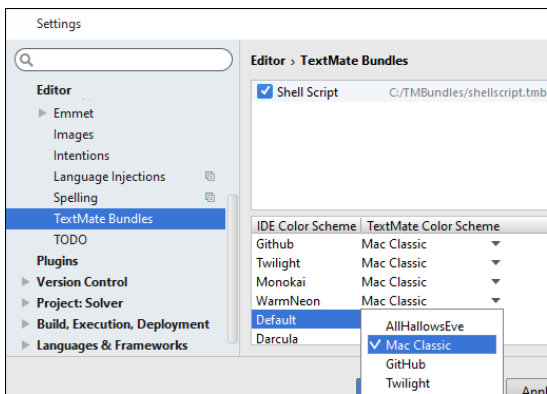

OK, off we go. On the main toolbar, click , and under the Editor node, click [TextMate Bundles](#). Then, in the TextMate Bundles area, click , and locate the desired bundle on your hard disk:

Click OK to apply changes. The Shell Script bundle appears in the list of recognized bundles, and its local path is visible to the right:

However, we have not yet defined which color scheme IntelliJ IDEA will use to highlight Shell Script syntax. As you already know, IntelliJ IDEA provides a number of color schemes, from the classic-looking ones to the fashionable dark schemes, like Darcula. Have a look at the color scheme mapping section in the lower part of the TextMate Bundles page. By default, the IntelliJ IDEA's Default color scheme maps to the Mac Classic. If we want to use a different color scheme for our bundle, we can click the "Mac Classic" cell in the table of mappings, and select the desired scheme from the list of available ones. However, let's stick to the suggested scheme:

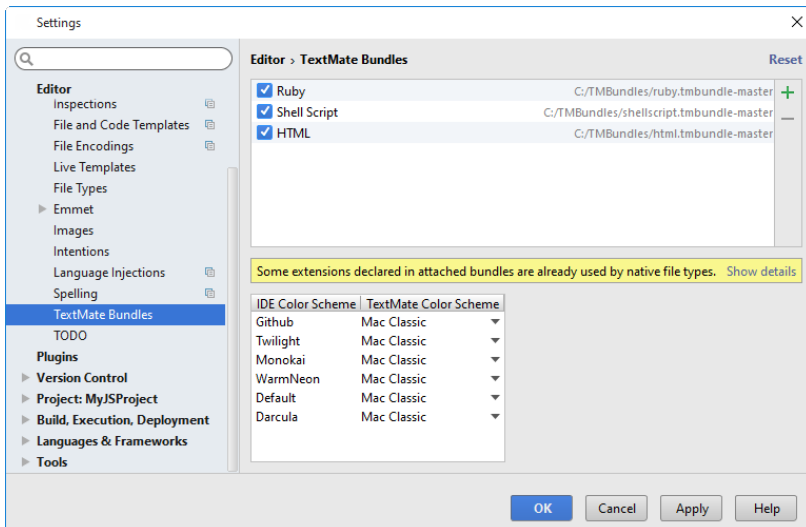

**Tip** If you want to use a custom TextMate color scheme, you can import a TextMate bundle with schemes, and it will become visible in the list of TextMate color schemes after clicking Apply:

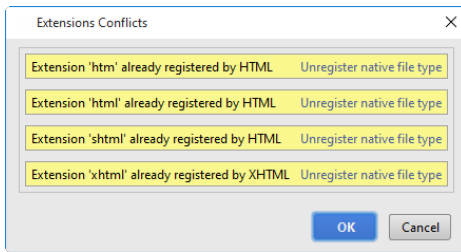

## Extension conflicts

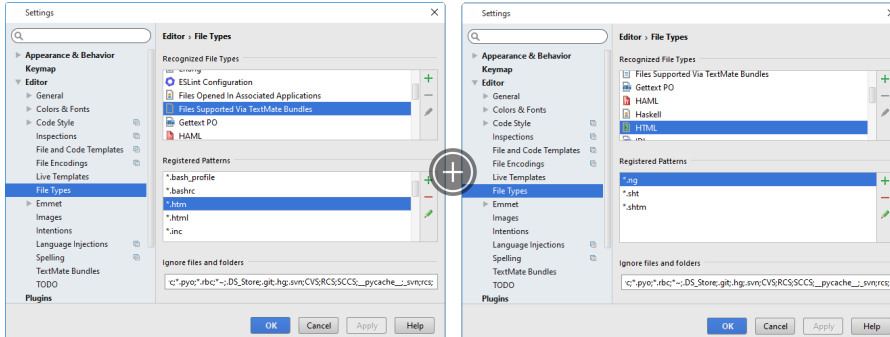

Suppose you've imported a bundle that runs into a conflict with the existing file types. The conflict is immediately reported:

Clicking the Show details link opens the dialog box that gives you the chance to unregister the required extensions from the native file types:

The node Files supported via TextMate Bundles now shows the new extensions ( `.htm`, `.html` ), and the node HTML lacks these extensions:

## Testing

Once a TextMate bundle is added, IntelliJ IDEA provides syntax highlighting for the file types registered with the bundle.

Here's a sample script that uses the Shell Script TextMate bundle we've cloned earlier:

```
run.bash x
#!/bin/sh
echo "This script checks the existence of..."
echo "Checking..."
if [ -f var/log/messages ]
then
    echo "var/log/messages exist"
echo
echo "done"
fi
```

## What this tutorial is about

This short tutorial aims to walk you step by step through defining Emacs as an external editor for IntelliJ IDEA.

Basics of [Emacs](#) are out of scope of this tutorial.

## Prerequisites

Make sure that:

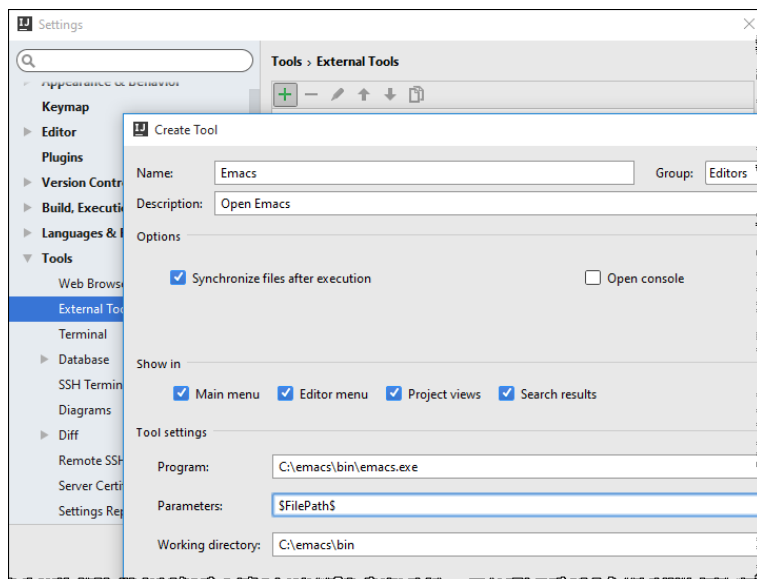

- You are working with IntelliJ IDEA 10.0 or later. This tutorial is created with IntelliJ IDEA version 2016.1.
- Emacs is [downloaded and properly installed](#) on your computer.

## Configuring Emacs as an external tool

Open Settings/Preferences dialog. To do that, you can, for example, choose File | Settings (on Windows and \*nix) or IntelliJ IDEA | Preferences (on macOS), or click  button on the main toolbar.

Then, under the Tools node, open the page [External Tools](#) . On this page, you have to specify your Emacs installation as an external editor for the current file. This is how it's done...

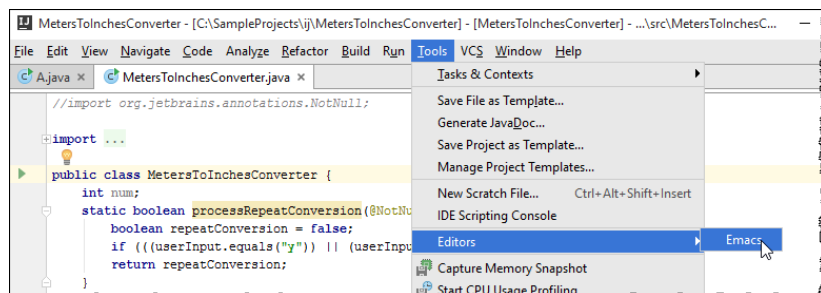

1. First, in the [External Tools](#) page, click  . The **Create/Edit Tool** dialog box opens.
2. In this dialog, do the following:
  - Type the tool name (Emacs) and optional description (Open Emacs)
  - Specify the name of the group, under which Emacs will appear in the Tools menu. In this example, the group name is `Editors` . This step is optional - if you specify no group name, then Emacs will appear in the Tools menu as is.
  - Clear the checkbox `Open console` .
  - Specify Emacs binary file location. You can either type it manually, or click the ellipsis button and find the desired binary in your file system.
  - Since you want to open the current file in Emacs, pass the file path as a parameter to the program: in the Parameters field, type `$FilePath$` .
  - Finally, specify the working directory - in our example, this is `$ProjectFileDir$`
  - Click `OK` .

3. Apply changes and close the Settings/Preferences dialog.

## Opening current file in Emacs

When you now look at the Tools menu, you will see the new node `Editors` . Pointing to this node reveals the Emacs command:

[Open a file for editing](#) . Next, on the Tools menu, choose `Editors|Emacs` - and see the current file in Emacs also:

```

emacs@UNIT-463

## Assigning a keyboard shortcut

By the way, IntelliJ IDEA makes it possible to assign a keyboard shortcut to this action: click  to open Settings/Preferences dialog, open the [Keymap page](#), find Emacs, and choose Add Keyboard Shortcut on the context menu:

Enter Keyboard Shortcut dialog box opens, where you have to specify, which shortcut you would like this action to be associated with. Let's, for example, use `Ctrl+Shift+Alt+E`:

No conflicts are reported, so click OK, and see the new shortcut appearing in the list of actions and on the Tools | Editors | Emacs menu:

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when IdeaVm Plugin is installed and enabled!

## Before you start

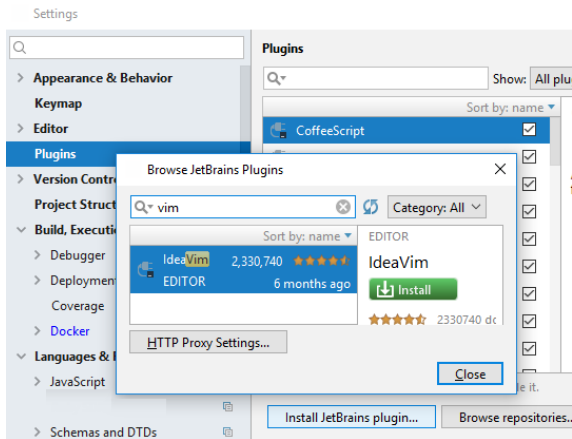

Make sure that:

- You are working with IntelliJ IDEA version 15.0.0 or higher. If you still do not have IntelliJ IDEA, download it from [this page](#) .  
To install IntelliJ IDEA, follow the instructions, depending on your platform.

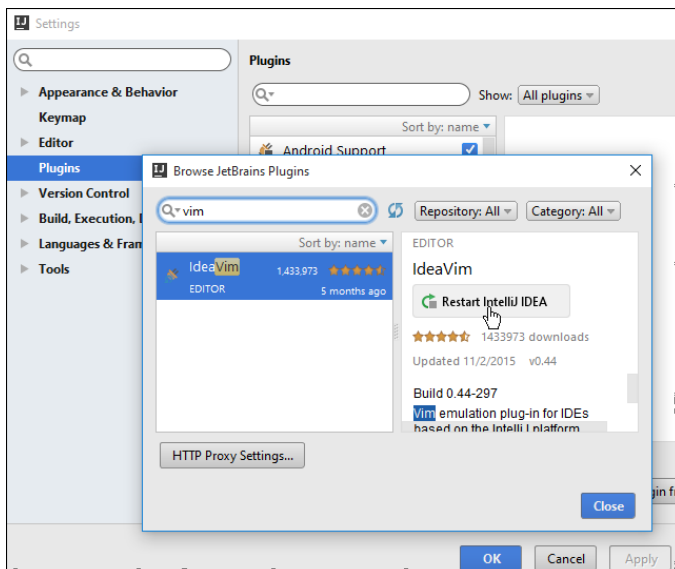

## Downloading and installing IdeaVm plugin

On the toolbar of the IntelliJ IDEA main window, press `Ctrl+Alt+S` to open the [Settings/Preferences](#) dialog, and then click [Plugins settings](#) .

You see the list of plugins currently installed on you computer. However, the IdeaVm plugin is not among them. Click the button [Browse JetBrains plugins](#) . IntelliJ IDEA shows the contents of the huge JetBrains repository... you can type the word "vim" in the search field to narrow down the list:

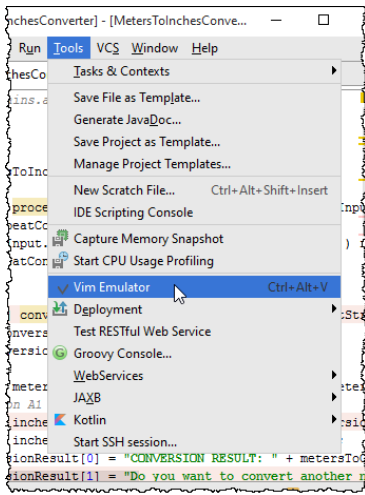

After installing the plugin, it actually becomes available after IntelliJ IDEA restart.

## What happens to IntelliJ IDEA's UI after restart?

First, on the Tools menu, a check command Vim Emulator appears:

After IntelliJ IDEA restart, this check command is selected. You can disable Vim by clearing this check command.

Second, in Settings/Preferences dialog, an additional page Vim Emulation appears after restart.

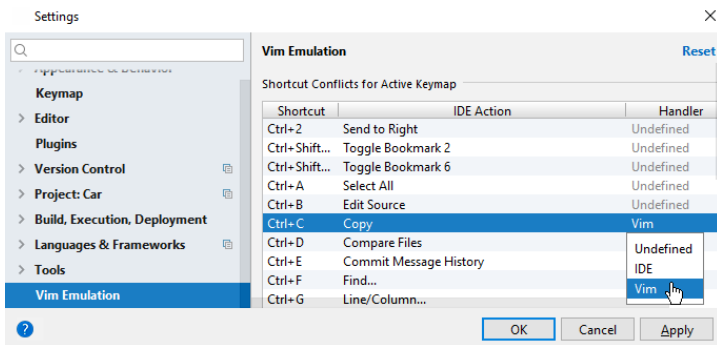

### Configuring shortcuts

Both Vim and IntelliJ IDEA are keyboard-centric. With [IdeaVim plugin](#), it is quite possible that IntelliJ IDEA's keymap runs into a conflict with the Vim keymap. That's why IntelliJ IDEA allows you choosing which keyboard shortcut you prefer for a certain action. This is how it's done.

Open Settings/Preferences dialog, and click Vim Emulation :

In the Shortcut column, select the shortcut you want to configure. Next, in the Handler column, click the corresponding cell, and see the drop-down list of three possible options (Undefined, IDE, Vim):

If you choose **IDE**, it means that the IntelliJ IDEA's shortcut for this particular action is enabled. When you press, say, `Ctrl+Z`, IntelliJ IDEA silently performs its action.

If you leave the handler undefined, then, on pressing the shortcut, say, `Ctrl+B`, IntelliJ IDEA shows the banner.

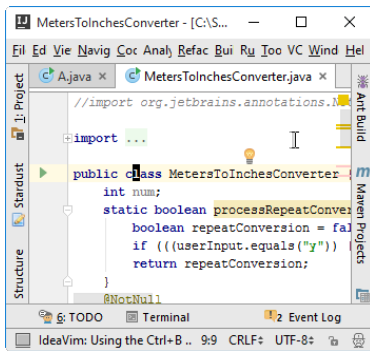

You can choose to redefine this shortcut as an IDE shortcut and thus accept the IntelliJ IDEA's keymap. To do so, click the link **IDE shortcut**.

If you click the down arrow and then the link **Vim Emulation**, then IntelliJ IDEA will show the Vim Emulation page of the Settings/Preferences dialog.

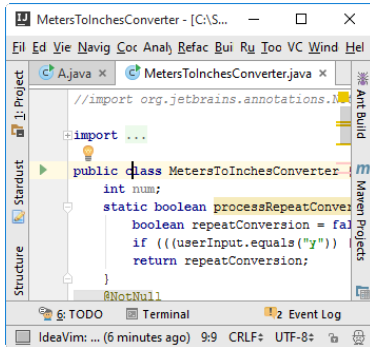

For the purposes of this tutorial, click the link **Vim Emulation**. Then, when you press `Ctrl+B`, IntelliJ IDEA will perform the Vim action for this keyboard shortcut.

### Editing modes

OK, now that you have Vim enabled, you see that the cursor has changed its shape - now it is a block, which means that you are in the [Normal mode](#) :

If you want to enter the [insert mode](#), press `i`, and the cursor will turn into a line:

In this mode you can type new or change the existing code. Same way, you can enter the various Vim modes: for example, press `r` for the [Replace mode](#).

By the way, as soon as you enter Vim emulation, it is also reported in the Status bar.

To return to the Normal mode, press `Escape`.

This part contains miscellaneous information related to the UI of the dialogs, tool windows and views, keyboard shortcuts, syntax references etc.:

- [Essentials](#)

IntelliJ IDEA is an advanced IDE. To get the most out of its capabilities and features, you should be familiar with its concepts. Concepts describe the basic notions of the IDE.

In this part:

- [Path Variables](#)
- [Supported Languages](#)
- [Scope](#)
- [Encoding](#)
- [Code Analysis](#)

## Introduction

To avoid complications when moving [projects](#) from one computer to another, IntelliJ IDEA provides path variables. (A path variable, obviously, is a variable whose value is an absolute path to a directory or file.)

Path variables are particularly useful when working with third-party [libraries](#) stored outside the project directory.

To illustrate, let's assume there is a project shared among a team of developers (e.g., through version control), and there is a library in this project defined at the project or module level.

All is well if this library is located in the project directory or one of the module [content roots](#). This, however, is rarely the case.

A more typical situation is when the library location is external to the project and modules. Such a library is referenced by its absolute path and there's no guarantee that this path is the same on every one of the computers used by the team.

The obvious solution is to define a path variable for the library location. In such a case, the library path may be set individually on each of the computers.

To summarize, you should define path variables under the following set of conditions:

- There are third-party libraries in your project defined at the project or module level.
- These libraries are stored outside the project directory and the module content roots.
- There is a need to work with the project on more than one computer (e.g., share the project among the development team members through version control).

## Ignored variables

If when opening a project, IntelliJ IDEA detects unresolved path variables, it asks you to define proper values for them. If for some reason you don't want to do that (e.g., you are not going to use the corresponding library or libraries), you have an option of adding the corresponding variables to a list of ignored variables.

There may also be other cases when the list of ignored variables is useful.

At the internal level, path variables are represented by strings in which the name of a variable is enclosed between a pair of dollar sign characters, for example, `$MY_PATH_VARIABLE$`.

Such a pattern, in principle, may occur in your project without the meaning of a path variable. For example, `$SOME_STRING$` may occur within program parameters passed to the JVM in a run/debug configuration, etc.

To tell IntelliJ IDEA that a string that starts and ends with a dollar sign character (e.g., `$SOME_STRING$`), actually, is not a path variable, you should add such a string (e.g., `SOME_STRING`) to the list of ignored variables.

In this section:

- [Supported languages](#)
- [Coding assistance](#)

## Supported languages

Development of a modern application involves using multiple languages, that is why IntelliJ IDEA is an IDE for polyglot programming. With the deep understanding of all the subtleties of the source code structure and syntax, IntelliJ IDEA extends its support to:

- Java. IntelliJ IDEA supports Java up to version Java 8 , with lambdas, type annotations etc. For the supported language level, IntelliJ IDEA provides code completion, code inspections, quick fixes and more.
- [XML /XSL](#) . Refer to the section [Markup Languages and Style Sheets](#) .
- Groovy. Refer to the section [Groovy](#) .
- JSP/JSPX
- [Flex](#) : advanced coding assistance for [ActionScript](#) , MXML , including code completion and inspections. Refer to [ActionScript and Flex](#) .
- [HTML /XHTML](#) . Refer to the section [Markup Languages and Style Sheets](#) .
- [CSS3](#) : coding assistance and compilation for [Less](#) ; basic support of [Sass 3](#) .

Refer to [Markup Languages and Style Sheets](#) .

- [Stylus](#) . Refer to section [Compiling Sass, Less, and SCSS to CSS](#) .
- [JavaScript](#) . Refer to the section [JavaScript](#) .
  - [CoffeeScript](#) . Refer to the section [CoffeeScript](#) .
  - [TypeScript](#)
- [PHP](#) up to version 5.4.0 with support of syntax highlighting in `.ini` files. Refer to the section [PHP](#) .
- [SQL](#) and its dialects (SQL-92, MySQL, SQLite Oracle, PostgreSQL, and Derby). Refer to [Databases and SQL](#) .
- FreeMarker
- Velocity up to version 1.7
- IDL
- Spring-AOP
- [Dart](#)
- [Drools Expert](#)

## Coding assistance

Coding assistance in IntelliJ IDEA includes:

- Syntax and error highlighting. The color attributes are configurable in the [Colors and Fonts | <language>](#) pages of the Settings/Preferences dialog.
- [File templates](#) for the supported languages that enable creating stub classes, scripts etc.
- [Live templates](#) for creating complicated code constructs.
- [Code completion](#) .
- [Code generation](#) .
- [Code folding](#) , [formatting](#) , and highlighting.
- [Intention actions and quick fixes](#) .
- [Ability to view code hierarchy](#) .
- [Quick access to the API documentation](#) .
- [Using macros in the editor](#) .
- [Advanced search and replace facilities](#) .
- [Advanced means of navigation](#) .
- [Refactoring](#) .
- [Import assistance](#) .
- [Language injection](#) .
- The [embedded local terminal](#) where you can execute commands without leaving IntelliJ IDEA.

Besides editing assistance, IntelliJ IDEA enables [debugging](#) for Java, Flex, JavaScript, and PHP, applications.

**Warning!** Debugging for JavaScript applications is supported only in the [Chrome](#) browser.

The polyglot arsenal of IntelliJ IDEA can be extended by [installing plugins](#) , for example, [Scala](#) , or La Clojure . With these plugins installed and enabled, IntelliJ IDEA provides the corresponding facets, coding assistance, running and debugging facilities.

**Note**

- Basics
- Types of scopes
- Defining scopes
- Scopes coloring
- Predefined scopes

## Basics

A **scope** (👤) is a subset of files, packages and/or directories in your project, to which you can limit the application of specific operations, e.g. [search](#), [code inspection](#), insertion of copyright notices, etc. Besides, you can configure [coloring](#) for each scope to see at once what sort of file you are dealing with.

Scopes get more helpful as your project grows larger. There is a number of [predefined scopes](#) that cover basic cases. Additionally, it is possible to [add custom scopes](#) to your project. For example, you can create custom scopes for tests or for the files you are responsible for in your team.

## Types of scopes

Scopes can be either shared or local:

- **Shared scopes** are accessible for the team members via VCS and are stored at the project level. If the project has a [file-based format](#), the shared scopes are stored in the `*.ipr` file; if the project has a [directory-based format](#), the shared scopes are stored in the `scopes` directory under `.idea`, as a file with the extension `xml`, i.e. `.idea/scopes/<scope_name>.xml`.
- **Local scopes** are intended for personal use only and are stored in your workspace (`*.iws` file in the file-based project format, or in the file `workspace.xml` under `.idea` in the directory-based format).

If necessary, you can share a local scope, make a shared scope local, or create a copy of the scope. For more information, see [Configuring Scopes and File Colors](#).

## Defining scopes

IntelliJ IDEA provides a special language that enables you to flexibly define the sets of entities included in a scope. See [Scope Language Syntax Reference](#) for details.

To create and edit **scopes**, use the [Scopes](#) page of the Settings/Preferences dialog.

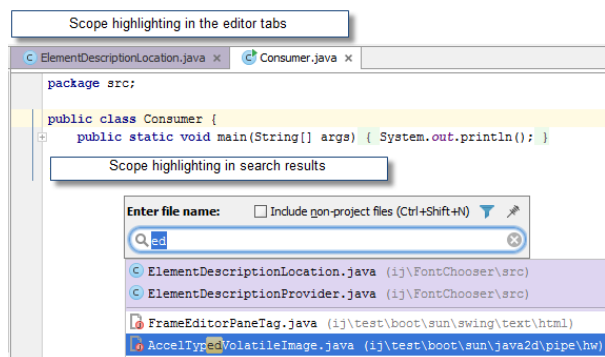

**Scopes** are defined in the following modes:

- Manually, by specifying file masks according to the [scope language syntax](#) in the Pattern text box.
- By selecting files and folders and clicking the buttons `Include`, `Include Recursively`, `Exclude`, and `Exclude Recursively`. Based on the inclusion/exclusion, IntelliJ IDEA creates an expression and displays it in the Pattern. Refer to the section [Configuring Scopes and File Colors](#).

To view the available scopes, click the ▼ (next to the Project header of the [Project Tool Window](#)).

## Scopes coloring

Files belonging to different scopes can be highlighted in different colors throughout the IntelliJ IDEA's user interface: in [navigation lists](#), in the editor tabs, in the [Project Tool Window](#). This allows much faster and easier navigation in large projects.

If some file is included into several scopes, the order of the scopes becomes important: IntelliJ IDEA uses the color of the uppermost scope (shown in the [Scopes](#) settings page) to highlight such file. Of course, you can change the order of the scopes, and thus the resulted highlighting.

For detailed instructions on how to configure the scope order and scope-color associations, see [Configuring Scopes and File Colors](#).

## Predefined scopes

IntelliJ IDEA provides a number of predefined scopes, for example:

- **Project Files**. This scope includes all the files within the project content roots (see [Module Contents](#)). [Module](#)

[dependencies](#) (libraries and SDKs), generally, are not included in this scope.

- **Problems** . This scope includes the files within the project content roots in which syntactic errors are found.
- **Project and Libraries** . This scope includes all the files within the project content roots, and also all [module dependencies](#), libraries and SDKs.  
In the [Project Tool Window](#) , this scope corresponds to the scope view All .
- **Project Production Files** . This scope is similar to the [Project Files scope](#) . The difference is that the test source roots are not included. In the [Project Tool Window](#) , this scope corresponds to the scope view Production .
- **Project Test Files** . This scope is limited to the project test source roots. In the [Project Tool Window](#) , this scope corresponds to the scope view Tests .
- **Non-Project Files** . This scope is available only as a view in the [Project Tool Window](#) . It is limited to [module dependencies](#) (libraries and SDKs).
- **Changed Files** . This scope corresponds to all changed files, that is, ones associated with all existing [changelists](#) .
- **Default** . This scope corresponds to the files associated with the [changelist](#) `Default` .
- **Favorite** '`<name>`' . This scope corresponds to a list of favorite items with the specified name. See [Managing Your Project Favorites](#) .
- **Open files** .This scope corresponds to the files opened in IntelliJ IDEA editor.
- **Current file** . This scope corresponds to the file currently active in IntelliJ IDEA editor.
- **Selected files** . This scope corresponds to the files currently selected in IntelliJ IDEA (e.g. in the [Project Tool Window](#) ).

Predefined scopes cannot be edited.

Different types of files use different ways to define encoding. IntelliJ IDEA recognizes encoding of files based on their contents.

Encoding has influence on the way IntelliJ IDEA reads or writes files. If a file has been modified but not yet saved, any changes in encoding affect file writing; if a file has not been modified, then reading is affected. IntelliJ IDEA suggests specific ways to change encoding of a file according to its type, using [File Encodings](#) Settings page, the [Status bar](#), or the [editor](#).

**Note** Encoding applies to directories and individual files. The encoding information saved in a file overrides the default encoding; encoding of a file or subdirectory overrides encoding settings on the higher levels.

### EncodingCan be changed in

File encoding is specified within the file, for example, in XML.	If a file contains explicit encoding declaration, you can change it in the <a href="#">Editor</a> . In this case IntelliJ IDEA provides code completion.
File encoding is defined by BOM.	In this case, you can't change encoding with which IntelliJ IDEA reads the file, but it is still possible to change encoding for writing such file.
UTF characters are detected in the file contents.	IntelliJ IDEA provides an option that <a href="#">automatically changes file encoding to UTF</a> , if the file contents can be reasonably interpreted as UTF.  This option only works for reading; a file can be saved with any encoding.
Encoding cannot be found out from the file content.	In this case, the default encoding is the one defined by the IDE encoding in the <a href="#">File Encodings</a> page of the Settings dialog. You can change it for <a href="#">multiple files and directories</a> , or for a <a href="#">single file</a> .
Properties files.	For the properties files, system default encoding is used. Though the characters in the other encodings are processed as unknown symbols, it is <a href="#">still possible</a> to use them, by feeding such characters as escape sequences (for which IntelliJ IDEA provides the Transparent native-to-ASCII conversion option), or defining the default encoding for properties files.

IntelliJ IDEA performs code analysis by applying inspections to your code. Numerous code inspections exist for Java and for the other supported languages.

The inspections detect not only compiling errors, but also different code inefficiencies. Whenever you have some unreachable code, unused code, non-localized string, unresolved method, memory leaks or even spelling problems – you'll find it very quickly.

IntelliJ IDEA's code analysis is flexibly configurable. You can [enable/disable](#) each code inspection and [change its severity](#) , create [profiles](#) with custom sets of inspections, apply inspections differently [in different scopes](#) , [suppress](#) inspections in specific pieces of code, and more.

The analysis can be performed in several ways:

- By default, IntelliJ IDEA analyses all open files and highlights all detected code issues right in the editor. On the right side of the editor you can see the analysis status of the whole file (the icon in the top-right corner).  
When an error is detected, this icon is  ; in case of a warning, it is  ; if everything is correct, the icon is  .
- Alternatively, you can run code analysis in a [bulk mode](#) for the specified scope, which can be as large as the whole project.
- If necessary, you can [apply a single code inspection](#) in a specific scope.

For the majority of the detected code issues, IntelliJ IDEA provides [quick fix suggestions](#) . You can quickly review errors in a file by navigating from one highlighted line to another by pressing   .

IntelliJ IDEA analyses your projects on the various levels:

- "On-the-fly" analysis helps you fix problems as they arise as you type, using [intention actions](#) .
- [Code inspections](#) are intended to point out issues related to the program design.
- Highlighting level allows you to control the scope of problems highlighted in the current file.
- [Dependencies analysis](#) helps you understand the structure of your source code, explore relationships between the components of your projects, track down dependencies and work through the code hierarchies.
- [Dataflow analysis](#) helps you with code archeology.
- [Reverse engineering](#) .

To access the New Project wizard:

If no project is currently open: select Create New Project option on the Welcome screen

Otherwise: File | New | Project

Use the New Project wizard to create a new project from scratch.

- [Project Category and Options](#)
- [Project Template](#)
- [J2ME Page](#)
- [Gradle Page](#)
- [Maven Page](#)
- [New Project Wizard Android Dialogs](#)
- [New Project: HTML5 Boilerplate](#)
- [New Project: Web Starter Kit](#)
- [New Project: React App](#)
- [New Project: Twitter Bootstrap](#)
- [New Project: Foundation](#)
- [New Project: Node.js Express App](#)
- [New Project: Meteor Application](#)
- [New Project: PhoneGap/Cordova](#)
- [New Project: Yeoman](#)
- [New Project: Composer Project](#)
- [New Project: Drupal Module](#)
- [New Project: Google App Engine for PHP](#)
- [New Project: PHP Empty Project](#)
- [Project Name and Location](#)

This page of the New Project wizard opens when you select File | New | Project in the main menu or Create New Project on the Welcome screen.

In the left-hand pane, select the project category. This may be the technology that you are going to use, the platform or runtime that your development is going to target, etc.

In the right-hand part of the page, select additional options and specify associated settings.

Don't worry about selecting "wrong" options at the moment. Just select the ones that you think suit you best. If necessary, you will be able to make the necessary changes to your project at a later time.

Note that the set of options you can select from depends on which [plugins](#) are currently enabled in IntelliJ IDEA.

## Java

Select this option if you are going to develop a [Java](#) application.

### ItemDescription

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Java Enterprise

Select this option if you are going to develop a [Java EE](#) application.

### ItemDescription

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

**Java EE version** Select the Java EE version to be supported. (Affects the corresponding version setting for the Web Application, EJB and JavaEE Application options.)

**Application Server** Specify the application server that you are going to use to deploy and run your application. As a result, IntelliJ IDEA will create a [run/debug configuration](#) for the specified server. (You can specify the server later.)  
You can select a server which IntelliJ IDEA is already aware of, or specify another "new" server.

To specify a new server, click New and select the server of interest. Then, specify the server settings:

- For a server installed locally, specify the path to the server installation directory. (Click  to select the directory in the [corresponding dialog](#) .)
- For a hosted server (Cloud Foundry or CloudBees), specify your user account details.

Select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## J2ME

Select this option if you are going to develop for [Java ME](#) .

### ItemDescription

---

**Project SDK** Specify an [SDK](#) for your project.  
If the necessary SDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and, in the [dialog that opens](#) , select the installation folder of the desired Java ME SDK. (By this time, the corresponding SDK must already be installed on your computer.)

---

**SQL Support** Select the checkbox to enable [SQL](#) support. Select the SQL dialect to be used by default from the list.

## Android

Select this option if you are going to develop for the [Android](#) OS.

For more information, see [Getting Started with Android Development](#) and [Android New Project References](#) .

## Clouds

Select this option if you are going to deploy your application to a cloud platform such as [CloudBees](#) , [Cloud Foundry](#) , [Heroku](#) or [OpenShift](#) . See also, [Working with Cloud Platforms](#) .

### ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

---

**Account** Specify your cloud user account.  
If the corresponding user account is already registered in IntelliJ IDEA, select it from the list.

Otherwise, click New , select the cloud platform and specify your user account settings in the dialog that opens.

---

**Application** Cloud platform-specific application settings.  
CloudBees and Cloud Foundry. IntelliJ IDEA will create a sample Java web application which you'll be able to deploy to the cloud and run straight away.

- Version. The version of the Servlet specification to be supported.
- Create web.xml. For version 3.0 or later: select this checkbox to create the [deployment descriptor](#) file `web.xml` . (For earlier versions, this file is always created.)

Heroku. You can select to create a new application or to git-clone the source code for one of your applications already deployed on Heroku.

- Template. A new sample application will be created. You'll be able to deploy this application to Heroku straight away.
- Existing. Select the application whose source code you want to clone.

OpenShift. You can select to git-clone the source code for one of your applications already deployed OpenShift or to create a new application.

- Existing. Select the application whose source code you want to clone.
- New. Select this option to create a new application. Specify the settings for your new application (for OpenShift terminology, see [OpenShift documentation](#) ):
  - Standalone Cartridge. Select the primary cartridge.
  - Gear size. Select the gear size.
  - Scaling. Select the checkbox if the application should be scalable.
  - Embeddable Cartridges. Select (additional) embedded cartridges.

## Spring

Select this option if you are going to develop a [Spring](#) application.

### ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

For information on other options and settings, see:

- [Spring](#)
- [Spring MVC, Spring Batch, or other Spring framework](#)
- [Additional Libraries and Frameworks](#)

## Java FX

Select this option if you are going to develop a [JavaFX](#) application.

## ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK (version 7 or later) is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and select **JDK** . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

## IntelliJ Platform Plugin

Select this option if you are going to develop a [plugin](#) for IntelliJ IDEA or other IntelliJ Platform-based IDE.

## ItemDescription

---

**Project SDK** Specify an [SDK](#) for your project.  
If the necessary SDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and, in the [dialog that opens](#) , select the installation folder of the desired IntelliJ IDEA version.  
(An IntelliJ IDEA installation acts as an IntelliJ Platform Plugin SDK.) (By this time, the corresponding IntelliJ IDEA version must already be installed on your computer.)

**Groovy** Select the checkbox to be able to use [Groovy](#) . Specify the Groovy installation to be used.  
Use **library**. If the desired version of Groovy is already defined in IntelliJ IDEA, select it from the list. (Groovy in IntelliJ IDEA is represented by a [library](#) .)

**Create**. Click this button to create a library for Groovy. In the [dialog that opens](#) , select the Groovy installation directory.

**SQL Support** Select the checkbox to enable [SQL](#) support. Select the SQL dialect to be used by default from the list.

## Spring Initializr

Select this option if you are going to develop a [Spring Boot](#) application.

## ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

**Initializr Service URL** Specify the Spring Initializr instance URL. By default, it is <https://start.spring.io> , but you can use any other custom instance if needed.

## Maven

Select this option if you are going to develop a [Java](#) application with dependencies managed by [Maven](#) .

## ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

**Create from archetype** If this checkbox is not selected, the new `pom.xml` file will contain the basic information.

If this checkbox is selected, the new module will be created on the base of a Maven archetype chosen from the list that includes both the standard archetypes, and the ones found in Maven indices. You can modify Maven properties on [Maven Settings Page](#) .

If you want to populate the list with some archetype from a remote Maven repository, click the **Add Archetype** button, and find the desired archetype by Maven coordinates specified in [Add Archetype Dialog](#) .

## Gradle

Select this option if you are going to develop a [Java](#) application with dependencies managed by [Gradle](#) .

See also [Getting Started with Gradle](#) and [New Project Gradle References](#) .

## ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and select **JDK** . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Groovy

Select this option if you are going to develop a [Groovy](#) application.

#### ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Groovy library** If the desired version of Groovy is already defined in IntelliJ IDEA, select it from the list. (Groovy in IntelliJ IDEA is represented by a [library](#) .)  
Create. Click this button to create a library for Groovy. In the [dialog that opens](#) , select the Groovy installation directory.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Grails

Select this option if you are going to develop a [Grails](#) application.

See also [Getting Started with Grails 3](#) .

#### ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Grails SDK Home** If the desired version of Grails is already defined in IntelliJ IDEA, select it from the list. (Grails in IntelliJ IDEA is represented by a [library](#) .)  
Click  this button to create a library for Grails. In the [dialog that opens](#) , select the Grails installation directory.

---

**Create** create-app - select this option if you want to create a Grails application.  
  
create-plugin - select this option if you want to create a Grails plugin project.

---

**Options** Use this field to specify additional options such as profiles, for example.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Application Forge

Select this option if you are going to develop a project using [Grails Application Forge](#) service.

See also [Grails Application Forge](#) .

#### ItemDescription

---

**Project SDK** Specify an [SDK](#) for your project.  
If the necessary SDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Project Type** Use this drop-down list to specify what you want to develop ( [Application](#) or [Plugin](#) ).

---

**Grails Version** Use this drop-down list to specify a Grails version for your project.

---

**Profiles** Use this drop-down list to specify a [profile](#) for the project.

---

**Features** Select the necessary checkboxes to specify features for your project.

## Griffon

Select this option if you are going to develop a [Griffon](#) application.

See also [Creating a Griffon Application Module](#) .

#### ItemDescription

---

**Project SDK** Specify an [SDK](#) (JDK) for your project.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Griffon library** If the desired version of Griffon is already defined in IntelliJ IDEA, select it from the list. (Griffon in IntelliJ IDEA is represented by a [library](#) .)  
Create. Click this button to create a library for Griffon. In the [dialog that opens](#) , select the Griffon installation directory.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#).

## PHP

Select PHP if you are going to develop an application using [PHP](#). This option is available only in the **Ultimate** edition when the **PHP** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

In the right-hand pane, choose one of the following project types:

- PHP Empty Project: choose this option to get just a project folder without any contents.

## Kotlin

Select this option if you are going to create a [Kotlin](#) project. Specify the associated settings.

### ItemDescription

Project name	Specify the project name.
Project location	Specify the path to the directory in which you want to create the project. (By default, a directory having the same name as the project is created.) You can click  ( <a href="#">Shift+Enter</a> ) and select the necessary directory in the <a href="#">dialog that opens</a> . (You can create a new directory in that dialog, e.g. by using  .)
Project SDK	Specify an SDK for your project. If the necessary SDK is already defined in IntelliJ IDEA, select it from the list. Otherwise, click <b>New</b> and select SDK type. Then, <code>inkotlin_intro_p</code> dialog that opens, select the installation folder of the desired SDK. (By this time, the corresponding SDK must already be installed on your computer. If it isn't, download and install it first.)
Kotlin runtime	Specify here the runtime library <code>kotlin-runtime.jar</code> . The library resides within the Kotlin plugin and contains the standard Kotlin classes. If the desired library is missing, click <b>Create</b> .  When a project is being created, one can either copy the said jar to the project (option <b>Copy to</b> ), or just refer to the jar from the Kotlin plugin (option <b>Use library from plugin</b> ).
More Settings	Click the arrow (  or  ) to show or hide additional settings. Mainly, these are the settings for the <a href="#">module</a> to be created (discussed below). Note that in certain cases those additional settings are unavailable.
Module name	Specify the module name.
Content root	Specify the path to the module content root folder. (This is where all the files that make up you module will be stored; for more information, see <a href="#">Configuring projects</a> .) To use a different folder, click  ( <a href="#">Shift+Enter</a> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)
Module file location	Specify the path to the folder where the <code>.iml</code> <a href="#">module file</a> should be created. By default, this file is created in the module content root folder (recommended).  To use a different folder, click  ( <a href="#">Shift+Enter</a> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)
Project format	Select the <a href="#">project format</a> to be used. (The <code>.idea</code> directory-based format is recommended).

## Static Web

Select Static Web if you are going to develop a Web application using [HTML /CSS](#), [JavaScript](#), [Node.js](#), and related frameworks.

Choose this option also if you want to generate a project stub based on a framework template.

In the right-hand pane, choose one of the following project types:

### Project Description type

Static Web	Choose this option to get just a project folder without any contents.
Angular CLI	<p>The feature is supported only in the <b>Ultimate</b> edition when the NodeJS and AngularJS plugins are installed and enabled.</p> <p>The plugins are not bundled with IntelliJ IDEA, but they can be installed from the <a href="#">JetBrains plugin repository</a> as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a>. Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.</p> <p>Choose this option to get a stub where later you can automatically generate specific structures, such as <a href="#">Classes</a>, <a href="#">Components</a>, <a href="#">Routes</a>, <a href="#">Pipes</a>, <a href="#">Services</a>, etc. using the <a href="#">Angular CLI</a> command line interface.</p> <p>In the right-hand pane:</p> <ol style="list-style-type: none"><li>1. Specify the project name and the path to the folder where the project-related files will be stored.</li></ol>

2. In the Node Interpreter field, specify the Node.js interpreter to use. Choose a configured interpreter from the drop-down list or choose Add to configure a new one, see [Configuring Node.js Interpreters](#)
3. In the Angular CLI field, specify the path to the `angular-cli` package.

---

AngularJS	<p>The feature is supported only in the Ultimate edition when the NodeJS and AngularJS plugins are installed and enabled.</p> <p>The plugins are not bundled with IntelliJ IDEA, but they can be installed from the JetBrains plugin repository as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a> . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.</p> <p>Choose this option to have the project structure set up and some sources generated based on the <a href="#">AngularJS framework</a> template.</p> <p>In the right-hand pane, specify the project name and the path to the folder where the project-related files will be stored.</p>
Foundation	<p>The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the <a href="#">Plugins settings</a> page as described in <a href="#">Enabling and Disabling Plugins</a> .</p> <p>Choose this option to have the project structure set up and some sources generated based on the <a href="#">Foundation</a> framework template.</p> <p>In the right-hand pane:</p> <ol style="list-style-type: none"><li>1. Specify the project name and the path to the folder where the project-related files will be stored.</li><li>2. From the Version drop-down list, choose the template version to use and click Create .</li></ol>
Dart	<p>The feature is supported only in the Ultimate edition when the Dart plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a> .</p> <p>Choose this option to have the project structure set up and some sources generated for a <a href="#">Dart</a> application.</p>
HTML5 Boilerplate	<p>The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the <a href="#">Plugins settings</a> page as described in <a href="#">Enabling and Disabling Plugins</a> .</p> <p>Choose this option to have the project structure set up and some sources generated based on the <a href="#">HTML5 Boilerplate</a> template.</p> <p>In the right-hand pane:</p> <ol style="list-style-type: none"><li>1. Specify the project name and the path to the folder where the project-related files will be stored.</li><li>2. From the Version drop-down list, choose the template version to use and click Create .</li></ol>
Meteor App	<p>The feature is supported only in the Ultimate edition when the Meteor plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a> .</p> <p>Choose this option to have the project structure set up and some sources generated based on the <a href="#">Meteor</a> frameworks.</p> <p>In the right-hand pane:</p> <ol style="list-style-type: none"><li>1. Specify the project name and the path to the folder where the project-related files will be stored.</li><li>2. Specify the location of the Meteor executable file (see <a href="#">Installing Meteor</a> ).</li><li>3. From the Template drop-down list, choose the sample to generate. To have a basic project structure generated, choose the Default option.</li><li>4. In the Filename text box, type the name for the mutually related <code>.js</code> , <code>.html</code> , and <code>.css</code> files that will be generated. The text box is available only if the Default sample type is selected from the Template drop-down list.</li></ol>
Node.js Express App	<p>The feature is supported only in the Ultimate edition when the Node.js plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in <a href="#">Installing, Updating and Uninstalling Repository Plugins</a> and <a href="#">Enabling and Disabling Plugins</a> .</p> <p>Choose this option to have the project structure set up and some project sources generated based on the <a href="#">Express</a> framework.</p> <p>In the right-hand pane:</p> <ol style="list-style-type: none"><li>1. Specify the project name and the path to the folder where the project-related files will be stored.</li><li>2. The path to the Node.js executable file <code>node.exe</code> and to the <a href="#">Node.js package manager</a> file <code>npm.cmd</code> .</li><li>3. The <a href="#">Express template engine</a> to use. From the Template engine drop-down list, choose one of the following:<ul style="list-style-type: none"><li>- <a href="#">Jade</a> - haml.js successor.</li><li>- <a href="#">EJS</a> - embedded JavaScript.</li><li>- <a href="#">Hogan.js</a> .</li><li>- <a href="#">Handlebars</a> .</li></ul></li><li>4. The CSS engine to use. From the CSS engine drop-down list, choose one of the following:<ul style="list-style-type: none"><li>- <a href="#">Plain CSS</a></li><li>- <a href="#">Stylus</a></li><li>- <a href="#">Less</a></li><li>- <a href="#">Compass</a> .</li><li>- <a href="#">Sass</a> .</li></ul></li></ol>

---

PhoneGap/Cordova App The feature is supported only in the Ultimate edition when the PhoneGap/Cordova plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

Choose this option to have the project structure set up and some sources generated based on the [PhoneGap](#) , [Apache Cordova](#) , and [Ionic](#) frameworks.

In the right-hand pane:

1. Specify the project name and the path to the folder where the project-related files will be stored.
2. Specify the location of the executable file `phonegap.cmd` , or `cordova.cmd` , or `ionic.cmd` (see [Installing PhoneGap/Cordova/Ionic](#) ).

---

React App The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

Choose this option to generate a project using a globally installed [create-react-app](#) package, see [React](#) for details.

In the right-hand pane:

1. Specify the project name and the path to the folder where the project-related files will be stored.
2. In the Node Interpreter field, specify the Node.js interpreter to use. Choose a configured interpreter from the drop-down list or choose Add to configure a new one, see [Configuring Node.js Interpreters](#)
3. In the create-react-app field, specify the path to the `create-react-app` package.
4. Optionally, in the Scripts version field, specify a custom package to use instead of [react-scripts](#) during the project generation. This can be one of the packages forked from `react-scripts` , for example, [react-awesome-scripts](#) , [custom-react-scripts](#) , [react-scripts-ts](#) , etc.

---

React Native The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

Choose this option to get a stub for developing a [React Native](#) application.

In the right-hand pane:

1. Specify the project name and the path to the folder where the project-related files will be stored.
2. In the Node Interpreter field, specify the Node.js interpreter to use. Choose a configured interpreter from the drop-down list or choose Add to configure a new one, see [Configuring Node.js Interpreters](#)
3. In the React Native field, specify the path to the `react-native-cli` package.

---

Twitter Bootstrap The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

Choose this option to create a project, set up its structure, and generate some sources based on the [Twitter Bootstrap](#) template.

In the right-hand pane:

1. Specify the project name and the path to the folder where the project-related files will be stored.
2. From the Version drop-down list, choose the template version to use and click Create .

---

Web Starter Kit The feature is supported only in the Ultimate edition when the JavaScript Support plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#) .

Choose this option to create a project, set up its structure, and generate some sources in accordance with the [Web Starter Kit](#) requirements.

In the right-hand pane:

1. Specify the project name and the path to the folder where the project-related files will be stored.
2. From the Version drop-down list, choose the template version to use and click Create .

---

Yeoman The feature is supported only in the Ultimate edition when the Yeoman plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

Choose this option to get interface for generating framework-specific project stubs using the [Yeoman](#) tool.

The right-hand pane shows all the previously installed [Yeoman generators](#) . Select the required generator from the list, click Next .

## Flash

Select this option if you are going to develop for the [Adobe Flash runtimes](#) using [Flex](#) or [ActionScript](#) . Specify the associated settings.

### ItemDescription

---

Target platform	Select the target environment for the content that you are going to develop: <ul style="list-style-type: none"><li>– Web for Flash player / Web browser-targeted content.</li><li>– Desktop for Adobe AIR-targeted content.</li><li>– Mobile for the content intended for mobile devices (Android, iOS, etc.).</li></ul>
-----------------	--

---

Pure ActionScript	Select this checkbox if you are not going to use MXML (i.e. all your source code will be written in ActionScript).
----------------------	--

---

Output type	Select the intended output type, that is, what your resulting content is going to be: <ul style="list-style-type: none"><li>– Application. A runnable application, an SWF file.</li><li>– Runtime-loaded module. A dynamically-loadable <a href="#">module</a>, an SWF file.</li><li>– Library. An SWC file.</li></ul>
-------------	--

---

Target devices	For a Mobile Application: use the Android and iOS checkboxes to specify the intended target devices for your application. As a result, IntelliJ IDEA enables or disables creating an application descriptor and packaging your application for the corresponding devices. (The Android and iOS checkboxes on this page correspond to the Enabled checkboxes on the <a href="#">Android</a> and <a href="#">iOS tabs</a> in the <a href="#">build configuration</a> that will be created.)
----------------	--

---

Flex/AIR SDK	Select the Flex or AIR <a href="#">SDK</a> to be used. If the list is empty or does not contain the required SDK, click  ( <a href="#">Shift+Enter</a> ) and add the required SDK in the Configure SDK dialog.
--------------	--

---

Target player	For the Web target platform: the target Flash Player version (readonly). (This setting is defined by the selected Flex SDK version.)
---------------	--

---

Create sample app	For the Application output type: select this checkbox if you want a sample application to be created. You can use this sample application for learning and also as a basis for your own application development.  If necessary, change the source file name suggested by IntelliJ IDEA.
----------------------	--

---

Create HTML wrapper template	For a Web Application: select this checkbox if you want an <a href="#">HTML wrapper</a> template for your application to be created. Select or deselect the associated options as needed: <ul style="list-style-type: none"><li>– Enable integration with browser navigation . Select this option to enable deep linking. Deep linking lets users navigate their interactions with the application by using the Back and Forward buttons in their browser.</li><li>– Check Flash player version . If you select this option, the compiled application will check for the correct version of Flash Player.</li><li>– Express install . If you select this option, the application will run an SWF file in the existing Flash Player to upgrade users to the latest version of the player.</li></ul>
------------------------------------	---

## Empty Project

If you select this option, IntelliJ IDEA will create just a minimal folder structure and the necessary project definition files. You'll be able to expand your project later.

Select the technologies, frameworks and languages to be supported, and specify the associated settings. For general info, see [Configuring projects](#) .

- [Web Application](#)

## Web Application

Select the checkbox to enable generic [Web application](#) development support. See also, [Enabling Web Application Support](#) .

### ItemDescription

Version	Select the version of the Servlet specification to be supported.
Create web.xml	For version 3.0 or later: select this checkbox to create the <a href="#">deployment descriptor</a> file <code>web.xml</code> . (For earlier versions, this file is always created.)

## Struts

Select the checkbox to enable [Apache Struts](#) 1.x support. See also, [Preparing to Use Struts](#) .

### ItemDescription

Version	Select the Struts version to be supported. If you also choose to download the library files that implement Struts (the Download option), the selected version will define which files you will be able to download.
Libraries	<p>You'll need a <a href="#">library</a> that implements Struts. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>- Download. Select this option to download the library files that implement the selected Struts version. (The downloaded files will be arranged in a <a href="#">library</a> .)</li><li>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>- Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## Struts 2

Select the checkbox to enable [Apache Struts 2](#) support. See also, [Preparing to Use Struts 2](#) .

You'll need a [library](#) that implements Struts 2. You can choose to use an existing library, create and use a new one, download

the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
- Download. Select this option to download the library files that implement Struts 2. (The downloaded files will be arranged in a [library](#) .)  
  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## WebServices

Select the checkbox to enable [Web Services](#) development support. See also, [Preparing to Develop a Web Service](#) .

### ItemDescription

Generate sample server code	Select this checkbox to have a sample <code>HelloWorld</code> class created in your source folder (e.g. <code>src</code> ).
Configure	Click this link to specify the settings for WS engines that you want to use. (The <a href="#">Web Services dialog</a> will open.)

## JSF

Select the checkbox to enable [JavaServer Faces](#) (JSF) support. See also, [Preparing for JSF Application Development](#) .

### ItemDescription

Version	Select the JSF version to be supported.
Libraries	<p>You'll need a <a href="#">library</a> that implements JSF. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)  Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</li><li>- Download. Select this option to download the library files that implement JSF. (The downloaded files will be arranged in a <a href="#">library</a> .)  Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>- Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## Primefaces, Richfaces, Openfaces, or Icefaces

Select the checkbox to be able to use the corresponding JSF component library ([PrimeFaces](#) , [RichFaces](#) , [OpenFaces](#) , or [ICEfaces](#) ). See also, [Preparing for JSF Application Development](#) .

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)  
  
Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)
- Download. Select this option to download the corresponding JSF component library files. (The downloaded files will be arranged in a [library](#) .)  
  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Google App Engine

Select the checkbox to be able to use [Google App Engine](#) . See also, [Creating Google App Engine Project](#) .

### ItemDescription

Google App Engine SDK	Specify the path to the Google App Engine SDK for Java installation directory. You can click  and select the corresponding directory in the <a href="#">dialog that opens</a> .
Persistence	If necessary, select the <a href="#">App Engine Datastore implementation</a> to be supported (JDO or JPA).
Download	If the path to Google App Engine SDK is not specified, you can click this link to open the <a href="#">Google App Engine Downloads page</a> . (This page lets you download the latest version of Google App Engine SDK for Java.)

## Groovy

Select the checkbox to enable [Groovy](#) support.

Select an existing Groovy library or create a new [library](#) for Groovy:

- Use library. Select the Groovy library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).
- Create. If Groovy is already installed on your computer, you can create a [library](#) for Groovy and use that new library. To do that, click Create and select the Groovy installation directory in the [dialog that opens](#) .

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

## Hibernate

Select the checkbox to enable [Hibernate](#) support. See also, [Enabling Hibernate Support](#) .

### ItemDescription

Create default hibernate configuration and main class	Select this checkbox to have a Hibernate configuration file <code>hibernate.cfg.xml</code> and a class with the <code>main()</code> method created.
Import database schema	Select this checkbox to have a database schema imported automatically.
Libraries	<p>You'll need a <a href="#">library</a> that implements Hibernate. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"> <li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).</li> </ul> <p>Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</p> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"> <li>– Download. Select this option to download the library files that implement Hibernate. (The downloaded files will be arranged in a <a href="#">library</a> .)</li> </ul> <p>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</p> <ul style="list-style-type: none"> <li>– Set up library later. Select this option to postpone setting up the library until a later time.</li> </ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## JavaEE Persistence

Select the checkbox to enable [Java Persistence API](#) (JPA) support. See also, [Enabling JPA Support](#) .

### ItemDescription

persistence.xml version	<p>Select the version of the <code>persistence.xml</code> file that you want to use.</p> <p>If you also choose to download the library files that implement JPA (the Download option), the selected version will define which files you will be able to download.</p>
Import database schema Libraries	<p>Select this checkbox to have a database schema imported automatically. Optionally, select the JPA implementation-specific database scheme to be imported from the list above the checkbox.</p> <p>You'll need a <a href="#">library</a> that implements JPA. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"> <li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).</li> </ul> <p>Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</p> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"> <li>– Download. Select this option to download the library files that implement the selected JPA version. (The downloaded files will be arranged in a <a href="#">library</a> .)</li> </ul> <p>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</p> <ul style="list-style-type: none"> <li>– Set up library later. Select this option to postpone setting up the library until a later time.</li> </ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be</p>

downloaded.

## JBoss Drools

Select the checkbox to enable [JBoss Drools](#) support.

You'll need a [library](#) that implements Drools. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Drools. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## OSGi

Select the checkbox to enable [OSGi](#) support.

You'll need a [library](#) that implements OSGi. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement OSGi. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## SQL Support

Select the checkbox to enable [SQL](#) support.

### ItemDescription

Default Dialect	Select the SQL dialect to be used by default for the module. Select Project Default to use the default project SQL dialect.
-----------------	---

## Thymeleaf

Select the checkbox to enable [Thymeleaf](#) support.

You'll need a [library](#) that implements Thymeleaf. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Thymeleaf. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## WebServices Client

Select the checkbox to enable Web Services client development support. See also, [Enabling Web Service Client Development Support](#).

### ItemDescription

Generate sample client code	Select this checkbox to have sample client code generated in your source folder (e.g. <code>src</code> ). To generate the code, IntelliJ IDEA will ask you to specify the corresponding <a href="#">WSDL</a> file.
Configure	Click this link to specify the settings for WS engines that you want to use. (The <a href="#">Web Services dialog</a> will open.)

## Batch Applications

Select the checkbox to enable [Batch Applications](#) development support.

### ItemDescription

Create batch.xml	Select the checkbox to create a <code>META-INF\batch.xml</code> mappings file (one with the <code>&lt;batch-artifacts&gt;</code> root element).
Create Sample Job Xml	Select the checkbox to create a sample job XML file ( <code>META-INF\batch-jobs\job.xml</code> ).

**Libraries**

You'll need a [library](#) that implements the batch framework. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#). (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#).)

- Download. Select this option to download the files that implement the batch framework. (The downloaded files will be arranged in a [library](#).)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## CDI: Contexts and Dependency Injection

Select the checkbox to enable [Contexts and Dependency Injection](#) (CDI) support.

You'll need a [library](#) that implements CDI. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#). (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#).)

- Download. Select this option to download the library files that implement CDI. (The downloaded files will be arranged in a [library](#).)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## DM Server

Select the checkbox to be able to use [SpringSource dm Server](#) and develop dm Server-targeted applications.

### ItemDescription

Server	Select the server to be used from the list (if the corresponding server is already defined in IntelliJ IDEA). To define a server in IntelliJ IDEA, click Add and specify the server settings in the Spring dmServer dialog that opens.
Facet	Select the deployment artifact type that the module will implement (the Spring DM facet type in IntelliJ IDEA terms): <ul style="list-style-type: none"><li>– Bundle, an OSGi bundle. IntelliJ IDEA will create:<ul style="list-style-type: none"><li>– The <code>META-INF\MANIFEST.MF</code> file for the bundle.</li><li>– A dm Bundle <a href="#">artifact configuration</a>.</li><li>– A project-level <a href="#">library</a> for the dm Server API. This library will be added to the <a href="#">module dependencies</a>.</li><li>– A dm Server-oriented <a href="#">run/debug configuration</a>.</li></ul></li></ul> <p>If necessary, specify <a href="#">additional options</a>.</p>

- PAR or Plan, a dm Server PAR or plan. Specify the [associated settings](#) .
- Configuration, a configuration artifact. Specify the [artifact name](#) .

For more information on dm Server deployment artifacts, see "Deployment Architecture" and "Developing Applications" in [SpringSource dm Server Programmer Guide](#) .

---

#### Bundle options

**Spring DM Support** Select this checkbox to enable [Spring](#) support (to create a Spring facet in IntelliJ IDEA terms). As a result, IntelliJ IDEA will create the following files:

- `META-INF\spring\module-context.xml`
- `META-INF\spring\osgi-context.xml`

At this step you are not suggested to download the library files that implement Spring. However, you will be able to do that after the module has been created by using the corresponding quick fix in the Project Structure dialog.

**Web module** Select this checkbox to enable generic [Web application](#) development support (to create a Web facet in IntelliJ IDEA terms). Specify the associated settings:

- Version. Select the version of the Servlet specification to be supported.
- Create web.xml. For version 3.0 or later: select this checkbox to create the [deployment descriptor](#) file `web.xml` . (For earlier versions, this file is always created.)

As a result, IntelliJ IDEA will create `web\WEB-INF\web.xml` (for version 3.0 or later - if so specified).

---

#### PAR or Plan options

**Name** For a PAR, this is the application identifier ( `Application-SymbolicName` ), for a plan - the plan name (the `name` attribute of the `<plan>` element).

**Version** The application or the plan version ( `Application-Version` or the `version` attribute of the `<plan>` element).

**Plan** Select this option to create a plan. IntelliJ IDEA will create:

- A `.plan` XML file.
- A dm Plan artifact specification.

**Platform Archive (PAR)** Select this option to create a PAR. IntelliJ IDEA will create:

- The `META-INF\MANIFEST.MF` file for the PAR.
- A dm Platform Archive artifact specification.

**Scoped** For a plan: select this checkbox to make the plan scoped (corresponds to `scoped="true"` within the `<plan>` element).

**Atomic** For a plan: select this checkbox to make the plan atomic (corresponds to `atomic="true"` within the `<plan>` element).

**Nested bundles** Use the controls in this area to manage other dm Server deployment artifacts within the PAR or plan. (In IntelliJ IDEA, these are represented by other modules within the same project if those modules have suitable dm Server facets. A PAR may include OSGi bundles and configuration artifacts; a plan - OSGi bundles, configuration artifacts, PARs and other plans).

- Add. Use this button to add the artifacts to the list. Select the necessary artifacts (IntelliJ IDEA modules) in the dialog that opens.
- Remove. Use this button to remove the selected artifacts from the list.
- Up. For a plan: use this button to move the selected artifact one line up in the list. (The order of artifacts defines their deployment order.)
- Down. For a plan: use this button to move the selected artifact one line down in the list.
- Versions. For a plan: use this button to specify the version or the range of versions for the selected artifact (corresponds to the `version` attribute of the `<artifact>` element).

---

#### Configuration option

**Name** Specify the OSGi name of the artifact (at the deployment stage, corresponds to the name of the file).

## EJB: Enterprise JavaBeans

Select the checkbox to enable [Enterprise JavaBeans](#) (EJB) support. See also, [Enabling EJB Support](#) .

---

#### ItemDescription

**Version** Select the EJB version to be supported.  
If you also choose to download the library files that implement EJB (the Download option), the selected version will define which files you will be able to download.

**Libraries** You'll need a [library](#) that implements EJB. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement the selected EJB version. (The downloaded files will be arranged in a [library](#) .)

- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Google Web Toolkit

Select the checkbox to be able to use [Google Web Toolkit](#) (GWT). See also, [Enabling GWT Support](#) .

### ItemDescription

GWT SDK	Specify the path to the GWT SDK installation directory. You can click <input type="text"/> and select the corresponding directory in the <a href="#">dialog that opens</a> .
Create sample application	Select this checkbox to have a sample application created. Specify the package for the application classes in the field underneath.
Download GWT	If the path to GWT SDK is not specified: you can click this link to open the <a href="#">Google Web Toolkit Downloads page</a> . (This page lets you download a GWT SDK.)

## JavaEE Application

The features that become available when you select this checkbox are mainly related to packaging your [Java EE application](#) in an Enterprise Application Archive ([EAR](#) ). For more information, see [Enabling Java EE Application Support](#) .

### ItemDescription

Version	The Java EE version.
---------	----------------------

## RESTful WebServices

Select the checkbox to enable [RESTful](#) Web Services (client and server) development support. See also, [RESTful WebServices](#) .

### ItemDescription

Generate server code	Select this checkbox to have a sample <code>HelloWorld</code> server class created in your source folder (e.g. <code>src</code> ).
Generate client code	Select this checkbox to have a sample <code>HelloWorldClient</code> class created in your source folder (e.g. <code>src</code> ).
Libraries	<p>You'll need a <a href="#">library</a> that implements the JAX-RS API. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"> <li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</li> </ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"> <li>– Download. Select this option to download the files that implement the JAX-RS API. (The downloaded files will be arranged in a <a href="#">library</a> .)</li> <li>– Set up library later. Select this option to postpone setting up the library until a later time.</li> </ul> <p>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</p> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## Tapestry

Select the checkbox to enable [Apache Tapestry](#) support. See also, [Enabling Tapestry Support](#) .

You'll need a [library](#) that implements Tapestry. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Tapestry. (The downloaded files will be arranged in a [library](#) .)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be

downloaded.

## Spring

Select the checkbox to enable [Spring](#) support. See also, [Spring](#) .

You'll need a [library](#) that implements Spring. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the  key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Spring. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Spring MVC, Spring Batch, or other Spring framework

Select a checkbox to add support for a particular Spring framework (e.g. [Spring MVC](#) , [Spring Batch](#) , etc.). See also, [Spring](#) .

You'll need a [library](#) that implements the selected framework. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the  key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement the selected Spring framework. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

There are sample projects for various application types (e.g. Java, Java EE, Spring). Such projects are created according to pre-defined project templates and normally include sample code, a [run configuration](#) for that code, etc.

To create a template-based project, select the Create project from template checkbox and an option of interest in the area underneath.

This page is available only for J2ME modules and provides JAD/JAM file settings depending on the selected J2ME SDK (WTK or DoJa). You can change these settings later in the Project Structure dialog ( Project Structure | Module | Mobile Module Settings ).

In this section:

– [WTK](#)

– [DoJa](#)

## WTK

### ItemDescription

---

MIDlet-Name	In this text box, specify the MIDlet suite name (corresponds to the JAD MIDlet-Name property). This option is necessary to identify MIDlet suite on a device.
MIDlet-JAR-URL	In this text box, specify the MIDlet JAR location. This option is also necessary to identify MIDlet suite on a device. The JAR file will be installed from the location MIDlet-JAR-URL afterward. You can specify the location manually, or click the ellipsis button and select the necessary location in the <a href="#">dialog that opens</a> .
MIDlet-Vendor	In this text box, specify the MIDlet vendor name, that is, the MIDlet suite provider.
MIDlet-Version	In this text box, specify your MIDlet version number.
Keep user-defined JAD file	Select this checkbox to preserve the <code>JAD</code> file (with settings specified above) to the project.

## DoJa

### ItemDescription

---

AppName	In this text box, type the application name (50 bytes maximum).
PackageUrl	In this text box, specify the URL address to access the application. Make sure the URL is an ASCII-format string. Also, an IP address cannot be specified directly.
Keep user-defined JAM file	Select this checkbox to add the <code>JAM</code> file containing settings specified above to the project.

Use this page to specify Gradle settings for your project.

#### ItemDescription

Use auto-import	Select this checkbox to resolve all the changes made to the Gradle project automatically every time you refresh your project.
Create directories for empty content roots automatically	Select this checkbox to create the default directory structure for a Gradle project, e.g. <code>/src/main/java</code> and <code>/src/test/java</code> .
Create separate module per source set	Select this checkbox to use the <a href="#">source set</a> feature in resolving your Gradle projects.
Use default gradle wrapper (recommended)	Select this option to use Gradle wrapper. Using Gradle wrapper lets you get automatic Gradle download for the build. It also lets you build with the precise Gradle version.
Use gradle wrapper task configuration	Select this option to use Gradle wrapper customization in script.
Use local gradle distribution	Select this option to run local build scripts.
Gradle home	<p>Use this field to specify the fully qualified path to your Gradle installation. This field becomes active when you select Use local gradle distribution .</p> <p>If Gradle location has been defined by the environment variables <code>GRADLE_HOME</code> or <code>PATH</code> , then IntelliJ IDEA deduces this location, and suggests this path as the default value.</p> <p>If Gradle location has not been deduced from the environment variables, specify it manually, or click the Browse button, and select the desired directory in the <a href="#">dialog that opens</a> . Note that the value entered in this field takes precedence over the environment variables.</p>
Gradle JVM	Use this drop-down list to specify JVM under which IntelliJ IDEA will run Gradle when you import the specified Gradle project and when you execute its tasks.

Use this dialog to specify additional settings for your new Gradle project.

#### ItemDescription

---

Add as module to	This field appears when you add a new module to the existing project. By default, the field displays the the name of your project. Click  to select a different name.
GroupId	Use this field to specify <code>groupId</code> of the new project, which will be added to the <code>build.gradle</code> file. If a parent Gradle project is specified, this coordinate can be inherited from the parent. To do that, select the <code>Inherit</code> checkbox.
ArtifactId	Use this field to specify <code>artifactId</code> of the new project, which will be added to the <code>build.gradle</code> file.
Version	Use this field to specify <code>version</code> of the new project, which will be added to the <code>build.gradle</code> file. If a parent Gradle project is specified, this coordinate can be inherited from the parent. To do that, select the <code>Inherit</code> checkbox.

Use this page to define the properties of a new Maven module.

## ItemDescription

Add as module to Specify the aggregator Maven project.

If you want the new module to be aggregated in an existing Maven project, click the ellipsis button, and select the desired aggregator. The new Maven Module will be added to the `<modules>` section of the `pom.xml` file of the aggregator, for example:

```
<
  modules
    <
      module
        mod1<
      module
        <
          module
            mod2<
          module
        modules
```

`none` means that the new module will not be aggregated into an existing Maven project.

Parent Click the ellipsis button and select the desired parent Maven project from the list of existing ones.

If a new module has a parent, the following section is added to its `pom.xml` file, for example:

```
<
  parent
  >
    <
      groupId
      >org.something<
    /groupId
  >
    <
      artifactId
      >parent1<
    /artifactId
  >
    <
      version
      >0.1<
    /version
  >
  <
  /parent
  >
```

`none` means that the new module doesn't have a parent and thus doesn't inherit properties and profiles of any Maven project.

GroupId Specify `GroupId` of the new module, which will be added to the `pom.xml` file of the module. By default, `GroupId` equals the module name. If a parent Maven project is specified, this coordinate can be inherited from the parent. To do that, select the inherit checkbox.

ArtifactId Specify `ArtifactId` of the new module, which will be added to the `pom.xml` file of the module. By default,

---

`ArtifactId` equals the module name.

Version Specify `Version` of the new module, which will be added to the `pom.xml` file of the module. If a parent Maven project is specified, this coordinate can be inherited from the parent. To do that, select the Inherit checkbox.

This dialog box is invoked by the Add Archetype button in the [Maven page](#) of the New Project wizard. It helps populate the list of archetypes with the ones found by the Maven coordinates and downloaded from the Maven repositories.

**ItemDescription**

---

GroupId	Specify <code>GroupId</code> of the archetype to be sought for in a Maven repository.
ArtifactId	Specify <code>ArtifactId</code> of the archetype to be sought for in a Maven repository.
Version	Specify <code>Version</code> of the archetype to be sought for in a Maven repository.
Repository (optional)	Optionally, enter the URL of the desired repository.

This page appears when you select Create from archetype option in the [project wizard for Maven](#) . Use this page to modify Maven default settings.

#### ItemDescription

---

**Maven home directory** Use this drop-down list to select a bundled Maven version that is available (for Maven2, version 2.2.1 and for Maven3, version 3.0.5) or the result of resolved system variables such as `MAVEN_HOME` or `MAVEN2_HOME` . You can also specify your own Maven version that is installed on your machine. You can click  and select the necessary directory in the [dialog that opens](#) .

---

**User settings file** Specify the file that contains user-specific configuration for Maven in the text field. If you need to specify another file, select Override checkbox, click the ellipsis button and select the desired file in the Select User Settings File dialog.

---

**Local repository** By default, this field shows the path to the local directory under the user home that stores downloads and contains the temporary build artifacts that you have not yet released. If you need to specify another directory, select Override checkbox, click the ellipsis button and select the desired path in the Select Local Repository dialog.

---

**Properties** By default, the columns in this area display system properties that are passed to Maven for creating a project from the archetype.

You can click the following buttons to modify displayed properties:

-  Add a Maven property.
-  Remove a Maven property.
-  Edit a Maven property.

- New Project
- Target Android Devices
- Add an Activity
- Customize the Activity

Use this page to configure your new project.

#### ItemDescription

---

Application name	Specify the name of your Android project. By default, IntelliJ IDEA automatically generates the name of the application.
Company Domain	Use this field to specify a qualifier that will be appended to the package name. By default, IntelliJ IDEA automatically generates the name of the qualifier.
Package name	By default, IntelliJ IDEA generate the package name automatically. You can click Edit to modify the specified name of the package.
Include C ++ Support	Select this checkbox to use C ++ for your Android application.
Project location	Use this field to specify the location of your project. You can click  and select the necessary directory in the <a href="#">dialog that opens</a> .

IntelliJ IDEA lets select form factors for your Android project.

**ItemDescription**

---

Phone and Tablet	Select this checkbox if your target device is either an Android phone or an Android tablet.
------------------	---

---

Minimum SDK	Use this drop-down list to select the minimum SDK for the Android form factor.
-------------	--

---

Wear	Select this checkbox if your target device is the Android Wear.
------	---

---

TV	Select this checkbox if your target device is the Android TV.
----	---

---

Android Auto	Select this checkbox if your target device is the Android Auto.
--------------	---

---

Glass	Select this checkbox if your target device is the Android Glass.
-------	--

IntelliJ IDEA lets you add an activity to your Android project depending on the form factor that you have selected in the [Target Android Devices](#) dialog.

#### ItemDescription

---

Add an activity to Module/Mobile(Auto)

The following [Activity templates](#) are available:

- Add No Activity
- Blank Activity
- Empty Activity
- Fullscreen Activity
- Google AdMob Ads Activity
- Google Maps Activity
- Login Activity
- Master/Detail Flow
- Navigation Drawer Activity
- Scrolling Activity
- Settings Activity
- Tabbed Activity

---

Add an activity to Wear

The following [Activity templates](#) are available:

- Add No Activity
- Always On Wear Activity
- Blank Wear Activity
- Display Notification
- Google Maps Wear Activity
- Watch Face

---

Add an activity to TV

The following [Activity templates](#) are available:

- Add No Activity
- Android TV Activity

---

Add an activity to Glass

The following [Activity templates](#) are available:

- Add No Activity

IntelliJ IDEA lets you customize the activity you have selected in the [Add an Activity](#) dialog.

**Activity** Use this field to specify the name of your activity.

Name

---

Layout Name

Use this field to specify the layout name.

---

Title

Use this field to specify the name of the title.

**Note** The appearance of other fields, drop-down lists and checkboxes depend on the type of form factors and activities you have previously selected.

**Warning!** The following is only valid when JavaScript Support Plugin is installed and enabled!

File | New | Project

Welcome Screen | Create New Project

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose Static Web in the left-hand pane and then choose HTML5 Boilerplate from the list in the right-hand pane.

The feature is supported only in the Ultimate edition when the HTML Tools plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

#### ItemDescription

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
Version	From this drop-down list, choose the version of the template in accordance to which the stub will be generated. Click  to refresh the list of available template versions.

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose Static Web in the left-hand pane and then choose Web Starter Kit from the list in the right-hand pane.

The feature is supported only in the Ultimate edition when the HTML Tools plugin is installed and enabled. The plugin is activated by default. If the plugin is disabled, enable it on the [Plugins settings](#) page as described in [Enabling and Disabling Plugins](#).

The feature is supported only in the Ultimate edition when the Meteor plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
Meteor	In this text box, specify the location of the Meteor executable file (see <a href="#">Installing Meteor</a> ).
Template	From this drop-down list, choose the sample to generate. To have a basic project structure generated, choose the Default option.
Filename	In this text box, type the name for the mutually related <code>.js</code> , <code>.html</code> , and <code>.css</code> files that will be generated. The text box is available only if the Default sample type is selected from the Template drop-down list.

**Warning!** The following is only valid when PhoneGap/Cordova Plugin is installed and enabled!

File | New | Project

Welcome Screen | Create New Project

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose Static Web in the left-hand pane and then choose PhoneGap/Cordova App from the list in the right-hand pane.

The feature is supported only in the Ultimate edition when the PhoneGap/Cordova plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
PhoneGap/Cordova	In this text box, specify the location of the executable file <code>phonegap.cmd</code> , or <code>cordova.cmd</code> , or <code>ionic.cmd</code> (see <a href="#">Installing PhoneGap/Cordova/Ionic</a> ).

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Yeoman and Node.js plugins are installed and enabled!

File | New | Project

Welcome Screen | Create New Project

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose Static Web in the left-hand pane and then choose Yeoman from the list in the right-hand pane.

The feature is supported only in the Ultimate edition when the Node.js and Yeoman plugins are installed and enabled. The plugins are not bundled with IntelliJ IDEA, but they can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) . Once enabled, the plugins are available at the IDE level, that is, you can use them in all your IntelliJ IDEA projects.

#### ItemDescription

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
Generators	<p>In this area, create a list of <a href="#">Yeoman generators</a> you need and select the one to use during the current project generation.</p> <ul style="list-style-type: none"><li>- To add a generator to the list:<ol style="list-style-type: none"><li>1. Click Install Generator .</li><li>2. From the dialog box that opens showing all the available generator packages, select the required package in the left-hand pane and click the Install Generator button that appears in the right-hand pane. You can install several packages one after another without leaving the dialog box. When the installation is over, click Close to return to the list of generators which is already expanded with the newly added package.</li></ol></li><li>- To create a project using a generator:<ol style="list-style-type: none"><li>1. In the Location field, specify the folder where the new project will be created. Type the path manually or click the <input type="text"/> and select the folder in the dialog box that opens.</li><li>2. If necessary, in the Options text box, specify additional flags to customize the project creation. The set of available flags depends on the selected generator.</li><li>3. Select the required generator from the list and click Next .</li><li>4. Specify the required settings in the New Project wizard that starts. The number of pages and their contents depend on the chosen generator.</li><li>5. On the last page of the wizard, select or clear the Run npm install&amp;bower install checkbox to specify whether you want to run <a href="#">Node Package Manager</a> and <a href="#">Bower</a> to install the packages that are required for developing the new project.</li><li>6. Click Next and choose to open the new project in the current window or in the new one.</li></ol></li></ul>
Options	In this text box, specify additional flags to customize the project creation. The set of available flags depends on the selected generator.
Configure Node.js and Yeoman	Click this link to open the <a href="#">Yeoman</a> dialog box and change the settings of <a href="#">Node.js</a> and <a href="#">Yeoman</a> .

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose PHP in the left-hand pane and then choose Composer Project from the list in the right-hand pane.

Use the dialog box to have IntelliJ IDEA create a project with Composer-specific structure. To do this, appoint the **Composer** instance to use and install the package you need in the project.

**The feature is supported only in the Ultimate edition when the Command Line Tools Support plugin is installed and enabled.**

The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

---

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
Composer.phar	<p>In this area, appoint the <code>composer.phar</code> file to use in project creation.</p> <ul style="list-style-type: none"><li>– Use existing composer.phar: choose this option to use commands from a previously downloaded <code>composer.phar</code> and specify its location in the text box.</li><li>– Download composer.phar from getcomposer.org: choose this option to have a new instance of Composer downloaded. The <code>composer.phar</code> file will be saved under the project root folder specified in the Location text box.</li></ul>
Package	<p>In this area, specify the package to install during the project creation.</p> <ul style="list-style-type: none"><li>– Available packages: from this list box, select the package to install. Use the search field, if necessary: start typing the search string, as you type, the list dynamically reduces to show the packages that match the entered pattern.</li><li>– Description: this read-only text box briefly explains the functionality of the selected package.</li><li>– Version to install: from this drop-down list, select the package version. The contents of the list depend on the specific package.</li></ul>
Settings	<p>In this area, specify advanced settings for generating a project stub and installing packages (dependencies):</p> <ul style="list-style-type: none"><li>– PHP interpreter: choose one of the configured PHP interpreters from the list. See <a href="#">Configuring Remote PHP Interpreters</a> for details.</li><li>– Command line parameters: in this text box, type the additional command line parameters. For example, to have a package added to the <code>require-dev</code> section instead of the default <code>require</code> section, type <code>--dev</code>. For more information about Composer command line options during installation, see <a href="https://getcomposer.org/doc/03-cli.md">https://getcomposer.org/doc/03-cli.md</a>.</li></ul>

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose PHP in the left-hand pane and then choose Drupal Module from the list in the right-hand pane.

Use this dialog box to generate and set up a module stub in compliance with the Drupal requirements.

The feature is supported only in the Ultimate edition when the [Drupal Support](#) plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

**ItemDescription**

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
installation path	In this text box, specify the root folder of the installation.
Set up PHP   Include paths	<ul style="list-style-type: none"><li>– Select this checkbox to have <i>Drupal</i> include paths automatically configured for the project. After you leave the dialog box, the following paths will be added to the <i>Include Paths</i> list on the <a href="#">PHP</a> page: <code>&lt;drupal installation root&gt;/includes</code>, <code>&lt;drupal installation root&gt;/modules</code>, and <code>&lt;drupal installation root&gt;/sites/all/modules</code></li><li>– Clear the checkbox to configure the include paths manually.</li></ul>
Version	From this drop-down list, choose the version of Drupal to use, the supported versions are 6, 7, and 8.

Use this dialog box to configure **Google App Engine for PHP** project settings.

The feature is supported only in the Ultimate edition when the Google App Engine for PHP plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains** plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

---

**ItemDescription**

---

**Application ID** In this text box, type the identifier of your application as you specified it on the [Create application](#) page.

---

**SDK directory** In this text box, specify the path to the folder where the [Google App Engine SDK for PHP](#) is installed.

---

**Python executable** In this text box, specify the location of the Python executable file. Type the path manually or click the **Browse** button  and choose the executable file in the dialog box that opens.

The right-hand pane of the [Project Category and Options](#) dialog box looks as follows when you choose PHP in the left-hand pane and then choose PHP Empty Project from the list in the right-hand pane.

The feature is supported only in the Ultimate edition when the PHP plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the JetBrains plugin repository as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

#### ItemDescription

Project Name	In this text box, specify the name of the project, by default it is the name of the folder specified in the location field.
Project Location	In this text box, specify the path to the project folder where the project-related files will be stored.
PHP Language Level	<p>In this drop-down list, specify the PHP functionality scope to get coding assistance for. Each functionality scope is associated with the PHP version that supports this functionality. Currently PHP 5.3 , PHP 5.4 , PHP 5.5 , PHP 5.6 , PHP 7 , PHP 7.1 , and PHP 7.2 levels are supported.</p> <p>No correlation between the PHP version used in the project and the language level is enforced. Although the language version of each interpreter is detected automatically, you can still tell IntelliJ IDEA to provide you with coding assistance that corresponds to another language level. However, if you attempt to use a code construct that is not supported by the specified language level, IntelliJ IDEA suggests a Switch to PHP &lt;version&gt; <a href="#">quick-fix</a>.</p>
Interpreter	From this drop-down list, choose the PHP interpreter to use in the current project by default. The list contains all the currently configured local and remote PHP interpreters. See <a href="#">Configuring Local PHP Interpreters</a> and <a href="#">Configuring Remote PHP Interpreters</a> for details.
Include path	<p>This area shows a list of <a href="#">paths to PHP-related items</a> below the PHP home directory. The specified include paths will be used:</p> <ul style="list-style-type: none"><li>– By the <code>require()</code> , <code>include()</code> , <code>fopen()</code> , <code>file()</code> , <code>readfile()</code> , and <code>file_get_contents()</code> functions when looking for files to use.</li><li>– By IntelliJ IDEA when resolving references to included files.</li></ul> <p>Use the Add  and Remove  buttons to manage the contents of the list. Use the Up  and Down  buttons to change the order of items in the list.</p>

Specify the project name, location and, if available, related settings.

#### ItemDescription

---

Project name	Specify the project name.
Project location	<p>Specify the path to the directory in which you want to create the project. (By default, a directory having the same name as the project is created.)</p> <p>You can click  ( <b>Shift+Enter</b> ) and select the necessary directory in the <a href="#">dialog that opens</a> . (You can create a new directory in that dialog, e.g. by using  .)</p>
More Settings	<p>Click the arrow (▶ or ▼) to show or hide additional settings. Mainly, these are the settings for the <a href="#">module</a> to be created (discussed below).</p> <p>Note that in certain cases those additional settings are unavailable.</p>
Module name	<p>Specify the module name.</p> <p>By default, the project name is used. If you accept this and other default module settings, the project folder will act as the <a href="#">module content root folder</a> .</p> <p>If you change the default module name, IntelliJ IDEA will suggest a new folder (within the project folder) as the module content root folder.</p>
Content root	<p>Specify the path to the module content root folder. (This is where all the files that make up your module will be stored; for more information, see <a href="#">Configuring projects</a> .) The default path is recommended.</p> <p>To use a different folder, click  ( <b>Shift+Enter</b> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>
Module file location	<p>Specify the path to the folder where the <code>.iml</code> <a href="#">module file</a> should be created.</p> <p>By default, this file is created in the module content root folder (recommended).</p> <p>To use a different folder, click  ( <b>Shift+Enter</b> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>
Project format	Select the <a href="#">project format</a> to be used. (The <code>.idea</code> directory-based format is recommended).

If a project is open in IntelliJ IDEA, you can access the New Module wizard from:

The main menu: File | New | Module .

The [Project Tool Window](#) : right-click a module folder and select New | Module .

The [Project Structure dialog](#) : in the leftmost pane select Modules , above the pane to the right click [+](#) and select New Module .

---

Use the New Module wizard to add a [module](#) to your [project](#) . (The new module will be created from scratch.)

- [Module Category and Options](#)
- [J2ME Page](#)
- [Android Facet Page](#)
- [Maven Page](#)
- [Module Name and Location](#)

In the left-hand pane, select the module category. This may be the technology that you are going to use, the platform or runtime that your development is going to target, etc.

In the right-hand part of the page, select additional options and specify associated settings.

Note that the set of options you can select from depends on which [plugins](#) are currently enabled in IntelliJ IDEA.

- [Java](#)
- [Java Enterprise](#)
- [J2ME](#)
- [Clouds](#)
- [Spring](#)
- [IntelliJ Platform Plugin](#)
- [Android](#)
- [Maven](#)
- [Gradle](#)
- [Groovy](#)
- [Grails](#)
- [Griffon](#)
- [Static Web](#)
- [Flash](#)

## Java

Select this option if you are going to use your new module to develop a [Java](#) application.

### ItemDescription

---

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Java Enterprise

Select this option if you are going to use your new module to develop a [Java EE](#) application.

### ItemDescription

---

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Java EE version** Select the Java EE version to be supported. (Affects the corresponding version setting for the Web Application, EJB and JavaEE Application options.)

**Application Server** Specify the application server that you are going to use to deploy and run your application. As a result, IntelliJ IDEA will create a [run/debug configuration](#) for the specified server. (You can specify the server later.)  
You can select a server which IntelliJ IDEA is already aware of, or specify another "new" server.

To specify a new server, click New and select the server of interest. Then, specify the server settings:

- For a server installed locally, specify the path to the server installation directory. (Click  to select the directory in the [corresponding dialog](#) .)
- For a hosted server (Cloud Foundry or CloudBees), specify your user account details.

Select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## J2ME

Select this option if you are going to use your new module to develop for [Java ME](#) .

### ItemDescription

---

**Module SDK** Specify an [SDK](#) for your module.  
If the necessary SDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click New and, in the [dialog that opens](#) , select the installation folder of the desired Java ME SDK. (By this time, the corresponding SDK must already be installed on your computer.)

---

**SQL Support** Select the checkbox to enable [SQL](#) support. Select the SQL dialect to be used by default from the list.

## Clouds

Select this option if you are going to deploy your application to a cloud platform such as [CloudBees](#) , [Cloud Foundry](#) ,

[Heroku](#) or [OpenShift](#) . See also, [Working with Cloud Platforms](#) .

#### ItemDescription

---

Module SDK	<p>Specify an <a href="#">SDK</a> (JDK) for your module. If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.</p> <p>Otherwise, click <a href="#">New</a> and select <a href="#">JDK</a> . Then, in the <a href="#">dialog that opens</a> , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)</p>
Account	<p>Specify your cloud user account. If the corresponding user account is already registered in IntelliJ IDEA, select it from the list.</p> <p>Otherwise, click <a href="#">New</a> , select the cloud platform and specify your user account settings in the dialog that opens.</p>
Application	<p>Cloud platform-specific application settings. CloudBees and Cloud Foundry. IntelliJ IDEA will create a sample Java web application which you'll be able to deploy to the cloud and run straight away.</p> <ul style="list-style-type: none"><li>- Version. The version of the Servlet specification to be supported.</li><li>- Create web.xml. For version 3.0 or later: select this checkbox to create the <a href="#">deployment descriptor</a> file <code>web.xml</code> . (For earlier versions, this file is always created.)</li></ul> <p>Heroku. You can select to create a new application or to git-clone the source code for one of your applications already deployed on Heroku.</p> <ul style="list-style-type: none"><li>- Template. A new sample application will be created. You'll be able to deploy this application to Heroku straight away.</li><li>- Existing. Select the application whose source code you want to clone.</li></ul> <p>OpenShift. You can select to git-clone the source code for one of your applications already deployed OpenShift or to create a new application.</p> <ul style="list-style-type: none"><li>- Existing. Select the application whose source code you want to clone.</li><li>- New. Select this option to create a new application. Specify the settings for your new application (for OpenShift terminology, see <a href="#">OpenShift documentation</a> ):<ul style="list-style-type: none"><li>- Standalone Cartridge. Select the primary cartridge.</li><li>- Gear size. Select the gear size.</li><li>- Scaling. Select the checkbox if the application should be scalable.</li><li>- Embeddable Cartridges. Select (additional) embedded cartridges.</li></ul></li></ul>

## Spring

Select this option if you are going to use your new module to develop a [Spring](#) application.

#### ItemDescription

---

Module SDK	<p>Specify an <a href="#">SDK</a> (JDK) for your module. If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.</p> <p>Otherwise, click <a href="#">New</a> and select <a href="#">JDK</a> . Then, in the <a href="#">dialog that opens</a> , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)</p>
------------	--

For information on other options and settings, see:

- [Spring](#)
- [Spring MVC, Spring Batch, or other Spring framework](#)
- [Additional Libraries and Frameworks](#)

## IntelliJ Platform Plugin

Select this option if you are going to use your new module to develop a [plugin](#) for IntelliJ IDEA or other IntelliJ Platform-based IDE.

#### ItemDescription

---

Module SDK	<p>Specify an <a href="#">SDK</a> for your module. If the necessary SDK is already defined in IntelliJ IDEA, select it from the list.</p> <p>Otherwise, click <a href="#">New</a> and, in the <a href="#">dialog that opens</a> , select the installation folder of the desired IntelliJ IDEA version. (An IntelliJ IDEA installation acts as an IntelliJ Platform Plugin SDK.) (By this time, the corresponding IntelliJ IDEA version must already be installed on your computer.)</p>
Groovy	<p>Select the checkbox to be able to use <a href="#">Groovy</a> . Specify the Groovy installation to be used. Use <a href="#">library</a> . If the desired version of Groovy is already defined in IntelliJ IDEA, select it from the list. (Groovy in IntelliJ IDEA is represented by a <a href="#">library</a> .)</p> <p>Create. Click this button to create a library for Groovy. In the <a href="#">dialog that opens</a> , select the Groovy installation directory.</p>
SQL Support	<p>Select the checkbox to enable <a href="#">SQL</a> support. Select the SQL dialect to be used by default from the list.</p>

## Android

Select this option if you are going to use your new module to develop for the [Android](#) OS. Select:

- Phone & Tablet Module to develop an Android application for an Android phone or an Android tablet.
- Android Wear Module to develop an Android application for the Android Wear.
- Android Library Module to develop a shared Android library.
- Android TV Module to develop an Android application for the Android TV.
- Glass Module to develop an Android application for the Android Glass.
- Import Gradle Project to import an existing Gradle project as a module.
- Import Eclipse ADT Project to import an existing Eclipse ADT project as a module .
- Import JAR/AAR Package to import an existing JAR or AAR package as a new module.
- Java Library to create a new Java library.

## Maven

Select this option if you are going to use your new module to develop a [Java](#) application with dependencies managed by [Maven](#) .

### ItemDescription

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

**Create from archetype** If this checkbox is not selected, the new `pom.xml` file will contain the basic information.

If this checkbox is selected, the new module will be created on the base of a Maven archetype chosen from the list that includes both the standard archetypes, and the ones found in Maven indices. You can modify Maven properties on [Maven Settings Page](#) .

If you want to populate the list with some archetype from a remote Maven repository, click the **Add Archetype** button, and find the desired archetype by Maven coordinates specified in [Add Archetype Dialog](#) .

## Gradle

Select this option if you want a module with a Gradle build script ( `build.gradle` ) to be created.

See also [Getting Started with Gradle](#) and [New Project Gradle References](#) .

### ItemDescription

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

## Groovy

Select this option if you are going to develop a [Groovy](#) application.

### ItemDescription

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

**Groovy library** If the desired version of Groovy is already defined in IntelliJ IDEA, select it from the list. (Groovy in IntelliJ IDEA is represented by a [library](#) .)

Create. Click this button to create a library for Groovy. In the [dialog that opens](#) , select the Groovy installation directory.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Grails

Select this option if you are going to develop a [Grails](#) application.

See also [Getting Started with Grails 3](#) .

### ItemDescription

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.

Otherwise, click **New** and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK. (By this time, the corresponding JDK must already be installed on your computer.)

**Grails SDK** If the desired version of Grails is already defined in IntelliJ IDEA, select it from the list. (Grails in IntelliJ IDEA is

**Home** represented by a [library](#) .  
Click  this button to create a library for Grails. In the [dialog that opens](#) , select the Grails installation directory.

---

**Create** create-app - select this option if you want to create a Grails application.  
create-plugin - select this option if you want to create a Grails plugin project.

---

**Options** Use this field to specify additional options such as profiles, for example.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Griffon

Select this option if you are going to develop a [Griffon](#) application.

See also [Creating a Griffon Application Module](#) .

### ItemDescription

---

**Module SDK** Specify an [SDK](#) (JDK) for your module.  
If the necessary JDK is already defined in IntelliJ IDEA, select it from the list.  
  
Otherwise, click New and select JDK . Then, in the [dialog that opens](#) , select the installation folder of the desired JDK.  
(By this time, the corresponding JDK must already be installed on your computer.)

---

**Griffon library** If the desired version of Griffon is already defined in IntelliJ IDEA, select it from the list. (Griffon in IntelliJ IDEA is represented by a [library](#) .)  
Create. Click this button to create a library for Griffon. In the [dialog that opens](#) , select the Griffon installation directory.

If necessary, select additional options and specify associated settings. For more information, see [Additional Libraries and Frameworks](#) .

## Static Web

Select Static Web if you are going to develop a Web application using [HTML /CSS](#) , [JavaScript](#) , [PHP](#) and related frameworks.

The other options are for developing a Web site or a Web front end using an [HTML5 Boilerplate](#) template, or the [Foundation](#) or the [Bootstrap](#) framework.

## Flash

Select this option if you are going to use your new module to develop for the [Adobe Flash runtimes](#) using [Flex](#) or [ActionScript](#) . Specify the associated settings.

### ItemDescription

---

**Target platform** Select the target environment for the content that you are going to develop:  
– Web for Flash player / Web browser-targeted content.  
– Desktop for Adobe AIR-targeted content.  
– Mobile for the content intended for mobile devices (Android, iOS, etc.).

---

**Pure ActionScript** Select this checkbox if you are not going to use MXML (i.e. all your source code will be written in ActionScript).

---

**Output type** Select the intended output type, that is, what your resulting content is going to be:  
– Application. A runnable application, an SWF file.  
– Runtime-loaded module. A dynamically-loadable [module](#) , an SWF file.  
– Library. An SWC file.

---

**Target devices** For a Mobile Application: use the Android and iOS checkboxes to specify the intended target devices for your application.  
As a result, IntelliJ IDEA enables or disables creating an application descriptor and packaging your application for the corresponding devices. (The Android and iOS checkboxes on this page correspond to the Enabled checkboxes on the [Android](#) and [iOS](#) tabs in the [build configuration](#) that will be created.)

---

**Flex/AIR SDK** Select the Flex or AIR [SDK](#) to be used.  
If the list is empty or does not contain the required SDK, click  ( [Shift+Enter](#) ) and add the required SDK in the Configure SDK dialog.

---

**Target player** For the Web target platform: the target Flash Player version (readonly). (This setting is defined by the selected Flex SDK version.)

---

**Create sample app** For the Application output type: select this checkbox if you want a sample application to be created.  
You can use this sample application for learning and also as a basis for your own application development.  
  
If necessary, change the source file name suggested by IntelliJ IDEA.

---

**Create HTML wrapper template** For a Web Application: select this checkbox if you want an [HTML wrapper](#) template for your application to be created.  
Select or deselect the associated options as needed:  
  
Enable integration with browser navigation . Select this option to enable deep linking.

- ~~Express install, deep linking, browser navigation, select the option to create deep linking.~~
- Deep linking lets users navigate their interactions with the application by using the Back and Forward buttons in their browser.
- Check Flash player version . If you select this option, the compiled application will check for the correct version of Flash Player.
- Express install . If you select this option, the application will run an SWF file in the existing Flash Player to upgrade users to the latest version of the player.

Specify the module name and location.

#### ItemDescription

Module name	Specify the module name.
Content root	<p>Specify the path to the module content root folder. (This is where all the files that make up your module will be stored; for more information, see <a href="#">Configuring projects</a>.)</p> <p>By default, a folder having the same name as the module is created in the project directory (recommended).</p> <p>To use a different folder, click  ( <a href="#">Shift+Enter</a> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>
Module file location	<p>Specify the path to the folder where the <code>.iml</code> module file should be created.</p> <p>By default, this file is created in the module content root folder (recommended).</p> <p>To use a different folder, click  ( <a href="#">Shift+Enter</a> ) and select the necessary folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>

The Tool Windows Reference contains detailed information about the functionality, controls and menus of the IntelliJ IDEA [tool windows](#) .

In this section:

- [Android Monitor Tool Window](#)

- [Version Control Tool Window](#)
- [V8 Heap Tool Window](#)
- [V8 Profiling Tool Window](#)

In this tool window, you can view and analyze the system debug output when running or debugging Android applications.

The tool window consists of a [toolbar](#) and the following nested tabs:

- [Logcat tab](#)
- [Monitors tab](#) that includes the following performance [monitors](#) :
  - [Memory](#)
  - [CPU](#)
  - [Network](#)
  - [GPU](#)

Select a physical or a virtual device from the devices drop-down list, and a process running on the selected device from the processes drop-down list. The information in each tab is filtered in accordance with your selection.

## Toolbar

The toolbar that is common for both nested tabs, provides quick access to the following actions:

### Icon Tooltip Description

	Screen Capture	Click this button to make a screenshot of the virtual or the connected physical device where the application is running. You can rotate the screenshot and add some visual effects in the dialog that opens, and save the capture.
	Screen Record	Click this button to start video recording of the application output on a physical device. This button only becomes available when you connect a physical Android device to your computer.
	System Information	Click this button to view system information on the selected process provided by the <a href="#">Dumpsys</a> tool. Logs open as text files in separate editor tabs. Select which type of information you want to view from the popup menu that opens: <ul style="list-style-type: none"> <li>- <b>Activity Manager State</b> : select this option to display system output of the <b>Activity Manager</b> - a component responsible for managing a stack of the application's activities.</li> <li>- <b>Package Information</b> : select this option to display system information on the application package.</li> <li>- <b>Memory Usage</b> : select this option to display detailed information on the application memory usage in kB.</li> <li>- <b>Memory use over time</b> : select this option to display detailed information on the system memory usage aggregated in the last 24 hours and the last 3 hours, and the current memory usage statistics.</li> <li>- <b>Graphics State</b> : select this option to display detailed application's graphics acceleration info.</li> </ul>
	Terminate Application	Click this icon to stop the application execution.
	Android Monitor Help	Click this icon to open the Android Monitor help page.

## Logcat tab

This tab shows all system debug output messages related to the selected process on the selected device.

## Toolbar

Use the toolbar controls and buttons to configure the scope and the presentation of log data, and to navigate through the log.

### Item Tooltip and shortcut Description

Log Level	N/A	From this drop-down list, select the <a href="#">priority</a> of log messages to be displayed. The available options are: <ul style="list-style-type: none"> <li>- Verbose</li> <li>- Debug</li> <li>- Info</li> <li>- Warn</li> <li>- Error</li> <li>- Assert</li> </ul>
	Find	Use this text box to search through the list of messages. As you type a search string, the messages that match the search pattern are displayed with the matching character strings highlighted. To finalize the search, press <a href="#">Enter</a> . Search patterns are stored in the search history list. To clear the search history, click the  button.
Regex	N/A	Select this option if you want to use a regular expression search pattern.
Filters	N/A	From this list, select an existing <a href="#">filter configuration</a> , or create a new one. A <a href="#">filter configuration</a> is a set of <a href="#">filtering parameters</a> . The use of <a href="#">filter configurations</a> provides more flexible control over the type and amount of

log data displayed than just specifying the information type by choosing a message priority in the Log level drop-down list.

- To display messages related to the selected process, select Show only selected application .
- If you want full log data to be displayed, select No Filters from the drop-down list.
- To apply a filter, select it from the drop-down list.
- To create a new filter configuration , select Edit Filter Configuration . In the Create New Logcat Filter dialog box that opens, click the Add toolbar button  and specify the following filtering parameters:
  - Log Tag : use this parameter if you only want messages from a certain system component to be displayed. Type a regular expression to specify the tag that indicates the relevant system component, such as `ActivityManager` , `AudioService` , etc., or a user-defined tag. For more details, see [Filtering Log Output](#) .
  - Log Message : use this parameter if you only want messages that contain certain elements or character strings to be displayed. Type a regular expression that defines the character string to be detected.
  - Package Name : use this parameter if you only want messages that refer to a specific Java package (class path) to be displayed.
  - PID : use this parameter if you only want messages that refer to a specific process (process ID) to be displayed.
  - Log Level : use this parameter if you only want messages with a certain priority level to be displayed.
- To update a filter, select Edit Filter Configuration , then in the Create New Logcat Filter dialog that opens select a filter from the list and edit the filter values.
- To remove a filter configuration from the list, choose Edit Filter Configuration . In the Create New Logcat Filter dialog box that opens, select the filter and click the Delete toolbar button  .

	Clear logcat	Click this button to remove log data from previous sessions on the selected device.
	Scroll to the end	Click this button to move the caret to the last line of the console output.
	Up the Stack Trace	Click this button to navigate up in the stack trace and have the cursor jump to the corresponding location in the source code.
	Down the Stack Trace	Click this button to navigate down in the stack trace and have the cursor jump to the corresponding location in the source code.
		Ctrl+Alt+Up
		Ctrl+Alt+Down
	Use Soft Wraps	Click this button to toggle the soft wrap mode of the output.
	Print	Click this button to print the logs.
	Restart	Click this button to restart logging.
	Logcat Header	Click this icon to configure the Logcat header. You can select the following options in the dialog that opens: <ul style="list-style-type: none"> <li>- Show date and time</li> <li>- Show process and thread IDs (PID_TID)</li> <li>- Show package name</li> <li>- Show tag</li> </ul>
	Logcat Help	Click this icon to open the Logcat help page.

## Monitors tab

The [Monitors](#) tab displays different Android performance monitors.

## Memory Monitor

The [Memory](#) monitor shows in real-time how your application allocates memory. It displays available and used memory in a graph, which is good for testing purposes and helps detect whether performance issues are related to garbage collection events:

## Memory Monitor Toolbar

Item	Tooltip	Description
	Enabled/Disabled	Click this icon to enable/disable the Android memory monitor.
	Initiate GC	Click this button to start garbage collection, whereupon you can examine the amount of heap memory the selected process uses (see <a href="#">Viewing heap usage</a> ).
	Dump Java Heap	Click this button to dump the contents of the Java heap memory to a file.
	Start Allocation	Click this button to start recording your application's memory allocations. Then

Tracking interact with your application and click the same button to stop allocation tracking. A pane with the recorded data will open as a separate editor tab. Allocation tracking is helpful to identify where similar object types are allocated and deallocated over a short period of time, and to detect places in your code that may cause inefficient memory usage.

	Help	Click this icon to open the Memory Monitor help page.
	Move Memory Monitor Up	Click this icon to move the Memory Monitor pane up.
	Move Memory Monitor Down	Click this icon to move the Memory Monitor pane down.
	Minimize/Maximize Memory Monitor	Click this icon to minimize/maximize the Memory Monitor pane.

## CPU Monitor

The [CPU](#) monitor shows in real time how much CPU is being used in a graph:

### CPU Monitor Toolbar

Item	Tooltip	Description
	Enabled/Disabled	Click this icon to enable/disable the CPU monitor.
	Start Method Tracing	Click this button to invoke profiling of a method, see <a href="#">Starting method profiling</a> . Interact with the application, and then click the same button to stop method tracing. A pane with the recorded data will open as a separate editor tab. Method tracking is useful to track down performance issues.
	Help	Click this icon to open the CPU Monitor help page.
	Move CPU Monitor Up	Click this icon to move the CPU Monitor pane up.
	Move CPU Monitor Down	Click this icon to move the CPU Monitor pane down.
	Minimize/Maximize CPU Monitor	Click this icon to minimize/maximize the CPU Monitor pane.

## Network Monitor

The [Network](#) monitor enables you to track your application network requests:

The Network Monitor is only available if you are running your application on a physical device, as it does not monitor emulators.

### Network Monitor Toolbar

Item	Tooltip	Description
	Enabled/Disabled	Click this icon to enable/disable the Network Monitor.
	Help	Click this icon to open the Network Monitor help page.
	Move Network Monitor Up	Click this icon to move the Network Monitor pane up.
	Move Network Monitor Down	Click this icon to move the Network Monitor pane down.
	Minimize/Maximize Network Monitor	Click this icon to minimize/maximize the Network Monitor pane.

## GPU Monitor

The [GPU](#) monitor displays how much time it takes to render the frames of a UI window:

Note that to use the GPU Monitor, you need to install the GPU Debugging Tools through the SDK Manager (for detailed instructions, see [GPU Debugger](#)).

## GPU Monitor Toolbar

### ItemTooltipDescription

	Enabled/Disabled	Click this icon to enable/disable the GPU Monitor.
	Help	Click this icon to open the GPU Monitor help page.
	Move GPU Monitor Up	Click this icon to move the GPU Monitor pane up.
	Move GPU Monitor Down	Click this icon to move the GPU Monitor pane down.
	Minimize/Maximize GPU Monitor	Click this icon to minimize/maximize the GPU Monitor pane.
		

The tool window is marked with the icon .

Use this tool window to add Ant build scripts to your project, control behavior of the build, and run build targets.

– [Ant Build](#)

– [Ant build results](#)

 IntelliJ IDEA implements the Ant Build tool window functionality with a bundled plugin, which can be completely disabled by clearing the Ant support check box on the the Plugins page of IntelliJ IDEAsettings ( [Ctrl+Alt+S](#) ).

## Ant Build

### ItemDescription

	Click this button to add an Ant build file to the current project.
	Click this button to remove the reference to the selected build file from the current project.
	Click this button to run the selected build target.
	When this button is pressed, only the <a href="#">primary targets</a> are visible.
	Use these buttons to expand or collapse all the nodes.
	Click this button to show the <a href="#">properties of the selected Ant build file</a> .
	Click this button to show the corresponding reference topic.

## Ant build results

Results of running Ant targets or the entire builds are shown in the [Messages tool window](#) .

For this tool window to be available, there must be a server [run/debug configuration](#) in your project, or a cloud user account must be registered in IntelliJ IDEA.

The Application Servers tool window lets you manage your applications on application servers and cloud platforms. You can start and stop server run/debug configurations and connect to cloud platforms, deploy and undeploy your [application artifacts](#) as well as perform other, associated tasks.

All the available functions are accessed by means of the toolbar icons and context menu commands.

- [Icons and commands for server run configurations](#)
- [Icons and commands for server artifacts](#)
- [Icons and commands for cloud user accounts](#)
- [Icons and commands for cloud apps](#)
- [Deployment status icons](#)

See also, [Working with Server Run/Debug Configurations](#) and [Working with Cloud Platforms](#) .

## Icons and commands for server run configurations

### IconCommandDescription

	Run/Connect	Start the selected run/debug configuration in the run mode. For a local configuration, normally, the corresponding server will be started. For a remote configuration, IntelliJ IDEA will connect to the server.
	Debug	Start the selected run/debug configuration in the debug mode.
	Stop/Disconnect	Stop the selected run/debug configuration. For a local configuration, normally, the corresponding server will be stopped. For a remote configuration, IntelliJ IDEA will disconnect from the server.
	Deploy All	Deploy all the artifacts associated with the selected run/debug configuration.
	Edit Configuration	Edit the settings for the selected run/debug configuration.
	Artifacts	Edit the deployment list for the selected run/debug configuration. (The <a href="#">Artifacts to Deploy dialog</a> will open.)

## Icons and commands for server artifacts

### IconCommandDescription

	(Re)deploy	Deploy or redeploy the selected artifact.
	Undeploy	Undeploy the selected artifact.
	Remove	Remove the selected artifact from the corresponding deployment list and undeploy the artifact from the server.

## Icons and commands for cloud user accounts

### IconCommandDescription

	Connect	Connect (log on) to the corresponding cloud platform.
	Disconnect	Disconnect (log off) from the corresponding cloud platform.
	Edit Configuration	Edit your cloud user account settings.
	Deploy	Deploy your app by means of a cloud deployment run/debug configuration.
	Debug	Deploy your app and start debugging it by means of a cloud deployment run/debug configuration.

## Icons and commands for cloud apps

### IconCommandDescription

	(Re)deploy	Deploy or redeploy the selected app.
	Undeploy	Undeploy the selected app.
	Debug	Start debugging the selected application.
	Edit Configuration	Edit the settings for an associated cloud deployment run/debug configuration.

## Deployment status icons

### IconStatus

	Unknown
	Deployed
	Undeployed

To open this tool window:

View | Tool Windows | Bean Validation

See also, [Showing a tool window](#) .

Note that this tool window is available only if there is a [library](#) that implements Bean Validation in the [dependencies](#) of one or more of your [modules](#) .

---

The Bean Validation tool window provides a categorized hierarchical view of your bean validation resources. These include the appropriately annotated Java sources as well as xml validation descriptors and constraint mappings.

At the top of the hierarchy are your modules. One level below are categories.

The main categories are constraints, constraint validators and constraints mappings.

You can show or hide the categories. You can also open the elements shown in the tool window in the editor.

– [Showing and hiding categories](#)

– [Opening elements in the editor](#)

## Showing and hiding categories

Use the toolbar buttons to show or hide the corresponding category.

### ItemTooltip Description

	<b>Constraints</b> Click this button to show or hide the elements related to bean validation constraints. Shown in this category are the constraints (constraint annotations) defined in your source code (  ) and also the ones available in the bean validation library that you are using (  ) .  For each of the constraints, the related elements are shown (if any). These may be the corresponding constraint validators or other entities that reference the constraint.
	<b>Validators</b> Click this button to show or hide bean validators. Shown in this category are the validators for which you developed the source code yourself (  ) and also the ones available in the bean validation library that you are using (  ) .
	<b>Constraint Mappings</b> Click this button to show or hide xml constraint mappings. Shown in this category are the xml files that contain the corresponding mappings. For each of the files, a structured view of mapping definition elements is provided.

## Opening elements in the editor

You can open the elements shown in the Bean Validation tool window in the editor. To do that, select the element of interest and press  .

To open the elements which are the "leaves" of the tree (i. e. the ones at the bottom of the hierarchy), you can also use a double click.

To open this tool window:

View | Tool Windows | CDI

See also, [Showing a tool window](#) .

Note that this tool window is available only if there is a [library](#) that implements CDI in the [dependencies](#) of one or more of your [modules](#) .

---

The CDI tool window provides a categorized hierarchical view of your CDI resources (beans).

At the top of the hierarchy are your modules. One level below are categories.

The categories correspond to bean types and qualifiers.

You can show or hide the categories. You can also open the elements shown in the tool window in the editor.

- [Showing and hiding categories](#)
- [Opening elements in the editor](#)

## Showing and hiding categories

To show or hide a category, click  on the title bar, and then click the necessary option.

The following options are available:

- @Named. Show or hide @Named beans (the elements annotated with `@Named` ).
- Custom Qualifiers. Show or hide the elements annotated with custom annotations.
- Scope Types. Show or hide scope types (the elements annotated with `@ApplicationScoped` , `@SessionScoped` , `@RequestScoped` , etc.).
- Deployment Types. Show or hide deployment types.

## Opening elements in the editor

You can open the elements shown in the CDI tool window in the editor. To do that, select the element of interest and press

 .

To open the elements which are the "leaves" of the tree (i. e. the ones at the bottom of the hierarchy), you can also use a double click.

Ctrl+Shift+X

The tool window is available only when the **Command Line Tool Support** plugin is installed and enabled as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

The tool window is marked with the icon . Use the tabs of this tool window to type and run commands in the command line and to validate `.xml` descriptors for structure consistence. See [PHP Command Line Tools](#) for details.

**Tip** The character set to be used in the tool window is chosen from the Console encoding drop-down list on the [Command Line Tool Support](#) page of the Settings/Preferences dialog box.

The tool window consists of the following tabs and areas:

- The Input pane for typing commands in the format `<tool alias> <command>`. The location of the Input pane (text box or pop-up window) depends on the Show console in setting on the [Command Line Tool Support](#) page.
- The **Output** tab shows the results of executing commands. The tab is named after the last invoked command.
- The Tool definition file errors tab is hidden by default. The tab is accessible only if any structure discrepancies are detected in the `.xml` descriptor during validation. See [How do I keep a tool descriptor consistent?](#) for details.

## Toolbar Options

ItemTooltip  
and  
Shortcut

	Stop Ctrl+F2	Click this button to cancel execution of a command without closing the tool window.
	To previous command Ctrl+Alt+Up	Click this button to navigate to the previous command.
	To next command Ctrl+Alt+Down	Click this button to navigate to the next command.
	Use Soft Wraps	Click this toggle button to have the soft wrap mode applied to the output.
	Scroll to the end	Click this button to navigate to the bottom of the output tab named after the last invoked command.
	Print	Click this button to have the contents of the console printed out. Upon clicking the button, IntelliJ IDEA opens the <a href="#">Print</a> dialog box, where you can configure the printing procedure and output.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.
	Export to Text Alt+O	Click this button to have the results of executing commands saved in a text file. In the <a href="#">Export Preview</a> dialog box, that opens, specify the target file, and click <a href="#">Save</a> .
	Ctrl+Shift+F4	Click this button to close the tool window. If one or more commands are still running, the <a href="#">Command Line Tool</a> dialog box opens. Specify whether you want to stop them or leave running in the background by clicking one of the following buttons: <ul style="list-style-type: none"> <li>– Terminate and close</li> <li>– Close without terminating</li> </ul>
	Help F1	Use this icon or shortcut to open the corresponding help page.

Ctrl+Shift+X

The pop-up window is available only when the **Command Line Tool Support** plugin is installed and enabled as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

---

In this Input pane, type the desired command in the format `<tool alias> <command>` .

View the results of command execution in the **output** tab of the dedicated **Command Line Tools Console** tool window. The tab is named after the last invoked command.

This tool window appears on [running with coverage](#) , and displays coverage measurement results.

In this section:

- [Toolbar](#)
- [Context menu](#)

## Toolbar

### ItemDescription

	Click this button to go up one level.
	When this button is pressed, all the packages are displayed as a single-level view.
	When this button is pressed, source code of the class selected in the tool window, automatically opens in a separate editor tab, and gains the focus.
	When this button is pressed, when source code of certain class gets the focus in the editor, the corresponding node is automatically highlighted in the tool window.
	<p>Click this button to generate a code coverage report and save it to the specified directory. See <a href="#">Generating Code Coverage Report</a> for details.</p> <p>The button is not available when the tests are executed on <i>Karma</i> because a coverage report is actually generated on the disk every time <i>Karma</i> tests are run. The format of a coverage report can be configured in the configuration file, for example:</p> <pre>// karma.conf.js module.exports = function(config) {   config.set({ ...   // optionally, configure the reporter   coverageReporter: { type : 'html', dir : 'coverage/' }   ... });};</pre> <p>The following <code>type</code> values are acceptable:</p> <ul style="list-style-type: none"> <li>– <code>html</code> produces a bunch of HTML files with annotated source code.</li> <li>– <code>lcovonly</code> produces an <code>lcov.info</code> file.</li> <li>– <code>lcov</code> produces HTML + <code>lcov</code> files. This format is applied by default.</li> <li>– <code>cobertura</code> produces a <code>cobertura-coverage.xml</code> file for easy Hudson integration.</li> <li>– <code>text-summary</code> produces a compact text summary of coverage, typically to the console.</li> <li>– <code>text</code> produces a detailed text table with coverage for all files.</li> </ul> <p>This toolbar button is duplicated by the main menu command <code>Analyze   Generate Coverage Report</code> .</p>
	<p>Click this button to close the tool window.</p> <p>This toolbar button is duplicated by the main menu command <code>Analyze   Hide Coverage Data</code> .</p>
	Click this button to show reference.

## Context menu

### ItemShortcutDescription

Jump to Source		Choose this command to open the selected file in the editor.
----------------	---	--

Alt+0

The tool window is available only when the **Dart** plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

IntelliJ IDEA integrates with the [Dart Analyzer tool](#) that performs static analysis of your Dart source code. All inconsistencies and potential problems are reported in the Dart Analysis tool window with the possibility to navigate to the fragment of the source code where the problem was detected.

On this page:

- [Messages List](#)
- [Grouping and Sorting](#)
- [Toolbar Buttons](#)
- [Context Menu](#)

## Messages List

All the problem reports are displayed in a table which consists of two columns, Description and Location, and a summary below.

Description	Location
Classes can only extend other classes	[DartPackageName] bin/main_part.dart:2
The name 'Foo' is already defined	[DartPackageName] bin/main_part.dart:2
Undefined class 'C'	[DartPackageName] bin/main_part.dart:2
Undefined class 'abcde'	[DartPackageName] bin/main_part.dart:4
Unused import	[DartPackageName] bin/main.dart:3
This function declares a return type of 'String', but ...	[DartPackageName] bin/main_part.dart:7

2 errors, 2 warnings, 2 hints.

- The Description column shows the message itself, which can be an **error message**, a **warning**, or a **hint**.
- The Location column shows the following data:
  - The name of the Dart package in which the problem arose. The Dart package name corresponds to the `project name` from `pubspec.yaml`.
  - The relative from the the Dart package root to the file where the problem arose.
  - The line number where the problem arose.
- The Summary area below the table shows the number of detected errors, warnings, or hints and the **filter** status.

## Grouping and Sorting

The messages in the Dart Analysis tool window can be grouped and sorted. By default, the messages are primarily sorted by their **severity**, that is, the error messages are shown at the top of the list, then come warnings, and finally hints are displayed. In each severity group, messages are grouped by the Dart package name, which is super handy for projects with multiple `pubspec.yaml` files. In each package group, the messages are grouped by their file paths. Finally, in each file group, the problems are sorted by the line number where they occurred.

You can re-configure the secondary sorting:

- Click the Location column header to switch between the ascending and descending order of the **Dart package name + file path** sorting. Note that this does not affect the order of severity groups, that is, errors are always shown first. Line numbers are not taken into consideration either, for each particular file problems are always shown in ascending order of line numbers.
- Click the Description column header to perform the secondary sorting alphabetically by the problem description. Note that this does no affect the primary grouping by severity.

To disable the primary grouping by severity, release the Group by Severity toggle button  on the toolbar. After that the severity of a problem is not taken into consideration at all and problem reports are sorted only by their Description or Location ( **Dart package name + file path** ). This sorting method guarantees that all the problems for each particular file are grouped together in the table, regardless of their severity.

## Toolbar Buttons

**Item**  
**Tooltip**  
**and**  
**shortcut**

	<b>Reanalyze Dart Sources</b>	Click this button to run the analysis of the Dart source code of the project without stopping the Dart Analysis server.
	<b>Restart Dart Analysis Server</b>	Click this button to kill the Dart Analysis server and then start it.

**Autoscroll to Source** If this button is pressed, the file that contains the selected error automatically opens in the editor, with the caret at the appropriate line.

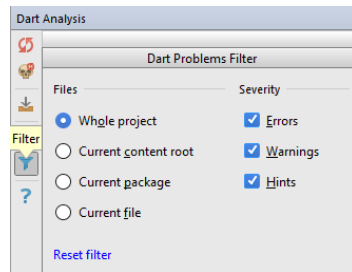

**Group by Severity**

- When this toggle button is pressed, the error messages are shown at the top of the list, then come warnings, and finally hints are displayed. In each severity group, messages are grouped by the Dart package name, which is super handy for projects with multiple `pubspec.yaml` files. In each package group, the messages are grouped by their file paths. Finally, in each file group, the problems are sorted by the line number where they occurred. You can re-configure the secondary sorting:
  - Click the Location column header to switch between the ascending and descending order of the `Dart package name + file path` sorting. Note that this does not affect the order of severity groups, that is, errors are always shown first. Line numbers are not taken into consideration either, for each particular file problems are always shown in ascending order of line numbers.
  - Click the Description column header to perform the secondary sorting alphabetically by the problem description. Note that this does not affect the primary grouping by severity.
- Release this toggle button to disable the primary grouping by severity. After that the severity of a problem is not taken into consideration at all and problem reports are sorted only by their Description or Location ( `Dart package name + file path` ). This sorting method guarantees that all the problems for each particular file are grouped together in the table, regardless of their severity.

**Filter** Click this button to open the Dart Problems Filter pop-up window where you can configure the criteria according to which a problem report is displayed in the tool window or not.

- In the Severity area, specify the types of messages to be shown, the available types are Errors , Warnings , and Hints . To have the problems of a severity level displayed, select the checkbox next to this severity level.
- In the Files area, choose the scope for which you want to see problem reports. The available options are:
  - Whole project
  - Current content root
  - Current package: when this option is selected but no `pubspec.yaml` file is detected up the folder hierarchy starting from the current file, then filtering is performed according to the content root where current file is located.
  - Current file
- Click the Reset all filters link to restore the default filter settings.

Filtering is applied immediately as soon as you change the current settings.

**Help** Use this button to navigate to the help topic for the tool window.

## Context Menu

**Item**      **Shortcut****Description**

Jump to source       Click this button to navigate to the fragment of code that caused the selected problem.

Copy       Take the line at caret to the clipboard.

## Overview

Database consoles let you compose and execute SQL statements for databases defined in IntelliJ IDEA as data sources. They also let you analyze and modify the retrieved data.

The input pane of a database console opens as a separate editor tab. This is where you compose your SQL statements.

When you execute your first statement (▶), the Database Console tool window opens. If the executed statement retrieves data (e.g. `SELECT`), there are two panes in the tool window shown on the Output and the Result tabs. (The tab showing retrieved data may be labeled Result # or, if appropriate, the table name may be shown.)

Otherwise, only the output pane is shown.

Additionally, you can open the Parameters pane (P) to manage parameters in SQL statements.

## Input pane

Use the input pane to compose and execute your SQL statements as well as to perform other, associated tasks.

The available functions are accessed by means of the toolbar icons, keyboard shortcuts and context menu commands.

## Toolbar icons and shortcuts

### ItemShortcutDescription

	<b>Execute</b>		Use this icon or shortcut to execute the selected (highlighted) SQL statement or statements. If nothing is selected, the current statement is executed.  See also, <a href="#">Run 'console.sql'</a> , <a href="#">Execute in Console</a> and <a href="#">Executing an SQL statement</a> .
	<b>Browse Console History</b>		Use this icon or shortcut to open a dialog that shows all the statements that you have run for the corresponding data source. See also, <a href="#">Executing auto-memorized statements</a> .
	<b>View Parameters</b>		Use this icon to open or close the <a href="#">Parameters pane</a> .
	<b>Settings</b>		Use this icon to open the <a href="#">Database page</a> of the Settings dialog to view or edit the settings for the database, Hibernate and JPA consoles, data editors and the Database tool window.
	<b>Transaction control</b>		Select the <a href="#">isolation level</a> for database transactions and the way the transactions are committed. – Auto. Each statement is executed in its own transaction that is implicitly committed. – Manual. Transactions are committed or rolled back explicitly by means of  or  on the toolbar.
	<b>Commit</b>		Commit the current transaction.
	<b>Rollback</b>		Roll back the current transaction.
	<b>Cancel Running Statements</b>		Use this icon or shortcut to terminate execution of the current statement or statements.
	<b>&lt;schema&gt;</b>		Select the default schema or database, or, for PostgreSQL or Redshift, form the schema search path. (This control may be unavailable).

Most useful context menu commands [for selecting the default schema or database](#) and [Controlling the schema search path for PostgreSQL and Redshift](#) .

**Item Shortcut Description**

**Edit as Table** If an `INSERT` statement is currently selected: Open the editor for working with the data in table format.

See also, [Editing data for INSERT statements in table format](#) .

**Change Dialect (<CurrentDialect>)** Use this command to change the SQL dialect being used. Select the necessary dialect from the list. In addition to particular dialects, also the following option is available:  
 - <Generic SQL>. Basic SQL92-based support is provided including completion and highlighting for SQL keywords, and table and column names. Syntax error highlighting is not available. So all the statements in the input pane are always shown as syntactically correct.

See also, [Changing the SQL dialect](#) .

**Explain Plan** Show an [execution plan](#) (a.k.a. explain plan) for the current statement. The result is shown in a mixed tree/table format on a dedicated Plan tab.

**Explain Plan (Raw)** Show an [execution plan](#) (a.k.a. explain plan) for the current statement. The result is shown in table format. (Technically, `EXPLAIN <CURRENT_STATEMENT>` or similar statement is executed.)

**Execute** Ctrl+Enter Execute the current statement or the sequence of selected statements.

**Execute to File** Execute the current statement (e.g. `SELECT` ) and save the result in a text file. Select the output format, and specify the file location and name.

**Run 'console.sql'** Ctrl+Shift+F10 Use this command or shortcut to execute all the statements contained in the console.

**Diagrams** Ctrl+Shift+Alt+U If the cursor is within the name of a schema: Open a UML class diagram for the schema.  
 - Show Visualisation ( Ctrl+Shift+Alt+U ). The diagram opens on a separate editor tab.  
 - Show Visualisation Popup ( Ctrl+Alt+U ). The diagram opens in a pop-up window.

**Toolbar of the Database Console tool window**

To hide or show the toolbar, click on the title bar and select Show Toolbar .

**Item Shortcut Description**

**Settings** Use this icon to open the [Database page](#) of the Settings dialog to view or edit the settings for the database, Hibernate and JPA consoles, data editors and the Database tool window.

**Enable SYS.DBMS\_OUTPUT** Ctrl+F8 For Oracle: use this icon or shortcut to enable or disable showing the contents of the DBMS\_OUTPUT buffer in the output pane.

**View Parameters** Use this icon to open or close the [Parameters pane](#) .

**Browse Console History** Ctrl+Alt+E Use this icon or shortcut to open a dialog that shows all the statements that you have run for the corresponding data source. See also, [Executing auto-memorized statements](#) .

**Restore Layout** Use this icon to restore the original tool window layout (after the rearrangements that you have made).

**Cancel Running Statements** Ctrl+F2 Use this icon or shortcut to terminate execution of the current statement or statements.

**Close** Ctrl+Shift+F4 Use this icon or shortcut to close the tool window.

**Output pane**

This pane shows the SQL statements that you have run as well as information about other operations performed in the console. These include turning the autocommit mode on or off, committing or rolling back a transaction, etc.

The information about the errors that occur is also shown in this pane.

For most of the events the following information is provided:

- Timestamp, that is, when the event took place.
- For data definition and data manipulation operations - how many rows were affected (e.g. added, changed or deleted).  
For data retrieval operations - how many rows were retrieved.
- Duration in milliseconds.

The summary info is also shown on the status bar.

Use the following context menu commands:

- Copy ( `Ctrl+C` ) to copy the text selected in the output pane to the clipboard.
- Compare with Clipboard to compare the text selected in the output pane with the contents of the clipboard.
- Clear All to clear all the contents of the output pane.

## Result pane

This pane shows the data retrieved from the database in table format. You can sort, add, edit and remove the data as well as perform other, associated tasks.

## Main functions

Most of the functions in the Result pane are accessed by means of controls on the toolbar, context menu commands for the data cells, and associated keyboard shortcuts.

### ItemShortcutDescription

 and 

These icons and corresponding commands are for switching between the result set pages, i.e. the pages that show the retrieved data.  
A fixed number of rows shown simultaneously is referred to as a **result set page**. If this number is less than the number of rows that satisfy the query, only a subset of all the rows is shown at a time.

In such cases, you can use  to switch between the subsets. (If all the rows are currently shown, these icons and the corresponding commands are inactive.)

The result set page size is set on the [Database page](#) of the Settings dialog.

 First Page

Use this icon or command to switch to the first of the [result set pages](#) to see the first series of rows.

 Previous Page

`Ctrl+Alt+Up`

Use this icon, command or shortcut to switch to the previous [result set page](#) to see the previous series of rows.

 Next Page

`Ctrl+Alt+Down`

Use this icon, command or shortcut to switch to the next [result set page](#) to see the next series of rows.

 Last Page

Use this icon or command to switch to the last of the [result set pages](#) to see the last series of rows.

 Reload Page

`Ctrl+F5`

Use this icon, command or shortcut to refresh the current table view. Use this function to:

- Synchronize the data shown with the actual contents of the database.
- Apply the [Result set page size](#) setting after its change.

 Add New Row

`Alt+Insert`

Use this icon, command or shortcut to add a new row to the table.  
Complete entering a value into a cell by pressing `Enter`. To save the new row, select **Submit New Row** from the context menu or press `Ctrl+Enter`.

If inappropriate in the current context (i.e. for the table currently shown), this function is not available.

See also, [Adding a row](#).

 Delete Rows

`Ctrl+Y`

Use this icon, command or shortcut to delete the selected row or rows.  
Rows are selected by clicking the cells in the column where the row numbers are shown. To select more than one row, use mouse clicks in combination with the `Ctrl` key.

If inappropriate in the current context (i.e. for the table currently shown), this function is not available.

`Tx Auto` Tx and Tx Isolation

Select the [isolation level](#) for database transactions and the way the transactions are committed.

- Auto. The current transaction is committed automatically when you submit your local changes to the database server.
- Manual. The changes submitted to the database server are accumulated in a transaction that can either be committed or rolled back.

 Submit

`Ctrl+Enter`

Submit local changes to the database server. See [Submitting and reverting changes](#).

 Commit

Commit the current transaction. See also, [Tx](#).

 Rollback

Roll back the current transaction. See also, [Tx](#).

 Cancel Query		Use this icon or shortcut to terminate execution of the current query.
 Compare With		Use this icon to compare the current table with another table. The tables open in the data editors and ones shown in the Database Console tool window are suggested for comparison.
 Pin Tab		Use this icon or command to pin the tab to the tool window to keep the query result. See also, <a href="#">Pinning the Result tab</a> .
 Tab-se...d (TSV) Data Extractor: <current_format>		Use this button or command to open a menu in which you can select an output format for your data. In addition to output formats, there are also the following options and commands: <ul style="list-style-type: none"> <li>– Allow Transposition. For delimiter-separated values formats (TSV, CSV): If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g.  ), the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.</li> <li>– Skip Generated Columns (SQL). For SQL INSERTs and UPDATES: When copying or saving data (<a href="#">Copy</a> , <a href="#">Dump Data   To File</a> , <a href="#">Dump Data   To Clipboard</a> ), don't include auto-increment fields.</li> <li>– Add Table Definition (SQL). For SQL INSERTs and UPDATES: When copying or saving data, add the table definition (CREATE TABLE).</li> <li>– Configure CSV Formats. Open the <a href="#">CSV Formats dialog</a> that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).</li> <li>– Go to Scripts Directory. Switch to the directory where the scripts that convert table data into various output formats are stored.</li> </ul>
 Dump Data   To Clipboard		Use this command to copy the table data onto the clipboard.
 Dump Data   To File		Use this command to save the table data in a file. In the dialog that opens, specify the location and name of the file.
 Export to Database		Export the data to another table, schema or database. Select the target schema (a new table will be created) or table (the data will be added to the selected table). In the dialog that opens, specify the data mapping info and the settings for the target table.
View Query		Use this button to view the query which was used to generate the table. To close the pane where the query is shown, press  .
		This icon provides access to the following commands: <ul style="list-style-type: none"> <li>– Transpose. Turn the transposed table view on or off. (In the transposed view, the rows and columns are interchanged. So, the rows are shown as columns and vice versa.)</li> <li>– Reset View. Restore the initial table view after reordering or hiding the columns, or sorting the data.</li> <li>– Settings. Open the <a href="#">Database page</a> of the Settings dialog to view or edit the settings for your database, Hibernate and JPA consoles, data editors and the Database tool window.</li> </ul>
Edit		Use this command or shortcut to start editing a value in the selected cell or cells. (Alternatively, you can double-click the cell or simply start typing.) To open the value completion suggestion list, press  . To enter the modified value, press  . To cancel editing, press  .  See also, <a href="#">Modifying cell contents</a> and <a href="#">Modifying values in a number of cells at once</a> .
Edit Maximized		Maximize the selected cell and start editing a value in it. When working in a maximized cell, use  to start a new line and  to enter the value. To restore an initial value and quit the editing mode, press  .  See also, <a href="#">Modifying cell contents</a> .
Set DEFAULT		If appropriate: Set the default value or values.
Set NULL		If appropriate: Replace the value or values with <code>null</code> .
Load File		If appropriate: Load a file into the field.
Revert		Revert the changes within the selection. See <a href="#">Submitting and reverting changes</a> .
Clone Row		Use this command or shortcut to create a copy of the selected row.
Quick Documentation		Use this command or shortcut to open the quick documentation view. To close the view, press  . For more information, see <a href="#">Using the quick documentation view</a> .
Transpose		Turn the transposed table view on or off. Alternatively, use    Transpose .
Go To   Row		Use this command or shortcut to switch to a specified row. In the dialog that opens, specify the row number to go to.
Go To   Related Data		Use this command or shortcut to switch to a related record. The command options are a combination of those for <a href="#">Go To   Referenced Data</a> and <a href="#">Go To   Referencing Data</a> . The command is not available if there are no related records.
Go To   Referenced Data		Use this command or shortcut to switch to a record that the current record references. If more than one record is referenced, select the target record in the pop-up that appears.

The command is not available if there are no referenced records.

**Go To | Referencing Data** Alt+F7

Use this command or shortcut to see the records that reference the current record. In the pop-up that appears there are two categories for the target records:

- First Referencing Row. All the rows in the corresponding table will be shown and the first of the rows that references the current row will be selected.
- All Referencing Rows. Only the rows that reference the current row will be shown.

The command is not available if there are no records that reference the current one.

**Copy** Ctrl+C

Copy the selection onto the clipboard. See also, [Copying and pasting data: data types are converted if necessary](#) .

**Paste** Ctrl+V

Paste the contents of the clipboard into the table. See also, [Copying and pasting data: data types are converted if necessary](#) .

**Save LOB**

Use this command to save the large object (LOB) currently selected in the table in a file.

Alt+J ,  
Shift+Alt+J  
Ctrl+W

See [Selecting cells and ranges: using unobvious techniques](#) .

## Sorting data

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  .

Finally, when you click the cell for the third time, the initial state is restored. That is, sorting by the corresponding column is canceled:  .

Here is an example of a table where data are sorted by two of its columns.

	id	name	relation
1	3	Dylan	brother
2	6	Jack	brother
3	1	Harry	father
4	2	Chloe	mother
5	5	Alice	sister
6	4	Emily	sister

To restore the initial "unsorted" state for the table, click  and select Reset View .

## Reordering columns

To reorder columns, use drag-and-drop for the corresponding cells in the header row. To restore the initial order of columns, click  and select Reset View .

	member_id	relation	name
1	5	sister	Alice
2	1	mother	Chloe
3	3	brother	Dylan
4	4	sister	Emily
5	2	father	Harry

## Hiding and showing columns

To hide a column, right-click the corresponding header cell and select Hide column .

To show a hidden column:

1. Do one of the following:

– Right-click any of the cells in the header row and select Column List .

– Press Ctrl+F12 .

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

2. Select (highlight) the column name of interest and press Space .

3. Press Enter or Escape to close the list.

To show all the columns, click  and select Reset View .

See also, [Using the Structure view to sort data, and hide and show columns](#) .

## Parameters pane

The Parameters pane shows the parameters detected in the input pane and lets you edit their values. To open or close this pane, use  on the toolbar.

To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press  or switch to a different cell. To quit the editing mode and restore an initial value, press  .

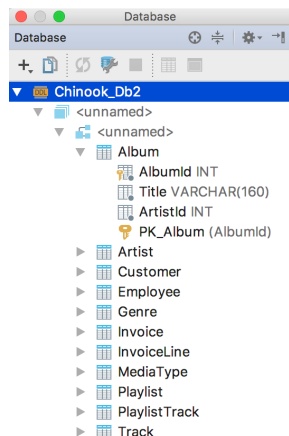

When you select a row in the table, the corresponding parameter is highlighted in the input pane.

See also, [Executing parameterized statements](#) .

## Overview

The Database tool window provides access to functions for working with databases and DDL [data sources](#) . It lets you view and modify data structures in your databases, and perform other associated tasks.

For more information, see [Working with the Database tool window](#) .

The available data sources are shown as a tree of data sources, schemas, tables and columns. If no data sources are currently defined, use the **New** command ( [Alt+Insert](#) ) to create a data source.

Most of the functions in this window are accessed by means of the toolbar icons or context menu commands. (If the toolbar is not currently shown, click  on the title bar and select Show Toolbar .) Many of the commands have keyboard shortcuts. If the toolbar is hidden, the [Synchronize](#) and [Open Console](#) commands can be accessed by means of the title bar icons ( and  respectively).

## Toolbar icons, context menu commands and shortcuts

**Icon****Command****Shortcut****Description****Available**

Icon	Command	Shortcut	Description	Available
			Collapse all the nodes.	All node types
	New	<a href="#">Alt+Insert</a>	Create a new data source, database, schema, database console, table, column, index, or a primary or foreign key. The list of options depends on which element is currently selected. See also, <a href="#">Creating a data source</a> , <a href="#">Creating a database or schema</a> , <a href="#">Creating and opening a new database console</a> , <a href="#">Creating a table, a column, an index, or a primary or foreign key</a> and <a href="#">Data Sources and Drivers dialog</a> .	DB data sources and their elements. If a DDL data source is selected, you can only choose to create another data source.
	Duplicate	<a href="#">Ctrl+D</a>	Create a copy of the selected data source. Specify the properties of the data source in the Data Sources and Drivers dialog that opens.	DB and DDL data source nodes
	Synchronize	<a href="#">Ctrl+Alt+Y</a>	Update the view of the selected element (i.e. synchronize the view of the element with its actual state in the database). See also, <a href="#">Auto sync</a> .	DB data sources and their elements
	Properties		Open the <a href="#">Data Sources and Drivers dialog</a> to manage your data sources and their settings.	All node types
	Disconnect	<a href="#">Ctrl+F2</a>	Close the database connection for the selected DB data source or data sources. (The names of the data sources with	DB data sources with active connections and their

			active database connections are shown in bold.)	elements
 or 	Open Editor	<b>F4</b> or <b>Ctrl+B</b>	Open the data editor or the definition editor for the selected item.	Corresponding elements in DB data sources
	Open Console	<b>Ctrl+Shift+F10</b>	Open the default <a href="#">database console</a> for the corresponding DB data source.	DB data sources and their elements (tables and table columns)
	Rename	<b>Shift+F6</b>	Rename the selected data source, table or column. Specify the new name in the dialog that opens. See also, <a href="#">Renaming items</a> .	All node types
	Modify Table, Modify Column, Modify Index, Modify Key, Modify Foreign Key	<b>Ctrl+F6</b>	Edit the definition of the selected table, column, index, or primary or foreign key. See also, <a href="#">Modifying the definition of a table, column, index, or a primary or foreign key</a> .	Corresponding elements in DB data sources
	Copy Reference	<b>Ctrl+Shift+Alt+C</b>	Copy the fully qualified name of the selected data source, table or column to the clipboard.	All node types
	Find Usages	<b>Alt+F7</b>	Find the usages of (references to) the selected item (data source, table or column) in your source files and libraries.	All node types
	Database Tools   Hide Schemas		Hide the selected schemas. See <a href="#">Showing and hiding schemas</a> .	Schemas in DB data sources
	Database Tools   Manage Shown Schemas		Open the Schemas popup for the current DB data source. See <a href="#">Showing and hiding schemas</a> .	DB data sources and their elements
	Database Tools   Forget Cached Schema		Use this command in problematic cases such as when your data structures start to display incorrectly, fail to synchronize, etc. As a result, IntelliJ IDEA deletes the information it has accumulated about your database. To check if this has eliminated the problem, use the <a href="#">Synchronize command</a> .	DB data sources
	Database Tools   Copy Settings		Copy the settings for the selected data source onto the clipboard.	DB data sources
	Database Tools   Drop Primary Key		Remove the primary key constraint for the current table.	Tables and columns in DB data sources
	Database Tools   Drop Foreign Key		Remove the foreign key constraint.	Columns with the foreign key constraint in DB data sources
	Database Tools   Truncate		Remove all the rows in the selected table.	Tables in DB data sources
	Drop or Remove	<b>Delete</b>	Remove the selected item.	All node types
	Open New Console		Create and open a new <a href="#">database console</a> for the corresponding DB data source.	DB data sources and their elements

Generate and Copy DDL	Ctrl+Shift+C	Generate DDL definitions for the selected data source, schema, table, view, stored procedure or function, and copy those definitions onto the clipboard.	All node types except columns
Open DDL in Console	Shift+F4	Open a DDL definition of the selected table or view in a database console.	Tables and views in DB data sources
Compare	Ctrl+D	Select two data sources, schemas or tables and then use this command to compare table structures for the selected items. The comparison results are shown in the <a href="#">differences viewer</a> differences viewer .	DB and DDL data sources and tables
Dump Data to File(s)		Save data for the selected tables and views in files. Select the output format (e.g. SQL Inserts, Tab-separated (TSV), JSON-Clojure.json.cj). See also, <a href="#">Saving data in files in various forms and formats</a> .	DB data sources, and schemas, tables and views within them
Dump with "mysqldump" or Dump with "pg_dump"		Run <a href="#">mysqldump</a> or <a href="#">pg_dump</a> for the selected items. See <a href="#">Creating database backups with mysqldump or pg_dump</a> .	MySQL and PostgreSQL data sources, and schemas, tables and views within them
Import Data from File		Import a text file containing delimiter-separated values (CSV, TSV, etc.) into your database. If a schema is currently selected, IntelliJ IDEA will create a new table for the data that you are importing. If a table is selected, IntelliJ IDEA will try to add the data to the selected table. See <a href="#">Importing delimiter-separated values into a database</a> .	Schemas, tables and columns in DB data sources. For columns, the result will be the same as for schemas
Restore with "mysql", Restore with "psql" or Restore		Run <code>mysql</code> , <a href="#">pg_restore</a> or <a href="#">psql</a> to restore a data dump. See <a href="#">Restoring data dumps with mysql, pg_restore or psql</a> .	MySQL data sources, databases and schemas. PostgreSQL data sources, databases, schemas and tables
Color Settings		Set or change the color for the selected element or elements. (The <a href="#">Database Color Settings dialog</a> will open.)	All node types
Scripted Extensions / Generate POJOs.cj		Generate a Java entity class for the selected table. In the dialog that opens, specify the directory in which the <code>.java</code> class file should be generated.	Tables
Scripted Extensions / Go to Scripts Directory		Switch to the directory where the <code>Generate POJOs.cj</code> example script file is located. See also, <a href="#">Extending the functionality of database tools</a> .	All node types
Diagrams	Ctrl+Shift+Alt+U	View a UML class diagram for the selected data	DB and DDL data sources

Ctrl+Alt+U

source or table. Select and tables

- Show Visualisation to open the diagram on a separate editor tab.
- Show Visualisation Popup to see the diagram in a pop-up window.

View | Quick Documentation (in the main menu)

Ctrl+Q

View basic information All node types

about the selected element. For example, the info about a table includes the names of the data source, database, schema and the table itself, the table definition ( `CREATE TABLE` ) and, if appropriate, the first 10 rows.

To close the documentation pop-up, press `Escape` .

## View options

The view options, generally, define what is shown in the tool window and how. To view or change these options, click  on the title bar.

### OptionDescription

**Group Schema** This option defines how schema elements are shown. When on, there are separate nodes for tables, views and stored routines (shown as folders). Tables, views and routines (procedures and functions) are shown as elements of the corresponding groups.

When off, there is no explicit grouping for tables, views, and routines. Tables and views are followed by procedures and functions.

**Group Contents** This option defines how table elements are shown. When on, there are separate nodes for columns, indexes, primary and foreign key constraints, and triggers (shown as folders). The elements appear in the corresponding groups.

When off, there is no such grouping and, generally, only columns are shown for tables.

**Show Keys and etc.** When this option is on, the primary and foreign key constraints, and indexes are shown as separate elements.

Otherwise, there are no separate elements for the keys and indexes.

The option is unavailable when the [Group Contents option](#) is on.

Show Empty Groups If the [Group Schema](#) or the [Group Contents option](#) is on, you can select to show or hide empty groups, i.e. the categories that contain no elements.

The Show Empty Groups option is on:

The Show Empty Groups option is off:

Sort When this option is off, columns, generally, are unsorted.

Alphabetically

When this option is on, the columns are ordered alphabetically.

Show Toolbar Select or deselect this option to show or hide the toolbar.

The rest of the options are common for all the tool windows, see [Viewing Modes](#).

## Icons for data sources and their elements

### IconDescription

	DB data source. Also, DBMS-specific icons are used: <ul style="list-style-type: none"><li> <a href="#">Amazon Redshift</a></li><li> <a href="#">DB2</a></li><li> <a href="#">Derby</a></li><li> <a href="#">H2</a></li><li> <a href="#">HSQLDB</a></li><li> <a href="#">Microsoft Azure</a></li><li> <a href="#">MySQL</a></li><li> <a href="#">Oracle</a></li><li> <a href="#">PostgreSQL</a></li><li> <a href="#">SQL Server</a></li><li> <a href="#">SQLite</a></li><li> <a href="#">Sybase</a></li></ul>
	DB data source with the read-only status, e.g.  for Derby.
	DDL data source
	Database
	Schema
	Table
	View
	Column
	A <code>NOT NULL</code> column
	Column with a primary key
	Column with a foreign key

	Column with an index
	Primary key
	Foreign key
	Index
	Trigger
	Stored procedure or function

## Title bar context menu and buttons

You can right-click on the window title bar and use the context menu to configure its [viewing mode](#) , associate the window with a different [tool window bar](#) , or resize and hide the window.

You can also use the toolbar buttons:

### Icon ShortcutDescription

	<a href="#">Ctrl+NumPad -</a> Use this button to collapse all expanded nodes in the current view.
	Click this button to access a subset of the context menu commands that let you configure window's <a href="#">viewing mode</a> .
	Use this command to hide the tool window. You can also use it in combination with the <a href="#">Alt</a> key to hides all tool windows attached to the same <a href="#">tool window bar</a> .

Alt+5

## Overview

This tool window becomes available when you start [debugging](#) .

It displays the output generated by the debugging session for your application. If you are debugging multiple applications, the output for each application is displayed in a separate tab named after the corresponding [run/debug configuration](#) .

For each application, there are the following nested tabs:

- **Console** : displays system information and error messages, and the console input and output of your application.
- **Debugger** : this tab is divided into the following areas:
  - [Frames / Threads](#)
  - [Variables](#)
  - [Watches](#)
- **Dump** : opens when the Get thread dump  button is clicked on the [Debugger toolbar](#) .
- **Elements** : appears if you are using Chrome browser for debugging.

Each area has a [context menu](#) that allows you to configure its behavior and navigate between tabs.

Each of the tabs and areas can be [hidden/restored](#) , or [moved](#) to a location of your choice.

## Debug toolbar

**Item**  
**Tooltip**  
**and**  
**Shortcut**

	Rerun  	Click this button to stop the current application and run it again. When an application is stopped, this button toggles to  .
	Debug  	When the current application is stopped, click this button to debug it again. When an application is running, this button toggles to  .
	Resume Program  	When an application is paused, click this button to resume program execution.
	Pause Program  	Click this button to pause program execution. Note that the button is not available for <a href="#">Run/Debug Configuration: Node.js</a> , <a href="#">Run/Debug Configuration: Attach to Node.js/Chrome</a> , and <a href="#">Run/Debug Configuration: NUnit</a> .
	Stop  	Click this button to terminate the current process externally by means of the standard <code>shutdown</code> script . Clicking the button once invokes <b>soft kill</b> allowing the application to catch the <code>SIGINT</code> event and perform graceful termination (on Windows, the  event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix <code>SIGKILL</code> is sent.
	View Breakpoints  	Click this button to open the <a href="#">Breakpoints</a> dialog box where you can configure breakpoints behavior.
	Mute Breakpoints	Use this button to toggle breakpoints status. When the button  is pressed in the toolbar of the <a href="#">Debug</a> tool window, all the breakpoints in a project are muted, and their icons become grey:  .  You can temporarily mute all the breakpoints in a project to execute the program without stopping at breakpoints.
	Get thread dump	Click this button to open the <a href="#">Dump tab</a> .
	Restore Layout	Click this button abandon changes to the current layout and return to the default state.
	Settings	Click this button to open the menu with the following options available: <ul style="list-style-type: none"> <li>- <a href="#">Show Values Inline</a> : select this option to enable the <a href="#">Inline Debugging</a> feature that allows viewing the values of variables right next to their usage in the editor.</li> <li>- <a href="#">Show Method Return Values</a> : select this option to display the return values of the last executed method.</li> <li>- <a href="#">Auto-Variables Mode</a> : select this option if you want IntelliJ IDEA debugger to automatically evaluate certain variables (the variables at breakpoints plus several lines before and after the breakpoint).</li> <li>- <a href="#">Sort Values Alphabetically</a> : select this option to sort the values in the <a href="#">Variables pane</a> in the alphabetical order.</li> </ul>

- Unmute Breakpoints on Session Finish : select this option to re-enable all disabled breakpoints after the debugging session has been finished.

	Pin	Click this button to pin or unpin the currently selected tab.
	Close	Click this button to close the selected tab.
		
	Help	Click this button to open the corresponding help page.
		

## Stepping toolbar

Item	Tooltip and Shortcut	Description
	Show Execution Point 	Click this button to highlight the current execution point in the editor and show the corresponding stack frame in the Frames pane.
	Step Over 	Click this button to execute the program until the next line in the current method or file, skipping the methods referenced at the current execution point (if any). If the current line is the last one in the method, execution steps to the line executed right after this method.
	Step Into 	Click this button to have the debugger step into the method called at the current execution point. If stepping into the called method is suppressed through the <a href="#">Stepping</a> page of the <a href="#">Settings</a> dialog box (for example, if it is of a standard Java SDK class or a simple getter), the method will be skipped. Change the settings or use the Force Step Into command.
	Force Step Into 	Click this button to have the debugger step into the method called in the current execution point even if this method is to be skipped.
	Step Out 	Click this button to have the debugger step out of the current method, to the line executed right after it.
	Drop frame	Interrupts execution and returns to the initial point of method execution. In the process, it drops the current method frames from the stack.
	Run to Cursor 	Click this button to resume program execution and pause until the execution point reaches the line at the current cursor location in the editor. No breakpoint is required. Actually, there is a temporary breakpoint set for the current line at the caret, which is removed once program execution is paused. Thus, if the caret is positioned at the line which has already been executed, the program will be just resumed for further execution, because there is no way to roll back to previous breakpoints. This action is especially useful when you have stepped deep into the methods sequence and need to step out of several methods at once.  If there are breakpoints set for the lines that should be executed before bringing you to the specified line, the debugger will pause at the first encountered breakpoint.
		
	Evaluate Expression 	Click this button to open the <a href="#">Evaluate Expression</a> dialog.

## Hide/restore toolbar

Icon	Tooltip	Description
	Hide	Click this button located in the upper-right corner of the Debug Console, Watches, Treads, Frames, or Variables pane to hide the corresponding area. When an area is hidden, its icon appears in upper-right corner of the Debugger.
	Restore 'Console' view	Click this button to make the <a href="#">Console</a> area visible. This button becomes available after clicking  .
	Restore 'Frames' view	Click this button to make the <a href="#">Frames</a> area visible. This button becomes available after clicking  .
	Restore 'Watches' view	Click this button to make the <a href="#">Watches</a> area visible. This button becomes available after clicking  .
	Restore 'Threads' view	Click this button to make the <a href="#">Threads</a> area visible. This button becomes available after clicking  .

 Restore Click this button to make the **Variables** area visible. This button becomes available after clicking **'Variables'** view

## Moving tabs and areas

If you are unhappy with the default layout of the Debug tool window, you can always move the tabs and areas. To do that, just drag a tab or an area to the desired location. The possible target gets highlighted.

Drop the tab or area in the highlighted location.

To restore the default layout of tabs and area, click  in the Debug toolbar.

## Context menu of a tab

Use the context menu of the **Frames / Threads**, **Variables** or **Watches** areas to configure the behavior of these areas or navigate between tabs.

### ItemDescription

Hide	Click this button to hide the corresponding area
Close Others	Click this button to hide all tabs except for the <b>Console</b> and Debugger tabs.
Focus On Startup	If this option is selected, the selected area gets the focus when you start a debugging session.
Focus On Breakpoint	If this option is selected, the selected area gets the focus when a breakpoint is reached.
Select Next Tab / Select Previous Tab	Use these options to switch between the <b>Console</b> and the Debugger tabs.

 **Ctrl+Alt+Right** /

 **Ctrl+Alt+Left**

The Debugger tab is divided into the following areas:

- [Frames /Threads](#)
- [Variables](#)
- [Watches](#)

The Frames pane enables you to gain access to the list of threads of your application. You can also [export to a text file](#) and [customize thread presentation](#). To examine a thread, select it from the drop-down list on top of the pane. The status and type of a thread is indicated by a special icon and a textual note next to the thread's name. For each thread, you can view the stack frame, examine frames, navigate between frames, and automatically jump to a frame's source code in the editor.

To examine the values stored in a frame, use the [Variables pane](#) of the Debug tool window.

In this topic:

- [Thread Status](#)
- [Threads Icons](#)
- [Context menu options](#)
- [Toolbar](#)

## Thread Status

Thread status	Description
RUNNING	The thread is active and running.
WAIT	The thread is waiting for a monitor.
UNKNOWN	The status of the thread cannot be determined.

## Threads Icons

Icon	Description
	A thread group, or a collection of related threads that can be managed as a unit.
	The current thread group.
	An active thread.
	A suspended thread.
	A frozen thread.
	A thread at breakpoint.
	The current thread at breakpoint.

## Context menu options

Item	Description
Drop Frame	Use this command to <a href="#">drop the selected frame</a> , i.e. go back in time while debugging. This option is only available if there are two or more frames.
Force Return	Use this command to force a return from the current method before the return statement is reached and without executing any more instructions from it. If the method returns a value, you will be prompted to specify it ( <a href="#">smart code completion</a> is provided). If the method has try-finally blocks, you will be prompted to choose whether you want to execute them or not.
Add Stepping Filter	Use this command to add a stepping filter in the dialog that opens.
Export Threads	Use this item to open the <a href="#">Export Threads dialog box</a> that allows you to export a thread to the specified text file.
Customize Threads View	Use this item to manage contents of the Frames tab. For example, you can opt to show thread groups, line numbers etc. Refer to the <a href="#">dialog description</a> for details.

## Toolbar

Item	Shortcut and Tooltip	Description
	Previous Frame/Next Frame <a href="#">Ctrl+Alt+Up</a> / <a href="#">Ctrl+Alt+Down</a>	Use the arrow buttons to navigate through the frame stack.
	Hide Frames from Libraries	Click this button to hide frames from libraries. If this button is released, all frames are displayed.

The Threads pane shows all threads of a process as a tree view, and allows exploring them, [customizing thread view](#) , and [exporting to a file](#) .

## Thread Status

**Thread status**

Thread status	Description
RUNNING	The thread is active and running.
WAIT	The thread is waiting for a monitor.
UNKNOWN	The status of the thread cannot be determined.

## Threads Icons

**IconDescription**

Icon	Description
	A thread group, or a collection of related threads that can be managed as a unit.
	The current thread group.
	An active thread.
	A suspended thread.
	A frozen thread.
	A thread at breakpoint.
	The current thread at breakpoint.

## Context menu options

**ItemDescription**

Item	Description
Suspend	Select this option to suspend the selected thread. When a thread is suspended, this menu option toggles to Resume.
Interrupt	Use this command to interrupt the active thread.
Drop Frame	Use this command to <a href="#">drop the selected frame</a> , i.e. go back in time while debugging. This option is only available if there are two or more frames.
Add Stepping Filter	Use this command to add a stepping filter in the dialog that opens.
Export Threads	Use this item to open the <a href="#">Export Threads dialog box</a> that allows you to export a thread to the specified text file.
Customize Threads View	Use this item to manage contents of the Frames tab. For example, you can opt to show thread groups, line numbers etc. Refer to the <a href="#">dialog description</a> for details.

## Toolbar

**ItemShortcut and Tooltip**

Item	Shortcut	Description
	Previous Frame/Next Frame Ctrl+Alt+Up / Ctrl+Alt+Down	Use the arrow buttons to navigate through the frame stack.
	Hide Frames from Libraries	Click this button to hide frames from libraries. If this button is released, all frames are displayed.

Use this dialog box to manage contents view and groupings of the Frames tab.

#### ItemDescription

Show thread groups	If this option is selected, threads appear in a hierarchy of thread groups, allowing you to drill down into each group to access its member threads.
Show stack frames for synthetic methods	Specify whether you want stack frames for synthetic methods to be shown.
Move current thread to the top	Select this checkbox to keep the current thread on top of the list.
Show line number	If this checkbox is selected, the line number is displayed.
Show class name	If this checkbox is selected, the name of a class containing the method is shown.
Show package name	If this checkbox is selected, the name of the class package is shown. This checkbox allows hiding package names in the Threads view.
Show source file name	Shows the name of source file that contains the method.
Show method arguments types	If this checkbox is selected, the method type is shown next to the method name in the <a href="#">Frames</a> or <a href="#">Threads</a> panes of the Debugger. For example, the unselected vs selected checkbox is shown in the following image:

Use this dialog to export a thread to the specified text file.

**ItemDescription**

---

Export to file	Type the target file to store the thread report.
	Use this button to navigate to the desired location in the Select Path dialog.
Save	Click to save the current threads in a text file indicated in the Export to file field.
Copy	Click to copy the thread status to the Clipboard.
Cancel	Use to discard all changes and close the dialog.

In this topic:

- [Overview](#)
- [Toolbar](#)
- [Context menu](#)
- [Variable types](#)

## Overview

The Variables pane enables you to examine the values stored in the objects of your application.

When a stack frame is selected in the [Frames pane](#), the Variables pane displays all data within its scope (method parameters, local and instance variables). In this pane, you can set labels for objects, inspect objects, evaluate expressions, add variables to watches and more.

## Toolbar

This toolbar appears only when the [Watches pane](#) is hidden so the configured watches are displayed in the Variables pane. Hiding/showing the Watches pane is controlled through the  toggle button:

- When the button is pressed, which is its default status, the Watches pane is hidden and the toolbar is shown in the Variables pane. So doing, the focus is with the [Debugger tab](#).
- When the button is released, the toolbar moves to the Watches pane.

### ItemShortcutDescription

	Insert	Click this button to create a new watch.
	Delete	Click this button to remove the selected watch from the list.
	Alt+Up Alt+Down	Use these buttons to change the order of watches.
	Ctrl+D	Use this button to create a copy of the selected watch.
	Show watches in Variables tab	Use this toggle button to have the Watches pane hidden or shown. By default, the button is pressed and displayed on the toolbar of the Variables pane. Consequently, the Watches pane is hidden and the watches are shown in the <a href="#">Variables pane</a> . <ul style="list-style-type: none"><li>– To have the Watches pane displayed separately and view the configured watches in it, release the Show watches in Variables tab toggle button. The Watches pane appears with the Show watches in Variables tab toggle button on the toolbar.</li><li>– To hide the Watches pane and view the watches in the Variables pane, press the  toggle-button on the toolbar of the Watches pane. The toggle button returns to the default location on the toolbar of the Variables pane.</li></ul>

## Context menu

### ItemShortcutDescription

Inspect	N/A	This command is available for fields, local variables and reference expressions, and opens a non-modal Inspection window, where you can concentrate on a particular reference. You can open as many Inspection windows as required. The view in the Inspection window is the same as in the <a href="#">Watches pane</a> , but requires less screen space.
Mark Object	F11	Use this command to add an object label.
Set Value	F2	Use this command to change the runtime value of a field or a variable.
Copy Value	Ctrl+C	Use this command to copy the value of the selected variable to the Clipboard. If multiple items are selected, not only variables' values, but also their structure is copied, so that when you copy-paste the selection to a text file, the indentation mimics the tree output of the debugger to produce an easy-to-read output. Alternatively, hover your mouse cursor over a value and view its contents in the tooltip.
Copy Value As	N/A	This menu item is available only in the <b>PHP</b> context. Choose this command to copy the selected variable to the Clipboard in one of the following formats: <ul style="list-style-type: none"><li>– <a href="#">print_r</a></li><li>– <a href="#">var_export</a></li><li>– <a href="#">json_encode</a></li></ul>
Copy JSON		This menu item is available only in the JavaScript context. Choose this command to copy the selected value in the <a href="#">JSON format</a> .
Compare Value with Clipboard	N/A	Use this command to compare the selected value with the value currently in the Clipboard.
Copy Name	N/A	Use this command to copy the name of the selected variable to the Clipboard.
 Evaluate Expression	Alt+F8	Use this command to <a href="#">evaluate the selected variable</a> in the dialog that opens.
 Add to Watches	N/A	This command is available for all nodes except static ones. Use this command to create an expression that references the node and add this expression to the <a href="#">Watches pane</a> .
Show Referring Objects	N/A	Use this command to display a list of objects referring to the currently selected variable.

Jump to Source		This command opens the source code of the selected variable or field in the editor and places the caret in the corresponding line.
Jump to Type Source		Use this command to navigate to the definition of the class of the selected variable or field.
View Text / View/Edit Text (for string values)	N/A	Use this command to display the text representation (if any) of the selected variable. Note that for the string values View Text turns into View/Edit Text . This makes it possible to change string values in a text area.
View as	N/A	<p>Use this command to select how you want variable values to be displayed. For numeric values, you can toggle between the decimal and hexadecimal formats. Objects are usually represented by their class name and instance identifier, but you can optionally show them in the string format.</p> <ul style="list-style-type: none"> <li>- Auto : this option is available for items where different layout is possible. If selected, IntelliJ IDEA looks through all available renderers and searches for the first suitable layout for the currently selected item. If none is found, the default layout is applied.</li> <li>- Hex : this option is available for numeric variables. If selected, the variable is shown in the hexadecimal format.</li> <li>- Primitive : this option is available for primitive variables. It shows the value appropriate for the corresponding primitive type.</li> <li>- Binary : this option is available for binary data. If selected, the variable is shown as a binary literal.</li> <li>- Timestamp : this option is available for <code>long</code> data. If selected, the variable is shown as a timestamp.</li> <li>- Boolean : available for boolean data. If selected, the variable is shown as a boolean value ( <code>true</code> or <code>false</code> ).</li> <li>- toString() : this option is available for all reference types where <code>toString()</code> is overridden (except for arrays), and shows the node's <code>toString()</code> value in the tree.</li> <li>- Array : this option is available for arrays.</li> <li>- Object : this is the default layout available for all non-primitive variable types.</li> <li>- Map : this options shows as a map.</li> <li>- Collection : this option shows as a collection.</li> <li>- File : this option is available for files and is the default layout for <code>java.io.File</code> type variables.</li> <li>- User-defined renderer : this option is available for renderers created by the user in <a href="#">Debugger   Java Type Renderers</a> , or in the <a href="#">Customize Data Views</a> dialog. The corresponding renderer name is shown in the menu.</li> </ul>
Adjust Range	N/A	This command is available for arrays and lists and lets you view the contents of an array within the specified range of indices.
Show types	N/A	Select this option if you want to show variables' types.
Mute Renderers	N/A	Select this option to mute automatic calculation of Java type renderers to reduce overhead.
Customize Data Views	N/A	Select this option to open the <a href="#">Customize Data Views</a> dialog where you can configure how data is represented.

## Variable types

The icon on the left of each variable indicates its type:

-  : static
-  : global
-  : field
-  : array
-  : primitive
-  : object

Use this dialog to configure the debugger data view options. Note that the same settings can be alternatively configured on the [Debugger page](#) in the Settings dialog.

- [Java tab](#)
- [Java Type Renderers tab](#)

## Java tab

### ItemDescription

Autoscroll to new local variables	Select this option to automatically scroll to new variables that appear in the scope when stepping.
Show value tooltip	Select this option to enable automatic display of tooltips for values. A tooltip in this context is a pop-up that provides an alternative, sometimes a more convenient presentation of values in the <a href="#">Variables pane</a> of the <a href="#">Debug Tool Window</a> .

To illustrate, let's assume that there is a statement like this in your code:

```
String s =
"Hello, World!
\n
Hello, World!";
```

When this statement is executed in the debugger, you'll see a line looking similar to this in the Variables pane:

```
s
= {java.lang.String@62}
"Hello, World!
\n
Hello, World!"
```

with the line break shown as `\n`.

If the Show value tooltip option is on and you click this line and then hold the mouse pointer on it, you'll see a yellow area (the "tooltip") in which the value of `s` is shown as

```
Hello, World!
```

```
Hello, World!
```

with a real line break in place of `\n`.

If this option is disabled, press `Alt` to display a value.

Show	In this section, select which elements you want the Debugger to display: <ul style="list-style-type: none"> <li>– Declared type</li> <li>– Synthetic fields</li> <li>– \$val fields as local variables</li> <li>– Fully qualified names</li> <li>– Object id</li> <li>– Static fields</li> <li>– Static final fields</li> </ul>
------	---

Show hex value for primitives	Select this option if you want numeric variables to be displayed in the hexadecimal format.
-------------------------------	---

Hide null array elements	Select this option if you want null array elements to be omitted.
--------------------------	---

Enable alternative view for Collection classes	Select this option to display collections and maps in a more convenient format.
--	---

Enable <code>toString()</code> object view	In this section, you can select classes if you need them and their descendants to be presented as a result of the <code>toString()</code> method call while debugging. Use the following controls: <ul style="list-style-type: none"> <li>– For all classes that override <code>toString()</code> method : select this option to show all classes as <code>toString()</code>.</li> <li>– For classes from the list : populate the list of classes to be shown as <code>toString()</code>, using the <code>+</code>, <code>+</code> and the <code>-</code> buttons. Use the checkboxes next to the class names to temporarily enable or disable particular filters.</li> <li>– <code>+</code> : click this button to add a class to the list using the Choose Class dialog.</li> <li>– <code>+</code> : click this button to add a custom class filter using the New Filter dialog. To define a filter, enter a string pattern, e.g. <code>*.Test</code>, <code>javax.swing.*</code>, etc.</li> <li>– <code>-</code> : click this button to remove a filter from the list.</li> </ul>
--	--

## Java Type Renderers tab

On this tab, you can create and customize rendering schemes for data presentation in the debugger Frame view.

If no rendering scheme is currently defined, start by clicking `+`.

## ItemDescription

	Click this icon to add a new rendering scheme to the list.
	Click this icon to remove the selected scheme from the list.
	Click this icon to create a copy of the selected scheme.
	Click these icons to move the selected item one line up or down in the list. Note that the order determines which renderer is used in case of ambiguity stemming of class inheritance.
Renderer name	Specify the name of a new renderer, or edit an existing renderer name.
Apply renderer to objects of type (fully-qualified name)	Specify the object type that will be represented by this renderer. Enter a fully qualified object name, or click the Browse button  and choose the desired type from the list in the Renderer Reference Type dialog.
When rendering a node	<p>This option determines how an object is displayed in the debugger when nodes are collapsed:</p> <ul style="list-style-type: none"><li>– Show type and object id : if cleared, types are shown without class information or id.</li><li>– Use default renderer : select this option to display the node in the default way.</li><li>– Use following expression : enter the Java expression you want to use to identify an object. You can use object properties, constants, and even a string math as part of your renderer. Note that you can use code completion (  ) when defining expressions.</li></ul> <p>All method calls and member variable access are relative to the object you're rendering. Use <code>this</code> to refer to an instance to which the renderer applies.</p> <div data-bbox="209 763 975 831" style="background-color: #ffff00; padding: 5px;"><p><b>Note</b> – Using heavy expressions in renderers may slow down data rendering in views. – Method calls should be used with caution because of possible side-effects.</p></div>
When expanding a node	<p>This option determines how an object is displayed in the debugger when nodes are expanded.</p> <p>Normally, expanding a node in the debugger lists the object's member variables (using the renderer appropriate for the corresponding object types). This option lets you override this behavior and select a single expression or a series of expressions to be displayed. You may use this to limit the amount of information displayed, or to be more precise in how the information is presented.</p> <ul style="list-style-type: none"><li>– Use default renderer : select this option to display the node children in the default way.</li><li>– Use following expression : enter the Java expression you want to use to identify an object. Test if a node can be expanded (optional) : enter a Boolean expression. If it is <code>true</code> , the renderer displays expandable nodes for the defined objects. Otherwise, no nodes are displayed.</li><li>– Use list of expressions : create a list of separate expressions to be calculated and presented as node children. Use:<ul style="list-style-type: none"><li> (  ) to create a new expression.</li><li> (  ) to remove the selected expression from the list.</li><li> (  ) to move the selected expression one line up in the list.</li><li> (  ) to move the selected expression one line down in the list.</li></ul></li></ul> <p>If you select the checkbox in the On-demand column next to a renderer, the evaluation of this expression will be done on demand. Simply click this expression when you need to evaluate it in the <a href="#">Variables</a> , <a href="#">Watches</a> or other view instead of having it evaluated automatically.</p> <div data-bbox="193 1391 975 1447" style="background-color: #ffff00; padding: 5px;"><p><b>Tip</b> You can use code completion (  ) when defining expressions.</p></div>
Append default children	Select this checkbox to add default children to the list of expressions. This checkbox is only available when the checkbox Use list of expressions is selected.

In this topic:

- [Overview](#)
- [Toolbar](#)
- [Context menu](#)

## Overview

By default, the Watches pane is hidden and the watches are shown in the [Variables pane](#).

- To have the Watches pane displayed separately and view the configured watches in it, release the Show watches in Variables tab toggle button  on the toolbar of the Variables pane. By default, the button is pressed.
- To hide the Watches pane and view the watches in the Variables pane, press the  toggle-button on the toolbar of the Watches pane.

In the Watches pane you can evaluate any number of variables or expressions in the context of the current stack frame. The values are updated with each step through the application, and become visible every time the application is suspended.

While the Evaluate Expression command on the context menu of the [Variables](#) pane enables you to see one expression at a time, the Watches pane shows multiple expressions that persist from one debug session to another, until you remove them.

You can create watches in this pane, in the [Variables](#) pane and even in the editor.

Watch expressions are always evaluated in the context of a stack frame that is currently inspected in the [Frames](#) pane. If an expression cannot be evaluated, it is displayed with a question mark.

## Toolbar

### ItemShortcutDescription

	Insert	Click this button to create a new watch.
	Delete	Click this button to remove the selected watch from the list.
	Alt+Up Alt+Down	Use these buttons to change the order of watches.
	Ctrl+D	Use this button to create a copy of the selected watch.
	Show watches in Variables tab	Use this toggle button to have the Watches pane hidden or shown. By default, the button is pressed and displayed on the toolbar of the Variables pane. Consequently, the Watches pane is hidden and the watches are shown in the <a href="#">Variables pane</a> . <ul style="list-style-type: none"><li>– To have the Watches pane displayed separately and view the configured watches in it, release the Show watches in Variables tab toggle button. The Watches pane appears with the Show watches in Variables tab toggle button on the toolbar.</li><li>– To hide the Watches pane and view the watches in the Variables pane, press the  toggle-button on the toolbar of the Watches pane. The toggle button returns to the default location on the toolbar of the Variables pane.</li></ul>

## Context menu

### ItemShortcutDescription

New Watch	Insert	Choose this command to create a new watch. A text field opens, where you can enter new watch expression.
Remove Watch	Delete	Choose this command to delete the currently selected watch expression from the list.
Edit	F2	Choose this command to change the selected watch expression.
Remove All Watches		Choose this command to delete all watch expressions from the list.
Inspect		Available for fields, local variables and reference expressions. Choose this command to open the Inspect window for the node, which allows you to perform the same operations as those available in the stack frame, with the only difference that the root node is the one you have selected. You can recursively call the new Inspect windows from within each other. Each window is not modal and immediately reflects all changes in its subtree.
Mark Object	F11	Choose this command to add a label to an object.
Set Value		This command is available on the context menu of a field or local variables, added to a watch and being currently in scope. Choose this command to assign the desired value to such variable.
Show Referring Object		Choose this command to display the list of objects referring to the current watch.
Jump to Source	F4	This command opens the source code of the selected variable or field in the editor and places the caret on a proper line.
Jump to Type Source	Shift+F4	Use this command to navigate to the definition of the class of the selected variable or field.
View as		Use this command to select the layout of the values. For the numeric values, you can toggle between the decimal and hexadecimal formats. The objects are usually represented by their class name and instance identifier, but you can optionally show them in string format. <ul style="list-style-type: none"><li>– Auto : Available for items where different layout is possible. With this layout IntelliJ IDEA looks through all available renderers searching for the first suitable layout for the current item. If none is found, the default layout is applied.</li><li>– Hex : This layout is available for numeric variables. If checked, the variable is shown in</li></ul>

hexadecimal format.

- Primitive : This layout is available for primitive type variables. It shows the value appropriate for the primitive type.
- toString() : This layout is available for all reference types where `toString()` is overridden except for arrays, and shows the node's `toString()` value in the tree.
- Array : Available for arrays.
- Object : Default layout. Available for all non-primitive type nodes.
- Map : Show as a map.
- Collection : Show as a collection.
- User-defined renderer : Available for renderers created by the user in the [Debugger | Type Renderers](#) or in the Customize Data Views dialogs. The corresponding renderer name is shown in the menu.

---

Copy Value Ctrl+C Copies the selected node value to the clipboard.

---

Copy Name Copies the selected node name to the clipboard.

This tab is marked with  and shows the output and error stream messages.

## Console Toolbar

**Item**  
**Tooltip**  
**and**  
**shortcut**

	Up/down the Stack Trace	Click this button to navigate up or down in the stack trace and have the cursor jump to the corresponding location in the source code.  
	Use Soft Wraps	Click this button to toggle the soft wrap mode of the output.  
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location in the source code.
	Print	Click this button to send the console text to the default printer.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.
	Toggle tasks executions/text mode	Click this button to view Gradle task execution in a tree mode.

## Context Menu Commands

**Item**  
**Description**

Compare with Clipboard	Opens the Clipboard vs Editor dialog box that allows you to view the differences between the selection from the editor and the current clipboard content. This dialog is a <a href="#">regular comparing tool</a> that enables you to copy the line at caret to the clipboard, find text, navigate between differences and manage white spaces.
Fold Lines Like This	Opens the <a href="#">Console</a> dialog that allows you defining the lines to be folded to hide extraneous information.
Copy URL	Choose this command to copy the current URL to the system clipboard. This command only shows on a URL, if it is included in an application's output.
Create Gist	Choose this command to open the Create Gist dialog box.
Clear All	Clears the output window.

## Keyboard Shortcuts

The  key combination allows you to send EOF (end of file), i.e. to signal that no more data can be read from a data source.

This tab appears when the Dump button  is clicked on the [Debugger toolbar](#) , or on choosing Run | Get Thread Dump on the main menu.

Use this tab to review the external thread dump or the one taken from the debugger in a handy way. The tab is divided into two parts. The left one displays all threads, and the right one - the stack trace for the selected thread.

In the Dump tab, all threads are sorted so that the most meaningful and useful threads are on top of the list. For your convenience, threads are displayed in varying shades of gray text, and deadlocks are highlighted in red.

In this topic:

- [Threads toolbar](#)
- [Thread types](#)

## Threads toolbar

**Item**  
**Tooltip**  
**and**  
**Shortcut**

	Filter  	Click this button to enable filtering the thread dump by a word in the stack trace. A search field appears in the list of threads, where you can type the search string. Note that <a href="#">plain search</a>  is also available in the right-hand part of the Dump tab, in the stack trace for the selected thread.
	Copy to Clipboard	Click this button to copy the whole thread dump to the Clipboard.
	Sort threads by name / Sort threads by type	Click these buttons to toggle between sorting threads in the alphabetical order, or by type.
	Export To Text File  	Click this button to export the current threads to a specified text file.

## Thread types

**Item**  
**Description**

	Thread is suspended.
	Thread is waiting on a monitor lock.
	Thread is running.
	Thread is executing network operation, and is waiting for data to be passed.
	Thread is idle.
	Event Dispatch Thread that is busy.
	Thread is executing disk operation.

In this tab, view the HTML source code that implements the active browser page and its [HTML DOM structure](#) . Any changes made to the page through the browser are immediately reflected in the tab.

### To Have the Tab Displayed:

1. Install the **JetBrains Chrome extension** in your Chrome browser, see [Installing JetBrains Chrome extension](#) .
2. Make sure the **LiveEdit** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the **JetBrains plugin repository** as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. Activate the **Live Edit** functionality by selecting the Update application in Chrome checkbox on the [Live Edit](#) page. For details, see [Activating Live Edit](#) .

### The Structure, Text, and Scripts Panes

The tab consists of three panes: Structure , Text , and Scripts .

The Structure pane shows the [HTML DOM structure](#) of the page that is currently active in the browser. The structure is updated dynamically according to the changes made on the page.

The Text pane shows HTML source code of the page that is currently active in th browser. The code is updated dynamically according to the changes made on the page.

The Scripts pane shows a tree of executed scripts.

The Structure and the Text panes are mutually synchronized. When you click a node in the DOM structure, IntelliJ IDEA scrolls through the contents of the Text pane. The panes are also synchronized with the browser: as soon as you click a node in the DOM structure or in the Text pane, IntelliJ IDEA highlights the corresponding element in the browser.

The Dependency Viewer tool window displays results of analyzing dependencies, backward and cyclic dependencies.

In this section:

- [Panes of the Dependency Viewer](#)
- [Analyzed Code Toolbar](#)
- Usage [Toolbar](#) and [Context Menu](#)

## Panes of the dependency Viewer

The Dependency Viewer consists of the following panes:

- Analyzed Code pane in the upper-left part of the tool window containing a tree view of your project's files and packages. Selecting a node (package or file), for which you want to find dependencies, populates the Parent Code pane.
- Parent Code pane in the upper-right part of the tool window represents the classes your selection depends on. In addition to the other classes in project, these dependencies also include any classes in the libraries and test sources, if the corresponding view filter is enabled.
- Usage pane in the lower-left part of the tool window is populated when you select an entry in the Parent Code pane.
  - For the [dependencies analysis](#) this pane contains the objects which your code is dependent on (that is, the code in the left pane uses them).
  - For the [backward dependencies analysis](#), these are the objects that depend on your code (that is, they use something of the code in the left pane).
  - For the [cyclic dependencies analysis](#) this pane shows the objects which the analyzed code refers to and which, in turn, refer back to your code.

## Analyzed Code Toolbar

**Item** **Tooltip** **Description**  
and  
**Shortcut**

	Close	Click this button to close the current tab of the tool window.
	Rerun	Click this button to rerun the dependency analysis in the same tab.  
	Flatten Packages	When the button is pressed, all packages display as a single-level tree view.
	Show Files	When the button is pressed, files display in the Analyzed Code and Parent Code panes. Otherwise, both panes display the packages only.
	Show Modules	When the button is pressed, items in the tree view display under the corresponding module nodes. Otherwise, the project items display under their packages.  
	Show Module Groups	When the button is pressed, the items in the tree are arranged by <a href="#">user defined module groups</a> .
	Group By Scope Type	When the button is pressed, the items in the tree are grouped by the type of scope, i.e. production, test or libraries.
	Show Illegals Only	When the button is pressed, the pane shows only illegal and invalid dependencies.
	Mark Illegal	Click this button to mark the selected dependency as illegal.
	Edit Rules	Click this button to open the <a href="#">Dependency Validation dialog</a> and define the rules for dependencies analysis.

The Dependency Validation dialog box opens when you click the  button on the **Analyzed Code** toolbar of the **Dependency Viewer** tool window.

Use the dialog box to declare rules that describe invalid dependencies.

#### ItemDescription

---

Deny usages of/	Drop-down menus appear on pressing the Add button to the right. Use the drop-down menus to select the usage scope pattern: <ul style="list-style-type: none"><li>– Deny means that the specified scope code is recognized as invalid</li></ul>
Allow usages of	<ul style="list-style-type: none"><li>– Allow means that the specified scope code is recognized as valid.</li></ul> <p>Scope pattern is defined in the <a href="#">Scopes</a> dialog box, by clicking the ellipsis button.</p>
in/ only in	Drop-down menus appear on pressing the Add button to the right. Use this drop-down menu to select the usage scope pattern where the previously selected usages are to be applied. For deny it means that the Deny usages of code are invalid if used within the in scope. For allow it means that the Allow usages of code is valid only in case if it is used within the only in scope. To set the scope pattern press the ellipsis button to call the <a href="#">Scopes</a> dialog box.
Add	Click this button to add a line to the pattern list.
Remove	Click this button to remove the selected pattern line from the list.
Move up/	Click this button to move the selected pattern line up or down in the list.
Move down	
Skip import statements	Select this checkbox to skip analyzing import statements. In this case references in the import statements are ignored.

For this tool window to be available, the Docker integration [plugin](#) must be installed and at least one Docker configuration must be defined.

The Docker tool window lets you manage your [Docker](#) images and containers.

All the available functions are accessed by means of the toolbar icons and context menu commands.

See also: [Docker](#) .

## Toolbar icons and context menu commands

### IconCommandDescription

#### Docker node

	Connect	Connect to Docker API. As a result, the list of Docker images and containers available locally is shown.
	Disconnect	Disconnect from Docker API. As a result, the list of Docker images and containers is hidden.
	Edit Configuration	Edit the Docker API connection settings.
	Deploy	Execute an existing <a href="#">Docker run configuration</a> or create a new one.
	Pull image	Pull an image from <a href="#">Docker Hub</a> or other image repository, e.g. <a href="#">Quay</a> . Opens the <a href="#">Pull Image dialog</a> .
	Filter	Open the Filter menu to showhide containers that are not running and images with no tags.

#### Images

	Create container	Create a container for the selected image according to an existing or new <a href="#">Docker run configuration</a>
	Delete image	Delete the selected image or images.
	Push image	Push the selected image to <a href="#">Docker Hub</a> or other image repository, e.g. <a href="#">Quay</a> . Opens the <a href="#">Push Image dialog</a> .
	Filter	Open the Filter menu to showhide containers that are not running and images with no tags.
	Copy image ID	Copy ID of the selected image to the clipboard.

#### Containers

	(Re)deploy	Restart the container using an associated <a href="#">Docker run configuration</a>
	Edit Configuration	Edit the settings for an associated run configuration.
	Start container	Start the selected container.
	Stop container	Stop the selected container.
	Delete container	Delete the selected container or containers.
	Filter	Open the Filter menu to showhide containers that are not running and images with no tags.
	Copy container ID	Copy ID of the selected container to the clipboard.
	Copy image ID	Copy ID of the associated image to the clipboard.
	Show log	Show the container log.
	Inspect	Show low-level container information in JSON format.
	Show processes	Show the list of processes running in the container.

Attach	Open the console for the <a href="#">ENTRYPOINT</a> container process, i.e. attach to the stdin/out of the process.
--------	---

Exec	Run a command in the container, e.g. <code>ls /tmp</code> , <code>/bin/bash</code> .
------	--

---

Compose node

	(Re)deploy	Restart the services using the associated <a href="#">Docker run configuration</a>
---	------------	--

	Edit Configuration	Edit the settings for the associated run configuration.
---	--------------------	---

---

Services

	Scale	Change the number of containers within the service.
---	-------	---

	Start	Start the service.
---	-------	--------------------

	Stop	Stop the service.
---	------	-------------------

Ctrl+Q

This tool window appears in the following cases:

- [Quick Documentation lookup](#) is pinned by clicking  in the upper-right side of the lookup window.
- [Quick Definition tooltip](#) is pinned by clicking  in the upper-right corner of the tooltip.

As a result, the tool window appears in the list of available tool windows in the View menu, and gets the corresponding sidebar icon  Documentation .

#### IconShortcutDescription

	Left or Right	Switch to the previous or next documentation page (e.g. after using hyperlinks).
	<b>Note</b>	On a macOS computer, you can also use the three-finger right-to-left and left-to-right swipe gestures.
	Shift+F1	View external documentation in the default browser.
	F4	Switch to the item (e.g. source) that corresponds to the documentation page currently shown.
		Turn the Auto-update from source option on or off. When the option is on, the information in the tool window is synchronized with your navigation in the editor and other places in the UI.
		Click this icon to show the font size slider. Move the slider to increase or decrease the font size as required.

- This tool window becomes available after [performing DSM analysis](#).
- Make sure that DSM Analysis plugin is installed and enabled. Refer to the [Plugins settings](#) page of the Settings dialog.

Here you can see the typical matrix view.

maven-artifact-test	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-error-diagnostics	32	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-monitor	58	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-descriptor	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-parameter-documenter	13	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-registry	65	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-project	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact-manager	35	2	-	-	-	-	-	-	10	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-profile	11	-	-	-	-	-	-	-	11	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact	11	...	1	-	-	-	-	-	...	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-reporting-and-modules	5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-repository-metadata	5	-	-	-	-	-	-	-	6	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-script-and-modules	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-api	49	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	18	-	-	-
maven-settings	...	5	-	-	-	-	-	-	16	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-model	...	-	-	-	-	-	-	-	...	59	-	-	-	-	-	-	-	-	-	-	57	-

The row headers represent program structure. Everything is collapsed now and only modules are shown. When expanded, the header is tree-like, allowing you to expand modules and dig into program packages. \* - node groups classes inside the package. The column headers are the same as the corresponding row headers. Thus they are not shown in order to save space. Instead, different visual aids are used on the row headers.

If you select a row, the matrix will look like this.

empty	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact-test	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-core	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-error-diagnostics	32	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-monitor	58	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-descriptor	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-parameter-documenter	13	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-plugin-registry	65	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-project	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-profile	11	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact-manager	35	2	-	-	-	-	-	-	10	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact	11	...	1	-	-	-	-	-	...	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-reporting-api	5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-repository-metadata	5	-	-	-	-	-	-	-	6	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-script-ant	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-script-beanshell	49	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	6	12	-	-
maven-plugin-api	...	5	-	-	-	-	-	-	16	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-settings	...	-	-	-	-	-	-	-	...	59	-	-	-	-	-	-	-	-	-	-	-	-
maven-model	...	-	-	-	-	-	-	-	...	59	-	-	-	-	-	-	-	-	-	-	57	-

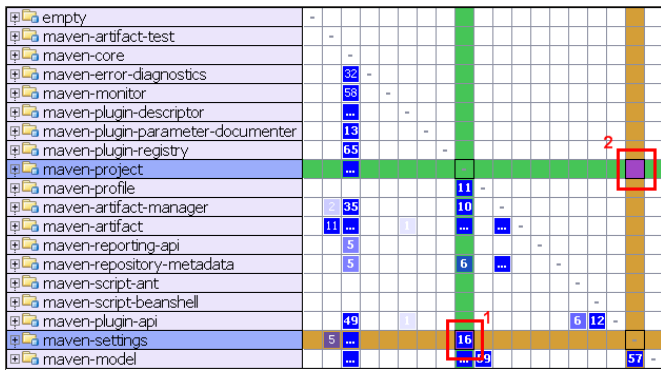

Here you can learn the following:

- The selected row and corresponding column are highlighted to visualize row dependencies.
- The ellipsis in the cell means that the `maven-core` module has many (more than 99) dependencies on `maven-project` module.
- The column shows the dependencies of the selected row.
- The row shows the dependencies on the selected row.
- This means that the `maven-project` module has 16 dependencies on `maven-settings` module.
- Various shades correspond to the number of dependencies.

empty	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact-test	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

maven-artifact-manager	35	2	-	-	-	-	-	-	10	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-artifact	11	...	1	-	-	-	-	-	...	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-reporting-api	5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-repository-metadata	5	-	-	-	-	-	-	-	6	...	-	-	-	-	-	-	-	-	-	-	-	-
maven-script-ant	...	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-script-beanshell	49	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	6	12	-	-
maven-plugin-api	...	5	-	-	-	-	-	-	16	-	-	-	-	-	-	-	-	-	-	-	-	-
maven-settings	...	-	-	-	-	-	-	-	...	59	-	-	-	-	-	-	-	-	-	-	-	-
maven-model	...	-	-	-	-	-	-	-	...	59	-	-	-	-	-	-	-	-	-	-	57	-

- Color annotations help to visualize row dependencies at a glance.
- `maven-core` depends on `maven-project`.
- `maven-project` depends on `maven-profile`.
- The dashes on the diagonal correspond to self dependencies which are not shown.

You can select any cell to explore the dependencies indicated in it.

The cell #1 was selected. These color annotations mean that `maven-project` has 16 dependencies on `maven-settings`. The symmetrical cell (cell #2) shows dependencies in the other direction - in this case zero.

There is a simple mnemonic rule - all dependencies always flow from Green to Yellow.

Instead of alphabetically sorting rows, DSM view sorts dependencies in a special way: classes, which are used most are moved to the bottom. In a project with good structure this creates a triangular shape in the lower left half of the matrix.

### Cycles

Mutual dependencies are shown in red. It means that the plugin and usability packages are both dependent on each other.

### Patterns

There are two types of visual patterns. Vertical lines represent *aggregators*.

Horizontal lines appear in lowest-level or utility functionality.

The Duplicates tool window displays results of the search for duplicates.

On this page:

- [Panels of the Duplicates tool window](#)
- [Left toolbar](#)
- [Upper toolbar](#)
- [Context menu commands](#)

## Panels of the Duplicates tool window

The window consists of the following panes:

- The left pane displays the tree view of the duplicate fragments of source code. Each node shows the following information:
  - The number of duplicated code fragments found in scope.
  - The 'cost' of the duplicate (which is an arbitrary unit calculated using an additive algorithm on the base of the code block size; generally, the larger is the code fragment, the higher is its cost).
  - The containing class where the duplicates are located.
- The right pane shows the differences between the duplicated fragments of source code, selected in the left pane.

## Left toolbar

### ItemShortcutDescription

	Rerun	Click this button to rerun the duplicates analysis in the active tab.
	Close Active Tab	Click this button to close the active tab.
		
	Autoscroll to Source	If the button is pressed, selecting an entry in the left pane opens the respective file in the editor.
	Eliminate Duplicates	Click this button to extract method from the duplicated code fragments. Refer to the <a href="#">Extract Method</a> refactoring for details.
		Click this button to show reference.

## Upper toolbar

### ItemTooltip/Image/ShortcutDescription

		Move to the next/previous difference
Whitespace		<p>Use this drop-down list to define how the differences viewer should treat white spaces in the text.</p> <ul style="list-style-type: none"> <li>– Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.</li> <li>– Trim whitespaces : (<code>"\t"</code>, <code>" "</code>), if they appear in the end and in the beginning of a line.           <ul style="list-style-type: none"> <li>– If two lines differ in trailing whitespaces only, these lines are considered equal.</li> <li>– If two lines are different, such trailing whitespaces are not highlighted in the <a href="#">By word</a> mode.</li> </ul> </li> <li>– Ignore whitespaces : white spaces are not important, regardless of their location in the source code.</li> <li>– Ignore whitespaces and empty lines : the following entities are ignored:           <ul style="list-style-type: none"> <li>– all whitespaces (as in the 'ignore whitespaces' option)</li> <li>– all added or removed lines consisting of whitespaces only</li> <li>– all changes consisting of splitting or joining lines without changes to non-whitespace parts.</li> </ul> </li> </ul> <p>For example, changing <code>a b c</code> to <code>a \n b c</code> is not highlighted in this mode.</p> <ul style="list-style-type: none"> <li>– Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).</li> </ul>

### Highlighting mode

Select the way differences granularity is highlighted.

The available options are:

- Highlight words : the modified words are highlighted
- Highlight lines : the modified lines are highlighted
- Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.

For example, `A \n B` vs. `A X \n B X` will be treated as two changes instead of one.

- Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.

	<b>Jump to Source</b>	Click this button to open the file in the active pane in the editor. The caret will be placed in the same position as in the Duplicates tool window .
		
	<b>Synchronize scrolling</b>	Click this button to simultaneously scroll both differences panes; if this button is released, each of the panes can be scrolled independently.
	<b>Editor settings</b>	Click this button to invoke the list of available settings. Select or clear this options to show or hide whitespaces, line numbers and indent guides, to use or disable the use of soft wraps, and to set the highlighting level. These commands are also available from the context menu of the differences viewer gutter.

## Context menu commands

**Item**  
**Keyboard Shortcut**

<b>Jump to Source</b>		Open in the editor the file that contains the selected duplicate, and place the caret at the beginning of the duplicate. The fragment of code is highlighted.
<b>Show Source</b>		Open in the editor the file that contains the selected duplicate, and highlight the fragment of code.
<b>Send to left/Send to right</b>		Use these commands, or the arrow icons   , to place the selected duplicate to the left or right pane of the differences viewer.

This tool window shows your deployment descriptors (e.g. `ejb-jar.xml` ) and EJBs. (The tool window is not available if there are no EJB [facets](#) in your project.)

## Main context menu commands

### CommandDescription

ER Diagram	For an EJB facet: Show an entity-relationship diagram.
Jump to Source (  )	Open the selected file in the editor. (Alternatively, you can double-click the file.)
New (  )	If an EJB facet is selected: Create an EJB, relationship or interceptor. The New command is also available for certain EJB types. See also, <a href="#">Creating EJB</a> .
Apply EJB 3.0 Style	Bring your EJBs in compliance with the <a href="#">EJB 3.0 specification</a> . See <a href="#">Migrating to EJB 3.0</a> .

Event Log in the right-hand part of the bottom [tool window bar](#)

The Event Log tool window shows the information about "important" events that take place in IntelliJ IDEA.

The information about problematic situations (e.g. errors and exceptions) is displayed in red. In such cases, clicking the more link (if present) opens a balloon with a more detailed description of the error or exception. Clicking a description link (depending on the error, the text may be different e.g. `NullPointerException` ) opens the IDE Fatal Errors dialog which lets you review the error and create a bug report.

- [General tab](#)
- [Database tab](#)
- [Toolbar](#)

## General tab

The General tab appears when the [Database tab](#) opens. In the absence of the Database tab, the information is shown in the output pane which, in this case, is not tabbed.

## Database tab

Shown on the Database tab are the events related to working with the [Database tool window](#) and the [Data editor](#) .

For the Database tool window, the following may be shown:

- The information about data synchronizations and various manipulations with databases such as creating, modifying and deleting tables and columns, etc.
- Error messages.

For the data editor only error messages are shown.

## Toolbar

### ItemDescription

	<b>Settings</b>	Use this icon to open the <a href="#">Notifications page</a> where you can select which events you want to be notified of and also which events should be logged.
	<b>Show balloons</b>	Use this icon to enable or disable showing notifications. Note that this icon is a toggle which turns the corresponding feature on or off.  When showing notifications is enabled, you are notified of the events that take place in IntelliJ IDEA. The corresponding notifications are shown in the balloons.  The alternative way to enable or disable this feature is by means of the Display balloon notifications checkbox on the <a href="#">Notifications page</a> .
	<b>Use Soft Wraps</b>	Use this icon to turn on or off the soft wrap mode for the output.
	<b>Scroll to the end</b>	Use this icon to go to the end of the event log.
	<b>Mark all as read</b>	Use this icon to mark all the messages as read.
	<b>Clear all</b>	Use this icon to delete all the messages and thus clear the log. This function can alternatively be accessed by means of the context menu.
	<b>Help</b>	Click this button or press <b>F1</b> to open this help topic.

## Title bar context menu and buttons

You can right-click on the window title bar and use the context menu to configure its [viewing mode](#) , associate the window with a different [tool window bar](#) , or resize and hide the window.

You can also use the toolbar buttons:

### Icon ShortcutDescription

		Click this button to access a subset of the context menu commands that let you configure window's <a href="#">viewing mode</a> .
	<b>Shift+Escape</b>	Use this command to hide the tool window. You can also use it in combination with the <b>Alt</b> key to hides all tool windows attached to the same <a href="#">tool window bar</a> .

Alt+2

**Note**

- Toolbar buttons
- Context menu commands
  - Title bar context menu and buttons
  - Context menu of the side bar button
- Using drag-and-drop

The Favorites tool window lets you manage the following lists:

- [Favorite project items](#) . Each list of Favorites in the tool window appears with the star icon ★ .
- [Bookmarks](#) . The list of bookmarks is marked with ✓ icon.
- [Breakpoints](#) . The list of breakpoints is marked with ● icon.

Initially, the lists are empty. So doing, the favorites list has the same name as the project.

The lists of bookmarks and breakpoints are filled in automatically, as the new bookmarks or breakpoints are added.

To add items to favorites, do one of the following:

- Select one or more items in the [Project Tool Window](#) or the [Find tool window](#) . Then choose File | Add To Favorites .
- Right-click an editor tab, and choose Add to Favorites or Add All to Favorites .

## Toolbar buttons

### ItemShortcutDescription

	<a href="#">Alt+Insert</a>	Use this button to create a new list of favorite items. In the Add New Favorites List dialog, specify the name for the new list and click OK .
	<a href="#">Ctrl+Enter</a>	Depending on the selection, this button does one of the following: <ul style="list-style-type: none"> <li>- If a Favorites list ★ , or one of the nested favorites is selected, click this button to rename this list.</li> <li>- If a bookmark under the Bookmarks list ✓ is selected, click this button to change short description of the selected bookmark.</li> <li>- If a breakpoint under the Breakpoints list ● is selected, click this button to <a href="#">configure the selected breakpoint</a> .</li> </ul>
	<a href="#">Alt+Delete</a>	Use this button to delete the selected list or list item. Depending on the selection, the following behaviors take place: <ul style="list-style-type: none"> <li>- If a Favorites list ★ , or one of the nested favorites is selected, click this button to delete an entire favorites list, or the selected item. So doing an item or a list is deleted from the Favorites tool window, but is left intact in project.</li> <li>- If a bookmark under the Bookmarks list ✓ is selected, click this button to delete this bookmark from the list and from the source code.</li> </ul> <p>Vice versa, if a bookmark is deleted from the source code, it is also removed from the Favorites tool window.</p> <ul style="list-style-type: none"> <li>- If a breakpoint under the Breakpoints list ● is selected, click this button to delete the selected breakpoint from the list and from the source code.</li> </ul> <p>Vice versa, if a breakpoint is deleted from the source code, it is also removed from the Favorites tool window.</p>

## Context menu commands

When you right-click an item in the content pane, the context menu for this item is shown. This menu provides access to all the functions available for the selected item.

The commands and functionality are similar to those in the [Project tool window](#) .

## Title bar context menu and buttons

You can right-click on the window title bar and use the context menu to configure its [viewing mode](#) , associate the window with a different [tool window bar](#) , or resize and hide the window.

You can also use the toolbar buttons:

### Icon ShortcutDescription

	<a href="#">Ctrl+NumPad -</a>	Use this button to collapse all expanded nodes in the current view.
		Click this button to access a subset of the context menu commands that let you configure window's <a href="#">viewing mode</a> .
	<a href="#">Shift+Escape</a>	Use this command to hide the tool window. You can also use it in combination with the <a href="#">Alt</a> key to hide all tool windows attached to the same <a href="#">tool window</a>

## Context menu of the side bar button

Right-click the side bar button to reveal this context menu. Refer to the section [Viewing Modes](#) for the detailed information about the viewing modes.

### ItemDescription

---

	Use this command to turn the Flatten Packages option on or off. If this option is off, the packages are shown as a hierarchy. If this option is on, all the packages appear at the same level and are identified by their qualified names.
	Use this command to turn the Compact Empty Middle Packages option on or off. If this option is off, the empty middle packages are shown as a hierarchy. If this option is on, all the packages appear at the same level and are identified by their qualified names.
	Use this command to turn the Show Members option on or off. If this option is on, the class members (fields, methods, etc.) are shown.
	Use this command to turn the Autoscroll to Source option on or off. If this option is on, IntelliJ IDEA automatically navigates from a file (or a class member) selected in the Favorites tool window to the corresponding source file (or its fragment) in the editor. If the corresponding file is not currently open, it will open automatically.
	Use this command to turn the Autoscroll from Source option on or off. If this option is on, IntelliJ IDEA automatically navigates from a file (or a class member) selected in the editor, to the corresponding file in the Favorites tool window.

## Using drag-and-drop

You can use drag-and-drop to:

- Add items to favorites: drag the item of interest from the Project tool window and drop it onto the desired favorites list in the Favorites tool window.
- Drag an external item from the Explorer/Finder and drop it onto the desired favorites list in the Favorites tool window.
- Move an item from one favorites list to another in the Favorites tool window.

## Basics

Find tool window displays results of the following searches:

- [Find/Replace in Path](#)
- [Find Usages](#)
- [Structural Search and Replace](#)
- [Refactoring Preview](#)
- [Find Usages of a data source](#) , a table, or a column.
- The Usages pane appears in the [Dependencies Viewer](#) , when an entry is selected in the Parent Code pane.

The results of each search are displayed in a separate tab, or replace the contents of the current tab, depending on the Open in new tab dialog setting. By default the window appears at the bottom of the screen.

It has a toolbar with a set of buttons, a pane of results, and additional buttons for [Replace in Path](#) , [Structural Replace](#), and [Refactoring Preview](#) operations.

**Warning!** Unless you find something, this tool window is not visible in the View menu.

## Toolbar buttons

**Item**   **Tooltip**   **Description**  
and  
shortcut

	Options  <a href="#">Ctrl+Shift+Alt+F7</a>	Click this button to open one of the <a href="#">Find Usages</a> dialogs, which corresponds to the symbol in question. You can edit the search settings and click Rerun button to execute the modified search query.
	Rerun  <a href="#">Ctrl+F5</a>	Rerun the last search. This button is not available for <a href="#">viewing code coverage results</a> .
	Close  <a href="#">Ctrl+Shift+F4</a>	Close the current tab or the tool window. This button is not available in Replace in Path and Refactoring Preview dialogs.
	Pin	Use to pin or unpin the tab. If a tab is pinned, the results for the next command are shown on a new tab.
	Recent find usages  <a href="#">Ctrl+E</a>	Show the list of recent searches. Select an item in the list to see the search results.
 	Expand all  <a href="#">Ctrl+NumPad Plus</a>  Collapse all  <a href="#">Ctrl+NumPad -</a>	Use these buttons to have all nodes expanded or collapsed.
	Previous/next occurrence  <a href="#">Ctrl+Alt+Up</a>  <a href="#">Ctrl+Alt+Down</a>	Navigate to the previous/next element in the tab of results.
	Autoscroll to source	Turns the Autoscroll to source option on or off. When the option is on and you select the search result, the corresponding source file opens in the editor and the appropriate fragment is highlighted in the file.
	Favorites	Click this button to add found usages to <a href="#">favorites</a> .
	Export to Text File  <a href="#">Alt+O</a>	Save the contents of the current result tab. In the Export preview dialog, specify the target file or copy information to the clipboard. Before saving, you can also modify the information to be saved.

	Help	Use this icon or shortcut to open the corresponding help page.
		
	Group by usage type	This button is available for <a href="#">Find Usages</a> only.
		
		<p>If this button is pressed, the search results are grouped by the following categories:</p> <ul style="list-style-type: none"> <li>- instanceof</li> <li>- import</li> <li>- cast target type</li> <li>- extends/implements clause</li> <li>- class static member access</li> <li>- method throws list</li> <li>- .class</li> <li>- field declaration</li> <li>- local variable declaration</li> <li>- method parameter declaration</li> <li>- catch clause parameter declaration</li> <li>- method return type</li> <li>- delegates to another object instance</li> <li>- delegates to another object instance with different parameters</li> <li>- delegates to super</li> <li>- delegates to super with different parameters</li> <li>- recursive method calls</li> <li>- string constants</li> <li>- comments</li> <li>- unclassified usage not related to any of the categories</li> </ul>
	Group by test/production	If this button is pressed, the usages are grouped according to the Production and Test scopes.
	Group by module	If this button is pressed, the found usages show under the corresponding module or library node.
		
		<b>Tip</b> This type of grouping is helpful, when a package is split between several modules.
	Group by package	If this button is pressed, all the usages found are displayed under their respective packages.
		
	Group by file structure	If this toggle is on, the found usages are shown under the corresponding method nodes.
		
	Merge usages from the same line	If this toggle is on, the duplicate usages found on the same line are merged.
		
	Show read access	This button is available for <a href="#">Find Usages</a> only.
		
		If this button is pressed, the search results include references to the read access methods.
	Show write access	This button is available for <a href="#">Find Usages</a> only.
		
		If this button is pressed, the search results include references to the write access methods.
	Show import statements	This button is available for <a href="#">Find Usages</a> only.
		
		If this button is pressed, the search results include the usages in the import statements.
	Preview usages	Turns showing the Preview pane on or off.
	Sort members alphabetically	Click this button to have all members sorted alphabetically. Otherwise, members are sorted in the order they are declared.

**Tip** The following buttons are available for Replace in Path only.

Do Replace All

Click this button to replace all occurrences

	<b>Alt+D</b>	in the current tab of results.
Replace Selected	<b>Alt+L</b>	Click this button to replace the selected occurrence in the current tab of results.

**Tip** The following buttons are available for Refactoring Preview only.

Do Refactor	<b>Alt+D</b>	Click this button to perform refactoring on all occurrences in the current search results.
Cancel	<b>Alt+C</b>	Click this button to discard search results and close the results tab.

**Tip** The following buttons are available for Structural Replace only.

Replace All		Click this button to replace all found occurrences.
Replace Selected		Click this button to replace the highlighted occurrence.
Preview Replacement		Click this button to show how the changes will apply to the selected node in the Find tool window. In this case, the corresponding occurrence is highlighted in the source code.

## Context menu commands

### Item ShortcutDescription

Jump to Source	<b>F4</b>	Navigate to the selected item in the source code.
Include	<b>Insert</b>	For an <b>excluded item</b> : include the item in the list of results.
Exclude	<b>Delete</b>	Exclude the selected item from the list of results. (Excluded items are shown strikethrough.) When you carry out the Replace All or the Do Refactor command, the excluded items are not affected.
Remove	<b>Alt+Delete</b>	Remove the selected item from the list of results.
Recent Find Usages	<b>Ctrl+E</b>	Show the list of recent searches. Select an item in the list to see the search results.
Add to Favorites		<a href="#">Add selected node to the Favorites list</a> .

On this page:

- [Errors pane](#)
- [Project Errors pane](#)
- [Toolbar](#)
- [Context Menu](#)

## Errors pane

The pane shows a list of all the discrepancies detected in the file which is opened in the active editor tab. At the top the full path to the file is displayed.

## Project Errors pane

The pane shows a list of all the discrepancies detected in all the files in the current project after you run Flow against the entire project by clicking  on the toolbar. The error messages are grouped by files in which they were detected.

## Toolbar

The toolbar is common for the Current Errors and the Project Errors panes.

### ItemTooltip Description

	and Shortcut	
	Show all errors	Click this button to switch to the Project Errors pane and view all the discrepancies detected in the current project.
	Help	Use this button to navigate to the help topic for the tool window.
	Close 	Click this button to terminate the Flow type checker and close the tool window.
	Expand all	Use these buttons to have all nodes expanded or collapsed.
	 Collapse all 	
	Clear All	Click this button to remove all the error messages from the currently active pane.

## Context Menu

The context menu is common for the Errors and the Project Errors panes.

### ItemDescription

Jump to source	Choose this option to open the file where the selected problem was detected and navigate to the fragment of code which caused the error.
Copy	Choose this option to copy the selected error message with the information on the file, the line, and the column where the error occurred.

**Warning!** The tool window is available only in a [Symfony2](#) or a [Yii](#) specific projects with the [MVC view enabled](#) .

In this tool window, examine the project in the terms of bundles, controllers, and other elements of the MVC pattern.

The Grails tool window is accessed by selecting Grails in the drop-down list located in the left-hand part of the title bar in [Project Tool Window](#) .

The special Grails tool window shows logical project structure displaying Controllers, Domain classes, Views, etc. as the Grails application elements rather than files and directories. From the Grails view, you can:

- Gain quick access to the application elements and their contents
- Navigate between the controller actions and associated views.
- Edit Groovy scripts from the [Scripts](#) directory

#### ItemDescription

---

 Click this button to navigate from a file in the Editor that gets the focus, to the corresponding node (file, class, field, method, etc.) in the Project tool window.

---

 Click this button to collapse all nodes (  )

---

 Click this button to open the menu for configuring the current view and changing the tool window viewing modes.

The menu items are options that you can turn on or off. An active item contains a check mark on the left side of its name.

The available options in the menu are as follows:

- [Compact Empty Middle Packages / Hide Empty Middle Packages](#)
- [Autoscroll to Source](#)
- [Autoscroll from Source](#)
- [Pinned](#), [Docked](#), [Floating](#), [Windowed](#), [Split Mode](#)

---

 Click this button to hide the tool window (  ).

When used in combination with the Alt key, clicking this button hides all the tool windows attached to the same tool window bar.

On the main menu select View | Tool Windows | Gradle

The Gradle tool window displays Gradle tasks, and all changes made to the underlying `build.gradle` file, or to the IntelliJ IDEA project structure.

If there is no linked Gradle project, the window is disabled. You need to reimport your Gradle project to enable the Gradle tool window.

In this section:

- [Gradle projects](#)
- [Gradle Tasks](#)
- [Toolbar](#)
- [Context Menu](#)
- [Context Menu Commands for Gradle Tasks](#)

## Gradle projects

### ItemDescription

	Click this button to open the menu for configuring the current view and changing the tool window viewing modes.
	The menu items are options that you can turn on or off. An active item contains a check mark on the left side of its name.
	The available options in the menu are as follows:
	– Group Tasks - select this option if you want to group your tasks. For example, build tasks will be included into the build directory.
	– Show Toolbar - select this option to show the toolbar for your Gradle projects.
	– <a href="#">Pinned, Docked, Floating, Windowed, Split Mode</a>
	– Group Tabs - deselect this option to see the views on separate tabs if more than one view is available in a tool window.
	– Move to - select this option to move the Gradle tool window to either top, left or right.
	– Resize - select this option to resize the Gradle tool window.

	Click this button to hide the tool window( <code>Shift+Escape</code> ).
	When used in combination with the Alt key, clicking this button hides all the tool windows attached to the same tool window bar.

## Gradle Tasks

### ItemDescription

Run Configurations	This area contains a list of the last executed tasks and command types under which these tasks were executed.
Tasks	This area contains a list of all available tasks.
Dependencies	This area contains a list project dependencies.

## Toolbar

### ItemDescription

	Click this button to refresh all registered Gradle projects after changes have been made to a Gradle script.
	Click this button to link a gradle project.
	Click this button to detach an external gradle project.
	Use this button to execute a Gradle task. When you click this icon, the Run Gradle Task dialog opens. You can enter the name of the task that you want to execute. Note that IntelliJ IDEA supports a code completion.
	Use these buttons to expand or collapse all the nodes.
	Click this button to import a module or a data to your gradle project via <a href="#">Project Data to Import</a> dialog. It might be useful for the multi-module projects.
	Click this button to work with Gradle projects in the offline mode. It might be helpful when the network connection is slow or when you need to work offline.
	Click this button to configure the settings of the current Gradle project in the <a href="#">Gradle settings</a> dialog box.

## Context Menu

### ItemDescription

	Select this option or use a shortcut to open <code>build.gradle</code> file.
	Select this option to refresh external projects.
	Select this option to detach an external project.
Use auto-import	Select this option to enable the auto-import feature for your project.

Task            Select this option to add, edit or remove an activation phase for your task. It might be useful for working with the  
Activation      Gradle multi-module projects.

## Context Menu Commands for Gradle Tasks

### CommandDescription

Run <task>	Choose this command to run the selected task with the task-specific run/debug configuration.
Debug <task>	Choose this command to debug the selected task with the task-specific run/debug configuration.
Create <task>	Choose this command to <a href="#">create run/debug configuration</a> for the selected Gradle task.
Execute before Sync, Execute after Sync	Choose these commands to set the respective flags for the selected task. In this case, <i>Before Sync</i> and <i>After Sync</i> comments appear next to the name of the node.
Execute before Build, Execute after Build	Choose these commands to set the respective flags for the selected task. In this case, <i>Before Build</i> and <i>After Build</i> comments appear next to the name of the node.
Execute before Rebuild, Execute after Rebuild	Choose these commands to set the respective flags for the selected task. In this case, <i>Before Rebuild</i> and <i>After Rebuild</i> comments appear next to the name of the node.
Assign Shortcut	Choose this command to <a href="#">associate the selected phase with a keyboard shortcut</a> . In this case, the comment with the shortcut appears next to the name of the node.

The special Griffon tool window shows logical project structure displaying Controllers, Model classes, Views, etc. as the Griffon application elements rather than files and directories. From the Griffon view, you can gain quick access to the application elements and their contents.

#### ItemDescription

---

 Click this button to navigate from a file in the Editor that gets the focus, to the corresponding node (file, class, field, method, etc.) in the Project tool window.

---

 Click this button to collapse all nodes (  ).

---

 Click this button to open the menu for configuring the current view and changing the tool window viewing modes.

The menu items are options that you can turn on or off. An active item contains a check mark on the left side of its name.

The available options in the menu are as follows:

- [Compact Empty Middle Packages / Hide Empty Middle Packages](#)
  - [Autoscroll to Source](#)
  - [Autoscroll from Source](#)
  - [Pinned, Docked, Floating, Windowed, Split Mode](#)
- 

 Click this button to hide the tool window (  ).

When used in combination with the Alt key, clicking this button hides all the tool windows attached to the same tool window bar.

On this page:

- [Accessing the Grunt Tool Window](#)
- [Building a Tree of Grunt Tasks](#)
- [Running Grunt Tasks and Targets](#)
- [Toolbar](#)
- [Context Menu of a Tree](#)
- [Context Menu of a Task or a Target](#)

## Accessing the Grunt Tool Window

- the tool window can be accessed this way only after you have opened it using the Show Grunt Tasks command.

The tool window is available only when:

1. The [Node.js](#) runtime environment is installed on your computer.
2. The [NodeJS](#) repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).
3. The `grunt-cli` package is installed globally and the `grunt` package is installed in the current project, see [Installing Grunt](#) for details.
4. At least one `Gruntfile.js` file is available in the current project.

The tool window opens when you invoke **Grunt** by choosing Show Grunt Tasks on the context menu of a `Gruntfile.js` in the Project tool window or of a `Gruntfile.js` opened in the editor.

As soon as you invoke **Grunt**, it starts building a tree of tasks according to the `Gruntfile.js` on which it was invoked. If a task has [targets](#), the task is displayed as a node and the targets are listed under it.

If you have several `Gruntfile.js` files in your project, you can build a separate tasks tree for each of them and run tasks without abandoning the previously built tasks trees. Each tree is shown in a separate tab.

## Building a Tree of Grunt Tasks

To build a tasks tree, do one of the following:

- Select the required `Gruntfile.js` file in the Project tool window or open it in the editor and choose Show Grunt Tasks on the context menu.
- In the Grunt tool window, click  on the toolbar and choose the required `Gruntfile.js` file from the list. IntelliJ IDEA adds a new node and builds a tasks tree under it. The title of the node shows the path to the `Gruntfile.js` file according to which the tree is built.

### To sort the tasks in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name.

By default, a tree shows the tasks in the order in which they are defined in `Gruntfile.js` (option Definition order).

## Running Grunt Tasks and Targets

### To run a task or a target

Double click the required task or target. Alternatively select it in the tree and press  or choose Run <task name> on the context menu.

### To run the default task

Select the root node in the tree, and choose Run default on the context menu of the selection.

### To run several tasks or targets

Use the multiselect mode: hold  (for adjacent items) or  (for non-adjacent items) keys and select the required tasks or targets, then choose Run on the context menu of the selection.

### To navigate to the definition of a task or a target

Select the required task or target in the tree, and choose Jump to source on the context menu of the selection.

The task or target execution output will be displayed in the [Run tool window](#). The name of the target is shown in the format `<task name>: <target name>`. The tool window shows the Grunt output, reports the errors occurred, lists the packages or

plugins that have not been found, etc. The name of the last executed task is displayed on the title bar of the tool window.

## Toolbar

### ItemTooltipDescription

	<b>Add Gruntfile</b>	Click this button to have a tasks tree for another <code>Gruntfile.js</code> file built. Choose the required <code>Gruntfile.js</code> file from the pop-up list. IntelliJ IDEA adds a new node and builds a tasks tree under it.
	<b>Remove Gruntfile</b>	Click this button to remove the tasks tree under the selected node.
	<b>Reload tasks</b>	Click this button to have the tasks tree under the selected node re-built. You may need a tree re-built after updating the corresponding <code>Gruntfile.js</code> file because Grunt does not apply changes to trees on the fly.
	<b>Collapse all</b>	Click this button to hide all the tasks trees and have only <code>Gruntfile.js</code> nodes displayed.
		Click this button to configure the current view and to change the viewing modes of the tool window, see <a href="#">Viewing Modes</a> for details. Note that most of the menu items are options that you can turn on or off. An option which is on has a check mark to the left of its name. The Grunt - specific options are: <ul style="list-style-type: none"><li>– Grunt Settings: choose this menu item to open the <a href="#">Grunt Settings dialog</a> and re-configure the current settings for Grunt and for the <a href="#">Node interpreter</a>, see <a href="#">Grunt</a>.</li><li>– Sort by: choose this menu item to configure the order in which tasks are shown in trees. Click  on the toolbar, choose Sort by on the menu, and then choose Name.</li></ul> By default, a tree shows the tasks in the order in which they are defined in <code>Gruntfile.js</code> (option Definition order).
	<b>Hide</b>	Click this button to hide the tool window. To have it displayed again, choose View   Tool Windows   Grunt on the main menu. The tool window appears again showing all the previously built trees of tasks.

## Context Menu of a Tree

### ItemDescription

Grunt Settings	Choose this menu item to open the Grunt Settings dialog box and view or edit the <code>Node.js</code> configuration
Jump to Source	Choose this menu item to open the <code>Gruntfile.js</code> file for which the current tree is built.
Reload tasks	Choose this menu item to have the tree of tasks under the selected node re-built.
Copy Path	Choose this menu item to save the path to the <code>Gruntfile.js</code> file according to which the current tree was built to the clipboard.
Remove Gruntfile.js	Choose this menu item to remove the tree of tasks under the selected node.

## Context Menu of a Task or a Target

### ItemDescription

Run <task/target name>	Choose this menu item to run the selected task or target.
Debug <task/target name>	Choose this menu item to debug the selected task or target.
Edit <task/target name> settings	Choose this menu item to open the Run/Debug Configuration dialog box and edit the predefined settings for the selected task or target.
Jump to Source	Choose this menu item to open the <code>Gruntfile.js</code> file for which the current tree is built and navigate to the definition of the selected task or target.

On this page:

- [Accessing the Gulp Tool Window](#)
- [Building a Tree of Gulp Tasks](#)
- [Running Gulp Tasks](#)
- [Toolbar](#)
- [Context Menu of a Tree](#)
- [Context Menu of a Task or a Target](#)

## Accessing the Gulp Tool Window

Context menu of a Gulpfile.js - Show Gulp Tasks

View | Tool Windows | Gulp - the tool window can be accessed this way only after you have opened it using the Show Gulp Tasks command or after you have run tasks through the **Gulp.js run configuration** .

The tool window is available only when:

1. The [Node.js](#) runtime environment is installed on your computer.
2. The **NodeJS** repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .
3. The `gulp` package is installed in the current project, see [Installing Gulp](#) for details.
4. At least one `Gulpfile.js` file is available in the current project.

The tool window opens when you invoke **Gulp.js** by choosing Show Gulp Tasks on the context menu of a `Gulpfile.js` in the Project tool window or of a `Gulpfile.js` opened in the editor. The tree is built according to the `Gulpfile.js` file on which **Gulp.js** was invoked. If you have several `Gulpfile.js` files in your project, you can build a separate tasks tree for each of them and run tasks without abandoning the previously built tasks trees. Each tree is shown under a separate node.

If you have several `Gulpfile.js` files in your project, you can build a separate tasks tree for each of them and run tasks without abandoning the previously built tasks trees. Each tree is shown under a separate node.

## Building a Tree of Gulp Tasks

To build a tree of tasks, do one of the following:

- Select the required `Gulpfile.js` file in the Project tool window or open it in the editor and choose Show Gulp tasks on the context menu.
- In the Gulp tool window, click  on the toolbar and choose the required `Gulpfile.js` file from the list. IntelliJ IDEA adds a new node and builds a tasks tree under it. The title of the node shows the path to the `Gulpfile.js` file according to which the tree is built.

### To sort the tasks in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name .

By default, a tree shows the tasks in the order in which they are defined in `Gulpfile.js` (option Definition order ) .

## Running Gulp Tasks

To run a task

Double click the required task. Alternatively select it in the tree and press  or choose Run <task name> on the context menu.

To run the default task

Select the root node in the tree, and choose Run default on the context menu of the selection.

To navigate to the definition of a task

Select the required task in the tree, and choose Jump to source on the context menu of the selection.

To run several tasks

Use the multiselect mode: hold  (for adjacent items) or  (for non-adjacent items) keys and select the required tasks, then choose Run on the context menu of the selection.

The task execution output will be displayed in the [Run tool window](#) .

## Toolbar

ItemTooltipDescription

	Add Gulpfile	Click this button to have a tasks tree for another <code>Gulpfile.js</code> file built. Choose the required <code>Gulpfile.js</code> file from the pop-up list. IntelliJ IDEA builds a tasks tree and shows it under a separate node.
---	--------------	---

	<b>Remove Gulpfile</b>	Click this button to remove the tasks tree under the selected node.
	<b>Reload tasks</b>	Click this button to have the tasks tree under the selected node re-built. You may need a tree re-built after updating the corresponding <code>Gulpfile.js</code> file because Gulp.js does not apply changes to trees on the fly.
	<b>Collapse all</b>	Click this button to hide all the tasks trees and have only <code>Gulpfile.js</code> nodes displayed.
		<p>Click this button to configure the current view and to change the viewing modes of the tool window, see <a href="#">Viewing Modes</a> for details. Note that most of the menu items are options that you can turn on or off. An option which is on has a check mark to the left of its name. The Gulp - specific options are:</p> <ul style="list-style-type: none"> <li>– Gulp Settings: choose this menu item to open the <a href="#">Gulp Settings dialog</a> and re-configure the current settings for Gulp and for the <a href="#">Node interpreter</a>, see <a href="#">Gulp</a>.</li> <li>– Sort by: choose this menu item to configure the order in which tasks are shown in trees. Click  on the toolbar, choose Sort by on the menu, and then choose Name.</li> </ul> <p>By default, a tree shows the tasks in the order in which they are defined in <code>Gulpfile.js</code> (option Definition order).</p>
	<b>Hide</b>	Click this button to hide the tool window. To have it displayed again, choose View   Tool Windows   Grunt on the main menu. The tool window appears again showing all the previously built trees of tasks.

## Context Menu of a Tree

### ItemDescription

<b>Gulp Settings</b>	Choose this menu item to open the Gulp Settings dialog box and view or edit the <code>Node.js</code> configuration
<b>Jump to Source</b>	Choose this menu item to open the <code>Gulpfile.js</code> file for which the current tree is built.
<b>Reload tasks</b>	Choose this menu item to have the tree of tasks under the selected node re-built.
<b>Copy Path</b>	Choose this menu item to save the path to the <code>Gulpfile.js</code> file according to which the current tree was built to the clipboard.
<b>Remove Gulpfile.js</b>	Choose this menu item to remove the tree of tasks under the selected node.

## Context Menu of a Task or a Target

### ItemDescription

<b>Run &lt;task name&gt;</b>	Choose this menu item to run the selected task.
<b>Debug &lt;task name&gt;</b>	Choose this menu item to debug the selected task.
<b>Edit &lt;task name&gt; settings</b>	Choose this menu item to open the Run/Debug Configuration dialog box and edit the predefined settings for the selected task.
<b>Jump to Source</b>	Choose this menu item to open the <code>Gulpfile.js</code> file for which the current tree is built and navigate to the definition of the selected task.

From the [Persistence tool window](#) (for a session factory or any node within it):

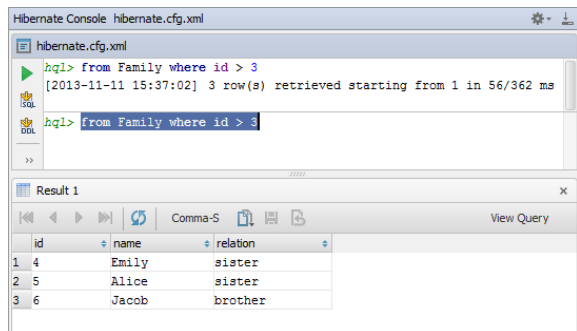

-  on the title bar
- Console from the context menu
- `Ctrl+Shift+F10`

When you open the Hibernate Console tool window, first, the input pane opens. This is where you compose your HQL queries.

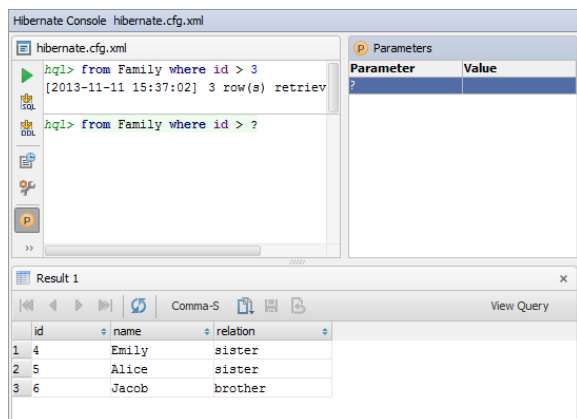

When you run your first query () , the output pane opens above the input pane. Basically, this is the log of operations performed in the console.

If your query retrieves data (e.g. `from` , `select` ), also the Result pane opens showing the retrieved data in table format.

Additionally, you can open the Parameters pane () to manage parameters in your queries.

On this page:

- [Toolbar icons and shortcuts](#)
- [Output pane](#)
- [Result pane](#)
- [Parameters pane](#)

See also, [Working with the Hibernate console](#) .

## Toolbar icons and shortcuts

Most of the functions in the Hibernate Console tool window are accessed by means of the toolbar icons and associated keyboard shortcuts.

### ItemShortcutDescription

	Execute Query	<code>Ctrl+Enter</code>	Use this icon or shortcut to run the current query.
	Generate SQL	<code>Ctrl+Shift+Enter</code>	Use this icon or shortcut to generate an SQL equivalent of the current query. The generated SQL statement will be shown in the output pane.
	Generate DDL	<code>Ctrl+Shift+Alt+Enter</code>	Use this icon or shortcut to generate DDL SQL statements ( <code>CREATE TABLE</code> , <code>ALTER TABLE</code> and <code>DROP TABLE</code> ) for all the objects (classes) associated with the corresponding session factory. The generated statements will be shown in the output pane.
		<code>Ctrl+Alt+E</code>	Use this icon or shortcut to open a dialog that shows all the queries that you have run in the console.

See also, [Running auto-memorized queries](#) .

 Settings		Use this icon to open the <a href="#">Database page</a> of the Settings dialog to view or edit the settings for the database, Hibernate and JPA consoles, data editors and the Database tool window.
 View Parameters		Use this icon to open or close the <a href="#">Parameters pane</a> .
 Restore Layout		Use this icon to restore the original tool window layout (after the rearrangements that you have made).
 Terminate Process		Use this icon or shortcut to terminate execution of the current query.
 Close		Use this icon or shortcut to close the console.

## Output pane

This pane shows the queries that you have run as well as the information about their execution. When errors occur, the corresponding information is also shown in this pane.

For most of the events the following information is provided:

- Timestamp, that is, when the event took place.
- For data manipulation operations - how many rows were affected (e.g. changed or deleted). For data retrieval operations - how many rows were retrieved.
- Duration in milliseconds.

Use the following context menu commands:

- Copy () to copy the text selected in the output pane to the clipboard.
- Compare with Clipboard to compare the text selected in the output pane with the contents of the clipboard.
- Clear All to clear all the contents of the output pane.

## Result pane

This pane shows the data retrieved from the database in table format. You can sort the data as well as perform other, associated tasks.

- [Main functions](#)
- [Using the header row](#)

Most of the functions in the Result pane are accessed by means of controls on the toolbar, context menu commands for the data cells, and associated keyboard shortcuts.

### ItemShortcutDescription

		These icons and corresponding commands are for switching between the result set pages, i.e. the pages that show the retrieved data. A fixed number of rows shown simultaneously is referred to as a <b>result set page</b> . If this number is less than the number of rows that satisfy the query, only a subset of all the rows is shown at a time.  In such cases, you can use  to switch between the subsets. (If all the rows are currently shown, these icons and the corresponding commands are inactive.)  The result set page size is set on the <a href="#">Database page</a> of the Settings dialog.
 First Page		Use this icon or command to switch to the first of the <a href="#">result set pages</a> to see the first series of rows.
 Previous Page		Use this icon, command or shortcut to switch to the previous <a href="#">result set page</a> to see the previous series of rows.
 Next Page		Use this icon, command or shortcut to switch to the next <a href="#">result set page</a> to see the next series of rows.
 Last Page		Use this icon or command to switch to the last of the <a href="#">result set pages</a> to see the last series of rows.
 Reload Page		Use this icon, command or shortcut to refresh the current table view. Use this function to: <ul style="list-style-type: none"><li>- Synchronize the data shown with the actual contents of the database.</li><li>- Apply the <a href="#">Result set page size</a> setting after its change.</li></ul>

 Tab-se...d (TSV) Data Extractor: <current_format>		Use this button or command to open a menu in which you can select an output format for your data. In addition to output formats, there are also the following options and commands: <ul style="list-style-type: none"><li>- Allow Transposition. For delimiter-separated values formats (TSV, CSV): If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. ) , the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.</li><li>- Skip Generated Columns (SQL). For SQL INSERTs and UPDATES: When copying or saving data (<a href="#">Copy</a> , <a href="#">Dump Data   To File</a> , <a href="#">Dump Data   To Clipboard</a> ), don't include auto-increment fields.</li><li>- Add Table Definition (SQL). For SQL INSERTs and UPDATES: When copying or</li></ul>
--	--	--

saving data, add the table definition (CREATE TABLE).

- Configure CSV Formats. Open the [CSV Formats dialog](#) that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).
- Go to Scripts Directory. Switch to the directory where the scripts that convert table data into various output formats are stored.

Copy All To Clipboard /  
Save All To File

- Copy All To Clipboard. Use this command to copy the table data onto the clipboard.
- Save All To File. Use this command to save the table data in a file. In the dialog that opens, specify the location and name of the file.

Note:

- The data extractor which is currently [active](#) is applied.
- If only a subset of corresponding rows is currently shown, all the appropriate rows are copied to the clipboard or saved in a file anyway. (The number of rows currently shown may be limited by the Result set page size parameter.)

Save LOB

Use this command to save the large object ([LOB](#)) currently selected in the table in a file.

Reset View

Use this command to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the corresponding query, and all the columns are shown.

View Query

Use this button to view the query which was used to generate the table. To close the pane where the query is shown, press [Escape](#).

Go To | Row

[Ctrl+G](#)

Use this command or shortcut to switch to a specified row. In the dialog that opens, specify the row number to go to.

Using the header row. In the Result pane, you can use the cells in the header row (i.e. the row where column names are shown) for:

- [Sorting data](#)
- [Reordering columns](#)
- [Hiding and showing columns](#)

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this:  name . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance:  name  1. The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order:  name  1.

Finally, when you click the cell for the third time, the initial state is resorted. That is, sorting by the corresponding column is canceled:  name .

Here is an example of a table where data are sorted by two of its columns.

	 id	 name	 relation
1	3	Dylan	brother
2	6	Jack	brother
3	1	Harry	father
4	2	Chloe	mother
5	5	Alice	sister
6	4	Emily	sister

To restore the initial "unsorted" state for the table, click  and select Reset View.

To reorder columns, use drag-and-drop for the corresponding cells in the header row. To restore the initial order of columns, click  and select Reset View.

	 member_id	 relation	 name
1	5	sister	lice
2	1	mother	hloe
3	3	brother	ylan
4	4	sister	mily
5	2	father	arry

To hide a column, right-click the corresponding header cell and select Hide column.

To show a hidden column:

1. Do one of the following:

- Right-click any of the cells in the header row and select Column List.

- Press [Ctrl+F12](#).

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

2. Select (highlight) the column name of interest and press `Space` .

3. Press `Enter` or `Escape` to close the list.

To show all the columns, click  and select Reset View .

See also, [Using the Structure view to sort data, and hide and show columns](#) .

## Parameters pane

The Parameters pane shows the parameters detected in the input pane and lets you edit their values. To open or close this pane, use  on the toolbar.

Parameter values can be specified just as text or numbers, or as [Groovy](#) expressions that contain object references and method calls. For example, the value for the `date` parameter in the query

```
SELECT o
FROM Order o
WHERE o.date > :date
```

could be specified as

```
new java.sql.Date(System.currentTimeMillis() - 24*3600*1000)
```

To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press `Enter` or switch to a different cell. To quit the editing mode and restore an initial value, press `Escape` .

When you select a row in the table, the corresponding parameter is highlighted in the input pane.

Alt+8

Use this tool window to analyze and navigate through hierarchies of classes, calls, methods.

**Warning!** The tool window is available only after you have [built a hierarchy](#) for the first time.

The contents of the tool window are not automatically updated as you navigate through the source code or switch between the editor tabs.

The tool window shows the results of the latest hierarchy command and is updated when you run the next hierarchy command, unless the tab with one of the previously built hierarchies is [pinned](#).

## Toolbar buttons

Item	Description	Available In
	When this button is pressed, the hierarchical tree shows both the parent and child classes of the selected class, which is marked with an arrow  in the tree of results.	Class hierarchies
<b>Tip</b> For the interfaces this button is disabled.		
	Depending on the hierarchy type: <ul style="list-style-type: none"> <li>For class hierarchies - when this button is pressed, the tool window shows all classes that extend the selected class.</li> <li>For call hierarchies - when this button is pressed, the tool window shows the callees of the selected method.</li> </ul>	Class hierarchies Call hierarchies
	Depending on the hierarchy type: <ul style="list-style-type: none"> <li>For class hierarchies - when this button is pressed, the tool window shows the hierarchy of each supertype of the current class.</li> <li>For call hierarchies - when this button is pressed, the tool window shows the callers of the selected method.</li> </ul>	Class hierarchies Call hierarchies
	When this button is pressed, the elements within a tree are sorted alphabetically.	All hierarchies
Scope	Use this drop-down list to limit the scope of the current hierarchy: <ul style="list-style-type: none"> <li>Project - IntelliJ IDEA traces usages of the method across the project.</li> <li>Test - IntelliJ IDEA traces usages of the method across the test classes.</li> <li>All - IntelliJ IDEA traces usages of the method across the project and the libraries.</li> <li>This class - the scope is limited to the current class.</li> </ul> <p>In addition to the pre-configured scopes, you can define your own one: select <a href="#">Configure</a> from the drop-down list, and define the required scope in the <a href="#">Scopes</a> dialog box that opens.</p>	Call hierarchies
In a method hierarchy, the tree-views of the following classes are available: <ul style="list-style-type: none"> <li> - where this method is defined.</li> <li> - where this method is not defined, but defined in the superclass.</li> <li> - where this method should be defined, because the class is not abstract.</li> </ul>		
	If you made any changes of the classes or the class structure, they become visible in the Hierarchy tool window only after you press this button.	All hierarchies
	Toggle the Autoscroll to source mode. When the button is pressed, every time the node is focused, the corresponding line of source code is highlighted in the editor.	All hierarchies
	When this button is pressed, the current tab will not be overwritten; instead, the results of the next command will be displayed in a new tab.	All hierarchies
	Click this button to export a hierarchy into a text file in the specified location.	All hierarchies
	Click this button to close the selected tab of results.	All hierarchies
	Click this button to show reference page.	All hierarchies

- You can access the tool window this way only when it is already opened through Analyse | Inspect Code .
- After you deactivate the tool window manually by clicking the Close button , the tool window is available again only through Analyse | Inspect Code .

The Inspection Results tool window displays inspection results on separate tabs.

The left-hand pane of each tab shows a tree view of the inspections for which problems are found. The right-hand pane shows summary information for an item selected in the left-hand pane.

On this page:

- [Toolbar buttons](#)
- [Context menu commands](#)
- [Inspection report](#)

## Toolbar buttons

### ItemShortcutDescription

		Click this button to run the inspection and show the results on the same tab.
		Click this button to close the current tab or the tool window.
		Expand all nodes
		Collapse all nodes
		Navigate to the next item.
		Navigate to the previous item.
		Use this icon or shortcut to open the corresponding help page.
		If this toggle is on, the problems are grouped into Errors and Warnings. Otherwise, the problems are grouped by inspections.
		Turns grouping by directories on or off.
		When this toggle is on, the resolved and excluded items are not shown.
		Turns the Autoscroll to source option on or off. When the option is on and you select an item, the corresponding source file opens in the editor and the appropriate fragment is highlighted.
		Click this button to <a href="#">export the inspection results into XML or HTML format</a> .
		Click this button to <a href="#">edit the current inspection settings</a> .
		Click this button to <a href="#">resolve the problem</a> for the selected inspection item by choosing one of the available quick fixes from the list.

## Context menu commands

### Item ShortcutDescription

Jump to Source		Open the file that contains the selected problem in the editor and place the cursor at the beginning of the corresponding code fragment.
Exclude		Exclude the selected items from further examination. Excluded nodes are shown strikethrough. If the filter toggle  is on, the excluded nodes are hidden.
Include		Include previously excluded items in the list of results. All nested subelements are included too.
		Select one of the suggested solutions.
Suppress problem / Suppress problem for class		Suppress the inspection for the selected problem or the selected class.
Edit Settings		Change the settings for the selected inspection or group of inspections in the <a href="#">Errors</a> dialog.
Disable inspection		Disable alerts for the selected inspection in the active tab of results. If the filter toggle  is on, the nodes for disabled inspections are hidden. See also, <a href="#">Disabling and Enabling Inspections</a> .
Run inspection on		Rerun the selected inspection and display the results on a new tab.

## Inspection report

The inspection report is shown in the right-hand pane of the results tab when an inspection node is selected in the left-hand

pane. The report may include the following:

- Problem resolution: A button for each of the available solutions. Clicking a button invokes the corresponding fix. If no buttons are present, you have to fix the problem yourself.
- Suppress: Click this button to reveal the list of inspection suppress options.
- Problem synopsis: A brief description of the problem.
- Disable inspection: Disable alerts for the selected inspection in the active tab of results. If the filter toggle  is on, the nodes for disabled inspections are hidden.  
See also, [Disabling and Enabling Inspections](#) .
- Run inspection on...: Rerun the selected inspection and display the results on a new tab.

This tool window shows deployment descriptors associated with JavaEE Application facets . (The tool window is not available if there are no such facets in your project.)

## Context menu

### CommandDescription

---

Jump to Source (  ) Open the selected descriptor file in the editor. (Alternatively, you can double-click the file.)

To open this tool window:

View | Tool Windows | Java Enterprise

See also, [Showing a tool window](#).

---

The Java Enterprise tool window lets you look at your project from the Java EE perspective.

The tool window includes a set of panes where the "Java EE contents" of a selected item are shown in a pane to the right. If appropriate, the Javadoc HTML documentation (or, sometimes, a diagram) is shown for an item in the rightmost pane.

The toolbar buttons are used to show or hide categories of items (e.g. the modules or CDI beans), or to change the way the items are shown.

The context menus include commands for switching between the panes ([Previous](#) or [Next](#)) and opening items in the editor ([Edit](#)).

You can filter the information in most of the panes by specifying the corresponding search string.

- [Toolbar icons](#)
- [Context menu commands](#)
- [Filtering information](#)

## Toolbar icons

With very few exceptions, the toolbar icons are toggles that can be on or off.

The first two icons ( and ) are available always. The rest of the icons appear only for certain Java EE technologies and frameworks (e.g. CDI, WebSocket).

### IconDescription

	<p>The state of the icon defines the level on which the Java EE technologies and frameworks are shown. When on, the technologies are shown on the first level (i.e. in the leftmost pane). In this case, if  is on, and the modules are shown in the pane to the right, you can select a technology and see, for example, in which modules the selected technology is used.</p> <p>When off, the technologies are shown on the second level. That is, your modules appear in the leftmost pane, and the technologies in the pane to the right. In this case, you can select a module and see which of the technologies are used in the selected module.</p>
	<p>If  is on, this icon is used to show or hide the modules. In this case, the modules, if shown, appear in the second pane from the left.</p>
	<p>For CDI: Use this icon to show or hide CDI beans.</p>
	<p>For CDI: Use this icon to show or hide producer methods and fields.</p>
	<p>Depending on the technology:</p> <ul style="list-style-type: none"><li>- For CDI: Use this icon to switch between showing a diagram or documentation in the rightmost pane. If on, the dependency injection diagrams are shown for selected items. Otherwise, the Javadoc HTML documentation is shown.</li><li>- For WebSocket: Use this icon to change the way the endpoint classes are shown and ordered. If off, the information for the classes is shown in the following order: the class name first and then the endpoint URL (if available). The classes in this case are ordered by their names.  If on, the endpoint URLs are shown first and are followed by the class names. The classes in this case are ordered by the endpoint URLs.</li><li>- For RESTful Web Services: use this icon to change the way resource classes and their methods are shown and ordered. If off, the information for the classes and methods is shown in the following order: the names first and then the resource URLs. The classes and methods in this case are ordered by their names.  If on, the resource URLs are shown first and the information is ordered by the URLs.</li></ul> <p>Note that the resource classes may be shown or hidden by means of . To show or hide the methods, use .</p>
	<p>For CDI: Use this icon to show or hide the <code>InjectionPoint</code> types. Note that if  is on, the injection points are shown on the diagrams in the rightmost pane, and this icon becomes inactive.</p>
	<p>For WebSocket: Use this icon to show or hide the classes annotated with <code>@ServerEndpoint</code>.</p>
	<p>For WebSocket: Use this icon to show or hide the classes annotated with <code>@ClientEndpoint</code>.</p>
	<p>For RESTful Web Services: Use this icon to show or hide the resource classes. If off, there is a pane showing the classes. When you select a class, its methods are shown in the pane to the right. So, in this case, the methods are grouped by the classes in which they are defined.  If on, the classes are not shown. The methods belonging to different classes are all shown in the same pane and at the same time.</p>
	<p>For RESTful Web Services: Click this icon and then the necessary option to show or hide the methods annotated with</p>

## Context menu commands

### CommandShortcutDescription

Previous	Left	Use this command or shortcut to switch to the pane to the left.
Next	Right	Use this command or shortcut to switch to the pane to the right.
Edit	Enter	Use this command or shortcut to switch to the editor to view or edit the source code for the selected item. For a module, this command results in showing the module settings in the <a href="#">Project Structure dialog</a> .

## Filtering information

When in the pane of interest, just start typing. As a result, only the items whose names contain the specified string will be shown.

From the [Persistence tool window](#) (for a persistence unit or any node within it):

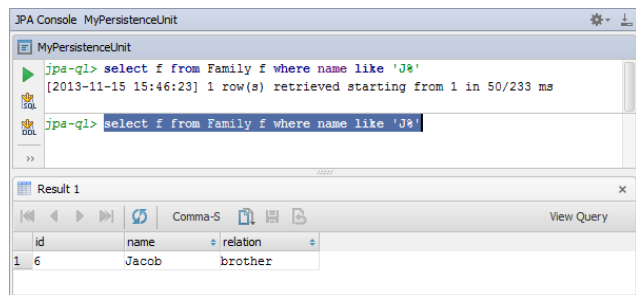

-  on the title bar
- Console from the context menu
- `Ctrl+Shift+F10`

When you open the JPA Console tool window, first, the input pane opens. This is where you compose your JPQL queries.

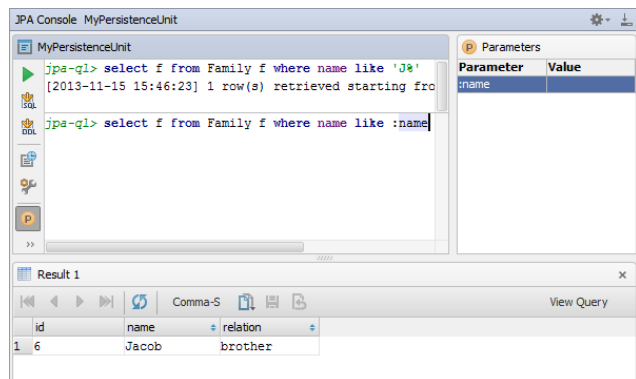

When you run your first query () , the output pane opens above the input pane. Basically, this is the log of operations performed in the console.

If your query retrieves data (e.g. `select` ), also the Result pane opens showing the retrieved data in table format.

Additionally, you can open the Parameters pane () to manage parameters in your queries.

On this page:

- [Toolbar icons and shortcuts](#)
- [Output pane](#)
- [Result pane](#)
- [Parameters pane](#)

See also, [Working with the JPA console](#) .

## Toolbar icons and shortcuts

Most of the functions in the Hibernate Console tool window are accessed by means of the toolbar icons and associated keyboard shortcuts.

### ItemShortcutDescription

	Execute Query	<code>Ctrl+Enter</code>	Use this icon or shortcut to run the current query.
	Generate SQL	<code>Ctrl+Shift+Enter</code>	Use this icon or shortcut to generate an SQL equivalent of the current query. The generated SQL statement will be shown in the output pane.
	Generate DDL	<code>Ctrl+Shift+Alt+Enter</code>	Use this icon or shortcut to generate DDL SQL statements ( <code>CREATE TABLE</code> , <code>ALTER TABLE</code> and <code>DROP TABLE</code> ) for all the objects (classes) associated with the corresponding persistence unit. The generated statements will be shown in the output pane.
		<code>Ctrl+Alt+E</code>	Use this icon or shortcut to open a dialog that shows all the queries that you have run in the console. See also, <a href="#">Running auto-memorized queries</a> .
	Settings		Use this icon to open the <a href="#">Database page</a> of the Settings dialog to view or edit the settings for the database, Hibernate and JPA consoles, data editors and

		the Database tool window.
 View Parameters		Use this icon to open or close the <a href="#">Parameters pane</a> .
 Restore Layout		Use this icon to restore the original tool window layout (after the rearrangements that you have made).
 Terminate Process		Use this icon or shortcut to terminate execution of the current query.
 Close		Use this icon or shortcut to close the console.

## Output pane

This pane shows the queries that you have run as well as the information about their execution. When errors occur, the corresponding information is also shown in this pane.

For most of the events the following information is provided:

- Timestamp, that is, when the event took place.
- For data manipulation operations - how many rows were affected (e.g. changed or deleted). For data retrieval operations - how many rows were retrieved.
- Duration in milliseconds.

Use the following context menu commands:

- Copy () to copy the text selected in the output pane to the clipboard.
- Compare with Clipboard to compare the text selected in the output pane with the contents of the clipboard.
- Clear All to clear all the contents of the output pane.

## Result pane

This pane shows the data retrieved from the database in table format. You can sort the data as well as perform other, associated tasks.

- [Main functions](#)
- [Using the header row](#)

Most of the functions in the Result pane are accessed by means of controls on the toolbar, context menu commands for the data cells, and associated keyboard shortcuts.

### ItemShortcutDescription

		<p>These icons and corresponding commands are for switching between the result set pages, i.e. the pages that show the retrieved data.</p> <p>A fixed number of rows shown simultaneously is referred to as a <b>result set page</b> . If this number is less than the number of rows that satisfy the query, only a subset of all the rows is shown at a time.</p> <p>In such cases, you can use  to switch between the subsets. (If all the rows are currently shown, these icons and the corresponding commands are inactive.)</p> <p>The result set page size is set on the <a href="#">Database page</a> of the Settings dialog.</p>
 First Page		Use this icon or command to switch to the first of the <a href="#">result set pages</a> to see the first series of rows.
 Previous Page		Use this icon, command or shortcut to switch to the previous <a href="#">result set page</a> to see the previous series of rows.
 Next Page		Use this icon, command or shortcut to switch to the next <a href="#">result set page</a> to see the next series of rows.
 Last Page		Use this icon or command to switch to the last of the <a href="#">result set pages</a> to see the last series of rows.
 Reload Page		Use this icon, command or shortcut to refresh the current table view. Use this function to: <ul style="list-style-type: none"> <li>- Synchronize the data shown with the actual contents of the database.</li> <li>- Apply the <a href="#">Result set page size</a> setting after its change.</li> </ul>
 <code>Tab-se...d (TSV)</code> Data Extractor: <current_format>		<p>Use this button or command to open a menu in which you can select an output format for your data.</p> <p>In addition to output formats, there are also the following options and commands:</p> <ul style="list-style-type: none"> <li>- Allow Transposition. For delimiter-separated values formats (TSV, CSV): If the table is shown transposed and you are copying selected cells or rows to the clipboard (e.g. ) , the selection is copied transposed (as shown) if the option is on and non-transposed (as in the original table) otherwise.</li> <li>- Skip Generated Columns (SQL). For SQL INSERTs and UPDATES: When copying or saving data (<a href="#">Copy</a> , <a href="#">Dump Data   To File</a> , <a href="#">Dump Data   To Clipboard</a> ) , don't include auto-increment fields.</li> <li>- Add Table Definition (SQL). For SQL INSERTs and UPDATES: When copying or saving data, add the table definition (CREATE TABLE).</li> <li>- Configure CSV Formats. Open the <a href="#">CSV Formats dialog</a> that lets you manage your delimiter-separated values formats (e.g. CSV, TSV).</li> <li>- Go to Scripts Directory. Switch to the directory where the scripts that convert table</li> </ul>

data into various output formats are stored.

Copy All To Clipboard /  
Save All To File

- Copy All To Clipboard. Use this command to copy the table data onto the clipboard.
- Save All To File. Use this command to save the table data in a file. In the dialog that opens, specify the location and name of the file.

Note:

- The data extractor which is currently **active** is applied.
- If only a subset of corresponding rows is currently shown, all the appropriate rows are copied to the clipboard or saved in a file anyway. (The number of rows currently shown may be limited by the Result set page size parameter.)

Save LOB

Use this command to save the large object (**LOB**) currently selected in the table in a file.

Reset View

Use this command to restore the initial table view after reordering or hiding the columns, or sorting the data. As a result, the data, generally, becomes unsorted, the columns appear in the order they are defined in the corresponding query, and all the columns are shown.

View Query

Use this button to view the query which was used to generate the table. To close the pane where the query is shown, press **Escape**.

Go To | Row

**Ctrl+G**

Use this command or shortcut to switch to a specified row. In the dialog that opens, specify the row number to go to.

Using the header row. In the Result pane, you can use the cells in the header row (i.e. the row where column names are shown) for:

- [Sorting data](#)
- [Reordering columns](#)
- [Hiding and showing columns](#)

You can sort table data by any of the columns by clicking the cells in the header row.

Each cell in this row has a sorting marker in the right-hand part and, initially, a cell may look something like this: . The sorting marker in this case indicates that the data is not sorted by this column.

If you click the cell once, the data is sorted by the corresponding column in the ascending order. This is indicated by the sorting marker appearance: . The number to the right of the marker (1 on the picture) is the sorting level. (You can sort by more than one column. In such cases, different columns will have different sorting levels.)

When you click the cell for the second time, the data is sorted in the descending order. Here is how the sorting marker indicates this order: .

Finally, when you click the cell for the third time, the initial state is restored. That is, sorting by the corresponding column is canceled: .

Here is an example of a table where data are sorted by two of its columns.

	id	name	relation
1	3	Dylan	brother
2	6	Jack	brother
3	1	Harry	father
4	2	Chloe	mother
5	5	Alice	sister
6	4	Emily	sister

To restore the initial "unsorted" state for the table, click  and select Reset View.

To reorder columns, use drag-and-drop for the corresponding cells in the header row. To restore the initial order of columns, click  and select Reset View.

	member_id	relation	name
1	5	sister	Alice
2	1	mother	Chloe
3	3	brother	Dylan
4	4	sister	Emily
5	2	father	Harry

To hide a column, right-click the corresponding header cell and select Hide column.

To show a hidden column:

1. Do one of the following:
  - Right-click any of the cells in the header row and select Column List.
  - Press **Ctrl+F12**.

In the list that appears, the names of hidden columns are shown struck through.

	member_id	name
1	5	Alice
2	1	Chloe
3	3	Dylan
4	4	Emily
5	2	Harry
6	6	Jack

2. Select (highlight) the column name of interest and press **Space**.

3. Press `Enter` or `Escape` to close the list.

To show all the columns, click  and select Reset View .

See also, [Using the Structure view to sort data, and hide and show columns](#) .

## Parameters pane

The Parameters pane shows the parameters detected in the input pane and lets you edit their values. To open or close this pane, use  on the toolbar.

Parameter values can be specified just as text or numbers, or as [Groovy](#) expressions that contain object references and method calls. For example, the value for the `date` parameter in the query

```
SELECT o
FROM Order o
WHERE o.date > :date
```

could be specified as

```
new java.sql.Date(System.currentTimeMillis() - 24*3600*1000)
```

To start editing a value, switch to the corresponding table cell and start typing. To indicate that you have finished editing a value, press `Enter` or switch to a different cell. To quit the editing mode and restore an initial value, press `Escape` .

When you select a row in the table, the corresponding parameter is highlighted in the input pane.

To open this tool window:

View | Tool Windows | JSF

See also, [Showing a tool window](#).

Note that this tool window is available only if there is a [library](#) that implements JSF in the [dependencies](#) of one or more of your [modules](#).

The JSF tool window provides a categorized hierarchical view of your JSF resources.

At the top of the hierarchy are your modules. One level below are categories.

The categories correspond to JSF element types (managed beans, converters, components, etc.).

You can show or hide the categories. You can also open the elements shown in the tool window in the editor.

– [Showing and hiding categories](#)

– [Opening elements in the editor](#)

## Showing and hiding categories

To show or hide a category, click on the title bar, and then click the necessary Show option.

The Show from libraries option is for showing the library elements referenced in your code.

## Opening elements in the editor

You can open the elements shown in the JSF tool window in the editor. To do that, select the element of interest and press

.

To open the elements which are the "leaves" of the tree (i. e. the ones at the bottom of the hierarchy), you can also use a double click.

 - Start a local server link.

In this tool window, start and stop the JSTestDriver Server to run unit tests against and capture the browser to execute unit tests in.

## Prerequisites

The tool window becomes available when the following prerequisites are met:

1. The **JSTestDriver** plugin is downloaded, installed, and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).
2. The current project contains at least one [test runner configuration files](#).

## Options

Item	Tooltip and shortcut	Description
	Run a local server	Click this button to have IntelliJ IDEA launch the default JSTestDriver server.
	Stop the local server	Click this button to have IntelliJ IDEA stop the currently running JSTestDriver server.
Capture a browser using the URL		This read-only field shows the URL address to access the Remote Console of the JSTestDriver. Copy the URL address and open it in the browser of your choice.
		The icons indicate available browsers. The icon that corresponds to the browser you just opened, is active. Click the icon to get ready for executing tests.

This tool window is marked with the icon .

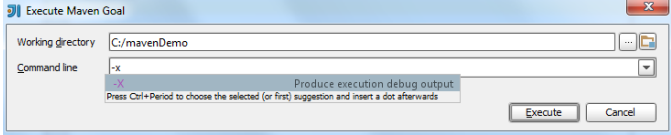

Use the Maven Projects tool window to view the available Maven projects, download sources and Javadocs, and execute phases of the build lifecycle. The tool window displays nodes for each Maven project, with the Lifecycle and Plugins subnodes. If at least one of the `pom.xml` files contains profile definition, the Profiles node is added to the tool window. This node contains all profiles defined in the Maven projects. The Maven Projects tool window also displays the Dependencies node if dependencies are added to your project.

–

## Toolbar Buttons

### ItemDescription

	Click this button to synchronize all Maven projects with the IntelliJ IDEA project. See <a href="#">Importing tab</a> of the Maven Integration dialog box.
	Click this button to launch Maven goals for generating sources and resources for the source and test directories, and read the resulting directory structure. According to the results of such generation, the IntelliJ IDEA folders are properly marked as the <a href="#">source or test roots</a> . See <a href="#">import settings</a> .
	Click this button to download missing sources and documentation. Select the desired download option from the submenu.  You can set up automatic downloading of sources and documentation at the <a href="#">Importing</a> page of the Maven Integration dialog.
	Click this button to add a Maven project. Select the desired <code>pom.xml</code> file in the <a href="#">dialog that opens</a> .
	Click this button to execute the selected phase of the build lifecycle or a plugin goal. If several goals are selected, they will be executed in the same order as in the tree. Note that by default this button is disabled, to activate it you need to select a build phase or a plugin goal to run.
	Click this button to execute a maven goal using a command line. 
	Click this button to toggle the offline mode.
	Click this button to turn on the Maven option <i>Skip test mode</i> , and omit running unit tests.
	Click this button to show the dependencies of the current Maven project in a <a href="#">UML pop-up frame</a> .
	Click this button to collapse all nodes under the selected Maven project.
	Click this button to configure the settings of the current Maven project in the <a href="#">Maven Integration</a> dialog box.
	Click this button to show reference page.
	Click this button to show the menu of the show options: <ul style="list-style-type: none"> <li>– Group Modules : select this option to group the nodes by directories.</li> <li>– Show Ignored Projects :when this option is selected, the ignored nodes are shown in the tool window with a strikethrough. Otherwise, the ignored nodes are hidden.</li> <li>– Show Basic Phases Only : when this option is selected, IntelliJ IDEA shows only the basic build phases; otherwise, the complete list of phases is shown.</li> <li>– Always Show ArtifactId : select this option to display the artifactId that is specified in the pom.xml of your Maven project.</li> <li>– Show version : when this option is selected, IntelliJ IDEA displays the version of your Maven project that is specified in the pom.xml.</li> <li>– Show Toolbar - select this option to show the toolbar for your Maven projects.</li> <li>– <a href="#">Pinned, Docked, Floating, Windowed, Split Mode</a></li> <li>– Group Tabs - deselect this option to see the views on separate tabs if more than one view is available in a tool window.</li> <li>– Move to - select this option to move the Maven Projects tool window to either top, left or right.</li> <li>– Resize - select this option to resize the Maven Projects tool window.</li> </ul>

## Context Menu Commands of a Lifecycle Phase

### CommandDescription

Create <project>[phase]	Choose this command to <a href="#">create run/debug configuration</a> for the selected phase of a lifecycle.
Run <project>[phase]	Choose this command to run the selected phase of a lifecycle with the phase-specific run/debug configuration.
Debug <project>[phase]	Choose this command to debug the selected phase of a lifecycle with the phase-specific run/debug configuration.
Execute before Make, Execute after Make	Choose these commands to set the respective flags for the selected phase of a lifecycle. So doing, <i>Before Make</i> and <i>After Make</i> comments appear next to the name of the node.

Execute before Rebuild, Execute after Rebuild	Choose these commands to set the respective flags for the selected phase of a lifecycle. In this case <i>Before Rebuild</i> and <i>After Rebuild</i> comments appear next to the name of the node.
Execute before Run/Debug	Choose this command to specify a run/debug configuration, prior to which the selected phase of a lifecycle should be executed. So doing, <i>Before Run</i> comment appears next to the name of the node.
Assign Shortcut	Choose this command to associate the selected phase with a keyboard shortcut. So doing, the comment with the shortcut appears next to the name of the node.

## Context Menu Commands of a Maven Project

This section describes only those context menu commands that are not available from the toolbar.

### CommandDescription

Ignore Project / Unignore Project	Choose the Ignore Projects command to ignore project in build, or, on the contrary, include in build the previously ignored project.  Ignored projects are not imported into IntelliJ IDEA.
Remove Project	Choose this command to delete the selected Maven modules from the Maven structure. So doing you can opt to delete the corresponding Maven module from the IntelliJ IDEA project as well.
Create / Open 'settings.xml'	Choose this command to create 'settings.xml' or 'profile.xml', or open such file if it has already been created.
Create / Open 'profiles.xml'	
Show Effective POM	Choose this command to generate the effective POM as an XML for this build, with the active profiles and super POM factored in. The effective POM displays the following information: <ul style="list-style-type: none"> <li>- the default project source folders structure</li> <li>- the output directory</li> <li>- plug-ins required</li> <li>- repositories</li> <li>- a reporting directory which Maven will be using while executing the desired goals</li> </ul>
Jump to source	Open in the editor the <code>pom.xml</code> file for the selected Maven project.

Alt+0

IntelliJ IDEA parses the output and displays it in a convenient format in the Messages window, letting you navigate to the source of the problem whenever possible.

**Note** The [Messages](#) tool window is only available if there are actually some messages to show.

On this page:

- [Results Context Menu](#)

## Toolbar Buttons

ItemTooltip Description and shortcut

	Rerun <a href="#">Ctrl+F5</a>	Click this button to rerun compilation. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Rerun Pub Command	Click this button to run the last executed pub command. The button is available only in Dart projects, see <a href="#">Using Pub</a> for details.
	Pause output	Click this button to pause the compilation process. This button is enabled when compilation is in progress. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Stop/Stop Pub Process	Click this button to terminate compilation or pub process. This button is enabled when compilation or a process is in progress.
	Close <a href="#">Ctrl+Shift+F4</a>	Click this button to terminate the process and close the console.
	Previous/Next Message <a href="#">Ctrl+Alt+Up</a> <a href="#">Ctrl+Alt+Down</a>	Navigate to the previous/next message. The buttons are not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Export to Text File <a href="#">Alt+O</a>	Save the current console contents. In the Export dialog, specify the target file or copy information to the Clipboard. Before saving, you can also edit the information to be saved. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Toggle tree/text mode	If this button is pressed, the output is displayed as plain text.  If this button is released, the output is displayed as a tree view. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Show all messages	When this button is pressed, the only error messages are displayed. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.
 	Expand all <a href="#">Ctrl+NumPad Plus</a>  Collapse all <a href="#">Ctrl+NumPad -</a>	Use these buttons to have all nodes expanded or collapsed. The buttons are not available in Dart projects, see <a href="#">Using Pub</a> for details.
	Hide warnings	When this button is pressed, the tree of messages shows error messages only. The button is not available in Dart projects, see <a href="#">Using Pub</a> for details.

	Autoscroll to source	If this button is pressed, the file that contains the selected error automatically opens in the editor, with the caret at the appropriate line. The button is not available in <b>Dart</b> projects , see <a href="#">Using Pub</a> for details .
	Compiler properties	Configure the <a href="#">compiler settings</a> . The button is not available in <b>Dart</b> projects , see <a href="#">Using Pub</a> for details .
	Help	Use this button to navigate to the help topic for the tool window. The button is not available in <b>Dart</b> projects , see <a href="#">Using Pub</a> for details .

## Results Context Menu

The menu items are not available in **Dart** projects , see [Using Pub](#) for details .

Item	Shortcut	Description
Jump to source	F4	Navigate to the selected item in the editor.
Copy	Ctrl+C	Take the line at caret to the clipboard.
Exclude from Compile		Skip the erroneous line in the next compilation.
Exclude from Validation		Choose this command to omit this warning in the next compilation.

|

This tool window is available every time you perform the Analyze Module Dependencies command and displays module dependencies as they are defined in the module settings. If any cyclic dependencies are encountered in the selected module, they are specially marked in the tool window. In this tool window, you can change direction of the dependencies, and perform more detailed analysis of the source code.

In this section:

- [Toolbar Buttons](#)
- [Context menu commands](#)

## Toolbar Buttons

### ItemDescription

	Click this button to close the current tab.
	Click this button to open the <a href="#">Specify Dependency Analysis Scope</a> dialog box and <a href="#">analyze dependencies</a> .
	Click this button to change direction of the dependencies.
	Click this button to open the reference.

## Context menu commands

Item	Shortcut	Description
Expand All		Fold or unfold all nodes.
Collapse All		
Open Module Settings		Open settings of the selected module in the <a href="#">Modules page</a> of the <a href="#">Project Structure</a> dialog.
		
Analyzè Dependencies		Choose one of these commands to perform analysis of dependencies. In the <a href="#">Specify Dependency Analysis Scope</a> dialog box, specify scope of analysis.
Analyzè Backward Dependencies		
Analyzè Cyclic Dependencies		

- the tool window can be accessed this way only after you have opened it using the Show npm Scripts command.

On this page:

- [Accessing the npm Tool Window](#)
- [Building a Tree of npm Scripts](#)
- [Running npm Scripts](#)
- [Toolbar](#)
- [Context Menu of a Tree](#)
- [Context Menu of a Script](#)

## Accessing the npm Tool Window

The tool window is available only when:

1. The [Node.js](#) runtime environment is installed on your computer.
2. The [NodeJS](#) repository plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).
3. At least one `package.json` file is available in the current project.

The tool window opens when you invoke `npm` by choosing Show npm Scripts on the context menu of a `package.json` in the Project tool window or of a `package.json` opened in the editor. Use the tool window to run `npm scripts`.

As soon as you invoke `npm`, it starts building a tree of scripts defined within the `scripts` property of the `package.json` file on which it was invoked. If you have several `package.json` files in your project, you can build a separate script tree for each of them and run scripts without abandoning the previously built trees. Each tree is shown under a separate node.

## Building a Tree of npm Scripts

To build a tree of scripts, do one of the following:

- Select the required `package.json` file in the Project tool window or open it in the editor and choose Show npm Scripts on the context menu.
- In the npm tool window, click  on the toolbar and choose the required `package.json` file from the list. IntelliJ IDEA adds a new node and builds a scripts tree under it. The title of the node shows the path to the `package.json` file according to which the tree is built.
- To re-build a tree, switch to the required node and click  on the toolbar.

### To sort the scripts in a tree by their names

Click  on the toolbar, choose Sort by on the menu, and then choose Name.

By default, a tree shows the scripts in the order in which they are defined in `package.json` (option Definition order).

## Running npm Scripts

### To run a script

Double click the required script. Alternatively select it in the tree and press  or choose Run <script name> on the context menu.

### To run several scripts

Use the multiselect mode: hold  (for adjacent items) or  (for non-adjacent items) keys and select the required scripts, then choose Run on the context menu of the selection.

The tool window shows the npm script output, reports the errors occurred, lists the packages or plugins that have not been found, etc. The name of the last executed script is displayed on the title bar of the tool window.

## Toolbar

### ItemTooltipDescription

	Add	Click this button to have a tree of scripts for another <code>package.json</code> file built. Choose the required <code>package.json</code> file from the pop-up list. IntelliJ IDEA adds a new node and builds a tree of scripts under it.
	Remove	Click this button to remove the tree of scripts under the selected node.
	Reload scripts	Click this button to have the tree of scripts under the selected node re-built. You may need a tree re-built after updating the corresponding <code>package.json</code> file because <code>npm</code> does not apply changes to trees on the fly.
	Collapse all	Click this button to hide all the scripts trees and have only <code>package.json</code> nodes

displayed.

 Click this button to configure the current view and to change the viewing modes of the tool window, see [Viewing Modes](#) for details. Note that most of the menu items are options that you can turn on or off. An option which is on has a check mark to the left of its name. The `npm`-specific options are:

- `npm Settings`: choose this menu item to open the [npm Settings dialog](#) and re-configure the current settings for `npm` and for the `Node interpreter`, see [NPM](#).
- `Sort by`: choose this menu item to configure the order in which scripts are shown in trees. Click  on the toolbar, choose `Sort by` on the menu, and then choose `Name`.

By default, a tree shows the scripts in the order in which they are defined in `package.json` (option `Definition order`).

 **Hide** Click this button to hide the tool window. To have it displayed again, choose `View | Tool Windows | Grunt` on the main menu. The tool window appears again showing all the previously built trees of tasks.

## Context Menu of a Tree

### ItemDescription

<code>npm Settings</code>	Choose this menu item to open the <code>npm Settings</code> dialog box and view or edit the <code>Node.js</code> configuration
<code>Jump to Source</code>	Choose this menu item to open the <code>package.json</code> file for which the current tree is built.
<code>Reload scripts</code>	Choose this menu item to have the tree of scripts under the selected node re-built.
<code>Copy Path</code>	Choose this menu item to save the path to the <code>package.json</code> file according to which the current tree was built to the clipboard.
<code>Remove package.json</code>	Choose this menu item to remove the tree of scripts under the selected node.

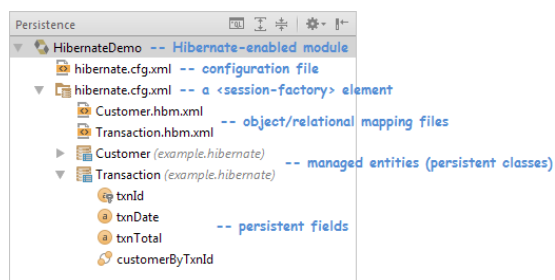

## Context Menu of a Script

### ItemDescription

<code>Run &lt;script name&gt;</code>	Choose this menu item to run the selected script.
<code>Edit &lt;script name&gt; settings</code>	Choose this menu item to open the <code>Run/Debug Configuration</code> dialog box and edit the predefined settings for the selected script.
<code>Jump to Source</code>	Choose this menu item to open the <code>package.json</code> file for which the current tree is built and navigate to the definition of the selected script.

The Persistence tool window shows your JPA and Hibernate project items.

At the top hierarchical level are JPA- and Hibernate-enabled modules. One level below are configuration files, and <persistence-unit> and <session-factory> elements. Further down in the hierarchy are mapping files, persistent classes, etc.

The tool window lets you create new items such as configuration files, <persistence-unit> and <session-factory> elements, persistent classes and fields, navigate to related source code in the editor, open consoles and entity-relationship diagrams, and more.

## Title bar icons

### ItemDescription

	Select a persistence unit or session factory (or any of the subordinate elements) and click this icon to open the <a href="#">JPA</a> or <a href="#">Hibernate console</a> . See also, <a href="#">Working with the JPA console</a> and <a href="#">Working with the Hibernate console</a> .
	Expand all the nodes.
	Collapse all the nodes.

## Context menu commands

### ItemDescription

ER Diagram	For a persistence unit or session factory: open an entity-relationship diagram for the selected persistence unit or session factory.
Console (  )	For a persistence unit or session factory: open the <a href="#">JPA</a> or <a href="#">Hibernate console</a> for the selected persistence unit or session factory. See also, <a href="#">Working with the JPA console</a> and <a href="#">Working with the Hibernate console</a> .
Assign Data Sources	For a persistence unit or session factory: associate the selected persistence unit or session factory with a database or DDL <a href="#">data source</a> . See <a href="#">Associating persistence units and session factories with data sources</a> .
Assign Naming Strategies	For a session factory: associate the selected session factory with a Naming Strategy implementation.
New (  )	Create a new item such as a persistent class, or configuration or mapping file, etc. See <a href="#">Using the New command</a> .
Jump to Source (  )	Open the selected file in the editor and switch to the corresponding code fragment.
Generate Persistence Mapping	Generate persistent classes and object/relational mappings for them. See <a href="#">Generating managed entity classes and O/R mappings</a> .

On this page:

- [Accessing the Phing Build Tool Window](#)
- [Toolbar](#)
- [Context Menu](#)

## Accessing the Phing Build Tool Window

- Open a Phing build file in the editor or select it in the [Project](#) tool window, and then choose Add as Phing build file on the context menu of the selection.
- Choose *View | Tool Windows | Phing Build* on the main menu. The tool window can be accessed after you have opened it through the context menu of a Phing build file in the editor or in the Project tool window.

In this tool window:

- Specify the location of the `phing.bat` file.
- Configure a list of Phing build files for packaging, deploying, or testing PHP applications.
- Appoint targets to be executed before running or debugging according to specific configurations.
- Run entire build files and specific build targets.

The functionality of the Phing tool window is available through the toolbar buttons > and the context menu of a build file or target.

## Toolbar

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	Add	Click this button add a new script to the list. In the Select Phing Build Script dialog box, that opens, choose the desired file.
	Remove	Click this button to remove the selected build file from the list.
	Run	Click this button to run the selected build file or target.
	Expand all	Click this button to have IntelliJ IDEA show a tree of targets defined in the selected build file.  
	Collapse all	Click this button to have IntelliJ IDEA collapse all the targets in the selected build file.  
	Properties	Click this button to have the Phing Properties dialog box opened. In this dialog box, specify the location of the <code>phing.bat</code> file. If necessary, configure the build procedure and the format of the output by specifying <a href="#">command line arguments</a> in the Command Line Options text box. If the set of arguments is too large to fit in the text box, click the  button or press  and type the desired arguments in the Command Line Options dialog box, that opens.  The button is only available if the list of build files is not empty.

## Context Menu

Item	Description	Available for
Run Build	Choose this option to have the selected build file executed.	Build files
Run Target	Choose this option to have the selected build target executed.	Build targets
Jump to Source	Choose this option to navigate to the source code of the selected build file or to the definition of the selected target.	Build files Build targets
Remove	Choose this option to remove the selected build file from the list.	Build files
Before Run/Debug	Choose this option to have the selected build target always executed before running or debugging the project according to specific run/debug configurations. In the Execute Target Before Run/Debug dialog box that opens, select the <a href="#">configurations</a> before which you want the target executed.	Build targets
Assign shortcut	Choose this option to open the <a href="#">Keymap dialog box</a> and configure a keyboard shortcut for the selected target as described in <a href="#">Configuring Keyboard Shortcuts</a> .	Build targets
Mark to hide	Choose this option to make the selected target <b>hidden</b> and thus suppress showing it in the build file tree. This may be helpful when you have targets some that are only called by other ones and are never run alone. <b>Hidden</b> targets do not become visible when you expand the node of a specific build file or click Expand All button  . To remove the <b>hidden</b> status of a target:  Select the build file in which it is defined and click the Settings button  on the	Build targets

1. Click this button to have the Phing Properties dialog box opened. In this dialog box:
  - Specify the location of the `phing.bat` file.
  - If necessary, configure the build procedure and the format of the output by specifying [command line arguments](#) in the Command Line Options text box. If the set of arguments is too large to fit in the text box, click the  button or press `Shift+Enter` and type the desired arguments in the Command Line Options dialog box, that opens.
  - In the Hiding Targets tab, mark targets for hiding and remove the `hidden` status. Among the targets defined in a build file, you may have some that are only called by other targets and are never run alone. You can suppress showing such targets in the build file tree by marking them as `hidden`.
2. In the [Phing Settings](#) dialog box that opens, switch to the Hiding targets tab where the Hide checkboxes next to the names of the `hidden` targets are selected. Clear the Hide checkboxes next to the targets for which you want the status `hidden` removed.

Properties 

Click this button to have the Phing Properties dialog box opened. In this dialog box:

- Specify the location of the `phing.bat` file.
- If necessary, configure the build procedure and the format of the output by specifying [command line arguments](#) in the Command Line Options text box. If the set of arguments is too large to fit in the text box, click the  button or press `Shift+Enter` and type the desired arguments in the Command Line Options dialog box, that opens.
- In the Hiding Targets tab, mark targets for hiding and remove the `hidden` status. Among the targets defined in a build file, you may have some that are only called by other targets and are never run alone. You can suppress showing such targets in the build file tree by marking them as `hidden`.

Build files

build targets

`Hidden` targets do not become visible when you expand the node of a specific build file or click [Expand All](#) button .

The button is only available if the list of build files is not empty.

The dialog box opens when you click the Settings button  on the toolbar of the **Phing Build** tool window.

In this dialog box:

- [Enable Phing integration](#) in the current project.
- [Configure Phing build properties externally](#) to pass them through a command line.
- [Show/hide](#) targets in a specific file.

On this page:

- [General Area](#)
- [Properties Tab](#)
- [Hiding Targets Tab](#)

## General Area

### ItemDescription

Path to Phing executable	In this text box, specify the location of the <code>phing.bat</code> file. Type the path manually or click the Browse button  and choose the file location in the dialog box that opens.
Command line options	In this text box, specify the additional command line arguments to be passed to Phing when the build is launched. If necessary, click the  and type the desired options in the Command Line Options dialog box. Type each option on a new line. When you close the dialog box, they are all displayed in the Command line options text box with spaces as separators.

## Properties Tab

Use this tab to configure a list of [property elements](#) externally. These properties are passed to Phing through a command line when build execution is launched and therefore they are every time re-calculated dynamically.

### ItemDescription

Add	Click this button to have an empty line for a new property element added to the list.
Remove	Click this button to remove the selected element from the list.
Property	In this text box, type the name of the property element.
Value	In this text box, specify the value of the element to be passed during build execution. Do one of the following: <ul style="list-style-type: none"><li>– Type the value manually.</li><li>– To use <a href="#">IntelliJ IDEA macros</a>, click the Insert macro button  and configure a list of relevant macro definitions in the <a href="#">Macros</a> dialog box that opens. To add a macro, select it in the list and click Insert .</li></ul>

## Hiding Targets Tab

In this tab, specify which targets defined in the currently selected build file you want to have shown or hidden in the file tree view.

Among the targets defined in a build file, you may have some that are only called by other targets and are never run alone. You can suppress showing such targets in the build file tree by marking them as **hidden** .

**Hidden** targets do not become visible when you expand the node of a specific build file or click Expand All button  .

### ItemDescription

Target	This field shows a list of all the targets defined in the current build file.
Hide	<ul style="list-style-type: none"><li>– When this checkbox next to the name of a target is selected, the target is not shown in the tree view of the file.</li><li>– When this checkbox is cleared, the corresponding target is displayed in the tree view of the file.</li></ul>

You can mark a target as **hidden** both directly from the Phing Build tool window or from the Phing Settings dialog box. However, the **hidden** status can be removed **only** through the Phing Settings dialog box.

This tool window is activated automatically if the Make project automatically option is enabled in [Compiler settings](#) . IntelliJ IDEA automatically compiles the project each time project files change on your disk (for example on save or autosave, or when you get the latest project revision from your version control system) and, if any problems are detected, they are displayed in the Problems tool window.

The Problems tool window only displays compiler errors that occurred as the result of the automatic make operation. On each automake, the list is updated with new errors, and old errors are deleted. Note that if automake is enabled, and you launch the make operation manually, the errors from this operation will also be displayed in the Problems tool window as well as in the [Messages](#) tool window.

**Note** The [Problems](#) tool window appears only if [auto make option](#) is enabled and your code contains a compilation error.

## Toolbar

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	<b>Previous message</b> <a href="#">Ctrl+Alt+Up</a>	Click this button to jump to the previous message.
	<b>Next Message</b> <a href="#">Ctrl+Alt+Down</a>	Click this button to jump to the next message.
	<b>Export to Text File</b> <a href="#">Alt+O</a>	Click this button if you want to export the contents of the tool window to a text file. Specify the name of the target file in the dialog that opens, and click Save .
	<b>Help</b>	Click this button to open IntelliJ IDEA help.
 	<b>Expand all</b> <a href="#">Ctrl+NumPad Plus</a>  <b>Collapse all</b> <a href="#">Ctrl+NumPad -</a>	Use these buttons to have all nodes expanded or collapsed.
	<b>Autoscroll to Source</b>	If this option is enabled, when you select a message in the Problems tool window, the focus in the editor automatically switches to the corresponding line in the source code.
	<b>Compiler Properties</b>	Click this button to open <a href="#">compiler settings</a> .

Alt+1

**Note**

- Views
- Title bar context menu
- Title bar buttons
- Content pane
- Context menu commands for the content pane items
- File status highlights

The Project tool window lets you look at your project from various viewpoints and perform the tasks such as creating new items (directories, files, classes, etc.), opening files in the editor, navigating to the code fragment of interest, and more.

Most of the functions in this tool window are accessed as context menu commands in the content pane and associated shortcuts.

## Views

The tool window provides a number of views.

Different views emphasize different project aspects and, generally, define which items are shown and how:

- Project view. In this view, all the project items along with their dependencies (SDKs and libraries) are shown. The emphasis is on the directory structure (though the packages are also shown).
- Packages view. The emphasis is on the package structure of the project. The modules, SDKs and libraries, by default, are not shown.
- Scopes views ( Project Files , Problems , etc.). What is shown in the content pane is limited to the corresponding predefined or user-defined [scope](#) . In other respects, depending on the currently selected view options, a scope view may resemble the Project or the Packages view.
- Scratches view. This view lets you manage your [scratch files](#) and [database consoles](#) .

The necessary view is selected from the list in the left-hand part of the title bar or, if the views are represented by tabs, by clicking the corresponding tab.

To configure a view, use the corresponding options in the [title bar context menu](#) . The necessary options can also be accessed by clicking  on the title bar.

## Title bar context menu

The context menu that appears by right-clicking on the title bar, provides settings for project [views](#) , [viewing modes](#) , as well as for switching between the views, resizing the tool window, and more .

The following table lists and briefly explains the available commands and options.

Item	Shortcut	Description
Select Next View or Tab	Alt+Right	These are the commands for switching between different <a href="#">views</a> .
Select Previous View or Tab	Alt+Left	
Show List of Views or Tabs	Alt+Down	
Edit Scopes		Use this command to open the <a href="#">Scopes dialog</a> in which you can create and edit used-defined <a href="#">scopes</a> . Note that this command is available only if the current view is a scope view.
Flatten Packages		If this option is off, the packages are shown as a hierarchy. If this option is on, all the packages appear at the same level and are identified by their qualified names.

**Compact Empty Middle Packages / Hide Empty Middle Packages**

This option lets you specify how or whether empty packages are to be shown. (Empty packages are ones that contain nothing but other packages.)

If the option is on, empty packages are shown compacted or not shown at all (hidden).

Option	Flatten Packages: OFF	Flatten Packages: ON
Compact Empty Middle Packages: OFF		
Compact Empty Middle Packages: ON		
Hide Empty Middle Packages: OFF		
Hide Empty Middle Packages: ON		

**Abbreviate Qualified Package Names**

This option is available only if the Flatten Packages option is on. If the option is on, most of the initial <name>. fragments in qualified package names are abbreviated.

Option	Abbreviate Qualified Names: OFF	Abbreviate Qualified Names: ON
Abbreviate Qualified Names: OFF		

**Show Members**

If this option is on, the files in the tree that contain classes turn into nodes. When such node is unfolded, the contained classes with their fields, methods, and other members of the selected item are shown.

Option	Show Members: OFF	Show Members: ON
Show Members: OFF		

**Autoscroll to Source**

If this option is on, IntelliJ IDEA will automatically open the selected item in the editor.

**Autoscroll from Source**

If this option is on, IntelliJ IDEA automatically locates documents that you open in the editor in the Project tool window.

**Sort by Type**

If the option is off, the items (files, classes, etc.) are sorted alphabetically. If the option is on, the files are sorted by their extensions. The .java files appear in the following order: interfaces, classes, enumerations, etc.

**Folders Always on Top**

If the option is on, all the folders are shown before the files. Otherwise, all the items are sorted alphabetically, and the files and folders appear intermixed.

**Show Excluded Files**

This option is available only in the Project view. (In other views, excluded files are never shown.) Turn this option on or off to show or hide [excluded folders and files](#).

Option	Show Excluded Files: OFF	Show Excluded Files: ON
Show Excluded Files: OFF		

**File Nesting...**

Click this option to open the [File Nesting Dialog](#) and configure presentation of files with the same names.

**Show Modules**

This option is available only in the Packages and scope views. (In the Project view, modules are always shown.) Turn this option on or off to show or hide modules.

**Show Libraries Contents**

This option is available only in the Packages view. (In the Project view, libraries are always shown; in the scope views, libraries are never shown.) Turn this option on or off to show or hide libraries and their contents.

Note that within the Libraries category are the libraries included in module dependencies and also the SDKs associated with your modules.

**Pinned, Docked, Floating, Windowed, Split Mode**

These options let you control general appearance and behavior of the tool window. See [Viewing Modes](#).

**Remove from Sidebar**

This command hides the tool window, removes the associated [tool window button](#) from the tool window bar and removes the tool window from the [quick access menu](#) (☰ or ☰).

To open the tool window again (and restore the associated features), use the main menu: View | Tool Windows | <Window Name> .

**Group Tabs**

If this option is on, there is a list in the left-hand part of the title bar from which you can select the necessary view. If this option is off, the views are represented by tabs which appear in the left-hand part of the title bar.

**Move to**

To associate the tool window with a different [tool window bar](#) , select this command, and then select the destination tool window bar ( Top , Left , Bottom or Right ).

**Resize**

To resize the tool window by moving one of its borders, select this command, and then select the necessary Stretch to option.

Note that this command is not available for the floating mode.

**Hide**  Use this command to hide the tool window.

## Title bar buttons

### ItemShortcutDescription

  If the [views](#) are currently shown as tabs (the [Group Tabs](#) option is off), this button appears to the right of the last visible tab.

 If the first or the last of the available views is currently selected, this button is shown as  or  .

Click this button to open the list of views, for example, to select a different view.

 Click this icon to navigate from a file in the editor to the corresponding node (file, class, field, method, etc.) in the Project tool window.

This icon is not available if the [Autoscroll from Source](#) option is currently on.

  Use this icon or shortcut to collapse all the nodes.

 Click this button to open the menu for configuring the current [view](#) and changing the tool window [viewing modes](#) .

Note that most of the menu items are options that you can turn on or off. An option which is on has a check mark to the left of its name.

The available options are a subset of the [title bar context menu](#) items. Depending on the current view, the menu may include the following options:

- [Edit Scopes](#)
- [Flatten Packages](#)
- [Compact or Hide Empty Middle Packages](#)
- [Abbreviate Qualified Package Names](#)
- [Show Members](#)
- [Autoscroll to Source](#)
- [Autoscroll from Source](#)
- [Sort by Type](#)
- [Folders Always on Top](#)
- [Show Excluded Files](#)
- [Show Modules](#)
- [Show Libraries Contents](#)
- [Pinned Mode, Docked Mode, Floating Mode, Windowed Mode, Split Mode](#)
- [Remove from Sidebar](#)
- [Group Tabs](#)
- [Move to](#)
- [Resize](#)

  Use this icon or shortcut to hide the tool window.

When used in combination with the  key, clicking this icon hides all the tool windows attached to the same [tool window bar](#) .

## Content pane

The content pane shows the project items such as directories, files, etc.

The icons for the main categories (node types) are shown and briefly explained in the following table. The icons used for the main file types are listed in [File Types Recognized by IntelliJ IDEA](#) ; the icons for the main symbols (classes, fields, methods, etc.) are shown in [Symbols](#) .

### ItemDescription

- |   |   |
|---|---|
|  | A module.   |
|  | A package.  |
|  | A folder (directory). Different folder types have different colors: <ul style="list-style-type: none"><li>- An "ordinary" folder  .</li><li>- A source folder  .</li><li>- A test source folder  .</li></ul> |

Libraries, a category for grouping the SDKs associated with your modules and the libraries included in module dependencies.  
When the Project view is selected, there is one such node for the whole project which is labeled External Libraries .

The subcategories in this case are the SDKs (for example, JSDKs ) and individual libraries () .

When the Packages view is selected, the corresponding node or nodes are labeled Libraries . If the Show Modules and the Show Libraries Contents options are selected, there is an individual Libraries node for each of the modules. The main subcategory in this case is a package () .

## Context menu commands for the content pane items

When you right-click an item in the content pane, the context menu for this item is shown. This menu provides access to all the functions available for the selected item:

Item	Shortcut	Description
New	Alt+Insert	Use this command to create a new item (module, package, directory, file, class, etc.) within the selected one (project, module, directory or package) in the Scratches view, this command also lets you create a database console.
Add Framework Support		For a module: use this command to add support for certain frameworks and technologies in the selected module. (The <a href="#">Add Frameworks Support dialog</a> will open.)
Cut	Ctrl+X	Use this command to move the selected item or items from the current location to the clipboard.
Copy	Ctrl+C	Use this command to copy the selected item or items to the clipboard.
Copy Path(s)	Ctrl+Shift+C	Use this command to copy the full path(s) of the selected item or items to the clipboard.
Copy Relative Path	Ctrl+Shift+Alt+C	Use this command to copy a relative path to the selected item to the clipboard.
Paste	Ctrl+V	Use this command to insert the contents of the clipboard into the selected location.
Jump to Source	F4	Use this command to open the selected file in the editor. If the file is already open, the corresponding editor tab will become active.
Open Module Settings	F4	Use this command to see the settings for the selected module. These will be shown on the <a href="#">Modules page</a> in the <a href="#">Project Structure dialog</a> .
Find Usages	Alt+F7	Use this command to find the usages of the selected item. (The <a href="#">Find Usages dialog</a> will open.)
Find in Path	Ctrl+Shift+F	Use this command to perform a text search. ( <a href="#">Find in Path dialog</a> will open.)
Replace in Path	Ctrl+Shift+R	Use this command to perform text search-and-replace. ( <a href="#">Replace in Path dialog</a> will open.)
Analyze		Use this command to access the functions related to code <a href="#">inspection</a> and <a href="#">analysis</a> .
Refactor		Use this command to perform one of the <a href="#">refactorings</a> available for the selected item.
Add to Favorites		Use this command to add the selected item to an existing or new list of favorite items. See <a href="#">Managing Your Project Favorites</a> .
Show Thumbnails	Ctrl+Shift+T	Use this command to view thumbnails for image files located in the selected directory. (The <a href="#">Thumbnails</a> tool window will open.)
Browse Type Hierarchy	Ctrl+H	For a file (normally, a class): use this command to see the class hierarchy for the selected file (class). (The <a href="#">Hierarchy tool window</a> will open.) See also, <a href="#">Viewing Structure and Hierarchy of the Source Code</a> .
Reformat Code	Ctrl+Alt+L	Use this command to reformat the source code in the selected file or in all files in the current directory. (The <a href="#">Reformat Code dialog</a> will open.) See also, <a href="#">Reformatting Source Code</a> .
Optimize Imports	Ctrl+Alt+O	Use this command to optimize imports (i.e. to remove unnecessary <code>import</code> statements) in the selected file or in all files in the current directory. (The <a href="#">Optimize Imports dialog</a> will open.) See also, <a href="#">Optimizing Imports</a> .

Delete	Delete	Use this command to delete the selected item. Use with care!
Change Dialect (<CurrentDialect>)		For SQL files and database consoles: change the SQL dialect associated with the file or console.
Remove Module	Delete	Use this command to remove a module from your project. Note that the files that make up the module are not physically removed from the disk.
Make Module '<name>'		Use this command to make the current module. See <a href="#">Compilation Types</a> and <a href="#">Reviewing Compilation and Build Results</a> .
Compile '<name>'	Ctrl+Shift+F9	Use this command to compile the selected source file or all the source files in the selected directory. See <a href="#">Compilation Types</a> and <a href="#">Reviewing Compilation and Build Results</a> .
Run '<item_name>'	Ctrl+Shift+F10	For an SQL file or database console: execute all the statements contained in the selected file or console.
Local History		Use this command to view local history for the selected file or directory, or to create a label for the current version of your project. See <a href="#">Local History</a> and <a href="#">Using Local History</a> .
Synchronize '<item_name>'		Use this command to synchronize the selected item with its version saved in the file system. (If you change a file or directory contents externally, IntelliJ IDEA, under certain circumstances, may not be aware of the corresponding changes unless you use this command.)
Show in Explorer		Use this command to open a file browser (e.g. Windows Explorer or Finder) and show the selected item there.
File Path	Ctrl+Alt+F12	Use this command to open the File Path menu. This menu shows the path from the file system root to the selected element with individual directories as the menu items.

When you select an item in this menu (e.g. a directory), a file browser (e.g. Windows Explorer or Finder) opens, and the selected item is shown there.

Compare With	Ctrl+D	Use this command to compare the selected file or directory with another file or directory. Select the other file or directory the <a href="#">dialog that opens</a> . See <a href="#">Comparing Folders</a> and <a href="#">Differences Viewer for Folders</a> .
Compare File with Editor		Use this command to compare the selected file with the file open on an active editor tab. See <a href="#">Comparing Files</a> and <a href="#">Differences Viewer for Files</a> .
Load/Unload Modules		<a href="#">Temporarily ignore unused modules</a>
Mark Directory As		Use this command to make the selected directory a source root or a test source root , to make the directory excluded, etc. The necessary category for the directory is selected from the submenu.
Mark as Plain Text		Use this command to exclude the selected file from project, so it is ignored by inspections, code completion, navigation, etc. The file will be indicated with a special icon  and shown as plain text in the editor. For more details, see <a href="#">Configuring projects</a> .
Diagrams	Ctrl+Shift+Alt+U or Ctrl+Alt+U	Use this command to open a diagram (e.g. a UML diagram) for the selected item. For more information, see <a href="#">Diagram Reference</a> .
Update Copyright		Use this command to update the copyright notice for the selected files and folders. See <a href="#">Generating and Updating Copyright Notice</a> .
WebServices		Use this command to access the functions related to developing Web services. See <a href="#">Web Services</a> and <a href="#">Web Service Clients</a> .

## File status highlights

If [VCS integration is enabled](#) for the current project, IntelliJ IDEA uses colors to denote VCS file status in the Project tool window. The following table presents information about the meaning of the colors.

Color	File Status	Description
Black	Up to date	File is unchanged.

 PhantomsTest.java

Gray	Deleted	File is scheduled for deletion from the repository.  <a href="#">privatent.txt</a>
Blue	Modified	File has changed since the last synchronization.  <a href="#">Advice.java</a>
Green	Added	File is scheduled for addition to the repository.  <a href="#">ResultTest.java</a>
Violet	Merged	File is merged by your VCS as a result of an update.  <a href="#">VcsHistoryDialog.java</a>
Brown	Unversioned	File exists locally, but is not in the repository, and is not scheduled for adding.  <a href="#">Test.xml</a>
Olive	Ignored	File will be ignored in any VCS operation.  <a href="#">Test.html</a>
Light brown	Hijacked	File is <a href="#">modified without checkout</a> . This status is valid for the files under Perforce, ClearCase and VSS. modified without checkout .  <a href="#">HelpTOC.xml</a>
Red	Merged with conflicts	During the last update, file was merged with conflicts.  <a href="#">HistoryTestCase.java</a>
Lilac	Externally deleted	File is deleted locally, but was not scheduled for deletion, and still exists in the CVS repository.  <a href="#">test1.txt</a>
Dark cyan	Switched	The file is taken from a different branch than the whole project. This status is valid for CVS and SVN.  <a href="#">test1.txt</a>

The dialog box opens when you click File Nesting on the [context menu of the title bar in the Project tool window](#) .

In this dialog box, configure presentation of files with the same names but different suffixes. Such bunches of files may appear in framework-specific projects, for example, if you use [Angular Material Design components](#) :

Also consider transpilation of TypeScript into JavaScript with sourcemaps generated:

IntelliJ IDEA can present such file bunches as plain structures or show parent files as folders (nests) with their child files inside. To configure file nesting, set correspondence between the suffixes of parent files and the suffixes of the child files.

IntelliJ IDEA provides a set of predefined rules. You can edit these rules as well as define your own custom ones.

**Tip** Note that the nesting rules are applied only to files with the same names within the same directory. If the names of two files match a pattern but the files are stored in different directories IntelliJ IDEA does not visually "move" any of them.

### ItemDescription

Show files with the same names as nested according to the rules below

- When the checkbox is selected, IntelliJ IDEA recognizes children files based on the patterns from the list and shows them grouped under the corresponding parents. Compare the presentation of the above TypeScript example with file nesting enabled:

- When the checkbox is cleared, IntelliJ IDEA shows parents and children at the same level.

Add (+) Click this button to add a new row and specify the "parent" file suffix and the matching "child" file suffix.

Remove (-) Click this button to remove the selected rule from the list.

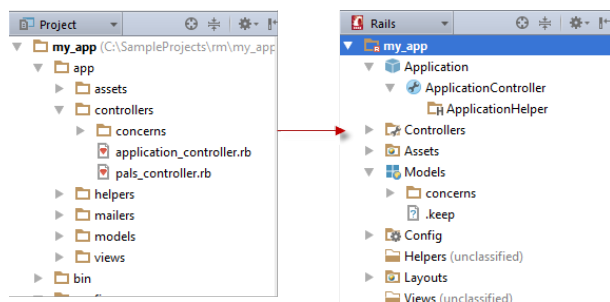

Use the default ruleset (🔄) Click this button to discard all your custom patterns and reload the default rules.

)

This feature is only supported when the Ruby plugin is installed.

Project Tool Window | View as | Rails

The special Rails view shows logical project structure displaying Controllers, Models, Views, DB migrations, etc as Rails elements rather than files and directories. From the Rails view, you can gain quick access to the application elements and their contents (controller methods, associated and partial views, etc.)

**When using the Rails view, note the following:**

- The Rails view doesn't display the `excluded directories`, `.idea`, and `script` directories.
- Controller views that don't have associated Rails actions, are shown under the corresponding controller class node.
- All non-view files from controller's `views` folder are shown under the corresponding controller class node.
- All layouts are shown under top-level Layouts node .
- Helpers (unclassified) node  contains all files, except for the helpers that correspond to controllers by naming conventions.
- Views (unclassified) node  contains all files and folders except for the controller's `views` folders.
- db (unclassified) node  contains all files and folders except for the `migrate` folder. Instead, migrations are shown in the Models | Migrations node.

Use the REST Client tool window for [testing a RESTful Web Service](#) . The tool window is intended for composing and submitting test requests to Web service methods based on the service API, as well as for viewing and analyzing server responses.

Please note the following:

- View | Tool Windows | REST Client - the tool window can be accessed this way after you have opened it using the Tools | Test RESTful Web Service command.
- The tool window is available only when the **REST Client** bundled plugin is enabled. The plugin is active by default. If not, activate it in the [Plugins settings](#) page of the [Settings](#) dialog box.

IntelliJ IDEA supports integration between the source code and the contents of the REST Client tool window controls.

On this page:

- [Common Request Settings](#)
  - [Toolbar](#)
- [Request Tab](#)
- [Cookies Tab](#)
- [Response Tab](#)
- [Response Headers Tab](#)

## Common Request Settings

In this area, choose the request method and specify the data to compose the [request URI](#) from.

The server response code and the content length are shown in the upper-right corner of the REST Client tool window.

### ItemDescription

**HTTP method** In this drop-down list, specify the [request method](#) . The available options are:

- [GET](#)
- [POST](#)
- [PUT](#)
- [PATCH](#)
- [DELETE](#)
- [HEAD](#)
- [OPTIONS](#)

**Host/port** In this text box, type the URL address of the host where the target Web service is deployed and the port it listens to. By default, the port number is `80` . If another port is used, specify it explicitly in the format `<host URL>:<port number>` .

**Path** In this drop-down list, specify the relative path to the target method.

You can enter the entire URL address of a method to test in the Host/port text box. Regardless of the chosen **HTTP method** , upon pressing  IntelliJ IDEA will split the URL address into the **host/port** and the path to the method. The extracted relative path will be shown in the Path text box and the extracted parameters will be added to the list in the Request Parameters pane of the Request tab.

## Toolbar

### ItemTooltip Description and shortcut

	Submit Request	Click this button to submit the generated test request to the server.  <b>Note</b> If a server is not trusted, IntelliJ IDEA shows a dialog box suggesting to accept the server, or reject it. If you accept the server as trusted, IntelliJ IDEA writes its certificate to the trust store. On the next connect to the server, this dialog box will not be shown.
	Replay Recent Requests	Click this button to have a Recent Requests pop-up list displayed and select the relevant request. The fields are filled in with the settings of the selected request. Click the Submit Request button  .
	Export Request	Click this button to have the current request settings saved in an XML file so they are available in another IntelliJ IDEA session. In the dialog box that opens, specify the name of the file to save the settings in and its parent folder. When necessary, you can retrieve the saved settings and run the request again.
	Import Request	Click this button to have the settings of a previously saved request retrieved from an XML file. In the dialog box that opens, select the relevant XML file.
	Generate Authorization Header	Click this button to open the Generate Authorization Header dialog box and specify your user name and password for accessing the target RESTful Web service through. Based on these credentials IntelliJ IDEA will generate an authentication header which will be used in <a href="#">basic authentication</a> . Learn more at <a href="http://www.ics.uci.edu/~fielding/pubs/dissertation/rest_arch_style.htm">http://www.ics.uci.edu/~fielding/pubs/dissertation/rest_arch_style.htm</a> .

	Update resource paths from code	Click this button to synchronize the contents of the Path drop-down list with the @Path annotations.
	Configure HTTP Proxy	Click this button to specify proxy server settings in the dialog box that opens.
	Close	Close the REST Client tool window.
	Help	Show this page.

## Request Tab

Use this tab to specify the parameters to be passed to the service in the generated test request either through the query string for `GET` requests or through the request body for other request types. Also configure interaction between the client side and the Web service by specifying the format of data that the service and the client accept.

### ItemDescription

**Headers**

In this pane, specify the technical data included in the [request header](#) . These data are passed through header fields and define the format of the input parameters ([accept](#) field), the response format ([content-type](#) field), the caching mechanism ([cache-control](#) field), etc.

To add a field to the list, click Add  , then specify the field name in the Name text box and the field value in the Value drop-down list.

The set of fields and their values should comply with the Web service API. In other words, the specified input format should be exactly the one expected by the Web service as well as the expected response format should be exactly the one that the service returns.

For `accept` , `content-type` , and some other fields IntelliJ IDEA provides a list of suggested values. Choose the relevant format type from the Value drop-down list.

**Request Parameters**

In this pane, specify the parameters to be passed to the target method through a query string inside the URL. This approach is used for requests of the type `GET` . By default, the pane shows an empty list with one line.

- To add a parameter, click Add  , then specify the name of the parameter in the Name text box and the value of the parameter in the Value drop-down list.
- To delete a parameter from the list, select it and click Remove  .
- To suppress sending the specified query string parameters and disable the controls in the Request Parameters pane, press the Don't send anything toggle button  .

The set of parameters and their types should comply with the Web service API, in particular, they should be exactly the same as the input parameters of the target method.

- select this checkbox This may be helpful, for example, if you want to test passing parameters through other request methods in the request body but still preserve the data typed in the Query string parameters pane.

**Request Body**

The pane is disabled when the `GET` , `DELETE` , `HEAD` , or `OPTIONS` request method is selected. In this pane, specify the input parameters to be passed to the target method inside a [request message body](#) .

- Empty: choose this option to send a request with an empty body.
- Text: choose this option to send a request with a string of parameters with values. Specify the parameters in the text box next to the option.
- File contents: choose this option to have the parameters inserted in the request body from a local text file. Specify the source text file in the File to send field.
- File upload(multipart/form-data): choose this option if you want to pass a binary file as a parameter, which requires that the file be converted. Specify the source binary file in the File to send field.

## Cookies Tab

Use this tab to create, save, edit, and remove cookies, both received through responses and created manually. The **name** and **value** of a cookie is automatically included in each request to the URL address that matches the **domain** and **path** specified for the cookie, provided that the **expiry date** has not been reached.

The tab shows a list of all currently available cookies that you received through responses or created manually. The cookies are shown in the order they were added to the list. When you click a cookie, its details become editable and are displayed in text boxes.

### ItemDescription

<b>Name</b>	In this fields, specify the name of the cookie to be included in the request.
<b>Value</b>	In this field, specify the value of the cookie to be included in requests.
<b>Domain</b>	In this field, specify the host and port the requests to which must be supplied with the <b>name</b> and <b>value</b> of the cookie.
<b>Path</b>	In this field, specify the path of the URL the requests to which must be supplied with the <b>name</b> and <b>value</b> of the cookie.
<b>Expiry date</b>	In this field, specify the expiry date of the cookie.
	Click this button to add a new row to the list and define a new cookie in it.
	Click this button to remove the selected cookie from the list.

## Response Tab

Use this tab to view responses from the Web service. By default, responses are shown in the plain text form. Use the icons of the tab to have them displayed in the editor in the HTML, XML, and JSON formats.

Item	Tooltip	Description
	View as HTML	Click this button to open a new tab in the main editor window and display there the response as HTML.
	View as XML	Click this button to open a new tab in the main editor window and display there the server response as XML.
	View as JSON	Click this button to open a new tab in the main editor window and display there the server response as JSON.
	Open in browser	Click this button to view the response in your default Web browser.

## Response Headers Tab

The tab shows the technical data provided in the [headers of Web service responses](#).

The functionality described on this page and in the chapter [Working with Web Servers: Copying Files](#) is available only in the **Ultimate Edition** of IntelliJ IDEA.

Tools | Deployment | Browse Remote Host

Use this tool window to view the folder structure of the target FTP/FTPS/SFTP servers and the data uploaded to them.

## Getting Access to the Remote Host Tool Window

- View | Tool Windows | Remote Host - the tool window can be accessed this way after you have opened it using the Tools | Deployment | Browse Remote Host command.
- The tool window is available only when the **Remote Hosts Access** bundled plugin is enabled. The plugin is active by default. If not, activate it in the [Plugins settings](#) page of the [Settings](#) dialog box.

## Toolbar

### ItemTooltip and Shortcut

Item	Description
Remote host	From this drop-down list, select the desired remote host configuration.
	Shift+Enter Click the browse button to <a href="#">add a new server</a> .
	Collapse All Click this button to have all nodes in the view collapsed. Ctrl+NumPad -
	Refresh Click this button to refresh the view. Ctrl+F5
	Close Click this button to close the tool window. Ctrl+Shift+F4

## Context Menu

### ItemDescription

Upload Here	Choose this option to have the files from the currently opened project uploaded according to the selected configuration. If the action is invoked from the context menu of a file, the corresponding local file is uploaded. If the action is invoked from a folder, the entire folder is uploaded.
Download from here	Choose this option to download the selected file or folder to the currently opened. The existing local files will be updated and the missing files will be created.
New	Choose this option to create a new remote file or folder in the selected folder. The option is available only from the context menu of a folder.
Rename	Choose this option to rename the selected file or folder.
Delete	Choose this option to remove the selected file or folder.
Cut	Choose this option to copy the name of the selected file or folder to the clipboard and remove the file or folder from the tree.
Copy	Choose this option to copy the name of the selected file or folder to the clipboard.
Paste	Choose this option to insert the previously copied name of a file or a folder into the tree.
Edit Local File	When you select a file and choose this option, IntelliJ IDEA opens its local copy in the editor and moves the focus to the corresponding. The option is available only when the project with the corresponding local file is currently opened in the editor.
Sync with Local	Choose this option to compare the selected remote folder with its local version. In the <a href="#">Differences Viewer for Folders</a> that opens, explore the differences and synchronize the files, where applicable, as described in <a href="#">Comparing two folders in the Difference Viewer</a> . See <a href="#">Comparing Deployed Files and Folders with Their Local Versions</a> for details.
Compare with Local Version	Choose this option to compare the selected remote file with its local version. In the <a href="#">Differences Viewer for Files</a> dialog box, that opens, explore the differences and apply them, if necessary, using the  and  buttons. For details, see <a href="#">Viewing Differences Between Files</a> . See <a href="#">Comparing Deployed Files and Folders with Their Local Versions</a> for details.
Edit Remote File	Choose this option to edit the selected file in the IntelliJ IDEA editor without adding it to the currently opened project. See <a href="#">Editing Individual Files on Remote Hosts</a> for details.
Copy Path	
Exclude Path	Choose this option to exclude the selected folder from upload/download, see <a href="#">Excluding Files and Folders from Upload/Download</a> for details.

Copy Path Choose this option to copy the absolute path to the selected file or folder on the server to the clipboard.

Alt+4

The Run tool window displays output generated by your application. If you are running multiple applications, each one is displayed in a tab named after the [run/debug configuration](#) applied.

The appearance of each tab depends on the type of the application being run and can include additional toolboxes and panes.

The main toolbar of the Run tool window lets you rerun, stop, pause, or terminate an application. The following table contains descriptions of the buttons that are common for most applications.

## Run Toolbar

**Item**  
**Tooltip**  
**and**  
**shortcut**

Item	Tooltip	Description
	Rerun	Click this button to stop the current application and run it again.
	Ctrl+F5	When an application is stopped (  ) , this button toggles to  .
	Rerun	Click this button to rerun the current application.
	Ctrl+F5	This button appears, when an application is stopped (  ). When an application is running, this button toggles to  .
	Pause Output	Click this button to have the process output paused. Note that the button is not available for <a href="#">Run/Debug Configuration: Node.js</a> , <a href="#">Run/Debug Configuration: Attach to Node.js/Chrome</a> , and <a href="#">Run/Debug Configuration: NodeUnit</a> .
	Dump Threads	Click this button to dump all threads of the current process showing their status in the Sun format. Note that the button is not available for <a href="#">Run/Debug Configuration: Node.js</a> , <a href="#">Run/Debug Configuration: Attach to Node.js/Chrome</a> , and <a href="#">Run/Debug Configuration: NodeUnit</a> .
	Exit	Click this button to terminate the current process gracefully using in-process internal mechanisms. Note that the button is not available for <a href="#">Run/Debug Configuration: Node.js</a> , <a href="#">Run/Debug Configuration: Attach to Node.js/Chrome</a> , and <a href="#">Run/Debug Configuration: NodeUnit</a> .
	Stop	Click this button to terminate the current process externally by means of the standard <code>shutdown</code> script. Clicking the button once invokes <code>soft kill</code> allowing the application to catch the <code>SIGINT</code> event and perform graceful termination (on Windows, the <code>Ctrl+C</code> event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix <code>SIGKILL</code> is sent.
	Restore Layout	Click this button to to have the changes to the current layout abandoned and return to the default state.
	Pin	Use to pin or unpin the tab. If a tab is pinned, the results for the next command are shown on a new tab.
	Close	Click this button to close the selected tab of the Run tool window and terminate the current process.
	Ctrl+Shift+F4	
	Help	Use this icon or shortcut to open the corresponding help page.
	F1	

## Context Menu Commands

**Item**  
**Description**

Compare with Clipboard	Opens the Clipboard vs Editor dialog box that allows you to view the differences between the selection from the editor and the current clipboard content. This dialog is a <a href="#">regular comparing tool</a> that enables you to copy the line at caret to the clipboard, find text, navigate between differences and manage white spaces.
Fold Lines Like This	Opens the <a href="#">Console</a> dialog that allows you defining the lines to be folded to hide extraneous information.
Copy URL	Choose this command to copy the current URL to the system clipboard. This command only shows on a URL, if it is included in an application's output.
Create Gist	Choose this command to open the Create Gist dialog box.
Clear All	Clears the output window.

## Console Toolbar

**ItemTooltip Description and shortcut**

	Up/down the Stack Trace	Click this button to navigate up or down in the stack trace and have the cursor jump to the corresponding location in the source code.  <b>Ctrl+Alt+Up</b>
	Use soft wraps	Click this button to toggle the soft wrap mode of the output.  <b>Ctrl+Alt+Down</b>
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location in the source code.
	Print	Click this button to send the console text to the default printer.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.
	Toggle tasks executions/text mode	Click this button to view Gradle task execution in a tree mode.

### Karma Server tab

The tab is shown only when you run JavaScript unit tests using the Karma test runner. Use the tab to view and analyze information from the server. For details, see [Karma](#).

This console shows which of the configured and marked for deployment [artifacts](#) are successfully deployed and which are not. Use the console to deploy and undeploy artifacts and configure their execution on the server.

**ItemTooltip** **Description**  
**and**  
**Shortcut**

	Artifact is deployed successfully	This icon next to an artifact indicates that the artifact has been successfully deployed to the server.
	Artifact is not deployed	This icon next to an artifact indicates that the artifact has not been deployed to the server yet or has been undeployed from the server.
	Deploy All	Click this button to have IntelliJ IDEA deploy all the artifacts from the list of items to be deployed in the Deployment tab of the <a href="#">Run/Debug Configuration</a> dialog box.
	Undeploy	Click this button to have the selected artifact undeployed from the server.
	 Refresh Deployment Status	Click this button to synchronize the deployment status indications for artifacts with the server.
	Update Resources On Frame Deactivation	<p>Click this button if you want the application to be updated automatically when you switch from IntelliJ IDEA to a different application. (Switching to a different application is referred to as <a href="#">frame deactivation</a> .)</p> <p>This button is a toggle that turns the corresponding option on or off. If enabled, the application assets to be updated are defined by the current setting of the On frame deactivation option in the <a href="#">active run/debug configuration</a> .</p> <p>Note that by changing the state of the button you also change the setting of On frame deactivation in the current run/debug configuration. For example, if you disable the button, the setting changes to Do nothing .</p>

The Logs tab is available, if [logging](#) has been activated in the current Run/Debug configuration. This tab is named after the log file. If there are multiple log files enabled for a run/debug configuration, the tab's name is composed of all the log file names delimited with the "|" characters; so doing, each specific log is displayed in its own tab:

## Log level

The logs can contain messages of the following types:

- All
- information
- warnings
- errors

Use the drop-down list of available message types to filter the log output and navigate through the messages.

## Search

Use the text field to type a string to find, and press  to start the search.

Click  to reveal to history of searches.

Click  to clear the text field.

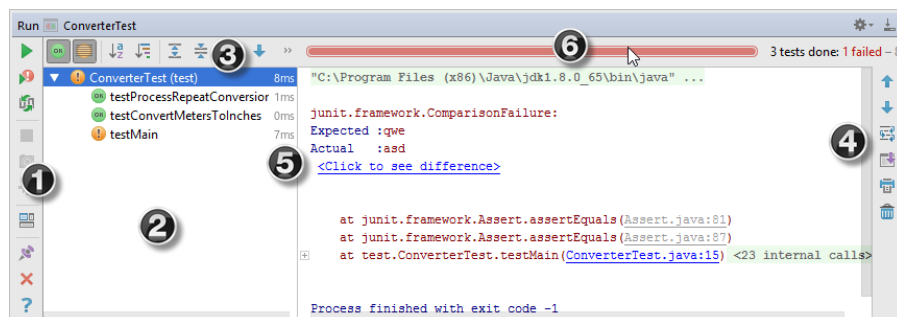

In this section:

- Basics
- Run toolbar
- Testing toolbar
- Test status icons
- Output pane
- Context menu commands

## Basics

The Test Runner tab opens in the [Run](#) tool window when a testing session begins, and features the same [toolbar buttons](#).

1. The [Run toolbar](#) is almost the same as that for the [Run](#) tool window, but features testing-specific buttons.
  2. The left-hand pane shows the tree view of all tests within the current run/debug configuration.
    - The root node represents the test selected to run.
    - The nested nodes represent the hierarchy of test suites and test cases.
    - The leaf nodes represent the individual tests.
- The status of each test is indicated by an [icon](#). Double-click a node to open the respective test class or test method in the editor.
3. The [testing toolbar](#) provides controls that enable you to monitor the tests and analyze results. Some of the commands are duplicated on the [context menus](#) of the test tree nodes.
  4. The [Output](#) pane shows the output of the current test suit.
  5. The inline statistics show the list of executed tests with the execution time of each test.
  6. The color of the status bar indicates whether the tests have passed successfully. If at least one of the tests fails, the status bar turns red.

## Run toolbar

ItemTooltip  
and  
Shortcut

	Rerun	Click this button to rerun the current process. The process reruns always in the same console regardless of whether this console is pinned or not.  <a href="#">Ctrl+F5</a>
	Rerun Failed Tests	Click this button to have IntelliJ IDEA execute failed tests. If you press <a href="#">Shift</a> and click this button, you can choose whether you want to Run the tests again, or Debug, i.e. rerun the failed tests in the Debug mode.
	Toggle auto-test	Press this toggle-button to turn on the <a href="#">autotest-like runner</a> . As a result, any test in the current run configuration tab restarts automatically on changing the related source code, without clicking the Rerun button . The button is not shown for Mocha and Jest tests. To activate the auto-rerun functionality for these test runners, add the <code>--watch</code> flag in the Extra Mocha options / Extra Jest options field of the <a href="#">Run/Debug Configuration: Mocha</a> or <a href="#">Run/Debug Configuration: Jest</a> dialog box respectively.
	Dump Threads	Click this button to dump all threads of the current process showing their status in the Sun format.  <a href="#">Ctrl+Break</a>
	Exit	Click this button to terminate the current process gracefully using in-process internal mechanisms. This button is available for GWT applications only.
	Stop	Click this button to terminate the current process externally by means of the standard mechanisms.  <a href="#">Ctrl+F2</a>
	Restore Layout	Click this button to to have the changes to the current layout abandoned and return to the default state.

	Pin	When this button is pressed, the current tab will not be overwritten; instead, the results of the next command will be displayed in a new tab.
		Click this button to close the selected tab of the Run tool window and terminate the current process.
		Click this button to show reference.

## Testing toolbar

**ItemTooltip and Shortcut**

	Show Passed	Click this button to show tests that passed successfully.
	Show Ignored	Click this button to show the ignored tests in the tree view of all tests within the current run/debug configuration or test class.
	Sort alphabetically	Click this button to sort tests in alphabetical order.
	Sort by duration	Click this button to sort tests by duration.
	Expand All/Collapse All	Click these buttons to have all nodes in the tree view of tests expanded. These buttons are only available if the tested application contains more than test case.
	  Previous/next Failed Test  	Click these buttons to navigate between the failed tests.
	Show coverage per test	Click this button to <a href="#">have the code coverage results shown</a> in the Project tool window. The button is available after all the tests are executed provided that <a href="#">code coverage is enabled</a> in the current run configuration.
	Export Test Results	Click this button to have the results of the selected test saved in a file. In the <a href="#">Export Test Results</a> that opens, specify the file to save the output in and the format in which the data will be saved. If you want to view the test results later, choose the <a href="#">XML</a> format. To view saved test results later, click  and specify the XML file where they are stored.
	Import Test Results	Click this button to view the test results that you previously saved in an <a href="#">XML</a> file or the results that IntelliJ IDEA has kept in its internal history. The pop-up menu that opens shows a list of internally saved results of test sessions, each item is supplied with the name of the run configuration and a time stamp. <div data-bbox="459 1294 671 1420" style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;">  <ul style="list-style-type: none"> <li> TestMain (3/15/2016 5:37 PM)</li> <li> TestMyClass (3/15/2016 5:37 PM)</li> <li> JUnitTest (3/15/2016 5:26 PM)</li> <li>Import From File ...</li> </ul> </div> <ul style="list-style-type: none"> <li>- To view the results of a testing session from the IntelliJ IDEA history, select the item with the suitable run configuration and time stamp.</li> <li>- To load the previously exported results, choose Import from file and then choose the required XML file in the dialog box that opens.</li> </ul> <p>The loaded test results are shown in the tab and the name of the corresponding run configuration is displayed on the title bar. To re-run the tests from the loaded session, click .</p>

	<p>Click this cog button to access the context menu with the following options:</p> <ul style="list-style-type: none"> <li>- Track Running Test: turn this option on to monitor execution of the current test. If a test suite contains multiple tests, the tree view of tests expands to show sequential test methods, as they are executed.</li> <li>- Show Inline Statistics: turn this option on to have the statistics shown next to a test result, displaying the time used for executing each test.</li> <li>- Scroll to Stacktrace: turn this option on to have the console scroll to the beginning of the trace of the last failed test.</li> </ul> <p>If you click the root node (the test package) in the tree view with this option turned off, the console will show the very beginning of the test. This option is helpful when a test package contains multiple test classes and test methods. If some of the tests fail, you can scroll in the console to the beginning of a stack trace of an exception or assertion.</p> <ul style="list-style-type: none"> <li>- Open Source at Exception: use this option to explore the results of a test that fails as an error, throwing an uncaught exception.</li> </ul> <p>If you double-click the failed test class or method in the tree view with this option turned on, the respective test class or method will open in the editor, with the caret placed at the line that caused the problem.</p> <ul style="list-style-type: none"> <li>- Autoscroll to Source: turn this option on to have the currently selected test in the tree view synchronized with the editor automatically.</li> </ul>
---	--

- Select First Failed Test When Finished: turn this option on to have the first failed test automatically selected in the tree view upon completing the tests.
- Include Non-Started Tests into Rerun Failed

## Test status icons

### IconDescription

	Test error. This status is assigned to tests that caused an exception from the tested source code.
	Test failed. If at least one test receives this status, then all its parents are marked as failed.
	Test ignored. In the PHP context, this icon indicates a skipped test.
	Test in progress.
	Test passed successfully.
	Test terminated. This status is assigned to tests that were cancelled by clicking the Stop button  . If at least one test receives this status, then all unfinished tests and their parents are marked as terminated.

## Output pane

This pane shows output of each test, generated at runtime, including all the messages sent to the output stream, and the error messages. The following table shows the toolbar buttons and context menu commands available for the Output pane.

### ItemKeyboardDescription Shortcut

	Up the Stack Trace	Click this button to navigate up in the stack trace and have the cursor jump to the corresponding location in the source code.
	Down the Stack Trace	Click this button to navigate down in the stack trace and have the cursor jump to the corresponding location in the source code.
	Use Soft Wraps	Click this button to toggle the soft wrap mode of the output.
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location in the source code.
	Print	Click this button to configure printing out the console output in the Print dialog box that opens.
Clear All		Choose this item on the context menu to have all messages for the selected test deleted.
Copy Content		Choose this item on the context menu to have the current contents of the Output pane placed to the Clipboard.
Compare with Clipboard		Choose this item on the context menu to invoke the <a href="#">Differences Viewer for Files</a> which shows the current contents of the Clipboard in the left-hand pane and the contents of the Output pane for the selected test in the right-hand pane.

## Context menu commands

### CommandKeyboardDescription shortcut

View assertEquals Difference		Choose this command to show the <a href="#">Differences viewer</a> for the strings being compared.  This command is only available when an assertion has failed.
Run <test name>		Run the selected test with the current <a href="#">temporary run/debug configuration</a> or choose another configuration from the subordinate context menu.
Debug <test name>		Debug the selected test with the current <a href="#">temporary run/debug configuration</a> or choose another configuration from the subordinate context menu.
Run <test name> with Coverage		Run the selected test and collect coverage data in accordance with the current <a href="#">temporary run/debug configuration</a> .
Create <test name>		<a href="#">Create a run/debug configuration</a> on the base of the selected test.

Save <test name>

Save the temporary run/debug configuration

Jump to Source

F4

Choose this command to move the focus to the editor, to the definition of a test class, or a test method.

Show Source

Ctrl+Enter

Choose this command to open source code in the editor, but leave the focus with the Test Runner tab.

Navigate to testdata

If a test class has a file with testdata, IntelliJ IDEA selects this file in the Project tool window .

The dialog box opens when you click the Export Test Results button  in the [Test Runner tab](#) of the [Run tool window](#).

In this dialog box, choose the format in which you want the test output saved and the file to save the test results in.

---

**ItemDescription**

---

Export format	In this area, choose the desired output format. The available options are: <ul style="list-style-type: none"><li>- HTML</li><li>- XML</li><li>- Custom, apply XSL template: choose this option to have the results presented according to your own code style. Select the relevant <code>*.xsl</code> code style definition file in the file chooser.</li></ul>
---------------	---

---

Output	In this section, specify the target file name ( File name ), and directory ( Folder ).
--------	--

---

Open exported file in browser	Select this checkbox to automatically open the above defined file with the test results in the default browser.
-------------------------------	---

A Groovy shell is a command-line application that lets you evaluate Groovy expressions, functions, define classes and run Groovy commands. The Groovy shell can be launched in Groovy projects.

Item	Tooltip and Shortcut	Description
------	----------------------	-------------

	Stop 	Click this button to stop the current process. Clicking the button once invokes <code>soft kill</code> allowing the application to catch the <code>SIGINT</code> event and perform graceful termination (on Windows, the <code>Ctrl+C</code> event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix <code>SIGKILL</code> is sent.
	Close 	Click this button to close the selected tab of the Run tool window and terminate the current process.
	Execute Groovy Code (  )	Run code, entered in the console.
	Help 	Use this icon or shortcut to open the corresponding help page.

Interactive Groovy console can be launched in any project.

Note that if dependencies in your project contain a Groovy library then the specified Groovy library will be used to launch the Groovy console. If the dependencies do not contain a Groovy library then the bundled Groovy library of the Groovy version 2.3.9 will be used.

## Editor for Groovy Console

Use the editor for the interactive Groovy console to write and evaluate your code.

### ItemDescription

	Click this icon to run the code entered in the editor in the Groovy console. You can view the results in the run tool window for Groovy console.
	Click this icon to see the module in which the Groovy console was launched. It might be helpful for multi-module projects.

## Run Tool Window for Groovy Console

Use this tool window to view the results of the Groovy console execution.

### ItemTooltip Description and Shortcut

	Stop  	Click this button to stop the current process. Clicking the button once invokes <code>soft kill</code> allowing the application to catch the <code>SIGINT</code> event and perform graceful termination (on Windows, the <code>Ctrl+C</code> event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix <code>SIGKILL</code> is sent.
	Close  	Click this button to close the selected tab of the Run tool window and terminate the current process.
	Up/down the Stack Trace    	Click this button to navigate up or down in the stack trace and have the cursor jump to the corresponding location in the source code.
	Use soft wraps	Click this button to toggle the soft wrap mode of the output.
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location in the source code.
	Print	Click this button to send the console text to the default printer.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.
	Execute Groovy Code (  )	Run code, entered in the console.
	Help  	Use this icon or shortcut to open the corresponding help page.

Note that the Play console is available for Play 1.x framework in the IntelliJ IDEA version 11.0. For later versions of IntelliJ IDEA refer to [Play 2.x](#) framework and its features.

The Tools | Play with Playframework command and the Play Framework tab or view in the Run tool window are available only under the following conditions:

- The Play framework Support [plugin](#) is enabled. See [Enabling and Disabling Plugins](#) .
- A Play application is currently open in IntelliJ IDEA. (In technical terms, the directory `<play_dir>\framework\lib` and the file `<play_dir>\framework\play-<version>.jar` are included in the [dependencies](#) of the [module](#) that represents your Play application.)

Use the Play Framework tab or view for running commands of the `play` command-line utility (the Play console) and performing other, related tasks.

The console workspace is divided into two parts. In the upper part, the console output is shown. The lower part is for the input; this is where you type the `play` commands (omitting the leading `play` ). The parts are separated with a horizontal line.

- [Toolbar](#)
- [Context menu for the output area](#)
- [Context menu for the input area](#)

## Toolbar

### IconShortcutDescription

	<code>Ctrl+F2</code>	Use this icon or shortcut to stop the Play application which is currently running (the one previously started by means of the <code>play run</code> command).
	<code>Ctrl+F4</code>	Use this icon or shortcut to close the Play Framework tab or view. If the Play application is currently running, you can also select to stop it in the dialog that opens.
	<code>Enter</code>	Use this icon or shortcut to run the current <code>play</code> command.
	<code>F1</code>	Use this icon or shortcut to open the corresponding help topic.
	<code>Ctrl+Alt+Up</code>	
	<code>Ctrl+Alt+Down</code>	
		Use this icon to turn the <a href="#">soft wrapping</a> mode in the console on or off.
		Use this icon to scroll down to the end of the console output.
		Use this icon to send the console output to the default printer.
		Use this icon to clear all the contents of the output area.

## Context menu for the output area

### CommandShortcutDescription

Copy	<code>Ctrl+C</code>	Use this command or shortcut to copy the selected text fragment to the clipboard. Note that this command is available only if something is currently selected in the output area.  If nothing is selected, you can still use <code>Ctrl+C</code> to copy all the contents of the output area to the clipboard.
Copy Reference	<code>Ctrl+Shift+Alt+C</code>	Use this command or shortcut to place the text <code>\Play Framework:1</code> onto the clipboard.
Compare with Clipboard		Use this command to compare selected text or all the contents of the output area (if nothing is currently selected) with the contents of the clipboard.
Search with Google		Use this command to search the Internet for the selected text fragment using Google. Note that this command is available only if something is currently selected in the output area.
Fold Lines Like This		Use this command to create a new folding pattern based on the current line. See also, <a href="#">Console</a> .
Clear All		Use this command to clear all the contents of the output area.

## Context menu for the input area

### CommandShortcutDescription

Cut	<code>Ctrl+X</code>	Use this command or shortcut to remove the selected text fragment from the
-----	---------------------	--

input area and to place it onto the clipboard.

Note that this command is available only if something is currently selected in the input area.

If nothing is selected, you can still use `Ctrl+X` to remove the whole command (without the leading `play`) and to place it onto the clipboard.

---

Copy	<code>Ctrl+C</code>	Use this command or shortcut to copy the text fragment selected in the input area to the clipboard. Note that this command is available only if something is currently selected in the input area.  If nothing is selected, you can still use <code>Ctrl+C</code> to copy the whole command (without the leading <code>play</code> ) to the clipboard.
Copy Reference	<code>Ctrl+Shift+Alt+C</code>	Use this command or shortcut to place the text <code>\Play Framework:1</code> onto the clipboard.
Paste	<code>Ctrl+V</code>	Use this command or shortcut to paste the last of the clipboard entries into the input area.
Paste from History	<code>Ctrl+Shift+V</code>	Use this command or shortcut to open the Choose Content to Paste dialog. This dialog lets you select the clipboard entry to be pasted into the input area.
Paste Simple	<code>Ctrl+Shift+Alt+V</code>	Use this command or shortcut to paste the last of the clipboard entries into the input area as plain text.
Compare with Clipboard		Use this command to compare selected text with the contents of the clipboard. If nothing is currently selected, the whole <code>play</code> command (without the leading <code>play</code> ) is used for comparison.
Search with Google		Use this command to search the Internet for the selected text fragment using Google. Note that this command is available only if something is currently selected in the input area.
Fold Lines Like This		Use this command to create a new folding pattern based on the current line. See also, <a href="#">Console</a> .

**Warning!** This page only appears when Python Plugin is installed and enabled!

Tools | Run manage.py task

\*.ipynb file toolbar | 

This tool window shows results of running the tasks of the `manage.py` utility.

**ItemDescription**

Click this button to run the previous task of the `manage.py` utility in a new tab.

Click this button to terminate the running process. After that, you can rerun it again.

Click this button to close the active tab.

**Note** This window is available only for modules with a Seam facet.

The Seam tool window provides a structured view of your Seam resources. These include annotated Java classes, the appropriate xml files, and the libraries referenced in your Seam components.

The resources are grouped by modules. The modules are the top hierarchical elements in the tree view.

You can expand and collapse the nodes in the tree view, access the dependency diagrams for your Seam components, and open the elements shown in the tool window in the editor.

- [Toolbar](#)
- [Context menu](#)
- [Opening elements in the editor](#)

## Toolbar

Use the toolbar buttons to expand and collapse the nodes in the tree view.

Item/Tooltip	Shortcut	Description
	Expand All	 Click this button to expand all the nodes.
	Collapse All	 Click this button to collapse all the nodes.

## Context menu

### Command/Description

Show Seam Components Dependencies	Use this command to open the diagram that shows the Seam components and dependencies between them for a selected module.
-----------------------------------	--

## Opening elements in the editor

You can open the elements shown in the Seam tool window in the editor. To do that, select the element of interest and press

.

To open the elements which are the "leaves" of the tree (i. e. the ones at the bottom of the hierarchy), you can also use a double click.

The Spring tool window lets you look at your project from the Spring perspective. It consists of two tabs:

- [Beans tab](#)
- [MVC tab](#)

Each tab consists of a set of panes where the contents of the selected item is shown in the pane to the right. The documentation (and, if applicable, a diagram) for the selected item is shown in the rightmost pane.

The toolbars in each tab control the amount and the type of data to be displayed.

The [context menu](#) commands allow you to switch between the panes and open items in the editor.

You can [filter the information](#) in the panes by entering a search string.

In this topic:

- [Beans tab](#)
  - [Beans tab toolbar](#)
- [MVC tab](#)
  - [MVC tab toolbar](#)
- [Context menu commands](#)
- [Filtering information](#)
- [Beans icons](#)

## Beans tab

The Beans tab allows you to view definitions for the Spring beans used in your project, and see how they are related to other beans.

The leftmost pane shows a list of modules that your project consists of. When you select a module, the list of filesets (contexts) appears on the right. The next pane shows the list of configuration files included in the selected context. The next pane shows the list of Spring beans defined in the selected configuration file. The rightmost pane shows documentation for the selected bean, and a diagram that shows this bean's relation to other beans.

### Beans tab toolbar

#### IconTooltipDescription

	Show modules	Select this option if you want the panes showing the modules, contexts and configuration files to be displayed. If this option is disabled, only the beans pane showing all beans used in your project is displayed.
	Show filesets	Select this option if you want the panes showing the filesets (contexts) and configuration files to be displayed. If this option is disabled, only the modules pane and the beans pane are displayed.
	Show configuration files	Select this option if you want the panes showing the configuration files to be displayed. If this option is disabled, only the modules pane, the filesets pane and the beans pane are displayed.
	Show Implicit Beans	Select this option if you want implicit beans to be displayed in the beans pane. Implicit beans are service beans added by the Spring framework and are not defined explicitly by the user.
	Show Infrastructure Beans	Select this option if you want infrastructure beans to be displayed in the beans pane. Infrastructure beans are service beans that form the structure of a context by pointing to configuration files where other beans are defined.
	Show Bean Documentation	Select this option if you want documentation for the selected bean to be displayed in the rightmost pane. The documentation pane shows the type of the selected bean (Spring Bean, specific namespace element, @Component, @Repository, etc.), the bean class, some bean attributes (prototype, @Qualifier, etc.), and the path to the file where this bean is declared.
	Show Bean Graph	Select this option if you want a diagram showing how the selected bean is related to other beans to be displayed in the rightmost pane.

## MVC tab

The MVC tab allows you to view controller mappings for the Spring MVC framework.

The leftmost pane shows a list of modules that your project consists of. When you select a module, the list of controllers that belong to this module appears on the right. The next pane shows the mappings defined for the selected controller. The rightmost pane shows documentation for the selected mapping.

### MVC tab toolbar

#### IconTooltipDescription

	Show modules	Select this option if you want the panes showing the modules to be displayed. If this option is disabled, only the controllers pane and the mappings pane are displayed.
	Show controllers	Select this option if you want the controllers pane to be displayed. If this option is disabled, only the modules pane and the mappings pane are displayed.

	Request Method	Click this icon to filter mappings by the HTTP method. Only the mappings that implement the methods selected in the popup menu are displayed in the mappings pane.
	Show documentation	Select this option if you want documentation for the selected mapping to be displayed in the rightmost pane. The documentation pane shows the mapping between the URL and the file that must be opened for this URL, and the HTTP method that this mapping implements.

## Context menu commands

The context menu is available in all panes of the [Spring Tool Window](#) and the [Spring Tool Window](#) except for the documentation pane.

### CommandShortcutDescription

Previous		Use this command to switch to the pane on the left of the current one.
Next		Use this command to switch to the pane on the right of the current one.
Edit		Use this command to view or edit the source code for the selected item in the editor. If a module is selected, this command opens this module's settings in the <a href="#">Project Structure</a> dialog.

## Filtering information

You can filter data in any pane of the [Beans tab](#) and the [MVC tab](#) except for the documentation pane. Place the cursor in a pane and start typing. As a result, only the items whose names contain the specified string will be displayed.

## Beans icons

The icons before the name of each bean in the list indicate the bean type:

-  : beans defined in XML files.
-  : Spring auto-discoverable beans declared through `@Component` annotations.
-  : service beans added by the Spring framework and not defined explicitly by the user.

The tool window is available only when the `Spy-js` plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

The tool window opens when you launch a run configuration of the type `Spy-js` or `Spy-js for Node.js`. As soon as the `Spy-js` tool captures an event, it shows the event itself, its details, and stack-traces. By clicking an event, you can open the `trace file`, which is a prettified `source file` with the script that the event launched.

The tool window consists of a common toolbar and two tabs with panes:

- [Trace Run Tab](#)
- [Trace Proxy Server Tab](#)

## Toolbar

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	Rerun 	Click this button to stop the current trace session and run it again. When the session is canceled externally by clicking  , the button toggles to  . Note that after the session restarts, you have to refresh the traced page in the browser to start capturing events.
	Rerun 	This button substitutes for  if the previous trace session was canceled externally by clicking  . Click  to initiate a new session. Note that after the session restarts, you have to refresh the traced page in the browser to start capturing events.
	Stop 	Click this button to terminate the current process externally by means of the standard <code>shutdown</code> script. Clicking the button once invokes <code>soft kill</code> allowing the application to catch the <code>SIGINT</code> event and perform graceful termination (on Windows, the  event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix <code>SIGKILL</code> is sent.
	Restore Layout	Click this button to to have the changes to the current layout abandoned and return to the default state.
	Pin	Use to pin or unpin the tab. If a tab is pinned, the results for the next command are shown on a new tab.
	Close 	Click this button to close the selected tab of the Run tool window and terminate the current process.
	Help 	Use this icon or shortcut to open the corresponding help page.

The tab consists of a toolbar and three panes: Events Pane , Event Stack Pane , and Quick Evaluation Pane .

On this page:

- [Events Toolbar](#)
- [Events Pane](#)
  - [Context Menu of a Document Node](#)
  - [Context Menu of an Event or Script](#)
  - [Configuring the Range of Events to Capture](#)
    - [Defining a new event filter](#)
    - [Activating a filter](#)
    - [Adding an event to an exclusion filter on the fly](#)
- [Event Stack Pane](#)
  - [Context Menu of a Script or Function](#)
- [Synchronization between the Panes and the Editor](#)
- [Quick Evaluation Pane](#)
  - [Context Menu of Function Call Details](#)

## Events Toolbar

Use the buttons on the toolbar to control the range of events to capture, configure their presentation, and navigate through the list of captured events.

Item	Tooltip and shortcut	Description
------	----------------------	-------------

	Expand all Ctrl+NumPad Plus	Click this button to have all the nodes in the list expanded.
	Collapse all Ctrl+NumPad -	Click this button to have all the nodes in the list collapsed.
	Up the Stack Trace	Click this button to navigate to the previous traced page in the stack trace.
	Down the Stack Trace	Click this button to navigate to the next traced page in the stack trace.
	Autoscroll to source	Press this toggle button to have the list in the Events pane automatically synchronized with the Editor . <ul style="list-style-type: none"><li>- When the button is pressed: as soon as you click an event in the Events pane, the details of the event are displayed in the Event Stack pane and the script that is invoked by the event is opened in the editor automatically.</li><li>When you navigate through the Event Stack with the Autoscroll to Trace mode turned on, the corresponding files are also automatically opened in the editor with the calling functions highlighted.</li><li>- When the button is released: the script that is invoked by the event is opened in the editor only upon double-clicking the event in the Event Stack pane.</li></ul>
	Capture Events	Click this button to configure the range of events to be captured and shown in the Events list. <p>By default, the <b>Spy-js</b> tool captures all events on all opened Web pages, excluding <b>https secure</b> web sites, unless you have specified a URL address explicitly in the run configuration. The Events pane of the <b>Spy-js</b> tool window shows all captured events. If for some reasons you do not want to have all events captured, you can suppress capturing some of them by applying user-defined event filters. When you click  , the pop-up list shows all the available filters, the currently applied filter is marked with a tick. By default the Capture All predefined filter is applied.</p> <p>To stop capturing events without stopping the application, choose <b>Mute All</b> . The application is still running but the Events pane shows the last captured event. This is helpful if you want to analyze a script and therefore need it to be displayed in the Events pane instead of being removed as new events are captured.</p> <p>To define a custom event filter:</p> <ol style="list-style-type: none"><li>1. Click  , and then choose <b>Edit Capture Exclusions</b> from the list.</li><li>2. In the <b>Spy-js Capture Exclusions Dialog</b> that opens, click <b>Add</b>  on the left-hand pane.</li><li>3. In the right-hand pane, specify the filter name in the <b>Exclusion name</b> field and configure a list of exclusion rules.<p>To add a rule, click  , the <b>Add Condition to Exclusion</b> dialog box opens. Type a pattern in the <b>Value/pattern</b> text box, in the <b>Condition type</b> drop-down list specify whether the pattern should be applied to event types or script names. Note that <a href="#">glob pattern matching</a> is used. When you click <b>OK</b> , IntelliJ IDEA brings you to the <b>Spy-js Capture Exclusions Dialog</b> .</p><p>To edit a rule, select it in the list, click  , and update the rule in the dialog box that opens. To remove a rule, select it in the list and click <b>-</b> .</p></li></ol> <p>To activate a filter, set a tick next to the required filter in the list.</p>
		Click this button to remove all or some events from tracing and have the corresponding trace files closed in the editor. Choose one of the following options on the drop-down list that is displayed:

- Remove all: choose this option to cancel tracing of all captured events without closing the trace files in the editor.
- Close all trace files: choose this option to have all trace files in the editor closed but keep tracing the corresponding event. To remove an event or script from tracing and close the corresponding trace files in the editor, choose Remove on the context menu of the event or script.
- Remove all inactive: choose this option to remove all nodes for pages that are not active anymore (for example, because the pages have been closed in browser).
- Save trace: choose this option to save an image of the current session. The `.json` files that store the calls and properties of the session are compressed into a `zip` archive. Upon request, when you choose Load trace, the `.json` files are extracted from the archive and loaded into Spy-js.
- Load trace: choose this option to have a previously saved image of a tracing session loaded into Spy-js. The `.json` files that store the calls and properties of that session are extracted and imported. Note that a loaded image does not restore the session because no scripts are actually executed. All you can do is analyze the flow and properties of previously executed code.
- Close all trace files on session stop: choose this option to have all trace files in the editor closed when you click the Stop button  to stop the tracing session externally by means of the standard `shutdown` script. Clicking the button once invokes `soft kill` allowing the application to catch the `SIGINT` event and perform graceful termination (on Windows, the `Ctrl+C` event is emulated). After the button is clicked once, it is replaced with  indicating that subsequent click will lead to force termination of the application, e.g. on Unix `SIGKILL` is sent.
- Enable Spy-js autocomplete and magnifier: choose this option to have the basic completion list expanded with runtime data ( `Spy-js autocompletion` ) and to get the possibility to evaluate expressions without actually running a debugging session ( `Spy-js magnification` ). By default, the functionality is turned off. The term `Spy-js autocompletion` denotes expanding the `basic completion list` with suggestions retrieved from the runtime data. The `Spy-js autocompletion` functionality is available from `source` files for the code that has already been executed (highlighted green in the corresponding trace file).

When you position the caret at a symbol in the source file and press `Ctrl+Space`, Spy-js retrieves data from the browser or from the running Node.js application and merges it with the basic completion list according to the following rules:

1. If an object both is present on the basic completion list and is retrieved from the runtime, the variant that provides more information about parameters, attributes, their type, etc. remains on the list.
2. Objects retrieved by `Spy.js` are shown on top of the list and marked with the  icon. If a retrieved object is specific for a browser, the object is marked with the  icon and with the icon of this browser.

The term `Spy-js magnification` denotes `evaluating expressions` without actually running a debugging session. When you click the expression in question or position the caret at it and press `Ctrl+Alt+F8`, a tooltip is displayed below the expression showing the expression value. If `Spy-js` retrieves several values, click  icon in the tooltip to expand the list of values.

The magnification functionality is available from source files for both executed and not yet executed code.

- `Spy-js` supports `source maps`, which means that you can now jump from the Event Stack pane right to the original source code in `ECMAScript 6`, `TypeScript` or `CoffeeScript` and observe what code fragments were executed. Use the following options to configure the way source maps are treated:
  - Enable source map look-up: choose this option to enable navigation to the `ECMAScript 6`, `TypeScript` or `CoffeeScript` source code using the source maps generated during compilation.
  - Enable source map generation: choose this option to generate source maps for everything to map the instrumented code. Choose this option if you are going to debug the original code in `Chrome Dev Tools` or `Firefox FireBug` development tools.
  - Always open source mapped trace if available: choose this option to have `Spy-js` try to open the mapped trace file when you invoke navigation from an event to its caller.

## Events Pane

The pane shows a tree of captured events. The top-level nodes represent `documents` that are Web pages involved in tracing. When you hover the mouse over a `document`, IntelliJ IDEA displays a tooltip with the URL address of the `document`, the browser in which it is opened, and the operating system the browser is running on. The `document` node is also supplied with an icon that indicates the browser in which it is opened.

Under each `document` node, events detected on the page and scripts started from it are listed. Events of the same type are grouped into visual containers. The header of a container displays the name of the events grouped in it, the average execution time across all the events within the container, and the number of events inside the container. You can expand each node and inspect the individual events in it.

Script file names have different colour indicators to help distinguishing between them when working with the Event Stack pane. By hovering your mouse over a script file name, you can see the full script URL.

Once an event is clicked, its call stack is displayed in the Event Stack pane. The stack is represented by a tree of function calls.

## Context Menu of a Document Node

### MenuDescription item

Remove	Choose this option to cancel tracing all the scripts on the selected page and remove the selected node with all the items under it from the Events pane. All the currently opened trace files remain opened in the editor.
Remove all children	Choose this option to delete the items under the selected page but keep tracing it so that new events from the page are still received. The document node itself remains in the Event pane, and all the currently opened trace files remain opened in the editor.
Remove and close trace file(s)	Choose this option to cancel tracing all the scripts on the selected page, remove the selected node and all the items under it from the Events pane, and close the corresponding trace files in the editor.

Close trace file(s)	Choose this option to close all the currently opened trace files that correspond to the selected document node and items under it. The document node and the items under it remain in the Events pane.
Refresh the page in browser	Choose this option to reload the page that corresponds to the selected document node. Tracing of the selected node is abandoned, a new document node for tracing the same page is created, and the old node becomes <i>inactive</i> .
Try closing the page in browser	Choose this option to close the page that corresponds to the selected node. Tracing of the selected node is abandoned, and the node becomes <i>inactive</i> .
Show application dependency diagram	Choose this option to build a diagram with the dependencies within the entire application. <ul style="list-style-type: none"> <li>– The diagram is opened in a separate editor tab. The nodes in the diagram represent your project files, while the edges represent the fact that there's one or more functions in the source file that invoke functions in the target file.</li> <li>– To examine the details of a node or an edge, select the node or the edge in question and view its Details tree in a dedicated pane in the upper right-hand corner of the editor. The pane displays the connecting function combinations, along with event(s) the calls are made within and the number of calls made.</li> </ul>

## Context Menu of an Event or Script

### MenuDescription item

Mute event	Choose this option to add an event to an exclusion filter on the fly.
Mute script	Choose this option to add a script to an exclusion filter on the fly.
Remove	Choose this option to cancel tracing the selected event or script, remove the selected item from the Events pane, but leave the corresponding trace files opened in the editor.
Add label	Choose this option to set a timestamp label. Timestamp labels help you to analyze your code execution within a specific period of time. For example, you can set two timestamp labels and view which events were captured between them. Or on the contrary, you can locate the events that were not captured within a certain period of time although you expected them to be and thus detect performance problems.
Show event dependency diagram	Choose this option to build a diagram with the dependencies in which the event selected event is invoked. <ul style="list-style-type: none"> <li>– The diagram is opened in a separate editor tab. The nodes in the diagram represent your project files, while the edges represent the fact that there's one or more functions in the source file that invoke functions in the target file.</li> <li>– To examine the details of a node or an edge, select the node or the edge in question and view its Details tree in a dedicated pane in the upper right-hand corner of the editor. The pane displays the connecting function combinations, along with event(s) the calls are made within and the number of calls made.</li> </ul>

## Configuring the Range of Events to Capture

By default, the **Spy-js** tool captures all events on all opened Web pages, excluding **https secure** web sites, unless you have specified a URL address explicitly in the run configuration. The Events pane of the Spy-js tool window shows all captured events. If for some reasons you do not want to have all events captured, you can suppress capturing some of them by applying user-defined event filters. All the available filters are listed upon clicking the Capture Events button  on the toolbar, the currently applied filter is marked with a tick. By default the Capture All predefined filter is applied.

To stop capturing events without stopping the application, choose Mute All. The application is still running but the Events pane shows the last captured event. This is helpful if you want to analyze a script and therefore need it to be displayed in the Events pane instead of being removed as new events are captured.

You can define new custom filters or add event patterns to existing filters on the fly.

### Defining a new event filter

1. Click the Capture Events button  on the toolbar, and then choose Edit Capture Exclusions from the list.
2. In the **Spy-js Capture Exclusions Dialog** that opens, click Add  on the left-hand pane.
3. In the right-hand pane, specify the filter name in the Exclusion name field and configure a list of exclusion rules.
  - To add a rule, click , the Add Condition to Exclusion dialog box opens. Type a pattern in the Value/pattern text box, in the Condition type drop-down list specify whether the pattern should be applied to event types or script names. Note that [glob pattern matching](#) is used. When you click OK, IntelliJ IDEA brings you to the **Spy-js Capture Exclusions Dialog**.
  - To edit a rule, select it in the list, click , and update the rule in the dialog box that opens. To remove a rule, select it in the list and click .

### Activating a filter

- Click  and set a tick next to the required filter in the list. If no filters are configured or none of the available filters fits the task, create a new filter as described above.

### Adding an event to an exclusion filter on the fly

While navigating through the tree of already captured events in the Events pane, you may come across some events or scripts that you definitely do not want to trace. You can create a filter as described above but in this case you will have to leave the pane. With IntelliJ IDEA, you can create an exclusion rule based on any event or

script, as soon as you have detected such event or script, right from the Events pane. The rule will be either added to the currently applied filter or a new filter will be created if the current setting is Capture All .

- To add an event to an exclusion filter on the fly, select the event to exclude and choose Mute <event name> event or Mute <script name> file .

If a user-defined filter is currently applied, the new rule is added to it silently. If Capture All is currently active, the [Spy-js Capture Exclusions Dialog](#) opens, where you can create a new filter based on the selected event or script or choose an existing filter and add the new rule to it.

## Event Stack Pane

Once an event in the Events pane is clicked, its call stack is displayed in the Event Stack pane. The stack is represented by a tree of function calls. Each tree node represents the invoked function. Node text contains the total execution time, the script file name and the function name. When you click a node, the Quick Evaluation pane shows additional function call details, parameter values and return value, occurred exception details if there was one during the function execution.

The pane is synchronized with the editor, so you can navigate from an item in the stack tree to the corresponding **trace file** or **source file** .

- A **trace file** is a write-protected prettified version of the script selected in the Events pane or the script whose function is double clicked in the Event Stack pane. A **trace file** is named `<file name>.js.trace` . When you double click an item in the stack tree or select it and choose Jump to Trace on the context menu of the selection, the corresponding **trace file** opens in the editor with the cursor positioned at the clicked function. Another approach is to press the Autoscroll to Trace toggle button and select various stack nodes. In this case, the trace file opens when you click an event or script in the Events pane.

You can not only jump to a function but also to the place in the code where it was called from. To do that, select the required item and choose Jump to Caller on the context menu.

The contents of the file are highlighted to display the code execution path of the selected stack node.

- When you are tracing an application with **ECMAScript6** , **CoffeeScript** , and **TypeScript** code, **Spy-js** also generates **mapped trace files** . These are **EcmaScript6** , **TypeScript** , or **CoffeeScript** trace files with the extensions `.ts.trace` , `.coffee.trace` , or `.js.trace` . The fragments of code in these files are highlighted as if they were really executed.

- You can also navigate to the **source file** displayed as is, without prettifying, by selecting an item in the Event Stack pane and choosing Jump to Source on the context menu of the selection. If the traced site is mapped with a IntelliJ IDEA project, IntelliJ IDEA detects the corresponding local file according to the mapping and opens this file in the editor. If you are tracing a site that is not mapped to a IntelliJ IDEA project, IntelliJ IDEA opens the read-only **page source** , just as if you chose View Page Source in the browser.

When the traced site is mapped with a IntelliJ IDEA project, IntelliJ IDEA opens the **source file** on any attempt to edit the opened **trace file** .

## Context Menu of a Script or Function

### ItemDescription

- Jump to Caller Choose this option to navigate to the fragment in the **trace file** from where the currently selected item was called. When you are tracing an application with **ECMAScript6** , **CoffeeScript** , and **TypeScript** code, IntelliJ IDEA opens either the **trace JavaScript** file or the **mapped trace file** (TypeScript, CoffeeScript, or ECMAScript6):
- If the Always open source mapped trace if available option is selected, the corresponding mapped trace file opens.
  - If the Always open source mapped trace if available option is not selected, the JavaScript trace file opens.

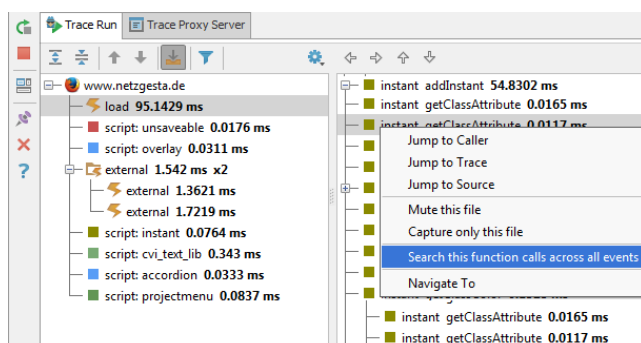

- Jump to Trace Choose this option to navigate to the definition of the currently selected item in the **trace file** .

- Jump to Source Choose this option to navigate to the definition of the currently selected item in the **source file** .

- Mute this File Choose this option to add the selected script to an exclusion filter on the fly, see [Configuring the Range of Events to Capture](#) .

- Capture only this file

- Search this function calls across all events Choose this option to navigate between the calls of a function within the whole trace (across all the traced events). This means that if you are tracing 5 pages in the browser and the Events pane, accordingly, shows 5 document nodes, IntelliJ IDEA searches for the calls of the selected function under all these nodes and displays the number of found calls of the function in the Status bar. The number of found calls is displayed in the Status bar, and the toolbar shows four previously hidden navigation chevron buttons.

Use the chevron buttons to navigate within the found calls:

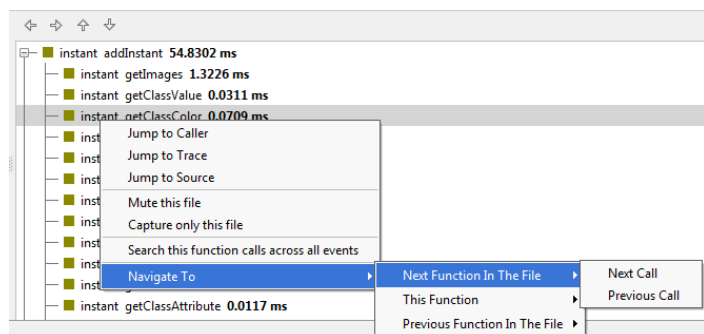

- To jump to the first detected call, click .
- To jump to the last detected call, click .
- To jump to the next detected call, click . The Status bar shows a message: Occurrence <number> of <total number of detected calls>
- To jump to the previous detected call, click .

The search results are reset and the search toolbar is hidden when you invoke another advanced search or navigation.

Also keep in mind that the number of call occurrences is calculated when you choose the Search this function calls across all events option. As you analyze the detected calls, the time passes, new events are captured, and the first detected call can happen to be already removed from the stack which means that it is no longer available for navigation.

**Navigate to** Use the options under this item to move through the whole stack based on calls and locate the functions that have not been called, that is, locate the fragments of code that have not been executed and analyze the reason for them to be skipped.

The following six actions are available: move to the next/previous call of the next/current/previous function in a trace file. The full list of actions is available from the context menu in the Event Stack pane. Moving to the next and previous calls of the selected function, to the previous call of the previous function, and to the next call of the next function are also available from the navigation toolbar of the Event Stack pane.

When you choose one of these actions, the cursor jumps to the call in the stack. If the Autoscroll to Trace toggle button is pressed, the corresponding trace file opens automatically with the cursor positioned at the call.

## Synchronization between the Panes and the Editor

The Events and Event Stack panes are synchronized: when you click an event or script in the Events pane, its call stack is displayed in the Event Stack pane. To have also the corresponding trace file opened in the editor, press the Autoscroll to Trace toggle button on the toolbar.

The Event Stack pane is synchronized with the editor: when you click an item in the stack tree twice, the corresponding trace file opens in the editor with the cursor positioned at the clicked function.

To synchronize the Events pane directly with the editor, press the Autoscroll to Trace toggle button on the toolbar. In this case, as soon as you click a node in the Events pane, its call stack is displayed in the Event Stack pane and the corresponding trace file is opened in the editor. With the Autoscroll to Trace mode turned on, when you navigate through the Event Stack the corresponding files are also automatically opened in the editor with the corresponding functions highlighted.

## Quick Evaluation Pane

When you click a node in the Event Stack pane, the Quick Evaluation pane shows additional function call details, parameter values and return value, occurred exception details if there was one during the function execution.

## Context Menu of Function Call Details

The context menu is available from all items displayed in the pane.

### ItemDescription

Inspect	Choose this option to open the Inspect dialog box.
Copy Value	Choose this option to copy the value of the selected node to the clipboard.
Compare Value with Clipboard	Choose this option to open the <a href="#">Differences Viewer for Files</a> which displays the value of the selected node and the value in the clipboard so you can compare them.
Copy Name	Choose this option to copy the name of the selected node to the clipboard.

The dialog box opens when you click the Capture Events button  toolbar button in the Events pane of the [Spy-js Tool Window](#). In this dialog box, define custom filters to configure the range of events displayed and traced in the tool window. See [Spy-js](#) for details.

The dialog box consists of two panes. The left-hand, Exclusions, pane shows a list of already existing user-defined event filters. The right-hand, Exclusion, pane shows the details of the filter selected in the Exclusions pane.

#### ItemDescription

---

Exclusions pane	<p>The pane shows a list of all currently available user-defined filters.</p> <ul style="list-style-type: none"><li>- To define a new event filter, click  on the toolbar, then specify the filter name and exclusion rules in the Exclusion pane.</li><li>- To create a filter based on an already existing one, make a copy of the source filter by selecting it and clicking , and then rename and edit the copy as required in the Exclusion pane.</li><li>- To temporarily disable a filter, clear the checkbox next to it.</li><li>- To remove a filter from the list, select it and click .</li></ul>
-----------------	---

Exclusion pane	<p>On this pane, configure custom event filters. For each filter, specify its name and create a list of exclusion rules.</p> <ul style="list-style-type: none"><li>- To add a rule, click , the Add Condition to Exclusion dialog box opens. Type a pattern in the Value/pattern text box, in the Condition type drop-down list specify whether the pattern should be applied to event types or script names. Note that <a href="#">glob pattern matching</a> is used. When you click OK, IntelliJ IDEA brings you to the <a href="#">Spy-js Capture Exclusions Dialog</a>.</li><li>- To edit a rule, select it in the list, click , and update the rule in the dialog box that opens.</li><li>- To remove a rule, select it in the list and click .</li></ul>
----------------	---

The tab consists of a toolbar and the console area that shows system information and error messages, information about the status of the **Spy-js** session, the availability of the proxy server, the currently active frames ("workers"), etc.

## Trace Proxy Server Toolbar

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	Stop Trace Proxy Server	Click this button to terminate the currently running process externally by means of the standard <code>shutdown</code> script.
	Up/Down the Stack Trace	Use these buttons to navigate through the stack trace from one reported error to another. These buttons are available only when errors are reported, for example, if the configuration file is corrupted.  
	Use soft wraps	Click this button to toggle the soft wrap mode of the output.  
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location in the source code.
	Print	Click this button to send the console text to the default printer.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.

## Structure tool window

This tool window displays the structure of a file currently opened in the editor and having the focus, or selected in the Project tool window.

For diagrams, this tool window shows the diagram preview.

View | Tool Windows | Structure

Alt+7

## File Structure pop-up window

This pop-up window displays the structure of a file, currently opened in the editor and having the focus.

Navigate | File Structure

Ctrl+F12

Both views help quickly navigate through the files' structure. Refer to the section [Navigating with Structure Views](#).

This section describes the buttons on the title bar of the tool window and the options on the context menu of the title bar. Turn these options on and off to have elements of certain types hidden or shown and configure the way they are presented.

The buttons on the title bar are common for all language contexts. The set of options on the context menu depends on the context.

- [Title Bar](#)
- [Java](#)
- [HTML, XML](#)
- [JavaScript, TypeScript, CoffeeScript, ActionScript](#)
- [Properties](#)
- [PHP](#)

**Tip** Refer to the section [Symbols](#) for the member icons in the tree view of a file in the Structure tool window.

## Title Bar

The buttons on the title bar are common for all language contexts.

### ItemTooltipDescription

	<b>Collapse All</b> Ctrl+NumPad -	Click this button to have all the nodes in the tool window collapsed.
	<b>Expand All</b> Ctrl+NumPad Plus	Click this button to have all the nodes in the tool window expanded.
		Click this button to open the context menu and configure the appearance of the tool window, its <a href="#">viewing mode</a> , and the way it presents the structure of the current file by turning the menu items on or off.
	<b>Hide</b> Shift+Escape	Click this button to hide the tool window.

## Java

### Icon TooltipDescription

	<b>Sort by Visibility</b>	Click this button to have the items sorted by their visibility in the following order:  public - protected - package local - private.
	<b>Sort Alphabetically</b>	Click this button to have the elements within a class sorted alphabetically.
<b>Tip</b> When both  (Sort by Visibility) and  (Sort Alphabetically) buttons are pressed, the items in the view are grouped according to their visibility levels. Within each visibility level group, the items are sorted alphabetically. When both buttons are released, the items are shown in the order they appear in the code.		
	<b>Group Methods by Defining Type</b>	Click this button to have all the methods that override/implement the methods of a particular class/interface grouped under the node that corresponds to this class/interface.
	<b>Show Properties</b>	Click this button to show getters, setters, and fields in the tree view.
	<b>Show Inherited</b>	Click this button to display all the methods and fields inherited by the current class and accessible from it. The

inherited members are displayed gray to distinguish them from the members defined in the current class.

	Show Anonymous	Click this button to have the inner anonymous classes shown in the tree view.
	Show Fields	Click this button to have all fields (properties) shown in the tree.
	Show non-public	Click this button to have all non-public class members displayed.  Turn off the option to hide all non-public members.
	Collapse All <code>Ctrl+NumPad -</code>	Click this button to have all the nodes in the tool window collapsed.
	Expand All <code>Ctrl+NumPad Plus</code>	Click this button to have all the nodes in the tool window expanded.
	Autoscroll to Source	Click this button to enable automatic navigation to the line of source code that corresponds to the selected node when the focus switches to the editor.
	Autoscroll from Source	Click this button to have IntelliJ IDEA automatically move the focus in the Structure tool window to the node that corresponds to the code where the cursor is currently positioned in the editor.

## HTML, XML

### IconTooltipDescription

	Sort Alphabetically	Click this button to have the elements within a class sorted alphabetically.
	HTML5 Outline	Click this button on to view HTML 5 outline of a HTML file:  
	Collapse All <code>Ctrl+NumPad -</code>	Click this button to have all the nodes in the tool window collapsed.
	Expand All <code>Ctrl+NumPad Plus</code>	Click this button to have all the nodes in the tool window expanded.
	Autoscroll to Source	Click this button to enable automatic navigation to the line of source code that corresponds to the selected node when the focus switches to the editor.
	Autoscroll from Source	Click this button to have IntelliJ IDEA automatically move the focus in the Structure tool window to the node that corresponds to the code where the cursor is currently positioned in the editor.

## JavaScript, TypeScript, CoffeeScript, ActionScript

### IconTooltipDescription

	Sort Alphabetically	Click this button to have the elements within a class sorted alphabetically.
	Group Methods by Defining Type	Click this button to have all the methods that override/implement the methods of a particular class/interface grouped under the node that corresponds to this class/interface.
	Show Fields	Click this button to have all fields (properties) shown in the tree.
	Show Inherited	Click this button to display all the methods and fields inherited by the current class and accessible from it. The inherited members are displayed gray to tell them from the members defined in the current class.
	Collapse All <code>Ctrl+NumPad -</code>	Click this button to have all the nodes in the tool window collapsed.
	Expand All <code>Ctrl+NumPad Plus</code>	Click this button to have all the nodes in the tool window expanded.
	Autoscroll to Source	Click this button to enable automatic navigation to the line of source code that corresponds to the selected node when the focus switches to the editor.
	Autoscroll from Source	Click this button to have IntelliJ IDEA automatically move the focus in the Structure tool window to the node that corresponds to the code where the cursor is currently positioned in the editor.

## Properties

### IconTooltipDescription

	Sort Alphabetically	Click this button to have the elements within a property file sorted
---	---------------------	--

alphabetically.

	Sort by Type	Click this button to have the elements within a class sorted according to their types.
	Group by prefix	Click this button to have the elements within a property file grouped according to their prefixes.
	Collapse All <code>Ctrl+NumPad -</code>	Click this button to have all the nodes in the tool window collapsed.
	Expand All <code>Ctrl+NumPad Plus</code>	Click this button to have all the nodes in the tool window expanded.
	Autoscroll to Source	Click this button to enable automatic navigation to the line of source code that corresponds to the selected node when the focus switches to the editor.
	Autoscroll from Source	Click this button to have IntelliJ IDEA automatically move the focus in the Structure tool window to the node that corresponds to the code where the cursor is currently positioned in the editor.

## PHP

### Title Bar

Besides the buttons that are common for all language contexts, the title bar in the PHP context contains two additional toggle buttons.

#### IconTooltipDescription

PHP	Toggle this button to view the hierarchy of PHP elements. The button is always present on the toolbar but is enabled only when the current PHP class or file contains fragments of HTML code.
HTML	Toggle this button to view the hierarchy of HTML elements in a PHP class or file. The button is only available if the current PHP class or file contains fragments of HTML code.

### Context Menu

#### IconTooltipDescription

	Sort by Visibility	Click this button to have the items sorted by their visibility in the following order:  public - protected - package local - private.
	Sort Alphabetically	Click this button to have the elements within a class sorted alphabetically.
	Show Inherited	Click this button to display all the methods and fields inherited by the current class and accessible from it. The inherited members are displayed gray to distinguish them from the members defined in the current class.
	Show Includes	Click this button to have all files included through <code>include</code> or <code>require</code> statements shown in the tree.
	Show Fields	Click this button to have all fields (properties) shown in the tree.
	Show Constants	Click this button to have constants shown in the tree.
	Collapse All <code>Ctrl+NumPad -</code>	Click this button to have all the nodes in the tool window collapsed.
	Expand All <code>Ctrl+NumPad Plus</code>	Click this button to have all the nodes in the tool window expanded.
	Autoscroll to Source	Click this button to enable automatic navigation to the line of source code that corresponds to the selected node when the focus switches to the editor.
	Autoscroll from Source	Click this button to have IntelliJ IDEA automatically move the focus in the Structure tool window to the node that corresponds to the code where the cursor is currently positioned in the editor.

The Struts Assistant tool window appears when you open a project that contains a module with enabled [Struts support](#). Use this tool window to [manage elements](#), [tiles](#), and [validators](#) in a Struts application.

The Struts Assistant tool window has three tabs:

- The [Struts tab](#) for [managing Struts elements](#) in the `struts-config.xml` configuration file.
- The [Tiles tab](#) for managing Struts tiles in the `tiles-defs.xml` definition file.
- The [Validator tab](#) for defining action-specific validation rules.

The Struts Assistant tool window displays three views:

- The Structure Tree shows the structure of the Struts configuration file `struts-config.xml` depending on the current tab.
- The Properties Table shows the attributes of the node selected in the Structure Tree.
- The Struts Web Flow Diagram graphically presents the relations among the elements of your application.  
The Struts Web Flow Diagram appears in the Struts tab only.

The views are synchronized. If a node is selected in the Structure Tree, the Properties Table shows the node's attributes. If a node has a corresponding diagram object, this diagram object is selected as well.

## Common Toolbar Buttons

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	Autoscroll to Source	Click this button to enable navigation from the selected element in the Structure Tree to the corresponding source code block in the <code>struts-config.xml</code> configuration file (opening it, if necessary).
	Autoscroll from Source	Click this button to enable navigation from a source code block in the <code>struts-config.xml</code> configuration file to the corresponding node in the Structure Tree.
	Expand all	Use these buttons to have all nodes expanded or collapsed.
	Collapse all	
		
		

The tab is available from the [Struts Assistant tool window](#).

Use this tab to [manage the Struts tiles](#) in your application.

## Root node tiles-defs.xml

**ItemName**    **Description**  
and  
**tooltip**

	tiles-defs.xml	The root node of the application tiles' structure tree.
---	----------------	---

Context menu (same for all nodes)

	Jump to source	Select this menu item to switch to the code block in the <code>tiles-defs.xml</code> file, text view, that corresponds to the selected item in the tree.
	Expand All	Click this button to expand all nodes.
	Collapse All	Click this button to collapse all nodes.

## Tile definition

**ItemName**    **Description**  
and  
**tooltip**

	Tile	The node under which an application tile is defined.
---	------	--

Context menu

	Add Put	Select this menu item to add a new <code>&lt;put&gt;</code> element to the tile definition.
	Add Put List	Select this menu item to add a list of <code>&lt;put&gt;</code> elements to the tile definition.
	Remove Definition	Select this menu item to remove the tile definition.

The tab is available from the [Struts Assistant tool window](#).

Use this tab to define [validation procedures](#) for specific actions.

## validator-rules.xml node

**ItemName**   **Description**  
and  
**tooltip**

	validator-rules.xml	The node under which the definitions of standard validation routines are placed.
Context menu (same for all nodes)		
	Jump to source	Select this menu item to switch to the code block in the <code>validator-rules.xml</code> file, text view, that corresponds to the selected item in the tree.
	Expand All	Click this button to expand all nodes.
	Collapse All	Click this button to collapse all nodes.
	Global	The node under which the definitions of global validation routines are placed.
Context menu		
	Add Constant	Select this menu item to add a constant to the selected validation routine.
	Add Validator	Select this menu item to add a standard routine validator.
	Remove	Select this menu item to remove the entire Global node or Global/Validator the selected Validator.
	validation.xml node	

The tab is available from the [Struts Assistant tool window](#).

Use this tab to [manage Struts elements](#) in the `struts-config.xml` configuration file.

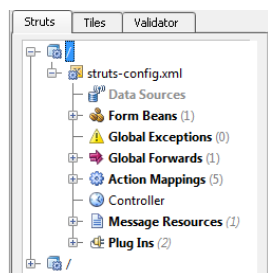

The tab displays three views:

- [Structure Tree](#)
- [Properties Table](#)
- [Web Flow Diagram](#)

The views are synchronized. If a node is selected in the Structure Tree, the Properties Table shows the node's attributes. If a node has a corresponding diagram object (for example, an Action cell or a Forward edge), this diagram object is selected as well.

## Structure Tree

The view shows the [Struts elements](#) that are used in your application as nodes of a structure tree. As you create, edit, and remove these nodes and their subordinate items, these changes are immediately reflected in the `struts-config.xml` configuration file.

### ItemName Description and tooltip

	struts-config.xml	The root node of the application structure tree.
Context menu (the same for all nodes)		
	Jump to source	Select this menu item to switch to the code block in the <code>struts-config.xml</code> file, text view, that corresponds to the selected item in the tree.
	Expand All	Click this button to expand all the nodes in the tree.
	Collapse All	Click this button to collapse all the nodes in the tree.

The view shows the following Struts element nodes:

- [Form Beans Node](#)
- [Global Exceptions Node](#)
- [Global Forwards Node](#)
- [Action Mappings Node](#)
- [Controller Node](#)
- [Message Resources Node](#)
- [Plugins Node](#)

## Form Beans Node

### ItemName Description and tooltip

	Form Beans	Under this node, manage form beans and their properties. The following actions are available through the context menu of the Form Beans node:
	Add Form	Select this menu item to add a new form

Bean	bean to the application.
Remove Form Beans	Select this menu item to remove all the form beans from the application.

 **Form Bean** A form bean node.  
The following actions are available through the context menu of a Form Bean :

Add Form Property	Select this menu item to add a form property to the bean.
Add Set Property	Select this menu item to add a set property to the bean or to a form property.
Remove Bean/ Form Property/ Set Property	Select this menu item to remove the entire bean or its form or set property.

 **Form Property** Bean's form property.

 **Set Property** A set property of the bean or a form property.

### Global Exceptions Node

**ItemName and tooltip**

	<b>Global Exceptions</b> Under this node, manage global exceptions and their properties. The following actions are available on the context menu of the Global Exceptions node:
Add Global Exception	Select this menu item to add a new global exception to the application.
Remove Global Exceptions	Select this menu item to remove all the global exceptions from the application.

 **Global Exception** A global exception node.  
The following actions are available on the context menu of a Global Exception :

Add Set Property	Select this menu item to add a set property to the global exception.
Remove Exception/ Set Property	Select this menu item to remove the entire global exception or its set property.

 **Set Property** A set property of the global exception.

### Global Forwards Node

**ItemName and tooltip**

	<b>Global Forwards</b> Under this node, manage global forwards and their properties. The following actions are available on the context menu of the Global Forwards node:
---	--

Add Global	Select this menu item to add a new global
------------	---

Forward forward to the application.

Remove Global Forwards Select this menu item to remove all the global forwards from the application.

 Global Forward A global forward node. The following actions are available on the context menu of a Global Forward :

Add Set Property Select this menu item to add a set property to the global forward.

Remove Exception/Set Property Select this menu item to remove the entire global forward or its set property.

 Set Property A set property of the global forward.

## Action Mappings Node

**ItemName and tooltip**

 Action Mappings Under this node, manage the action mappings within the application, mapping properties, forwards, and exceptions. The following operations are available on the context menu of the Action Mappings node:

Add Action Select this menu item to add a new action to the application.

Remove Action Mappings Select this menu item to remove all the action mappings from the application.

 Action An action node. The following operations are available on the context menu of an Action :

Add Exception Select this menu item to add an exception to the Exceptionaction.

Add Forward Select this menu item to add a forward to the Forward action.

Add Set Property Select this menu item to add a set property to the action or actions's forward or action's exception.

 Exception An exception defined within the action.

 Global Forward A forward within the action.

 Set Property A set property of the action, or action's forward, or action's exception.

## Controller Node

**ItemName and tooltip**

 Controller Under this node, manage the properties of the application controller. The following operations are available on the context menu of the Controller node:

Add Set Property Select this menu item to add a set property

Property to the controller.

Set A set property of the controller.  
Property

Remove Select this menu item to remove the Controller/controller or its set property from the application.

Set  
Property

## Message Resources Node

**ItemName and tooltip**

	<b>Message Resources</b>	<p>Under this node, manage the message resources of the application.</p> <p>The following operations are available on the context menu of the Message Resources node:</p> <hr/> <p>Add Message Resource Select this menu item to add a message resource to the application.</p> <hr/> <p>Remove Message Resources Select this menu item to remove the all message resources from the application.</p>
	<b>Message Resource</b>	<p>A message resource of the application.</p> <p>The following operations are available on the context menu of a Message Resource :</p> <hr/> <p>Add Set Property Select this menu item to add a set property to the message resource.</p> <hr/> <p>Remove Message Resources/ application. Select this menu item to remove the message resource or its set property from the application.</p> <p>Set Property</p>
	<b>Set Property</b>	<p>A set property of the message resource.</p>

## Plugins Node

**ItemName and tooltip**

	<b>Plugins</b>	<p>Under this node, manage the application plugins.</p> <p>The following operations are available on the context menu of the Plugins node:</p> <hr/> <p>Add Plugin Select this menu item to add a new plugin to the application.</p> <hr/> <p>Remove Plugins Select this menu item to remove all plugins from the application.</p>
	<b>Plugin</b>	<p>A plugin node.</p> <p>The following operations are available on the context menu of a Plugin :</p> <hr/> <p>Add Set Property Select this menu item to add a set property to the plugin.</p> <hr/> <p>Remove Plugin/Set Property Select this menu item to remove the entire plugin or its set property.</p>

Set A set property of the plugin.  
Property

## Properties Table

The view shows the attributes of the node selected in the Structure Tree.

### ItemDescription

Name	The names of the attributes of the element selected in the Structure Tree.
Value	The values of the attributes of the element selected in the Structure Tree.

## Web Flow Diagram

The view graphically presents the relations among the elements of your application. The diagram features common [graph](#) [view](#) elements.

Forwards and exceptions are displayed as directed graph edges.

## Icons used on the Web Flow Diagram

### ItemDescription

	Struts Action
	Struts JSP page
	Struts global forward
	Struts global exception

The dialog opens in various cases when you need to select a class that implements a specific element.

The dialog contains two tabs:

– [Search by Name](#)

– [Project](#)

## Search by Name Tab

Use the tab to search a relevant class by specifying its name or part of the name.

### ItemDescription

---

Search pattern area      In this text field, type a part of the name of the relevant class.

---

Search results area      The area shows a list of the classes that meet the search pattern. The contents of the area change dynamically as you type.

## Project Tab

Use this tab to select the relevant class in the project tree.

Ctrl+Shift+T

The Thumbnails tool window provides the functions similar to those of an image browser. It shows thumbnails for folders and image files, and lets you perform related navigation and image management tasks.

To open the tool window, use the [Show Thumbnails command](#) in the [Project Tool Window](#) ( [Ctrl+Shift+T](#) ). Then, unless you close the tool window, you can show and hide it as described in the section [Manipulating the Tool Windows](#) .

- [Title bar context menu](#)
- [Title bar icons](#)
- [Toolbar icons](#)
- [Content pane: context menu commands](#)

## Title bar context menu

The title bar context menu provides the options for controlling the tool window viewing modes. It also contains the commands for associating the tool window with a different tool window bar, resizing and hiding the tool window.

To access the menu, right-click the window name ( Thumbnails ).

Note that most of the menu options may alternatively be accessed by means of the [title bar icons](#) .

### Item ShortcutDescription

Pinned, Docked, Floating, Split Mode	These options let you control general appearance and behavior of the tool window, see <a href="#">Viewing Modes</a> .
Move to	To associate the tool window with a different <a href="#">tool window bar</a> , select this command, and then select the destination tool window bar ( Top , Left , Bottom or Right ).
Resize	To resize the tool window by moving one of its borders, select this command, and then select the necessary Stretch to option. Note that this command is not available in the floating mode.
Hide	<a href="#">Shift+Escape</a> Use this command to hide the tool window.

## Title bar icons

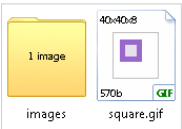

### Item ShortcutDescription

	Use this icon to open the menu for changing the tool window <a href="#">viewing modes</a> .
	<a href="#">Shift+Escape</a> Use this icon or shortcut to hide the tool window . When used in combination with the <a href="#">Alt</a> key, clicking this icon hides all the tool windows attached to the same <a href="#">tool window bar</a> .

## Toolbar icons

The toolbar icons provide access to the most frequently used functions available in the tool window. The same and other functions are available as [context menu commands](#) in the content pane.

### Item ShortcutDescription

	<a href="#">Backspace</a> Use this icon or shortcut to move one level up in the folder hierarchy. The path to the current folder is shown on the title bar to the right of the tool window name.
	<a href="#">Ctrl+Alt+NumPad Plus</a> Use this icon or shortcut to turn the Recursive option on or off. If this option is off, subfolders of the current folder and image files located in the root of the current folder are shown.  If this option is on, the subfolders are not shown; the image files located in the current folder and all its subfolders are shown.  The following picture shows the contents of the same folder with the Recursive off and on.
<div style="display: flex; justify-content: space-around;"> <div style="text-align: center;"> <p>Recursive: OFF</p>  </div> <div style="text-align: center;"> <p>Recursive: ON</p>  </div> </div>	
	Use this icon to show or hide a "chessboard". The "chessboard" (a checkered area) is shown underneath the images so that you can see transparent image areas for <a href="#">.gif</a> and

.png files.

The following picture shows the same thumbnail with the "chessboard" shown and hidden.

Ctrl+F4

Use this icon to close the tool window.

## Content pane: context menu commands

When you right-click an item in the content pane, the context menu for this item is shown.

The following table lists and briefly explains the main context menu commands for thumbnails. Other commands, functionally, are similar to those in the [Project Tool Window](#).

### Item ShortcutDescription

Browse	Enter	For a folder: use this command to view the folder contents (subfolders and images). The same command may alternatively be accessed by double-clicking a folder.
Jump to Source	F4 or Enter	For an image file: use this command to view the selected file in the editor. The same command may alternatively be accessed by double-clicking an image thumbnail.
Level up	Backspace	Use this command to move one level up in the folder hierarchy.
Recursive	Ctrl+Alt+NumPad Plus	Use this command to turn the <a href="#">Recursive option</a> on or off.
Show or Hide Chessboard		Use this command to show or hide the <a href="#">chessboard</a> .
Close thumbnails	Ctrl+F4	Use this command to close the tool window.
Jump to External Editor	Ctrl+Alt+F4	For an image file: use this command to open the image in an external editor.

Alt+6

IntelliJ IDEA constantly scans your project for comments in the source code that match the [TODO patterns](#) defined on the Editor | TODO page of IntelliJ IDEA settings ([Ctrl+Alt+S](#)), and displays results in the TODO tool window.

The TODO tool window is marked with the icon  and consists of the following tabs:

- Project tab that show the TODO items for the whole project.
- Current File tab.
- Scope Based tab that enables viewing TODO items pertaining to a certain scope, selected from the drop-down list, and ignoring the other items.
- Current Changelist, if [version control integration](#) is enabled.

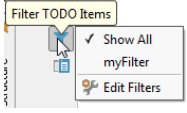

This tool window helps you view, sort, and group the TODO items in a convenient way as well as to navigate to the related source code.

On this page:

- [Toolbar buttons](#)
- [Context menu commands](#)

## Toolbar buttons

**Item** **Tooltip** **Description**  
and  
shortcut

	Previous TODO	Navigate to the previous TODO item.
	<a href="#">Ctrl+Alt+Up</a>	
	Next TODO	Navigate to the next TODO item.
	<a href="#">Ctrl+Alt+Down</a>	
	Help	Use this icon or shortcut to open the corresponding help page.
	<a href="#">F1</a>	
	Expand all	Use these buttons to have all nodes expanded or collapsed.
	Collapse all	
	<a href="#">Ctrl+NumPad Plus</a>	
	<a href="#">Ctrl+NumPad -</a>	
	Autoscroll to Source	Toggle the Autoscroll to source mode. When this button is pressed, every time the node is focused, the corresponding line of source code is highlighted in the editor.
	Filter TODO items	Click this button to select the desired filter from the list, or invoke the <a href="#">TODO dialog</a> and edit the list of TODO patterns and filters as required.
		
	Preview Usages	If this button is pressed, a pane to the right shows the source code of the selected file, with the corresponding TODO item highlighted.

**Tip** The following buttons are available in the Project and Scope Based tabs.

	<a href="#">Ctrl+D</a>	If this button is pressed, the TODO items show under the corresponding module or library node.
	<a href="#">Ctrl+P</a>	If this button is pressed, the TODO items show under the corresponding packages.
	<a href="#">Ctrl+F</a>	If this button is pressed, the TODO items show as a flat list. Thus, if a package is somewhere deep within your project, you do not need to dig deep into the hierarchy.

## Context menu commands

**Item** **Keyboard** **Description**  
**Shortcut**

Jump to Source

Navigate to the selected usage in the

F4 source code.

---

Local History

Show Local History submenu for the selected search result. Refer to the [Local Version Control](#) procedures for details.

---

<VCS>

Show menu of the VCS, associated with the directory. See [Version Control Procedures](#) and [Reference](#) for details.

## Title bar context menu and buttons

You can right-click on the window title bar and use the context menu to configure its [viewing mode](#), associate the window with a different [tool window bar](#), or resize and hide the window.

You can also use the toolbar buttons:

### Icon ShortcutDescription

---

 Click this button to access a subset of the context menu commands that let you configure window's [viewing mode](#).

 [Shift+Escape](#) Use this command to hide the tool window. You can also use it in combination with the [Alt](#) key to hides all tool windows attached to the same [tool window bar](#).

IntelliJ IDEA shows this tool window only when the TypeScript Language Service is activated on the [TypeScript page](#) as described in [TypeScript](#). Use this tool window to view the errors detected by the TypeScript Language Service and the built-in TypeScript compiler.

## Errors

The tab lists the discrepancies in the code detected by the TypeScript Language Service. The list is updated dynamically as you change your code.

- By default, the list contains only the errors from the file in the active editor tab and the full path to this file is displayed at the top. To show the errors across the entire project, press the Show project errors toggle button  on the toolbar. The tab shows error messages grouped by files in which they were detected.
- To navigate to the code in question, select the corresponding error message and choose Jump to Source on the context menu.

## Compile Errors

**Tip** The default compilation scope is entire project. To change this default settings, choose the relevant scope from the Compile scope list on the [TypeScript page](#).

The tab lists the errors that occurred during compilation.

- By default, the list is updated dynamically as you edit your code. To change this setting, clear the Recompile on changes checkbox on the [TypeScript page](#).
- By default, the list contains only the errors from the file in the active editor tab. To view the compilation errors across the entire compilation scope, click  on the toolbar and choose Compile All from the list. The error messages are shown grouped by files in which they were detected.
- To navigate to the code in question, select the corresponding error message and choose Jump to Source on the context menu.

## Toolbar

**ItemTooltip** **Description**  
and  
**shortcut**

	Compile	Click this button and choose the range of files to compile. <ul style="list-style-type: none"> <li>– To run the compiler in all the files from the default scope, choose Compile All. The default scope is specified in the Compile scope field on the <a href="#">TypeScript page</a>.</li> <li>– To run the compiler in the file opened in the active editor tab, choose the path to the file.</li> <li>– To use the scope defined in a <code>tsconfig.json</code> file, choose the path to the required one.</li> </ul>
	Configure	Click this button to open the <a href="#">Typescript page</a> and edit the TypeScript settings.
	Restart TypeScript Service	Click this button to clear the tabs and run the TypeScript Language Service anew.
	Help	Click this button to open the <a href="#">TypeScript tool window page</a> .
	Show project errors	By default, this toggle button is released and the tab shows the errors from the current TypeScript file. Press this toggle button to show the errors across the entire project.
	Close <code>Ctrl+Shift+F4</code>	Click this button to terminate the compiler and the TypeScript Language Service and close the tool window.
 	Expand all <code>Ctrl+NumPad Plus</code>  Collapse all <code>Ctrl+NumPad -</code>	Use these buttons to have all nodes expanded or collapsed.
	Clear All	Click this button to remove all the error messages from the currently active pane.

## Context Menu

The context menu is common for the Errors and the Compile Errors tabs.

**ItemDescription**

Jump to Choose this option to open the file where the selected error was detected and navigate to the fragment of code which

source caused the error.

---

Copy Choose this option to copy the selected error message with the information on the file, the line, and the column where the error was detected.

## Console

The tab shows the log of the TypeScript Language Service since the tool window was opened.

Alt+9

This tool window is available if [version control integration is enabled](#) for your project.

The tool window accommodates several views/tabs, which display VCS-related information and allow you to manage changelists, perform VCS-specific actions, view changes made by other team members, etc.:

- [Console](#) tab: this tab shows the results of executing VCS-related commands.
- [Local Changes](#) tab: this tab is always present and shows the list of files that have been modified locally and have not been committed to the repository yet.
- [History](#) tab: this tab is added to the Version Control tool window when the Show History command is invoked through VCS | <specific\_VCS> .
- [Integrate to Branch Info View](#) tab: this view is available after running integration with the Run status after update setting specified.
- [Log](#) tab: this tab is only available if you are using Git or Mercurial as your version control system. It shows all changes committed to all branches of the local and remote repositories, or to a specific branch or repository.
- [Repository and Incoming](#) tabs: the Repository tab shows the changes committed to the repository under the VCS roots within the current project. The Incoming tab shows the changes committed to the repository by other team members, and not checked out locally.
- [Shelf](#) tab: this tab is added to the tool window when you [shelve](#) a change or a changelist.
- [Update Info](#) tab: this tab becomes available when [local information is synchronized](#) with the server.

## Title bar context menu and buttons

You can right-click on the window title bar and use the context menu to configure its [viewing mode](#) , associate the window with a different [tool window bar](#) , or resize and hide the window.

You can also use the toolbar buttons:

### Icon ShortcutDescription

✱-	Click this button to access a subset of the context menu commands that let you configure window's <a href="#">viewing mode</a> .
←	Use this command to hide the tool window. You can also use it in combination with the <a href="#">Alt</a> key to hides all tool windows attached to the same <a href="#">tool window bar</a> .

The tab displays:

- Version control-related commands generated based on the settings you specify through the IntelliJ IDEA interface.
- The results of executing version control-related commands.

```

## Toolbar

**Item Tooltip and Shortcut**

	Up the stack trace / Down the stack trace	Click these buttons to navigate up or down in the stack trace and have the cursor jump to the corresponding location.
	Ctrl+Alt+Up	
	Ctrl+Alt+Down	
	Use Soft Wraps	Click this button to toggle the soft wrap mode of the output.
	Scroll to the end	Click this button to navigate to the bottom of the stack trace and have the cursor jump to the corresponding location.
	Print	Click this button to send the console text to the default printer.
	Clear All	Click this button to remove all text from the console. This function is also available on the context menu of the console.

## Context Menu Commands

**Item Description**

Compare with Clipboard	Opens the Clipboard vs Editor dialog box that allows you to view the differences between the selection from the editor and the current clipboard content. This dialog is a <a href="#">regular comparing tool</a> that enables you to copy the line at caret to the clipboard, find text, navigate between differences and manage white spaces.
Fold Lines Like This	Opens the <a href="#">Console</a> dialog that allows you defining the lines to be folded to hide extraneous information.
Copy URL	Choose this command to copy the current URL to the system clipboard. This command only shows on a URL, if it is included in an application's output.
Create Gist	Choose this command to open the Create Gist dialog box.
Clear All	Clears the output window.

Alt+9

The Local Changes tab lists all files that have been modified locally and have not yet been committed to the repository.

**Tip** You can assign a custom shortcut for the Show Local Changes action in Settings | Keymap | Version Control Systems to open the Local Changes tab.

Use this tab to [commit](#) and [revert](#) changes, [manage changelists](#), [view differences](#), [view changes in UML Class diagram](#), and [clean up](#) locked folders.

In this topic:

- [Toolbar](#)
- [Changelists pane](#)
  - [Context menu of a selection](#)
- [Preview Diff Pane](#)

## Toolbar

**Item** **Tooltip** **Description**  
**and**  
**Shortcut**

	Refresh 	Click this button to refresh the status of all files in your workspace, modified both through IntelliJ IDEA or through any other application.
<p><b>Note</b> If you are using <a href="#">Perforce</a> as your version control system, only the status of files modified through IntelliJ IDEA will be updated. This approach improves performance, as it does not require connecting to the server, but it does not let you get an update on the changes made outside IntelliJ IDEA, for example through the p4v client application. If you want to get an update on all changes to your workspace, use the <a href="#">Force Refresh</a> option.</p>		
	Force Refresh	This button is only available if you are using <a href="#">Perforce</a> as your version control system.
Click this button to refresh the status of files in your workspace, both modified through IntelliJ IDEA or through other applications.		
	Commit Changes	Click this button to <a href="#">check in</a> the selected change or changelist. You can also attach and detach <a href="#">Perforce jobs</a> to/from changelists via the <a href="#">Commit Changes</a> dialog.
	Revert 	Click this button to roll back the selected changes.
	New Changelist 	Click this button to <a href="#">create a new changelist</a> .
	Delete Changelist 	Click this button to delete the selected changelist. Note that you cannot delete the default changelist.
	Set Active Changelist	Click this button to <a href="#">make the selected changelist active</a> . The active changelist is highlighted.
	Move to Another Changelist 	Click this button to <a href="#">move</a> the selected file to another changelist.
	Shelve Silently 	Click this button to <a href="#">shelve</a> the selected file or changelist silently, without displaying the <a href="#">Shelve Changes</a> dialog.
	Show Diff 	Click this button to view the differences between your local version of the selected file and its latest version in the repository.
	Show Changes 	Use this button to show classes from the selected changelist in a UML Class diagram (for details see <a href="#">Viewing Changes as Diagram</a> ).
	 	Click these buttons to <a href="#">expand</a> or <a href="#">collapse</a> all nodes.
	Group by Directory 	Click this button to display the changed files grouped by directories. If the button is released, the changed files are grouped by changelists.
	Copy 	Click this button to copy the path to the selected file to the clipboard.

	Show Ignored Files	Click this button to show the Ignored files node with the list of existing <a href="#">files ignored by the VCS</a> .
	Configure Ignored Files	Click this button to <a href="#">configure the list of files</a> that will be ignored by your version control system.
	Preview Diff	Click this button to have IntelliJ IDEA open or close the <a href="#">Preview Diff pane</a> to compare the current file with the latest committed revision.
		Click this button to show the corresponding IntelliJ IDEA help page.

## Changelists pane

This pane shows all your changelists, and the files that have been modified in each changelist.

If new files have been added to your project that have not yet been checked-in to a version control system, the Unversioned Files node appears under which all such files are listed. If you have a large number of unversioned files (over 50), they are not displayed in the changelists pane. Instead, the Click to browse link appears. Click this link to open the Unversioned Files dialog to review the list of unversioned files. You can quickly delete unversioned files from the Changelists pane or the Unversioned Files dialog by pressing  , or add them to the VCS by pressing  .

## Context menu of a selection

### Item ShortcutDescription

	Commit Changes	NA	Select this option to <a href="#">check in</a> the selected file or changelist. You can also attach and detach <a href="#">Perforce jobs</a> to changelists via the <a href="#">Commit Changes</a> dialog.
	Revert		Select this option to roll back the selected changes.
	Move to Another Changelist		Select this option to <a href="#">move</a> the selected item to another changelist.
	Show Diff		Select this option to view the differences between your local copy and the latest version in the repository.
	Jump to Source		Select this option to open the selected file(s) in the editor.
	New Changelist		This option is only available if a changelist is selected. Select this option to <a href="#">create a new changelist</a> .
	Delete Changelist	NA	This option is only available if a changelist is selected. Select this option to delete the selected changelit.
	Delete	NA	This option is only available if single files are selected, not a changelist.
	Check Out	NA	This option is only available if a file under the Modified without Checkout node is selected. Use this option to check out the selected file from the repository.
	Add to VCS	NA	This option is only available if a file under the Unversioned Files node is selected. Use this option to add the selected files to your version control system.
	Ignore	NA	This option is only available if a file under the Unversioned Files node is selected. Use this option to <a href="#">ignore</a> the selected file if you want to leave it unversioned.
	Create Patch	NA	Select this option to <a href="#">create a patch</a> .
	Shelve Changes	NA	Select this option to <a href="#">shelve the selected changes</a> .
	Shelve in Perforce	NA	This option is only available if you are using Perforce as a version control system.  Select this option to shelve your changes in Perforce. You will be asked to select which files you want to shelve and provide a description. After you've shelved your changes, the corresponding changelist will appear. You can unshelve it any time from the changelist's context menu.
	Refresh		Select this option to refresh the status of files in your workspace.
	Local History	NA	Select this option and choose one of the following from the popup menu: – Show History : select this option to <a href="#">View local history</a> of the selected file or folder. – Put Label : select this option to <a href="#">add a label</a> to the current version of the selected file or folder.
	<Specific version control system>	NA	Select this option to invoke a popup menu with options specific for the version control system you are using.

## Preview Diff Pane

This pane opens when you click the Preview Diff button  on the toolbar. In this pane you can examine the changes made to the selected file compared to its base revision.

The pane consists of two areas:

- The affected code as it was in the base revision.
- The affected code as it is after a change has been made.

### ItemTooltip Description and Shortcut

 Previous Use these buttons to jump to the next/previous difference.

Difference / Next When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons  /  once more and compare other files, depending on the [Go to the next file after reaching last change](#) option in the [Differences Viewer settings](#) .

Difference  

This behavior is supported only when the Differences Viewer is invoked from the [Version Control](#) tool window.

 Compare Click these buttons to compare the local copy of the previous/next file with its update from the server.

Previous/Next File  **Note** These controls are only available if more than one file has been modified locally.

 Jump to Source Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer .

Viewer type  Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only.

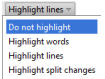

Both types of viewers enable you to

- Edit code. Note that one can change text *only* in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.
- Perform the Apply/Append/Revert actions.

Whitespace  Use this drop-down list to define how the differences viewer should treat white spaces in the text.

- Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.
- Trim whitespaces : (`"\t"`, `" "`) , if they appear in the end and in the beginning of a line.
  - If two lines differ in trailing whitespaces only, these lines are considered equal.
  - If two lines are different, such trailing whitespaces are not highlighted in the [By word](#) mode.
- Ignore whitespaces : white spaces are not important, regardless of their location in the source code.
- Ignore whitespaces and empty lines : the following entities are ignored:
  - all whitespaces (as in the 'Ignore whitespaces' option)
  - all added or removed lines consisting of whitespaces only
  - all changes consisting of splitting or joining lines without changes to non-whitespace parts.

For example, changing `a b c` to `a \n b c` is not highlighted in this mode.
- Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).

Highlighting mode  Select the way differences granularity is highlighted.

The available options are:

- Highlight words : the modified words are highlighted
- Highlight lines : the modified lines are highlighted
- Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.

For example, `A \n B` vs. `A X \n B X` will be treated as two changes instead of one.

- Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.

 Collapse unchanged fragments Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the Diff & Merge settings page.

 Synchronize scrolling Click this button to simultaneously scroll both differences panes; if this button is released, each of the panes can be scrolled independently.

 Editor settings Click this button to invoke the list of available settings. Select or clear this options to show or hide whitespaces, line numbers and indent guides, to use or disable the use of soft wraps, and to set the highlighting level.

These commands are also available from the context menu of the differences viewer gutter.

 Show diff in external tool Click this button to invoke an external differences viewer, specified in the [External Diff Tools](#) settings page.

This button only appears on the toolbar when the Use external diff tool option is enabled in the [External Diff Tools](#) settings page.

 Help Click this button to show the corresponding help page.

NA

Annotate

This option is only available from the context menu of the gutter.

Use this option to explore who introduced which changes to the repository version of the file in question, and when. The annotations view lets you see detailed information for each line of code, such as the version from which this line originated, the ID of the user who committed this line, and the commit date.

You can [configure the amount of information displayed in the annotations pane](#) .

For more details on annotations, refer to [Viewing Changes Information](#)

The most useful shortcuts in the Diff Pane are the following:

#### ShortcutDescription

<code>Ctrl+Shift+D</code>	Use this keyboard shortcut to show the popup menu of the most commonly user diff commands.
<code>Ctrl+Tab</code>	Use this keyboard shortcut to switch between the left and the right panes.
<code>Ctrl+Shift+Tab</code>	Use this keyboard shortcut to select the position obtained by <code>Ctrl+Tab</code> in the opposite pane.
<code>Ctrl+Z</code> / <code>Ctrl+Shift+Z</code>	Use this keyboard shortcut to undo/redo a merge operation. Conflicts will be kept in sync with the text.

Alt+9

This tab is only available if you are using [Git](#) or [Mercurial](#) for version control.

This tab shows all changes committed to all branches of the local and remote repositories, or to a [specific](#) branch or repository.

The log is updated automatically in the background mode on every change (a commit, fetch, rebase, etc.), even if the Log tab is closed.

**Tip** You can assign a custom shortcut for the Show VCS Log action in Settings | Keymap | Version Control Systems to open the Log tab.

The tab contains the following panes:

- The [Commits](#) pane is located on the left of the tool window and shows the commits to all or [selected](#) branches from the local and remote repositories.
- The [Changed Files](#) pane is located on the right of the tool window and shows the list of files that were modified within the selected commit.
- The [Commit Details](#) pane is located on the right under the [Changed Files](#) pane and shows the details of the selected commit.

## Commits Pane

The commits pane consists of the following areas:

- [Commits](#)
- [Toolbar](#) (some of the toolbar commands are duplicated in the [context menu](#)).

## Commits

This area shows a list of all commits performed to the selected branch, or to all branches. For each commit, the list shows the commit message, the author, and the commit date. The latest commit in each branch is supplied with a label with the name of the branch in which it was performed.

There are the following labels:

- local (Mercurial) and regular (Git/Mercurial) for tags.
- tip (Mercurial) for the latest revision in the repository.
- HEAD (Git/Mercurial) for the current working revision.

For Git, the color of the label depends on the branch type (local or remote).

For Mercurial, there are different color labels for bookmarks, open heavy branches and closed heavy branches.

Note that clicking an arrow takes you to the next commit in a long branch:

In multi-repository projects, the colored stripe on the left indicates which root the selected commit belongs to (each root is marked with its own color). Hover the mouse cursor over the colored stripe to invoke a tip that shows the root path:

You can also enable the [Show Root Names](#) option if you want to expand the Roots column with full root names.

Committed changelists often correspond to issues in tracking systems. You can jump to such issues in a browser right from the Commits pane. This functionality is available if:

- The [pattern](#) of the bug tracking system is specified in the [Issue Navigation](#) Settings dialog box.
- The corresponding issue number is mentioned in the commit message.

After issue navigation has been configured, issue numbers in commit messages are rendered as links. Clicking such link brings you to the corresponding page of your issue tracker.

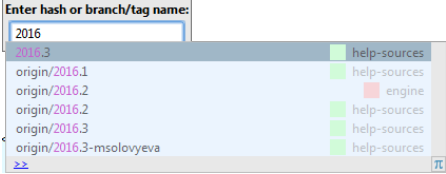

# Toolbar

**Item** **Tooltip** **Description**  
and  
**Shortcut**

	N/A	Use this text box to search through the list of commits. You can enter full commit names or messages or their fragments, revision numbers, or regular expressions. To finalize the search, press <code>Enter</code> or move the focus away from the search field.  <b>Tip</b> You can quickly switch the focus to the search field by pressing <code>Ctrl+L</code> .
	N/A	Click this button to show previous search patterns.
	N/A	Click this button to clear the search and return to the full list of commits.
	N/A	Click this button to invoke the following options: <ul style="list-style-type: none"> <li>– <b>Regex</b>: if this option is selected, anything you type in the search field is treated as a <b>regular expression</b>, for example, <code>#\d+</code>.</li> <li>– <b>Match Case</b>: if this option is selected, only entries with the matching case count.</li> </ul>
<b>Branch</b>	N/A	Use this drop-down list to filter commits by the branch. If you want to see commits from all local and remote branches, select <b>All</b> .
<b>User</b>	N/A	Use this drop-down list to filter commits by the author. To view all commits by a specific author, click <b>Select</b> and start typing the author's name. To view commits by all users, select <b>All</b> .
<b>Date</b>	N/A	Use this drop-down list to filter commits by a time-frame or a specific date. To view commits made on a specific date, click <b>Select</b> and specify the date. To view commits made on all dates, select <b>All</b> .
<b>Paths</b>	N/A	Use this drop-down list to filter commits by the folder (for projects that have one root), or by the root and folder (for multi-root projects). To view commits to a specific folder, click <b>Select Folders</b> and specify the folder name. For multi-repository projects, you can also select the check-box next to one or several roots in the <b>Roots</b> section.
	IntelliSort	If this option is enabled, you get a more convenient way to view merges by displaying the incoming commits first, directly below the merge commit.
	Show long edges	If this option is enabled, long branches are displayed in full, even if there are no commits in them. If this option is disabled (by default), long branches are replaced with a down arrow.
	Refresh	Click this button to refresh the list of commits.  <code>Ctrl+F5</code>

 **Go to Hash/Branch/Tag** `Ctrl+F`

Click this button and specify a hash, tag or branch you want to jump to.

You can select a reference with the same name from different repositories. The name of each repository is displayed on the right along with its color indicator.

 **Cherry-pick (for Git)** **Graft (for Mercurial)**

Click this button to [apply changes from the selected commit to the current branch](#).

**Note** This button is disabled if the selected commit is already contained in the current branch.

 **Highlight non-picked commits**

This command is only available if you are using Git as your version control system. Click this button to highlight the commits from the selected branch that have not yet been applied to the current branch.

 **Quick settings**

Click this button to invoke one of the following commands:

- **Show Root Names**: enable this option if you want to expand the **Roots** column on the left showing full root names in a multi-repository project.

- **Compact References View**: if this option is enabled, branch references for a single commit are displayed in a collapsed view: `origin/171.3780`  
If you want to expand each branch reference on a line, deselect this option: `origin/171.3780` `idea/171.3780.29`
- **Show Tag Names**: enable this option if you want tag names to be displayed in addition to the tag icon:  
`idea/171.3780.29`

If this option is disabled, you can still view a tag name by hovering the mouse over the tag icon.

- Collapse Linear Branches : enable this option to collapse all branches on the graph so that a dotted line is shown instead of successive commits.

It is also possible to collapse an individual expanded branch by clicking it.

- Expand Linear Branches : enable this option to expand all collapsed branches to show successive commits on the graph.

It is also possible to expand an individual collapsed branch by clicking it.

- Highlight : select which types of commits you want to highlight:
  - My Commits : if enabled, your commits are highlighted in bold font.
  - Merge Commits : if enabled, merge commits are grayed out.
  - Current Branch : if enabled, commits to the current branch are highlighted with a blue background.

## Context menu commands

Item	Description	Available in
Copy Revision Number 		Use this command to copy the revision number of the selected commit to the clipboard. Git
		Mercurial
Create Patch 		Use this command to <a href="#">create a patch</a> based on the selected commit. Git
		Mercurial
Cherry-pick (Git)	Use this command to <a href="#">apply the changes from the selected commit to the current branch</a> . Git	
Graft (Mercurial) 		Mercurial
Checkout Revision	Use this command to check out the state of files recorded in the selected commit. Git	
Update to Revision	Use this command to change your working copy parent revision to the selected commit. New commits will carry on from the revision (commit) you update to. Mercurial	
New Branch		Use this command to create a new branch based on the selected commit. Git
		Mercurial
New Tag		Use this command to add a new tag to the selected commit. Git
		Mercurial
Branch <branch_name> / Branches	<p>This command appears for all branches that point to the selected commit ( Branch &lt;branch_name&gt; if there is one branch, or Branches if there are multiple branches) and provides the same options as the ones available from the <a href="#">Branches popup and submenu</a> :</p> <ul style="list-style-type: none"> <li>- Checkout as new local branch</li> <li>- Compare</li> <li>- Rebase onto</li> <li>- Merge</li> <li>- Delete</li> </ul> <p>If the <a href="#">Control repositories synchronously</a> option is enabled, and the selected branch exists in multiple repositories, an additional menu option named In All Repositories appears that allows you to perform the same operations in all repositories simultaneously.</p>	Git
		Mercurial
Reset Current Branch to Here	Use the command to reset the current branch head to the selected commit. In the Git Reset dialog that opens, select the mode in which the working tree will be updated. Git	
Undo Commit	This command is only available for the commits made by you, and allows you to revert the changes and undo the selected commit. Git	
Open in GitHub 	Use this command to open the page that corresponds to the selected commit on <a href="#">GitHub</a> . Git	
MQ	<p>Use this submenu to manage <a href="#">Mercurial Queues</a> :</p> <ul style="list-style-type: none"> <li>- Import : use this command to turn the selected changeset into a patch.</li> <li>- Goto patch : use this command to open the MQ: &lt;project_name&gt; tab that shows a queue of patches that have not been applied yet.</li> <li>- Rename Patch : use this command to rename the selected patch.</li> <li>- Finish Patches : use this command to turn the selected patch into a permanent changeset.</li> </ul>	Mercurial

## Changed files pane

This pane shows a list of files that were modified within the currently selected commit.

## Toolbar

Many of the options available in the toolbar are duplicated in the context menu.

**Item**  
**Tooltip**  
**and**  
**Shortcut**

Item	Tooltip	Shortcut
	Show Diff	Click this button to open the <a href="#">Differences Viewer for Files</a> where you can compare the current and the previous revision of the selected file.
		<span>Ctrl+D</span>
	Show Diff with Local	Click this button to show the differences between the selected revision of the selected file and its current local copy.
	Edit Source	Click this button to open the local copy of the selected file for editing.
		<span>F4</span>
	Open Repository Version	Click this button to open the repository version of the selected file for editing.
	Revert Selected Changes	Click this button to roll back the changes in the selected file.
	Show History for Revision	Click this button to open the <a href="#">History tab</a> for the selected file that lets you explore the history of all file revisions.
	Changes View Settings	Click this button to select the following options: – Show Details : click to show the <a href="#">Commit details pane</a> . – Show Changes to Parents : click to display changes to both parents for a merge commit to review merge results, and <a href="#">see how exactly conflicts were resolved</a> during a merge.
	Group by Directory	Click this button to transform a flat list of files into a tree of packages with files.
		<span>Ctrl+P</span>
	Expand All/Collapse All	Click this button to expand/collapse all nodes. Note that these buttons are only available only when tree-view is enabled.
		<span>Ctrl+NumPad Plus</span>

## Commit Details

This area is displayed when the [Show Details](#)  option is enabled.

This area shows the details on the commit selected in the [Commits](#) list, such as the commit message, hash, author, the link to the author's email, date, time, root and branches.

If the selected commit is contained in more than six branches, only the first six are displayed and the Show All link appears that you can click to expand a complete list of branches.

The History tab is added to the [Version Control tool window](#) on invoking the Show History command for a file or directory through the menu of a particular VCS. A new tab is created for each file or directory with the following name: History: <file\_name> . The set of toolbar buttons differs slightly depending on your version control system.

All commands available from the toolbar are also available from the context menu of a selection.

**ItemTooltip  
and  
Shortcut**

ItemTooltip	Description	Shortcut
	Compare Click this button to compare the selected revision of a file with its previous revision in the <a href="#">Differences Viewer for Files</a> .	Ctrl+D
	Show Diff with Local Click this button to compare the selected revision of a file with its local copy in the <a href="#">Differences Viewer for Files</a> .	
	Create Patch Click this button to create a patch from the selected revision.	
	Get Click this button to retrieve the selected revision. If the local copy has already been modified, IntelliJ IDEA prompts to overwrite the local version, or cancel the operation.	
	Annotate Click this button to open the selected revision of a file in the editor with annotations.	
	Show All Affected Files Click this button to open the Paths Affected in Revision dialog where you can view all files that were modified in the selected revision.	Shift+Alt+A
	Copy Revision Number Click this button to copy the revision number of the commit that the selected file belongs to to the clipboard.	
	Compare all classes from revision on UML Click this button to view all classes of the selected revision as a UML Class diagram. See section <a href="#">Viewing Changes as Diagram</a> .	Ctrl+Shift+D
	Open in GitHub Click this button to open the page that corresponds to the selected commit on <a href="#">GitHub</a> .	
	Show All Branches Click this button to display changes from branches other than the current one.	
	Show Branches <b>Note</b> This option is only available if you are using Perforce for version control. Click this button to show branches.	
	Show All Revisions Submitted In Selected Changelist <b>Note</b> This option is only available if you are using Perforce for version control. Click this button to display the list of all revisions committed in the same changelist as the selected revision of a file.	
	Refresh Click this button to refresh the current information.	
	Show Details Click this button to show the commit message for the selected revision.	
	Close Click this button to close the current history tab.	Ctrl+Shift+F4

This view is available after running integration with the Run status after update setting specified. The view displays a list of files or packages affected by the latest integration. The items are displayed under the following nodes:

- Modified
- Merged
- Not in repository
- Locally added

**ItemTooltip  
and  
shortcut**

		Click this button, to group information within nodes by packages. If the button is released, files are presented in plain lists.
	Ctrl+NumPad Plus	Click this button to expand all nodes.
	Ctrl+NumPad -	Click this button to collapse all nodes.
		Click this button to close the view.
	F1	Click this button to show the corresponding reference page.

Alt+9

The Repository and Incoming tabs are only available for non-distributed version control systems (i.e. all VCSs supported by IntelliJ IDEA except for Git and Mercurial).

The Repository tab shows the changes committed to the repository under the VCS roots within the current project. The Incoming tab shows the changes committed to the repository by other team members, and not yet checked out locally. Both tabs display the information stored in the history cache. The number of changelists displayed depends on the [cache scope](#).

Each tab contains the following panes:

- The [Changelists](#) pane shows changelists.
- The [Changed Files](#) pane shows the list of files that were modified and committed within the selected changelist.

Note that if you are using SVN 1.5 or higher both on the server and in the local working copies, the Repository tab also features a [Merge Info](#) pane that configures the view in the other two panes and provides control over integration between branches.

## Changelists Pane

The pane shows the changelists committed and stored in the history cache. When you click a changelist, the files affected by the selected commit are displayed in the [Changed Files](#) pane.

Committed changelists often correspond to issues in tracking systems. You can have such issues opened in the browser right from the Changelists pane. This functionality has the following prerequisites:

- The [pattern](#) of the bug tracking system is specified in the [Issue Navigation](#) Settings dialog box.
- The corresponding issue number is mentioned in the commit message.

After issue navigation has been configured, issue numbers in commit messages are rendered as links. Clicking such link brings you to the corresponding page of your issue tracker.

Item Tooltip and Shortcut	Description	Available In
	Refresh  Ctrl+F5	Click this button to refresh the information in the view.  Both tabs
	Show Details  Ctrl+Q	Click this button to show the following information on the selected changelist: – Changelist number – User and client name – Date and time of commit  Both tabs
	Create Patch	Click this button to <a href="#">create a patch</a> based on the selected changelist.  Repository tab
	Revert Changes	Click this button to create a <i>reverse patch</i> for the selected changelist and roll back the changes made previously. You can use this action to revert changes committed by any user. The Select Target Changelist dialog box opens.  Note that if the reverse patch applies to a version committed earlier, this rollback attempt may fail because of the conflicts with the later changes.  Repository tab
	Clear	Click this button to clear the history cache. The commits list will be emptied. To restore it, click <a href="#">Refresh</a> .  Repository
	Edit Revision Comment	Click this button to edit the message for the selected commit.  Repository
	Update Project  Ctrl+T	Click this button to <a href="#">update the project</a> to the latest available version.  Incoming tab
	Expand All  Ctrl+NumPad Plus	Click this button to expand all nodes.  Both tabs
	Collapse All  Ctrl+NumPad -	Click this button to collapse all nodes.  Both tabs
	Copy	Click this button to copy the commit message of the selected changelist to the Clipboard.  Both tabs

	 Help	Click this button to show the corresponding help topic.	Both tabs
	 Highlight Integrated	Click this button to have the Merge Info pane displayed. The button is enabled only when both the server side and the client side use Subversion 1.5.	Repository tab
Filter by		Use this drop-down list to hide the changelists that are of no interest to you, and only view only the changelists that satisfy a certain criterion. The following options are available: <ul style="list-style-type: none"> <li>- User : select this option to filter the commits by the user.</li> <li>- Structure : select this option to filter the commits by the target module or folder.</li> <li>- Client : select this option to filter the commits by the computer from which they were made.</li> <li>- None : select this option to turn off filtering and return to the default view.</li> </ul>	Both tabs
Group by		Use this drop-down list to group changelists following a certain criterion. The following options are available: <ul style="list-style-type: none"> <li>- Date : select this option to group the commits by date.</li> <li>- User : select this option to group the commits by users.</li> <li>- Client : select this option to group the commits by the computer from which they were made.</li> </ul>	Both tabs
Search		Use this text box to enter a search pattern and locate the commits whose commit messages matches the specified string. As you type, the list dynamically reduces to show the changelists with the commit messages that match the specified pattern. To save the search pattern, press Enter .  To view the list of recent search patterns, click the  button.  To clear the list of search patterns, click the  button.	Repository tab

## Changed files pane

ItemTooltip  
and  
Shortcut

ItemTooltip and Shortcut	Description	
	Show Diff	Click this button to show the differences between the current and the previous revision of the selected file.  
	Show Diff with Local	Click this button to show the differences between the selected revision of the selected file and its current local copy.
	Edit Source	Click this button to open the local copy of the selected file for editing.  
	Open Repository Version	Click this button to open the repository version of the selected file.
	Revert Selected Changes	Click this button to revert the changes to the selected file and roll back to its previous revision.
	Integrate to Branch	Click this button to integrate the changes from the selected file to the target branch.
	Compare Subversion Properties	This option is only available if you are using <a href="#">Subversion</a> as your version control system. Click this button to view the differences in file properties between the current version and the previous revision.
	Show History	Click this button to open the History view of the selected file in the <a href="#">Version Control</a> tool window.

	<b>Group by Directory</b>	Click this button to transform a flat list of files into a tree of packages with files.
	<b>Expand All</b>	Click this button to expand all nodes. The button is available only when the files in the pane are displayed grouped by directories.
	<b>Collapse All</b>	Click this button to collapse all nodes. The button is available only when the files in the pane are displayed grouped by directories.

## Merge Info pane

The pane is available only if you are using SVN 1.5 or higher both on the server and in the local working copies.

In this pane, specify a pair of branches whose integration with each other you want to monitor. The Changelists pane will show the changelists related to the specified branches and provide the information on the [integration status](#) of each changelist.

You can specify several pairs of branches if several projects or roots are involved.

### Item Tooltip Description and Shortcut

	<b>From</b>	Specify the URL address of the source branch. IntelliJ IDEA suggests the URL address selected in the Checkout from Subversion dialog box.
	<b>To</b>	Do the following: <ul style="list-style-type: none"> <li>Specify the path to the target branch. Click  or press <b>Shift+Enter</b> to open the Select Branch dialog box.</li> <li>Specify the path to the local working copy to which you will apply patches created based on the selected changelists. Click  to open the Configure Working Copy Paths dialog box and select a working copy.</li> </ul>
	<b>Highlight Integrated</b>	Click this button to have each changelist in the Changelists pane supplied with an indication of whether it is integrated or not.
	<b>Integrate To Branch</b>	Click this button to integrate the selected changelist into the working copy. The Integrate To Branch dialog box opens.
	<b>Undo Integrate To Branch</b>	Click this button to revert the last integration of the selected changelist into the working copy.
	<b>Mark As Merged</b>	Click this button to indicate that the selected changelist is integrated into the working copy without actually integrating the changelist. The action affects the administrative information in the <code>.svn</code> folder. The icon next to the selected changelist changes from  to  .
	<b>Mark As Not Merged</b>	Click this button to indicate that the selected changelist is not integrated into the working copy without actually reverting integration. Update the administrative information in the <code>.svn</code> folder. The icon next to the selected changelist changes from  to  .
	<b>Filter Out Not Integrated</b>	Click this button to display only changelists that have not been integrated into the working copy.
	<b>Filter Out Integrated</b>	Click this button to display only changelists that have been integrated into the working copy.
	<b>Filter Out Others</b>	Click this button to hide extraneous changelists in the Changelists pane. Extraneous changelists are changelists that are <a href="#">managed in another VCS</a> or are located under another root.

Show Working Copies Click this button to open the [Subversion Working Copies Information](#) dialog box.

---

Refresh Click this button to refresh the information in the Changelists pane.

This tab is added to the [Version Control tool window](#) when you [shelve](#) a change or a changelist, and is displayed until you permanently remove all shelved changes, including the already [unshelved](#) ones, and imported external patches.

By default, this tab shows all shelved changes that have not been unshelved yet. Changes are grouped into shelves. A shelf is a changelist created when you shelve changes. A shelf is identified by the commit message. You can have IntelliJ IDEA show the unshelved changes. They can be restored and re-applied as many times as necessary, until they are removed permanently.

For details, see [Shelving and Unshelving Changes](#) .

**Note** You can assign a custom shortcut for the Show Shelf action in [Settings | Keymap | Version Control Systems](#) .

## Toolbar

**Item** **Tooltip** **Description**  
**and**  
**shortcut**

	Show Diff <a href="#">Ctrl+D</a>	Choose this option to open the <a href="#">Differences Viewer for Files</a> and compare the shelved version of a file with its current local version.
	Unshelve Silently <a href="#">Ctrl+Alt+U</a>	Click this icon to unshelve changes silently, without displaying the Unshelve Changes dialog.
	Create Patch	Choose this option to create a patch file based on shelved changes. In the Create Patch dialog box that opens, specify the file to save the patch in, and the changes to create a patch from. By default, all changes from the shelf are selected. To view which changes are included, click the Selected link. For details, see <a href="#">Creating Patches</a> .
	Show/Hide already unshelved	Click this button to have IntelliJ IDEA show or hide all available shelved changes, both already applied and not. Note that this button is duplicated on the context menu.
	Preview Diff	Click this icon to compare the shelved version of the selected file with its local version in the Preview pane.
	Clean Already Unshelved	Click this icon to explicitly remove all unshelved changes if you are not going to reuse them.
	Shelf Settings	Click this icon to jump to the Shelf settings page where you can modify the default shelf location, and enable <a href="#">automatic shelving of base revisions of files</a> for <a href="#">Git</a> and <a href="#">Mercurial</a> .

## Context menu

The context menu is available by right-clicking a change, a change list, or anywhere in the tab.

**Item** **Shortcut** **Description**

	<a href="#">Ctrl+Shift+U</a>	Choose this option to apply changes from the selected shelf. In the <a href="#">Unshelve Changes</a> dialog that opens, specify the changelist you want to add the changes to. For details, see <a href="#">Shelving and Unshelving Changes</a> .
Unshelve		
Restore		Choose this option to re-activate the unshelved changes. By default, unshelved changes are no longer shown in the list of available shelved changes, therefore you first need to have IntelliJ IDEA display it by choosing Show Already Unshelved . You can restore any change as many times as you need until the change is permanently removed by choosing Delete . For details, see <a href="#">Shelving and Unshelving Changes</a> .
	<a href="#">Ctrl+D</a>	Choose this option to open the <a href="#">Differences Viewer for Files</a> and compare the shelved version of a file with its current local version.
Show Diff		
		Choose this option to compare the shelved version of the selected file with its local version in the <a href="#">Differences Viewer for Files</a> .
Compare with Local		
		Choose this option to create a patch file based on shelved changes. In the Create Patch dialog box that opens, specify the file to save the patch in, and the changes to create a patch from. By default, all changes from the shelf are selected. To view which changes are included, click the Selected link. For details, see <a href="#">Creating Patches</a> .
Create Patch		
Import Patches		Choose this option to apply patches created externally or through IntelliJ IDEA. In the dialog that opens, choose the files to import patches from. The imported patches are treated as shelved changes and are shown in the Shelf tab where you can unshelve them at any time.
Rename	<a href="#">Shift+F6</a>	Choose this option to modify the name of the selected shelved changelist.
Delete	Delete	Choose this option to permanently delete the selected shelved change. You can remove any change no matter whether it has been already unshelved or not. For details, see <a href="#">Shelving and Unshelving Changes</a> .

Show Already Unshelved

Choose this option to have IntelliJ IDEA show all available shelved changes, both already applied and not. By default, unshelved changes are hidden. For details, see [Shelving and Unshelving Changes](#).

---

Click this icon to explicitly remove all unshelved changes if you are not going to reuse them.

Clean Already Unshelved

This tab is available when [local information is synchronized](#) to the server.

**Item Tooltip  
and  
shortcut**

	Group by Packages	When this button is pressed, the update information within nodes is grouped by packages.
	Group by Changelists	When this button is pressed, the update information within nodes is grouped by changelists, and by the day the changelist has been committed. The Update Info tab is divided into two panes: the left pane shows the changelists, grouped by the check-in date, and the right pane shows the <a href="#">list of changed files</a> . Grouping by changelists is not available if the project is under Git or Mercurial control.
	Expand all	Use these buttons to have all nodes expanded or collapsed.
		
		Ctrl+NumPad Plus
	Collapse all	
		Ctrl+NumPad -
	Show Diff	Click this button to open the <a href="#">Differences Viewer for Files</a> , where you can compare the local copies of all the project files one after another with their updates from the server. Use the buttons Compare Next File  and Compare Previous File  to scroll through the list of updated files.
	Close	Click this button to close the tab.
		Ctrl+Shift+F4
	Help	Click this button to show reference page.
		F1

The controls of the Changed files pane appear when the button  is pressed.

	Show Diff	Click this button to show differences between the selected and the previous revision for the selected file in the Changes Files pane.
		Ctrl+D
	Show Diff with Local	Click this button to show differences between the selected revision of a file, and its current local copy.
	Edit Source	Click this button to open local copy of the selected file for editing.
		F4
	Open Repository Version	Click this button to open repository version of the selected file.
	Revert Selected Changes	Click this button to revert selected changes.
	Show History	Click this button to open the History view of the selected file in the <a href="#">History Tab</a> of the Version Control tool window.
	Group by Directory	When the button is not pressed, the pane shows a flat list of files. When the button is pressed, the pane shows files in their respective packages. In the latter case, expand and collapse buttons appear in the toolbar.
		Ctrl+P
	Expand all	Use these buttons to have all nodes expanded or collapsed.
		
		Ctrl+NumPad Plus
	Collapse all	
		Ctrl+NumPad -
	Select All	Click this button to select all files in the Changed Files pane.
		Ctrl+A

This tab is only available if your project is under [Mercurial](#) version control.

It displays all patches and allows you to manage the [Mercurial Queue](#).

You can drag-and-drop patches in the queue to change the order in which they will be applied.

## Toolbar and Context Menu

Item	Shortcut	Description	Available from
 Reload from file	Ctrl+F5	Use this command to refresh the list of patches from the <code>series</code> file. Note that when you drag-and-drop patches in the queue, the corresponding changes in the <code>series</code> file will only be saved when you switch to a different tab, or perform some other external action. This allows you to revert such changes simply by reloading from file.	Toolbar
 Goto	Shift+Alt+G	Use this command to apply the selected patch and all patches above it in the queue. The applied patches will become visible in the <a href="#">Log tab</a> and the changes will be registered in the working copy of the repository.	Toolbar Context menu
 Move and Push	Shift+Alt+P	Use this command to apply the selected patch without applying whatever other patches may be before it in the patch stack.	Toolbar Context menu
 Fold	Shift+Alt+D	Use this command to merge the selected non-applied patch with the topmost applied patch, and remove it from the list.	Toolbar Context menu
 Delete	Delete	Use this command to delete the selected patch from the series file	Toolbar
Apply Patch	N/A	Use this command to apply the selected patch. The <a href="#">Apply Patch</a> dialog will be displayed where you can select which changes you want to restore.	Context menu

The tool window opens when you take a snapshot and choose to open it. The tool window shows the collected profiling data. If the window is already opened and shows the profiling data for another session, a new tab is added. Tabs that were opened automatically are named after the run configurations that control execution of the applications and collecting the profiling data.

If you want to open and analyze some previously saved memory profiling data, choose **V8 Profiling - Analyze V8 Heap Snapshot** on the main menu and select the relevant `.snapshot` file. IntelliJ IDEA creates a separate tab with the name of the selected file.

The tool window has three tabs that present the collected information from different points of view.

On this page:

- [Containment](#)
- [Biggest Objects](#)
- [Summary](#)
- [Details Pane](#)
- [Toolbar](#)
- [Context Menu of an Object](#)

## Containment

The tab shows the objects in your application grouped under several top-level entries: **DOMWindow objects**, **Native browser objects**, and **GC Roots**, which are roots the **Garbage Collector** actually uses. See [Containment View](#) for details.

For each object, the tab shows its **distance from the GC root**, that is the shortest simple path of nodes between the object and the GC root, the **shallow size** of the object, and the **retained size** of the object. Besides the absolute values of the object's size, IntelliJ IDEA shows the percentage of memory the object occupies.

## Biggest Objects

The tab shows the most memory-consuming objects sorted by their **retained sizes**. In this tab, you can spot memory leaks provoked by accumulating data in some global object.

## Summary

The tab shows the objects in your application grouped by their types. The tab shows the number of objects of each type, their size, and the percentage of memory that they occupy. This information may be a clue to the memory state.

## Details Pane

Each tab has a Details pane, which shows the path to the currently selected object from GC roots and the list of object's **retainers**, that is, the objects that keep links to the selected object. Every heap snapshot has many "back" references and loops, so there are always many retainers for each object.

## Navigating through a Snapshot

- To help differentiate objects and move from one to another without losing the context, mark objects with text labels. To set a label to an object, select the object of interest and click  on the toolbar or choose **Mark** on the context menu of the selection. Then type the label to mark the object with in the dialog box that opens.
- To navigate to the function or variable that corresponds to an object, select the object of interest and click  on the toolbar or choose **Edit Source** on the context menu of the selection. If the button and the menu option are disabled, this means that IntelliJ IDEA has not found a function or a variable that corresponds to the selected object. If several functions or variables are found, they are shown in a pop-up suggestion list.
- To jump from an object in the Biggest Objects or Summary tab or Occurrences view to the same object in the Containment tab, select the object in question in the Biggest Objects or Summary tab and click  on the toolbar or choose **Navigate in Main Tree** on the context menu of the selection. This helps you investigate the object from the containment point of view and concentrate on the links between objects.
- To search through a snapshot:
  1. In the Containment tab, click  on the toolbar.
  2. In the [V8 Heap Search Dialog](#) that opens, specify the search pattern and the scope to search in. The available scopes are:
    - **Everywhere**: select this checkbox to search in all the scopes. When this checkbox is selected, all the other search types are disabled.
    - **Link Names**: select this checkbox to search among the object names that V8 creates when calling the **C++ runtime**, see <http://stackoverflow.com/questions/11202824/what-is-in-javascript>. In the [V8 Heap Tool Window](#), link names are marked with the `%` character (`%<link name>`).
    - **Class Names**: select this checkbox to search among functions-constructors.
    - **Text Strings**: select this checkbox to perform a textual search in the contents of the objects.
    - **Snapshot Object IDs**: select this checkbox to search among the unique identifiers of objects. V8 assigns such a unique identifier in the format `<id>` to each object when the object is created and preserves it until the object is destroyed. This means that you can find and compare the same objects in several snapshots taken within the same session. In the [V8 Heap Tool Window](#), object IDs are marked with the `@` character (`@<object id>`).

- Marks: select this checkbox to search among the labels you set to objects manually by clicking  on the toolbar of the Containment tab.

The search results are displayed in the Details pane, in a separate Occurrences of '<search pattern>' view. To have the search results shown grouped by the search scopes you specified, press the Group by Type toggle button on the toolbar.

When you open the dialog box next time, it will show the settings from the previous search.

## Toolbar

The toolbar is common for all tabs and most of the toolbar buttons are available in all tabs.

### ItemDescriptionAvailable in

	Click this button to set a label to the selected object. This helps you differentiate objects and move from one to another without losing the context.	Containment tab, Biggest Objects tab, Summary tab, Details pane, Occurrences view
	Click this button to find a function in a snapshot: in the <a href="#">V8 Heap Search Dialog</a> that opens, specify the search pattern and the scope to search in. The available scopes are: <ul style="list-style-type: none"> <li>– Everywhere: select this checkbox to search in all the scopes. When this checkbox is selected, all the other search types are disabled.</li> <li>– Link Names: select this checkbox to search among the object names that V8 creates when calling the C++ runtime , see <a href="http://stackoverflow.com/questions/11202824/what-is-in-javascript">http://stackoverflow.com/questions/11202824/what-is-in-javascript</a> . ## Context Menu of an Object

### ItemDescription

Mark	Choose this option to set a label to the selected object. This helps you differentiate objects and move from one to another without losing the context.
Navigate in Main Tree	Choose this option to jump from an object in the Biggest Objects or Summary tab or Occurrences view to the same object in the Containment tab. This helps you investigate the object from the containment point of view and concentrate on the links between objects.
Jump to Source	Choose this option to navigate to the function or variable that corresponds to the selected object.

The dialog box opens when you click  on the toolbar in the [V8 Heap Tool Window](#). Use the dialog box to find constructors, object IDs, character strings, etc. in a snapshot. The search results are displayed in the Details pane, in a separate Occurrences of '<search pattern>' view.

#### ItemDescription

---

Search	In this text box, type the search pattern to look for. Select the Case Sensitive checkbox if necessary.
Scope	<p>In this area, specify the type of objects to limit the search to. When the Everywhere checkbox is selected, all the other search types are not available.</p> <ul style="list-style-type: none"><li>- Everywhere: select this checkbox to search in all the scopes. When this checkbox is selected, all the other search types are disabled.</li><li>- Link Names: select this checkbox to search among the object names that V8 creates when calling the C++ runtime, see <a href="http://stackoverflow.com/questions/11202824/what-is-in-javascript">http://stackoverflow.com/questions/11202824/what-is-in-javascript</a>. In the <a href="#">V8 Heap Tool Window</a>, link names are marked with the % character ( %&lt;link name&gt; ).</li><li>- Class Names: select this checkbox to search among functions-constructors.</li><li>- Text Strings: select this checkbox to perform a textual search in the contents of the objects.</li><li>- Snapshot Object IDs: select this checkbox to search among the unique identifiers of objects. V8 assigns such a unique identifier in the format to each object when the object is created and preserves it until the object is destroyed. This means that you can find and compare the same objects in several snapshots taken within the same session. In the <a href="#">V8 Heap Tool Window</a>, object IDs are marked with the @ character ( @&lt;object id&gt; ).</li><li>- Marks: select this checkbox to search among the labels you set to objects manually by clicking  on the toolbar of the Containment tab.</li></ul>

The tool window is opened automatically when you stop the **Node.js** application you are profiling. If the window is already opened and shows the profiling data for another session, a new tab is added. Tabs that were opened automatically are named after the run configurations that control execution of the applications and collecting the profiling data.

If you want to open and analyze some previously saved profiling data, choose **V8 Profiling - Analyze V8 Profiling Log** on the main menu and select the relevant V8 log file `isolate-<session number>`. IntelliJ IDEA creates a separate tab with the name of the log file.

Based on the collected profiling data, IntelliJ IDEA builds three call trees and displays each of them in a separate pane. Having several call trees provides the possibility to analyze the application execution from two different points of view: on the one hand, which calls were time consuming ("heavy"), and on the other hand, "who called whom".

On this page:

- [Toolbar](#)
- [Context Menu](#)
- [Top Calls Pane](#)
- [Bottom-up Pane](#)
- [Top-down Pane](#)
- [Flame Chart](#)
- [Selecting a Fragment in the Timeline](#)
- [Synchronization in the Flame Chart](#)

## Toolbar

**Item** **Tooltip** **Description** **Available**  
in

	Jump to source	Click this button to navigate to the function definition.	Top Calls Bottom-up Top-down
	Filter	Click this button to filter out light calls and have IntelliJ IDEA display only the calls that indeed cause performance problems. Using the slider, specify the minimum <b>Total%</b> or <b>Parent%</b> value for a call to be displayed and click Done .	Top Calls Bottom-up Top-down
	Expand Heavy Traces	When a tab for a profiling session is opened, by default the nodes with heaviest calls are expanded. While exploring the trees, you may like to fold some nodes or expand other ones. Click this button to restore the original tree presentation.	Top Calls Bottom-up Top-down
 	Expand All/ Collapse All	Click these buttons to expand or collapse all the nodes in the current pane.	Top Calls Bottom-up Top-down
	Export to text file/ Export Timeline Chart	Click this button to save the call tree in the current pane to a text file or the current timeline chart to a <code>.png</code> file. Then specify the target file in the dialog box that opens.	All
	Help	Click this button to navigate to the Help topic for the tool window.	All
	Close	Click this button to close the V8 Profiling tool window.	All
	Zoom	Click this button to open the selected fragment of the flame chart in a separate tab and have the selected fragment enlarged to fit the tab width so you can examine the fragment with more details.	Flame Chart

## Context Menu

The context menu is available only from items in the Top Calls , Bottom-up , and Top-down panes.

**Item** **Description**

Copy Call	Choose this option to copy the name of the selected function and the name of the file where it is defined to the Clipboard.
Copy	Choose this option to copy the name of the selected function, the name of the file where it is defined, and the measurements data. This may be helpful if you want to compare the measurements for a function from two sessions, for example, after you make some improvements to the code.
Compare with Clipboard	Choose this option to compare the selected with the contents of the Clipboard in the <a href="#">Difference Viewer</a> that opens.
Expand Node/	Choose these options to expand or collapse the selected tree node.

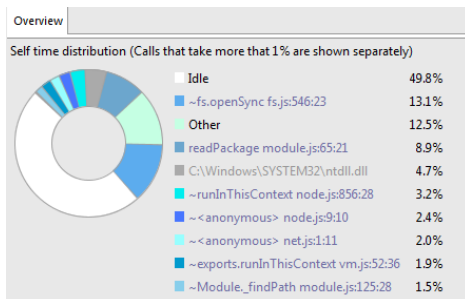

Collapse Node

## Top Calls Pane

The Top Calls pane shows a list of performed activities sorted in the descending order by the **Self** metrics. For each activity IntelliJ IDEA displays its **Total**, **Total%**, and **Self%** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined.

Calls	Total	Total %	Self %
Unknown <total>	1153	98%	0%
JavaScript	730	62%	62%
Function: ~<anonymous> jcs:1:11	730	62%	62%
Function: ~_rng uuid.js:20:29	83	7%	7%
Function: ~ScriptBreakPoint.set native debug.js:266:40	59	5%	5%
Function: ~exports.runInThisContext vm.js:68:36	45	3%	3%
Function: ~runInThisContext node.js:733:28	40	3%	3%
Function: ~FrameMirror.evaluate native mirror.js:895:40	16	1%	1%
Function: ~fs.statSync fs.js:707:23	14	1%	1%
LazyCompile: ~test native regexp.js:129:20	6	0%	0%
LazyCompile: ~captureStackTrace native messages.js:808:27	6	0%	0%
Function: ~fs.lstatSync fs.js:702:24	6	0%	0%
Function: ~fs.openSync fs.js:440:23	5	0%	0%
LazyCompile: Join native array.js:68:14	4	0%	0%

The diagram in the Overview pane shows distribution of self time for calls with the **Self%** metrics above 1%.

## Bottom-up Pane

The Bottom-up pane also shows the performed activities sorted in the descending order by the **Self** metrics. Unlike the Top Calls pane, the Bottom-up pane shows only the activities with the **Total%** metrics above 2 and the functions that called them.

This is helpful if you encounter a **heavy** function and want to find out where it was called from.

For each activity IntelliJ IDEA displays its execution time in **ticks** and the **Of Parent** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined.

## Top-down Pane

The Top-down pane shows the entire call hierarchy with the functions that are execution entry points at the top. For each activity IntelliJ IDEA displays its **Total**, **Total%**, **Self**, and **Self%** metrics. For each function call, IntelliJ IDEA displays the name of the file, the line, and the column where the function is defined. Some of the functions may have been optimized by V8, see [Optimizing for V8](#) for details.

- The functions that have been optimized are marked with an asterisk (\*) before the function name.
- The functions that possibly require optimization but still have not been optimized are marked with a tilde (~) character before the function name. Though optimization may be delayed by the engine or skipped if the code is short-running, a tilde (~) points at a place where the code can be rewritten to achieve better performance.

Calls	Total	Total %	Self	Self %
Function: listOnTimeout timers.js:94:23	1084	92%	0	0%
Function: ~Module.runMain module.js:488:26	1084	92%	0	0%
Function: Module_load module.js:268:24	1084	92%	0	0%
Function: ~Module.load module.js:339:33	1070	91%	0	0%

## Flame Chart

Use the multicolor chart in the Flame Chart tab to find where the application paused and explore the calls that provoked these pauses. The chart consists of four areas:

- The upper area shows a timeline with two sliders to limit the beginning and the end of a fragment to investigate.
- The bottom area shows a stack of calls in the form of a multicolor chart. When called for the first time, each function is assigned a random color, whereupon every call of this function within the current session is shown in this color.
- The middle area shows a summary of calls from the **Garbage Collector**, the engine, the external calls, and the execution itself. The colors reserved for the **Garbage Collector**, the engine, the external calls, and the execution are listed on top of the area:

- The right-hand pane lists the calls within a selected fragment, for each call the list shows its duration, the name of the called function, and file where the function is defined.

## Selecting a Fragment in the Timeline

To explore the processes within a certain period of time, you need to select the fragment in question. You can do it in two ways:

- Use the sliders:

- Click the **window** between two sliders and drag it to the required fragment:

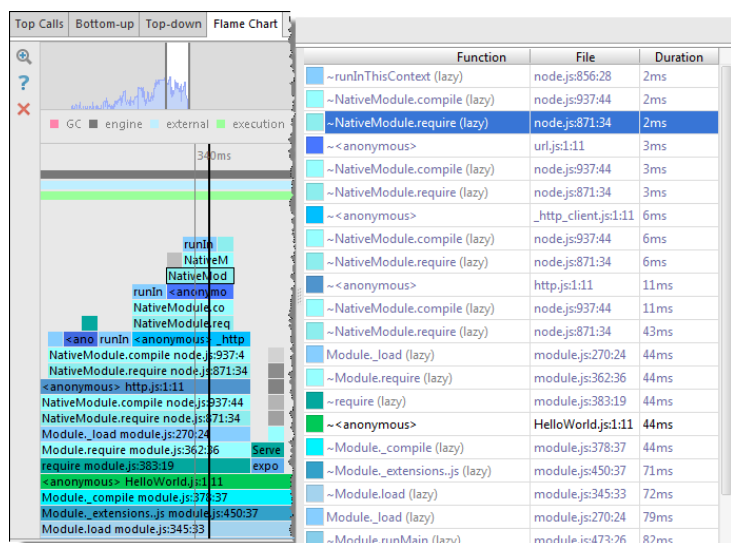

In either case, the multicolor chart below shows the stack of calls within the selected fragment.

To enlarge the chart, click the selected fragment and then click the Zoom button  on the toolbar. IntelliJ IDEA opens a new tab and shows the selected fragment enlarged to fit the tab width so you can examine the fragment with more details.

## Synchronization in the Flame Chart

The bottom and the right-hand areas are synchronized: as you drag the slider in the bottom area through the timeline the focus in the right-hand pane moves to the call that was performed at each moment.

Moreover, if you click a call in the bottom area, the slider moves to it automatically and the focus in the right-hand pane switches to the corresponding function, if necessary the list scrolls automatically. And vice versa, if you click an item in the list, IntelliJ IDEA selects the corresponding call in the bottom area and drags the slider to it automatically.

IntelliJ IDEA supports navigation from the right-hand area to the source code of called functions, to the other panes of the tool window, and to areas in the flame chart with specific metrics.

- To jump to the source code of a called function, select the call in question and choose Jump to Source on the context menu of the selection.
- To switch to another pane, select the call in question, choose Navigate To on the context menu of the selection and then choose the destination:
  - Navigate in Top Calls
  - Navigate in Bottom-up
  - Navigate in Top-down

IntelliJ IDEA switches to the selected pane and moves the focus to the call in question.

- To have the flame chart zoomed at the fragments with specific metrics of a call, select the call in question, choose Navigate To on the context menu of the selection, and then choose the metrics:
  - Navigate to Longest Time
  - Navigate to Typical Time
  - Navigate to Longest Self Time
  - Navigate to Typical Self Time

You can also navigate to the stacktrace of a call to view and analyze exceptions. To do that, select the call in question and choose Show As Stacktrace . IntelliJ IDEA opens the stacktrace in a separate tab, to return to the Flame Chart pane, click V8 CPU Profiling tool window button in the bottom tool window.

This tool window shows your deployment descriptors, servlets, filters, listeners, and web resource directory contents. (The tool window is not available if there are no Web facets in your project.)

## Main context menu commands

### CommandDescription

---

Jump to Source ( Open the selected file in the editor. (Alternatively, you can double-click the file.)

**F4** )

New ( If a Web facet is selected: Create a new servlet, filter or listener. If a directory is selected: Create a new file or directory.

**Alt+Insert** )

From the Welcome screen (if no project is currently open): Import Project

File | New | Project from Existing Sources

File | New | Module from Existing Sources

From the Project Structure dialog: Modules | [+](#) | Import Module

---

Use this wizard to import existing sources into IntelliJ IDEA and, as a result, to create a new [project](#) ( New | Project from Existing Sources ) or to add a [module](#) (or a number of modules) to an existing project ( New | Module from Existing Sources ).

- [Origin of the Sources](#)
- [Import Existing Sources. Project Name and Location](#)
- [Import Existing Sources. Source Root Directories](#)
- [Import Existing Sources. Libraries](#)
- [Import Existing Sources. Module Structure](#)
- [Import Existing Sources. Project SDK](#)
- [Import Existing Sources. Frameworks](#)
- [Import from Bnd/Bndtools. Page 1](#)
- [Import from Eclipse. Page 1](#)
- [Import from Eclipse. Page 2](#)
- [Import from Flash Builder. Page 1](#)
- [Import from Flash Builder. Page 2](#)
- [Import Project from Gradle. Page 1](#)
- [Import from Maven. Page 1](#)
- [Import from Maven. Page 2](#)
- [Import from Maven. Page 3](#)
- [Import from Maven. Page 4](#)
- [Import Project from SBT. Page 1](#)

If the sources that you are importing come from [Bnd/Bndtools](#) , [Eclipse](#) , [Flash Builder](#) , [Gradle](#) , or [Maven](#) , select Import project from external model or Import module from external model , and select Bnd/Bndtools , Eclipse , Flash Builder , Gradle , or Maven respectively.

Otherwise, select Create project from existing sources or Create module from existing sources .

Specify the project name and location.

#### ItemDescription

---

Project name Specify the name of the project to be created.

---

Project location Specify the path to the directory in which your sources, libraries and other assets of interest are located.  
You can click  (  ) and select the necessary directory in the [dialog that opens](#) .

Note that the specified directory will act as the project root directory. (In technical terms, this is where the `.idea` directory will be created. For more information, see [Configuring projects](#) .)

This page shows the directories in which source files are found. Potentially, these directories may be your [source root directories](#) .

Use the checkboxes to select the directories which you want to include in your project as the source root directories .

---

**ItemDescription**

Mark All

Use this button to select all the directories.

Unmark All

Use this button to deselect all the directories.

This page lets you select and configure the [libraries](#) to be included in your project.

In the left-hand pane, under Libraries , the list of libraries and archives found in the specified location are shown. When you highlight an item in this pane, its contents are shown in the right-hand pane under Library contents .

Use the checkboxes to select the libraries which you want to include in your project. Use other controls available on this page to rename the libraries, and also split or merge them (see below).

**ItemDescription**

---

Click this icon to rename the selected (highlighted) library or archive.

---

Click this icon to join several selected (highlighted) libraries or archives into a new library.

---

Click this button to split the selected (highlighted) library into two parts. In the Split Library dialog, select the files to be extracted into the new library.

This page lets you select and configure the [modules](#) to be included in your project.

In the left-hand pane, under Modules , the modules that potentially may be included in your project are shown. When you highlight a module in this pane, its dependencies are shown in the right-hand pane under Module dependencies . (If you highlight a number of modules, their aggregated dependencies are shown.)

Use the checkboxes to select the modules which you want to include in your project. Use other controls available on this page to rename the modules, and also split or merge them (see below).

#### ItemDescription

Click this icon to rename the selected (highlighted) module.

Click this icon to join several selected (highlighted) modules into a new one.

Click this icon to split the selected (highlighted) module into two parts. In the Split Module dialog, select the [content roots](#) to be assigned to the new module.

Specify the [SDK](#) to be used in your project .

If the necessary SDK is already defined in IntelliJ IDEA, select it in the pane under [+](#) and [-](#) (in the left-hand part of the page).

Otherwise, click [+](#) and select the [SDK type](#) . Then, in the [dialog that opens](#) , select the installation folder of the desired SDK.  
(By this time, the corresponding SDK must already be installed on your computer. If it isn't, download and install it first.)

If within the specified location IntelliJ IDEA finds the files that are indicators of certain frameworks and technologies, you can choose to enable support for these frameworks and technologies. To select the necessary frameworks and technologies, use the corresponding checkboxes.

#### ItemDescription

---

- Group by
- Specify how the files-indicators should be grouped:
- Type. The files are grouped by frameworks and technologies. The files that belong to the same technology appear in the same group. Group names correspond to the names of the frameworks and technologies.
  - Directory. The files are grouped by their locations. The files located in the same directory appear in the same group.

Use this page to select a Bnd/Bndtools project to import.

---

**ItemDescription**

---

Select Bnd/Bndtools projects to import	Use this area to select a Bnd/Bndtools project that you want to import.
Select all	Click this button to select all the checkboxes next to Bnd/Bndtools projects for importing.
Unselect all	Click this button if you want to clear all the checkboxes next to Bnd/Bndtools projects.
Open Project Structure after import	Select this checkbox to open the <a href="#">Project Structure</a> dialog right after you import your project.

Use this page to define the source workspace and the target location for the imported Eclipse projects.

---

**ItemDescription**

Select Eclipse project directory	Specify the path to the Eclipse workspace that contains projects to be imported. You can type the path, or click the ellipsis button and locate the desired directory in the Select Path dialog.
----------------------------------	--

---

IntelliJ IDEA project and module files location	<b>OptionDescription</b>
---	--------------------------

---

Create module files near .classpath files	If you select this option, an IntelliJ IDEA module per each Eclipse project will be created in the respective projects directory; the IntelliJ IDEA project in the specified format will be created in the root of the Eclipse workspace, or Eclipse project directory.
---	---

---

Keep project and module files in	If you select this option, enter the target location of the *.iml files to be created from the imported Eclipse projects, or click the ellipsis button, and navigate to the desired location.
----------------------------------	---

---

Project file format	Choose <a href="#">file-based</a> or <a href="#">directory-based format</a> of saving project.
---------------------	--

---

Link created IntelliJ IDEA modules to Eclipse project files	Check this option to automatically keep the Eclipse projects and IntelliJ IDEA modules synchronized.
---	--

---

Detect test sources	Specify the list of roots, where test sources should be sought for. Refer to the <a href="#">Compiler</a> section for the wildcards syntax.
---------------------	---

Use this page to browse the projects detected in the selected Eclipse workspace and choose the ones to be imported to the IntelliJ IDEA project.

**ItemDescription**

---

Select Eclipse projects to import    In the list of projects detected in the specified root, select the ones to be imported. Each Eclipse project will be converted into an IntelliJ IDEA module.

---

Open Project Structure after import    Select this checkbox to have the [Project Structure](#) dialog box opened when the import is completed.

Specify the Flash Builder projects to be imported and associated settings.

#### ItemDescription

Flash Builder workspace or project...	<p>Specify the location of a file or directory that you want to use as a source of import. This can be:</p> <ul style="list-style-type: none"><li>- A Flash Builder workspace or project directory</li><li>- A <code>.project</code> file</li><li>- A <code>.fxp</code> or <code>.fxpl</code> file</li><li>- A <code>.zip</code> file that contains an ActionScript project or projects.</li></ul> <p>Type the path to the necessary file or directory right in the field, or click  and select the desired file or folder in the <a href="#">dialog that opens</a> .</p>
Project name	<p>When creating a project: specify the name of the IntelliJ IDEA <a href="#">project</a> to be created.</p>
Project location	<p>When creating a project: specify the project location. (This is where the <code>.idea</code> directory or a <code>.ipr</code> file will be created, see <a href="#">Configuring projects</a> . Besides, if you are importing an archive ( <code>.fxp</code> , <code>.fxpl</code> , or <code>.zip</code> ), the archive will be extracted into this folder or its subfolder.)</p> <p>Edit the path in the field or click  and select the desired folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>
Create subfolder...	<p>When creating a project: this option is available if there is only one project within the Flash Builder source that you are importing. In such a case, you have an option of creating a subfolder in the <a href="#">project folder</a> and placing the imported project there.</p> <p>If the source contains two or more projects, the individual subfolders will be created for each of them.</p>
Project format	<p>When creating a project: if necessary, change the suggested <a href="#">project format</a> .</p>
Extract project to or	<p>When importing into an existing project: if you are importing an archive ( <code>.fxp</code> , <code>.fxpl</code> , or <code>.zip</code> ), you can specify where the archive should be extracted. If the source contains two or more projects, individual subfolders in the specified location will be created for each of them.</p>
Multiple projects found...	<p>Edit the path in the field or click  and select the desired folder in the <a href="#">dialog that opens</a> . (You can create a new folder in that dialog, e.g. by using  .)</p>

If you are importing a Flash Builder workspace, this page shows the projects detected therein. Select the projects that you want to import.

**ItemDescription**

---

Select Flash Builder projects to import      Select the projects that you want to import.

---

Open Project Structure after import      Select this checkbox to have the [Project Structure dialog](#) opened when the import is completed.

## ItemDescription

Gradle project	Specify the address of the <code>build.gradle</code> file of the project you want to import. Type the path manually, or click the browse button  and locate the desired file in the file chooser dialog.
Create directories for empty content roots automatically	Select this option to add a <code>src</code> directory to your project automatically when you import a project from Gradle model.
Create separate module per source set	Select this checkbox to use the <a href="#">source set</a> feature in resolving your Gradle projects.
Use default gradle wrapper (not configured for the current project)	Select this option to use Gradle wrapper. Using Gradle wrapper lets you get automatic Gradle download for the build. It also lets you build with the precise Gradle version.
Use customizable gradle wrapper	Select this option to configure a Gradle wrapper inside your <code>build.gradle</code> file. In this case IntelliJ IDEA ensures that the configured customizable wrapper settings are used for working with Gradle.
Use local gradle distribution	Select this option to run local build scripts.
Gradle home	By default, IntelliJ IDEA displays the path to the Gradle installation, as defined in the <code>GRADLE_HOME</code> environment variable, or specified as the <a href="#">Gradle home project setting</a> . If the path is unknown, or you want to use a different Gradle installation, click the browse button  and locate the desired directory in the path chooser dialog.
Project format	Select the format in which you want to store your project. For the details on the two available formats, refer to the <a href="#">Configuring projects</a> section.
Global Gradle Settings	Use this area to set global Gradle settings. You can select from the following options: <ul style="list-style-type: none"><li>– Offline work - use this checkbox to work with Gradle in the offline mode. In this case Gradle will use dependencies from the cache. Gradle will not attempt to access the network to perform dependency resolution. If required dependencies are not present in the dependencies' cache, a build execution will fail.</li><li>– Service directory path - use this field to override the default Gradle home location directory.</li><li>– Gradle VM options - use this field to specify VM options for your Gradle project. When specifying the options, follow these rules:<ul style="list-style-type: none"><li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li><li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg" or "some arg"</code> .</li><li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop="\quoted_value"</code> .</li></ul></li></ul>

Use this page to specify the import preferences. The default import settings are defined in the [Maven Integration dialog](#).

#### ItemDescription

Root directory	Specify the directory where the Maven projects you want to import are located.
Search for projects recursively	Select this checkbox to make import look for the nested <code>pom.xml</code> files.
Project format	Select the format in which you want to store your project. For the details on the two available formats, refer to the <a href="#">Configuring projects</a> section.
Keep project files in	Select this checkbox to specify the desired location for storing project and module files.
Import Maven projects automatically	Select this checkbox if you want IntelliJ IDEA to perform reimport automatically each time you change your <code>pom.xml</code> .
Create IntelliJ IDEA modules for aggregator projects (with 'pom' packaging)	Clear this checkbox to skip creating IntelliJ IDEA modules. You might want to do that if the Maven project you import is an aggregator, and its <code>packaging</code> element has the value <code>pom</code> .
Create module groups for multi-module Maven projects	If this checkbox is selected, IntelliJ IDEA will create a module group from an aggregative Maven project, with the nested modules included in this group.
Keep source and test folders on reimport	If this checkbox is selected, the source and test folders are kept when you reimport a project.
Exclude build directory (PROJECT_ROOT/target)	Clear this checkbox to disable the automatic exclusion of target folders.  Note if a <code>/target</code> directory contains <code>/target/generated-sources</code> , then the <code>/target</code> directory cannot be excluded since <code>/target/generated-sources</code> directory is marked as <code>sources</code> . Other subdirectories in the <code>/target</code> directory are excluded.
Use Maven output directories	If this checkbox is not selected, the build is created in the regular IntelliJ IDEA's output directory <code>USER_HOME\IdeaProjects\&lt;project&gt;\classes\Production\</code> .  If this checkbox is selected, the build is generated in the Maven's output directory, and the results of IntelliJ IDEA's compilation are reused. However, IntelliJ IDEA itself does not reuse Maven build results and performs compilation <i>from scratch</i> .
Generated sources folders	Specify the directory of your source root when you reimport a project.  You can select one of the following options: <ul style="list-style-type: none"><li>- Detect automatically This is a default option. When you select this option, IntelliJ IDEA automatically detects the location of the generated sources. IntelliJ IDEA also detects which directory to mark as a source root.  Note that IntelliJ IDEA searches for the generated sources only in <code>target/generated-sources</code> and <code>target/generated-sources/*</code> directories.</li><li>- target/generated-sources This option enables you to mark the directory as a source root manually.</li><li>- subdirectories of "target/generated-sources" This option enables you to mark a subdirectory as a source root manually.</li></ul>
Phase to be used for folders update	Select Maven phase to be used for folders update. This might be useful if you adjust your plugins so that the additional sources are loaded at some phase.
Automatically download	Specify the automatic download of sources and documentation comments into a local repository when you open a Maven project.  You can select one or both of the following checkboxes: <ul style="list-style-type: none"><li>- Sources</li><li>- Documentation</li></ul>
Dependency types	Use this field to specify dependency types that you want to include in your import.
Environment settings	Click this button to specify <a href="#">Maven Environment</a> settings.

Use this page to specify Maven environment settings.

---

**ItemDescription**

---

Maven home directory	Use this drop-down list to select a bundled Maven version that is available (for Maven2, version 2.2.1 and for Maven3, version 3.0.5) or the result of resolved system variables such as <code>MAVEN_HOME</code> or <code>MAVEN2_HOME</code> . You can also specify your own Maven version that is installed on your machine. You can click  and select the necessary directory in the <a href="#">dialog that opens</a> .
----------------------	---

---

User settings file	Specify the path to the file that contains user-specific configuration for Maven.
--------------------	---

---

Local repository	By default, the field shows the path to the local directory under the user home that stores downloads and contains the temporary build artifacts that you have not yet released.
------------------	--

---

Override	Select this checkbox next to a field where you need to specify a different directory, click the ellipsis button and select the desired path.
----------	--

Use this page of the wizard to select the Maven profiles to be applied to the new project.

**ItemDescription**

---

Select profiles

Check the build profiles to be applied to the new project.

Use this page to select the Maven project to be imported into the new IntelliJ IDEA project.

---

**ItemDescription**

---

Select Maven projects to import      In the list of Maven projects, detected in the specified root, check the projects to be imported.

Open project structure after import      Check this option to open the [Project Structure dialog](#) after completing the import.

Use this page to create a name for your new IntelliJ IDEA project.

---

**ItemDescription**

---

Project name Specify the name of your IntelliJ IDEA project.

---

Project file location Specify the location of your project directory where IntelliJ IDEA stores the configuration data for your project and its components.

You can use ellipsis button to navigate to the appropriate directory.

Use this page to specify SBT import project settings.

#### ItemDescription

SBT project	Specify the name of the project that you import.
Use auto-import	Select this checkbox to resolve all changes made to the SBT project automatically every time you refresh your project.
Create directories for empty content roots automatically	Select this checkbox to add an <code>src</code> directory to your project.
Download sources and docs	Select this checkbox to download dependencies and their sources for your project.
Download SBT sources and docs	Select this checkbox to download SBT dependencies and their sources for your project. The dependencies are used in build files such as <code>build.sbt</code> .
Project SDK	Use this field to specify SDK to be used in your project.  If the project SDK is already defined in IntelliJ IDEA, select it from the list. Otherwise, click New and select the installation folder of the desired IntelliJ IDEA version.
Global SBT settings	Use this area to set global SBT settings.
JVM	Use this area to set JVM. You can choose from the following options: <ul style="list-style-type: none"><li>– From project JDK - use this option if you want to use a default JVM from your project's JDK.</li><li>– Custom - use this option if you want to use a custom JVM.</li></ul>
JVM Options	Use this area to set the following JVM options: <ul style="list-style-type: none"><li>– Maximum heap size, MB - use this field to specify the maximum heap size available to the process that launches the compiler. The default 768 Mb is suitable for most of the purposes.</li><li>– VM parameters - use this field to type the string to be passed to the VM when IntelliJ IDEA launches the compiler. If you need more room to type, click  to open the VM parameters dialog where the text entry area is larger.</li></ul>
Launcher (sbt-launch.jar)	Use this area to specify the SBT launcher. You can choose from the following options: <ul style="list-style-type: none"><li>– Bundled - select this option if you want to use a default launcher located the plugin directory. The latest version of the launcher is usually available.</li><li>– Custom - select this option if you want to use a custom launcher. Specify the path to the location of your custom launcher.</li></ul>

In this dialog box, appoint the packages to be added to the current project.

#### ItemDescription

---

**Available packages** From this list, select the package that you need in your project. The list shows all the available packages, the packages that are already installed are marked with a tick. Use the search field, if necessary: start typing the search string, as you type, the list dynamically reduces to show the packages that match the entered pattern. The Description read-only text box briefly explains the functionality of the selected package.

---

**Version to install** From this drop-down list, select the package version. The contents of the list depend on the specific package.

---

**Install** When you click this button, IntelliJ IDEA starts downloading the appointed package. When the process is completed, IntelliJ IDEA creates a new folder under the vendor node stores the downloaded package in it, and adds the package to the list in the `require` section of `composer.json`.

---

**Settings** In this area, specify the advanced installation options:

- PHP interpreter: choose one of the configured PHP interpreters from the list.
- Command line parameters: in this text box, type the additional command line parameters. For example, to have a dependency added to the `require-dev` section instead of the default `require` section, type `--dev`. For more information about Composer command line options during installation, see <https://getcomposer.org/doc/03-cli.md>.

From the [Project Tool Window](#) : right-click a module folder and select Add Framework Support .

Select the technologies, frameworks and languages to be supported, and specify the associated settings. For general info, see [Configuring projects](#) .

- [Web Application](#)
- [Struts](#)
- [Struts 2](#)
- [WebServices](#)
- [JSF](#)

## Web Application

Select the checkbox to enable generic [Web application](#) development support. See also, [Enabling Web Application Support](#)

### ItemDescription

Version	Select the version of the Servlet specification to be supported.
Create web.xml	For version 3.0 or later: select this checkbox to create the <a href="#">deployment descriptor</a> file <code>web.xml</code> . (For earlier versions, this file is always created.)

## Struts

Select the checkbox to enable [Apache Struts](#) 1.x support. See also, [Preparing to Use Struts](#) .

### ItemDescription

Version	Select the Struts version to be supported. If you also choose to download the library files that implement Struts (the Download option), the selected version will define which files you will be able to download.
---------	--

Libraries	<p>You'll need a <a href="#">library</a> that implements Struts. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>- Download. Select this option to download the library files that implement the selected Struts version. (The downloaded files will be arranged in a <a href="#">library</a> .)</li><li>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>- Set up library later. Select this option to postpone setting up the library until a later time.</li></ul>
-----------	--

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Struts 2

Select the checkbox to enable [Apache Struts 2](#) support. See also, [Preparing to Use Struts 2](#) .

You'll need a [library](#) that implements Struts 2. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Struts 2. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## WebServices

Select the checkbox to enable [Web Services](#) development support. See also, [Preparing to Develop a Web Service](#) .

### ItemDescription

Generate sample server code	Select this checkbox to have a sample <code>HelloWorld</code> class created in your source folder (e.g. <code>src</code> ).
Configure	Click this link to specify the settings for WS engines that you want to use. (The <a href="#">Web Services dialog</a> will open.)

## JSF

Select the checkbox to enable [JavaServer Faces](#) (JSF) support. See also, [Preparing for JSF Application Development](#) .

### ItemDescription

Version	Select the JSF version to be supported.
Libraries	<p>You'll need a <a href="#">library</a> that implements JSF. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <code>Ctrl</code> key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>- Download. Select this option to download the library files that implement JSF. (The downloaded files will be arranged in a <a href="#">library</a> .)</li><li>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>- Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## Primefaces, Richfaces, Openfaces, or Icefaces

Select the checkbox to be able to use the corresponding JSF component library ([PrimeFaces](#) , [RichFaces](#) , [OpenFaces](#) , or [ICEfaces](#) ). See also, [Preparing for JSF Application Development](#) .

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the corresponding JSF component library files. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Google App Engine

Select the checkbox to be able to use [Google App Engine](#) . See also, [Creating Google App Engine Project](#) .

#### ItemDescription

Google App Engine SDK	Specify the path to the Google App Engine SDK for Java installation directory. You can click  and select the corresponding directory in the <a href="#">dialog that opens</a> .
Persistence	If necessary, select the <a href="#">App Engine Datastore implementation</a> to be supported (JDO or JPA).
Download	If the path to Google App Engine SDK is not specified, you can click this link to open the <a href="#">Google App Engine Downloads page</a> . (This page lets you download the latest version of Google App Engine SDK for Java.)

## Groovy

Select the checkbox to enable [Groovy](#) support.

Select an existing Groovy library or create a new [library](#) for Groovy:

- Use library. Select the Groovy library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).
- Create. If Groovy is already installed on your computer, you can create a [library](#) for Groovy and use that new library. To do that, click Create and select the Groovy installation directory in the [dialog that opens](#) .

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

## Hibernate

Select the checkbox to enable [Hibernate](#) support. See also, [Enabling Hibernate Support](#) .

#### ItemDescription

Create default hibernate configuration and main class	Select this checkbox to have a Hibernate configuration file <code>hibernate.cfg.xml</code> and a class with the <code>main()</code> method created.
Import database schema	Select this checkbox to have a database schema imported automatically.
Libraries	<p>You'll need a <a href="#">library</a> that implements Hibernate. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).</li><li>– Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the  key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>– Download. Select this option to download the library files that implement Hibernate. (The downloaded files will be arranged in a <a href="#">library</a> .)</li><li>– Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>– Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## JavaEE Persistence

Select the checkbox to enable [Java Persistence API](#) (JPA) support. See also, [Enabling JPA Support](#) .

#### ItemDescription

persistence.xml version	Select the version of the <code>persistence.xml</code> file that you want to use. If you also choose to download the library files that implement JPA (the Download option), the selected version will define which files you will be able to download.
Import database schema Libraries	Select this checkbox to have a database schema imported automatically. Optionally, select the JPA implementation-specific database scheme to be imported from the list above the checkbox. <p>You'll need a <a href="#">library</a> that implements JPA. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).</li><li>– Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the  key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>– Download. Select this option to download the library files that implement the selected JPA version. (The downloaded files will be arranged in a <a href="#">library</a> .)</li></ul>

- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## JBoss Drools

Select the checkbox to enable [JBoss Drools](#) support.

You'll need a [library](#) that implements Drools. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Drools. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## OSGi

Select the checkbox to enable [OSGi](#) support.

You'll need a [library](#) that implements OSGi. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement OSGi. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## SQL Support

Select the checkbox to enable [SQL](#) support.

### ItemDescription

Default Dialect	Select the SQL dialect to be used by default for the module. Select Project Default to use the default project SQL dialect.
-----------------	---

## Thymeleaf

Select the checkbox to enable [Thymeleaf](#) support.

You'll need a [library](#) that implements Thymeleaf. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Thymeleaf. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## WebServices Client

Select the checkbox to enable Web Services client development support. See also, [Enabling Web Service Client Development Support](#).

### ItemDescription

Generate sample client code	Select this checkbox to have sample client code generated in your source folder (e.g. <code>src</code> ). To generate the code, IntelliJ IDEA will ask you to specify the corresponding <a href="#">WSDL</a> file.
Configure	Click this link to specify the settings for WS engines that you want to use. (The <a href="#">Web Services dialog</a> will open.)

## Batch Applications

Select the checkbox to enable [Batch Applications](#) development support.

### ItemDescription

Create batch.xml	Select the checkbox to create a <code>META-INF\batch.xml</code> mappings file (one with the <code>&lt;batch-artifacts&gt;</code> root element).
Create Sample Job Xml	Select the checkbox to create a sample job XML file ( <code>META-INF\batch-jobs\job.xml</code> ).
Libraries	<p>You'll need a <a href="#">library</a> that implements the batch framework. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>– Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files (<code>.jar</code>) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a>. (Use the <code>Ctrl</code> key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a>.)</p> <ul style="list-style-type: none"><li>– Download. Select this option to download the files that implement the batch framework. (The downloaded files will be arranged in a <a href="#">library</a>.)</li></ul> <p>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</p> <ul style="list-style-type: none"><li>– Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## CDI: Contexts and Dependency Injection

Select the checkbox to enable [Contexts and Dependency Injection](#) (CDI) support.

You'll need a [library](#) that implements CDI. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files (`.jar`) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#). (Use the `Ctrl` key for multiple selections.)
- Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#).)
- Download. Select this option to download the library files that implement CDI. (The downloaded files will be arranged in a [library](#).)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## DM Server

Select the checkbox to be able to use [SpringSource dm Server](#) and develop dm Server-targeted applications.

### ItemDescription

Server	Select the server to be used from the list (if the corresponding server is already defined in IntelliJ IDEA). To define a server in IntelliJ IDEA, click Add and specify the server settings in the Spring dmServer dialog that opens.
Facet	Select the deployment artifact type that the module will implement (the Spring DM <a href="#">facet</a> type in IntelliJ IDEA terms): <ul style="list-style-type: none"><li>– Bundle, an OSGi bundle. IntelliJ IDEA will create:<ul style="list-style-type: none"><li>– The <code>META-INF\MANIFEST.MF</code> file for the bundle.</li></ul></li></ul>

- A dm Bundle [artifact configuration](#) .
- A project-level [library](#) for the dm Server API. This library will be added to the [module dependencies](#) .
- A dm Server-oriented [run/debug configuration](#) .

If necessary, specify [additional options](#) .

- PAR or Plan, a dm Server PAR or plan. Specify the [associated settings](#) .
- Configuration, a configuration artifact. Specify the [artifact name](#) .

For more information on dm Server deployment artifacts, see "Deployment Architecture" and "Developing Applications" in [SpringSource dm Server Programmer Guide](#) .

---

#### Bundle options

**Spring DM Support** Select this checkbox to enable [Spring](#) support (to create a Spring facet in IntelliJ IDEA terms). As a result, IntelliJ IDEA will create the following files:

- META-INF\spring\module-context.xml
- META-INF\spring\osgi-context.xml

At this step you are not suggested to download the library files that implement Spring. However, you will be able to do that after the module has been created by using the corresponding quick fix in the Project Structure dialog.

**Web module** Select this checkbox to enable generic [Web application](#) development support (to create a Web facet in IntelliJ IDEA terms). Specify the associated settings:

- Version. Select the version of the Servlet specification to be supported.
- Create web.xml. For version 3.0 or later: select this checkbox to create the [deployment descriptor](#) file `web.xml` . (For earlier versions, this file is always created.)

As a result, IntelliJ IDEA will create `web\WEB-INF\web.xml` (for version 3.0 or later - if so specified).

---

#### PAR or Plan options

**Name** For a PAR, this is the application identifier ( `Application-SymbolicName` ), for a plan - the plan name (the `name` attribute of the `<plan>` element).

**Version** The application or the plan version ( `Application-Version` or the `version` attribute of the `<plan>` element).

**Plan** Select this option to create a plan. IntelliJ IDEA will create:

- A `.plan` XML file.
- A dm Plan artifact specification.

**Platform Archive (PAR)** Select this option to create a PAR. IntelliJ IDEA will create:

- The `META-INF\MANIFEST.MF` file for the PAR.
- A dm Platform Archive artifact specification.

**Scoped** For a plan: select this checkbox to make the plan scoped (corresponds to `scoped="true"` within the `<plan>` element).

**Atomic** For a plan: select this checkbox to make the plan atomic (corresponds to `atomic="true"` within the `<plan>` element).

**Nested bundles** Use the controls in this area to manage other dm Server deployment artifacts within the PAR or plan. (In IntelliJ IDEA, these are represented by other modules within the same project if those modules have suitable dm Server facets. A PAR may include OSGi bundles and configuration artifacts; a plan - OSGi bundles, configuration artifacts, PARs and other plans).

- Add. Use this button to add the artifacts to the list. Select the necessary artifacts (IntelliJ IDEA modules) in the dialog that opens.
- Remove. Use this button to remove the selected artifacts from the list.
- Up. For a plan: use this button to move the selected artifact one line up in the list. (The order of artifacts defines their deployment order.)
- Down. For a plan: use this button to move the selected artifact one line down in the list.
- Versions. For a plan: use this button to specify the version or the range of versions for the selected artifact (corresponds to the `version` attribute of the `<artifact>` element).

---

#### Configuration option

**Name** Specify the OSGi name of the artifact (at the deployment stage, corresponds to the name of the file).

## EJB: Enterprise JavaBeans

Select the checkbox to enable [Enterprise JavaBeans](#) (EJB) support. See also, [Enabling EJB Support](#) .

---

#### ItemDescription

**Version** Select the EJB version to be supported.  
If you also choose to download the library files that implement EJB (the Download option), the selected version will define which files you will be able to download.

**Libraries** You'll need a [library](#) that implements EJB. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement the selected EJB version. (The downloaded files will be arranged in a [library](#) .)
- Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Google Web Toolkit

Select the checkbox to be able to use [Google Web Toolkit](#) (GWT). See also, [Enabling GWT Support](#) .

### ItemDescription

GWT SDK	Specify the path to the GWT SDK installation directory. You can click <input type="text"/> and select the corresponding directory in the <a href="#">dialog that opens</a> .
Create sample application	Select this checkbox to have a sample application created. Specify the package for the application classes in the field underneath.
Download GWT	If the path to GWT SDK is not specified: you can click this link to open the <a href="#">Google Web Toolkit Downloads page</a> . (This page lets you download a GWT SDK.)

## JavaEE Application

The features that become available when you select this checkbox are mainly related to packaging your [Java EE application](#) in an Enterprise Application Archive ([EAR](#) ). For more information, see [Enabling Java EE Application Support](#) .

### ItemDescription

Version	The Java EE version.
---------	----------------------

## RESTful WebServices

Select the checkbox to enable [RESTful](#) Web Services (client and server) development support. See also, [RESTful WebServices](#) .

### ItemDescription

Generate server code	Select this checkbox to have a sample <code>HelloWorld</code> server class created in your source folder (e.g. <code>src</code> ).
Generate client code	Select this checkbox to have a sample <code>HelloWorldClient</code> class created in your source folder (e.g. <code>src</code> ).
Libraries	<p>You'll need a <a href="#">library</a> that implements the JAX-RS API. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.</p> <ul style="list-style-type: none"><li>- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( <code>.jar</code> ) are already available on your computer, you can arrange those files in a <a href="#">library</a> and use that new library. To do that, click Create and select the necessary files in the <a href="#">dialog that opens</a> . (Use the <input type="text"/> key for multiple selections.)</li></ul> <p>Optionally, click Configure to edit the selected library. (For an existing library the <a href="#">Edit Library dialog</a> will open, for the library that you have just created - the <a href="#">Create Library dialog</a> .)</p> <ul style="list-style-type: none"><li>- Download. Select this option to download the files that implement the JAX-RS API. (The downloaded files will be arranged in a <a href="#">library</a> .)</li><li>Optionally, click Configure to edit the library settings and contents. (The <a href="#">Downloading Options dialog</a> will open.)</li><li>- Set up library later. Select this option to postpone setting up the library until a later time.</li></ul> <p>Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.</p>

## Tapestry

Select the checkbox to enable [Apache Tapestry](#) support. See also, [Enabling Tapestry Support](#) .

You'll need a [library](#) that implements Tapestry. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA). Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the  key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Tapestry. (The downloaded files will be arranged in a [library](#) .)

Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Spring

Select the checkbox to enable [Spring](#) support. See also, [Spring](#) .

You'll need a [library](#) that implements Spring. You can choose to use an existing library, create and use a new one, download the library files if they are not yet available on your computer, or postpone setting up the library until a later time.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement Spring. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)
- Set up library later. Select this option to postpone setting up the library until a later time.

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

## Spring MVC, Spring Batch, or other Spring framework

Select a checkbox to add support for a particular Spring framework (e.g. [Spring MVC](#) , [Spring Batch](#) , etc.). See also, [Spring](#) .

You'll need a [library](#) that implements the selected framework. You can choose to use an existing library, create and use a new one, or download the library files if they are not yet available on your computer.

- Use library. Select the library to be used from the list (if the corresponding library is already defined in IntelliJ IDEA).  
Create. If the corresponding library files ( `.jar` ) are already available on your computer, you can arrange those files in a [library](#) and use that new library. To do that, click Create and select the necessary files in the [dialog that opens](#) . (Use the `Ctrl` key for multiple selections.)

Optionally, click Configure to edit the selected library. (For an existing library the [Edit Library dialog](#) will open, for the library that you have just created - the [Create Library dialog](#) .)

- Download. Select this option to download the library files that implement the selected Spring framework. (The downloaded files will be arranged in a [library](#) .)  
Optionally, click Configure to edit the library settings and contents. (The [Downloading Options dialog](#) will open.)

Configure. Click this button to edit the settings for the library selected next to Use library or the one that is about to be downloaded.

---

Visibility	From this drop-down list, select the desired visibility modifier.
Type	Specify the type of the new field. Note that <a href="#">code completion</a> works here. As you type, the suggestion list shrinks to show the matching options. Non-existent type is marked as a syntax error.
Name	Specify the name of the new field.
Initializer	Specify the initial value of the new field. Note that such value should correspond to the declared type. For example, if the type is String , the suggested initializer should be enclosed in quotes. Note that <a href="#">code completion</a> works here. As you type, the suggestion list shrinks to show the matching options. Non-existent type is marked as a syntax error.
Static	Select this checkbox to add <code>static</code> to the field declaration.
Final	Select this checkbox to add <code>final</code> to the field declaration.
Preview	This read-only area shows the draft declaration as you fill in the dialog fields.

Use this dialog box to reach a navigable console stack trace for external applications. From each message in this stack trace, you can navigate right to the source code that caused the reported problem.

**ItemDescription**

---

Unscramble stacktrace	Select this checkbox to unscramble the external stack trace, if your source code is scrambled.
Unscrambler	Here you can select the unscrambler tool. IntelliJ IDEA ships with the Zelix Klass Master unscrambler plugin. You can develop your own plugin to unscramble stack trace of the code being processed with any other obfuscator.
Log file	Specify the location of the unscrambler log file.
Put a stack trace or a complete thread dump here	Paste here the external stack trace or thread dump.
Automatically detect and analyze thread dumps copied to the clipboard outside of IntelliJ IDEA.	If this checkbox is selected, IntelliJ IDEA will monitor and analyze the contents of the clipboard. You can select this checkbox only once and your clipboard will be scanned every time you switch to IntelliJ IDEA. As soon as something looking like a stack trace gets copied to the clipboard, IntelliJ IDEA will show this stack trace in the corresponding tool window.
Show changed in last <this_many> days	Select this checkbox to specify the time period in which you want to check last changes in stack traces. The default time period is set to 31 days.
Normalize	If the stack trace text is corrupted (lines are cut or wrapped, or too long, etc.) after processing with some software (for example, bug tracker or mail client), click this button to restore the normal stack trace structure.

Move the [artifacts](#) that you want to deploy to a server to the pane under Chosen .

**ItemDescription**

Add	Move the artifacts selected in the Available pane to the Chosen pane.
Remove	Move the artifacts selected in the Chosen pane to the Available pane.
Add all	Move all the artifacts to the Chosen pane.
Remove all	Remove all the artifacts from the Chosen pane.

Shift+F11

Use this dialog to navigate between bookmarks, and manage the collection of anonymous bookmarks and bookmarks with mnemonics in a project.

## Toolbar options

ItemShortcutDescription

  Click to add/edit description for the selected bookmark.

  Click to delete the selected bookmark.

  Use these buttons to reorder bookmarks.

The left pane of the Bookmarks dialog displays the list of bookmarks created with the brief description, if any. The order of bookmarks in the collection defines the order in which Navigate | Bookmarks | Next/Previous Bookmark command visits the bookmarks. The right pane displays the preview of the file where the selected bookmark is toggled.

To close the dialog box, press .

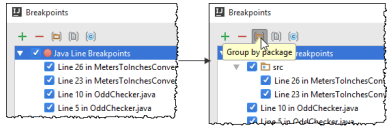

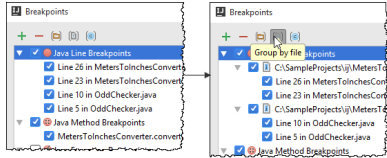

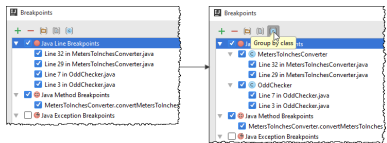

Ctrl+Shift+F8

In this section:

- [Breakpoint options](#)
- [Context menu commands](#)
- [Speed search of a breakpoint](#)

## Toolbar

Item	Tooltip and shortcut	Description
	Add Breakpoint	Click to show the list of available <a href="#">breakpoint types</a> . Select the desired type to create a new breakpoint.
	<span>Alt+Insert</span> Remove Breakpoint	Click this button to remove selected breakpoints.
	Group by Package	Click this button to display breakpoints under their respective packages, rather than under their types: 
	Group by File	Click this button to display breakpoints under their respective files, rather than under their types: 
	Group by Class	Click this button to display breakpoints under their respective classes, rather than under their types: 

## Breakpoint options

The controls of this part of the Breakpoints dialog depend on the type of the selected breakpoint.

### OptionDescriptionTypes of breakpoints

**Suspend**  Select this checkbox to enable suspend policy for a breakpoint. For Line/ Method/ Exception breakpoints and Field Watchpoints select one of the radio buttons to specify the way the running of the program is paused when a breakpoint is reached. If you work with Flex or JavaScript breakpoints, you only need to specify whether you want to suspend program execution when the breakpoint is hit.

If the checkbox is not selected, no threads are suspended.

#### SuspendDescription policy

All	When a breakpoint is hit, all threads are suspended.
Thread	When a breakpoint is hit, the thread where the breakpoint is hit, is suspended.
Make default	Click this button if you want the suspend policy specified for the breakpoint in question to be used as the default one for the subsequently created breakpoints.

**Tip** This button only appears, when Thread option is selected.

Line/Exception/Field/Method

- This feature is useful, for instance, to create a **master** breakpoint, which, being hit, enables lots of dependent ones. Another way to use is to obtain logging information or calculate some expression at a certain point (to be shown in the console) not interrupting the program execution.
- There are certain cases when IntelliJ IDEA will not stop at a breakpoint. Consider the following:
  1. Two breakpoints are set at the different methods of a class, and their suspend policy is set to All .
  2. When one of the breakpoints is hit, some step actions are performed.
  3. If at the time of stepping another thread hits the second breakpoint, IntelliJ IDEA will not stop there.

Condition	<p>Select this checkbox and specify a condition for hitting a breakpoint in the text field.</p> <p>A condition is a Java Boolean expression (including a method returning <code>true</code> or <code>false</code> ), for example, <code>str1.equals(str2)</code> .</p> <p>This expression should be valid at the line where the breakpoint is set, and is evaluated every time the breakpoint is reached. If the evaluation result is <code>true</code> , user-selected actions are performed.</p> <p>If the result is <code>false</code> , the breakpoint does not produce any effect. If the Debugger cannot evaluate the expression, it displays the Condition evaluation error message. You can select whether you would like to stop at this breakpoint or ignore it.</p> <p>Conditions for field/method/exception breakpoints are calculated in the context for the given field/method/exception.</p> <p>To the right of the Condition field, there is the button  ( <code>Shift+Enter</code> ) that opens the multiline editor.</p> <p>Thus it's possible to enter multiline expressions, for example:</p> <pre data-bbox="311 929 766 1064">if (myvar == expectedVariable) {     System.out.println (myvar);     anotherVariable = true; } return true;</pre>	All types
Log message to console	<p>Select this checkbox if you want a log message to be displayed in the console output when the breakpoint is hit.</p>	All types
Evaluate and log	<p>Select this checkbox if you wish to evaluate a certain expression at this breakpoint and to export result to the console output.</p> <p>To the right of this field, there is the button  ( <code>Shift+Enter</code> ) that opens the multiline editor.</p> <div data-bbox="295 1276 766 1433" style="background-color: #ffff00; padding: 5px;"> <p><b>TIP</b> If the expression to be evaluated is incorrect when a particular breakpoint is reached, the console output displays an error message:</p> <pre>Unable to evaluate expression &lt;your_expression&gt;</pre> </div>	Line breakpoints
Remove once hit	<p>Select this checkbox, if the you want the breakpoint to be deleted after hitting it.</p>	All types
Disabled until selected breakpoint is hit	<p>From the drop-down list, select the breakpoint in question. The option <code>None</code> corresponds to the always <b>enabled</b> breakpoint.</p> <p>Besides that, you can also choose the behavior of this breakpoint, when the selected one is hit:</p> <ul style="list-style-type: none"> <li>- Disable again</li> <li>- Leave enabled</li> </ul>	All types
<b>Filters</b>		
Catch class filters	<p>Select this checkbox if you want to filter out where the exceptions are caught.</p> <p>Define a catch class filter in two ways:</p> <ul style="list-style-type: none"> <li>- Click the Browse button  and configure the filter in the <b>Class Filters</b> dialog box that opens.</li> <li>- Type the filter manually in the text box. Use the following syntax:           <ol style="list-style-type: none"> <li>a. Use spaces to separate catch class names and patterns from each other.</li> <li>b. The catch classes to be excluded should have a minus in preposition.</li> </ol> </li> </ul> <p>For example, the filter <code>-java.* -sun.*</code> means that the corresponding exception breakpoint should not be triggered for the exceptions caught inside <code>java</code> and <code>sun</code> packages.</p>	Exception
Instance filters	<p>An instance filter is used to limit breakpoint hits only with particular</p>	Line/Exception/Field/Method

object instances using instance IDs. The instance ID value can be introduced manually or using the Instance Filters dialog box called by clicking the ellipsis button. Existing instance filters are indicated by the instance ID delimited with spaces.

<p>Class filters</p>	<p>Select this checkbox to have the breakpoint behave differently in relation to particular classes. Define the class filter to appoint the classes where you want the breakpoint to be hit and the classes where the breakpoint should not be triggered.</p> <p>Classes in a filter can be identified by their names or by means of class patterns .</p> <p>A class pattern is a string that may start or end with an asterisk (*). The asterisk in a pattern means any number (including zero) of any characters. The patterns are matched against fully qualified class names.</p> <p>The breakpoint behavior is different in relation to classes specified by their names or using class patterns.</p> <p>A filter specified through a class name points at the class itself as well as at all its subclasses (i.e. the classes directly or indirectly extending this one).</p> <p>A filter specified through a class pattern points at the classes whose fully qualified names match the pattern. The subclasses of such classes are selected only if their fully qualified names also match the specified pattern.</p> <p>You can define a class filter in two ways:</p> <ul style="list-style-type: none"> <li>- Click the Browse button  and configure the filter in the <a href="#">Class Filters</a> dialog box that opens.</li> <li>- Type the filter manually in the text box. Use the following syntax: <ul style="list-style-type: none"> <li>- Use spaces to separate class names and class patterns from each other.</li> <li>- The classes to be excluded should have a minus in preposition.</li> </ul> </li> </ul> <p>For example, the filter <code>package1.Class1 *s2 -package3.Class3</code> means that the corresponding breakpoint:</p> <ul style="list-style-type: none"> <li>- Should be triggered in the class <code>package1.Class1</code> and all its subclasses, and also in the classes whose fully qualified class names end in <code>s2</code> .</li> <li>- Should not be triggered in the class <code>package3.Class3</code> and all its subclasses.</li> </ul>	<p>Line/Exception/Field/Method</p>
----------------------	--	------------------------------------

<p>Pass count</p>	<p>Specify the integer number, on which hit of the breakpoint it should be triggered. After the specified number of passes, the breakpoint is hit. This function is helpful for debugging loops or methods called several times. When the execution process comes to a breakpoint, where Pass count is set, the debugger reduces the count value by 1 and compares it to zero. If the comparison result is <code>true</code> , the breakpoint is hit. If it is <code>false</code> , no other actions are performed until the next breakpoint is reached.</p> <p>The Pass count condition can be satisfied only once. In other words, if you have a loop inside a method and the Pass count condition has been honored once, the breakpoint will not be hit the next time the said method is called.</p> <p>This option is only enabled, when Condition , Instance filters and Class filters options are disabled.</p>	<p>Line/Exception/Field/Method</p>
-------------------	---	------------------------------------

<p>Watch</p>		
<p>Field access</p>	<p>Stands for triggering breakpoint every time the field is accessed.</p>	<p>Field watchpoints</p>
<p>Field modification</p>	<p>This checkbox is selected when simple read attempts shouldn't cause the breakpoint to trigger.</p>	<p>Field watchpoints</p>
<p>Method entry</p>	<p>Stands for triggering breakpoint every time the method is entered.</p>	<p>Method breakpoints</p>
<p>Method exit</p>	<p>Stands for triggering breakpoint every time the method is exited.</p>	<p>Method breakpoints</p>
<p>Notifications</p>		
<p>Caught exception/Uncaught exception</p>	<p>Specify in which cases you will be notified about hitting an exception breakpoint.</p>	<p>Exception breakpoints</p>

## Context menu commands

Command	Description
<p>Move to group</p>	<p>Point to this command to <a href="#">move the selected breakpoint to a new group</a> , to one of the existing groups ( <code>&lt;group name&gt;</code> ), or out of a group ( <code>&lt;no group&gt;</code> ).</p>
<p>Edit description</p>	<p>Choose this command to <a href="#">enter or change description of a breakpoint</a> .</p>

## Speed search of a breakpoint

### To find a particular breakpoint

- Start typing address or description of the target breakpoint.

IntelliJ IDEA highlights the line with the matching address or description.

The dialog box opens when you select the Class Filters checkbox and click the Browse button  in the [Breakpoints](#) dialog box.

Use this dialog box to configure class filters that determine in which classes a specific breakpoint will be hit and in which classes this breakpoint should not be triggered.

---

#### ItemDescription

---

**Class Filter** In this area, configure the set of classes where the selected breakpoint must be hit. Specify the classes either explicitly or using a [class pattern](#) .

A class pattern is a string that may start or end with an asterisk (\*). The asterisk in a pattern means any number (including zero) of any characters. The patterns are matched against fully qualified class names.

The breakpoint behavior is different in relation to classes specified by their names or using class patterns.

A filter specified through a class name points at the class itself as well as at all its subclasses (i.e. the classes directly or indirectly extending this one).

A filter specified through a class pattern points at the classes whose fully qualified names match the pattern. The subclasses of such classes are selected only if their fully qualified names also match the specified pattern.

- The list shows all the specified class names and class patterns. To have the breakpoint hit in the class or classes identified by a name or pattern, select the checkbox next to the corresponding item.
-  : click this button to open the Choose Class dialog box and specify a new class to be included in the filter. You can search for classes either by their names or using the project tree view.
-  : click this button to open the [New Filter](#) dialog box, where you can type the class pattern.
-  : click this button to have the selected item deleted from the list. Accordingly, the breakpoint will be no longer hit in the class or classes that match the removed name or pattern.

---

**Class Exclusion Filter** In this area, configure the set of classes where hitting the selected breakpoint is suppressed. Specify the classes either explicitly or using a [class pattern](#) .

**Filter**

- The list shows all the specified class names and class patterns. To suppress hitting the breakpoint in the class or classes identified by a name or pattern, select the checkbox next to the corresponding item.
-  : click this button to open the Choose Class dialog box and specify a new class to be included in the exclusion filter. You can search for classes either by their names or using the project tree view.
-  : click this button to open the [New Filter](#) dialog box, where you can type the class pattern.
-  : click this button to have the selected item deleted from the list. Accordingly, hitting the breakpoint in the class or classes that match the removed name or pattern will no longer be suppressed.

The dialog box opens when you click  in the Class Filter or Class Exclusion Filter area of the [Class Filters](#) dialog box.

In this dialog box, specify **class patterns** that identify the classes to be included in the currently configured class filter.

A class pattern points at the classes whose fully qualified names match the pattern. The subclasses of such classes are included in a filter only if their fully qualified names also match the specified pattern.

---

**ItemDescription**

Enter the filter pattern In this text box, specify the **class pattern** . A class pattern may start or end with an asterisk (\*), which stands for any number (including zero) of any characters. The patterns are matched against fully qualified class names.

**Tip** You can type a pattern manually or click the Browse button  to open the Choose Class dialog box, locate the classes to be defined through the pattern, and compose the pattern based on this prompt. You can search for classes both by their names or in the project tree view.

Use this dialog to configure the behavior of Ant build scripts.

#### ItemDescription

Maximum Heap Size	Use this field to change the amount of memory allocated to the Ant build process. Increase this value if the Ant process runs out of memory.
Maximum Stack Size (MB)	Use this field to change the stack memory size. The default value is 2 MB.
Make build in background	<p>If this option is enabled, build process runs in background. Otherwise, the modal progress dialog is displayed.</p> <p><b>Warning!</b> Compilation requires significant processor resources and can result in serious slow-down of performance. When build process runs in the background, you can find IntelliJ IDEA not responding to your actions.</p>
Close message view if no error occurred	If this option is enabled, Ant Messages window does not open for the successful builds.
Properties tab	Use this tab to specify the runtime properties that should be passed to the build script. These properties are equivalent to the ones defined after the <code>-D</code> option of the command line. A property is defined as a pair "name-value". The value can be hardcoded, or dynamically evaluated at runtime from a macro.
Add	Use this button to create a new entry in the list of runtime properties.
Remove	Use this button to delete the selected property from the list.
Execution tab	Use this tab to configure how IntelliJ IDEA will launch the build script.
Run with Ant	In this option group you can determine the Ant version to run the selected <code>build.xml</code> .
Use project default Ant	Click this radio button to run the default Ant version.
Use custom Ant	Click this radio button to run Ant version of your choice. From the combo box, you can select any Ant version that has been configured and registered with IntelliJ IDEA. Use the ellipsis button to modify Ant configuration.
Set Default	Click this button to configure the default Ant.
Ant command line	Use this field to supply command line arguments. You can include any arguments, except <code>-logger</code> . The arguments should be preceded with dashes and separated with spaces.
Run under JDK	Use this field to define JDK to use for running Ant target. By default, you can select the project or module JDK. Use the ellipsis button to configure JDK.
Additional Classpath tab	Use this tab to add libraries and directories that Ant loads at runtime.
Add	Click this button to add a directory of archive to the Classpath.
Add All In Directory	Click this button to add a directory with all its contents to the Classpath.
Move Up/Down	Use these buttons to change the order of classpath entries. The order of entries in the dialog defines the order in which Ant loads the resources.
Remove	Click this button to delete selected entry from the list.
Filters tab	Use this tab to configure which build targets show in the Ant Build tool window, when filtering is applied. The tab displays a list of build targets of the selected build file. The left column displays the names of the build targets, the right column contains optional description of the target. If a target is checked, it will show up in the Ant Build tool window after pressing  ; otherwise such target will be hidden.

The dialog box opens when you click the Upload to Web Server checkbox in the [Run/Debug Configuration](#) dialog box and click the Browse button  next to it.

Use the dialog box to configure a list of folders and files to be uploaded according to previously defined mappings and to edit these mappings, if necessary.

---

**ItemDescription**

---

Add	Click this button to have a new row added to the list and specify the item to upload. Type the path manually or click the Browse button  to select the desired location in the Choose Path dialog box, that opens.
Remove	Click this button to remove the selected entry from the list.
Edit Mappings	Click this button to open the <a href="#">Deployment</a> dialog box, where you can define mappings between local folders and the corresponding paths on the FTP/SFTP server.

Use this dialog to define the sensitivity of search, and set limitation that will help you avoid reporting about every similar code construct. Your preferences are specified in a language-specific context.

#### ItemDescription

CSS – Do not show duplicates containing less than <number> CSS properties : Set the size of duplicated language constructs that are shown in the results window.

CoffeeScript – Anonymize Variables: when this checkbox is selected, two identical functions that use different variable names are considered duplicates, for example:

```
var test01 = function(a,b){
  return (a*b)
}

var test01 = function(a,b){
  return (a*b)
}
```

– Anonymize Functions  
– Anonymize Literals

– Do not show duplicates simpler than: Set the size of duplicated language constructs that are shown in the result window. By default, the constructs less than 10 units are not included (and this limitation cannot be changed).  
– Anonymize uncommon subexpressions simpler than: Set the value of the subelements within language constructs that can be considered similar, to show the construct as duplicate in the result window. The larger is the number, the larger constructs are taken as similar by IntelliJ IDEA.  
The values are set as arbitrary weights based on the element size calculated with additive algorithm. The larger is the element, the higher is the calculated value.

ECMA Script level 4 – Anonymize Variables: when this checkbox is selected, two identical functions that use different variable names are considered duplicates, for example:

```
var test01 = function(a,b){
  return (a*b)
}

var test01 = function(a,b){
  return (a*b)
}
```

– Anonymize Functions  
– Anonymize Literals

– Do not show duplicates simpler than: Set the size of duplicated language constructs that are shown in the result window. By default, the constructs less than 10 units are not included (and this limitation cannot be changed).  
– Anonymize uncommon subexpressions simpler than: Set the value of the subelements within language constructs that can be considered similar, to show the construct as duplicate in the result window. The larger is the number, the larger constructs are taken as similar by IntelliJ IDEA.  
The values are set as arbitrary weights based on the element size calculated with additive algorithm. The larger is the element, the higher is the calculated value.

Groovy – Anonymize Variables: when this checkbox is selected, two identical functions that use different variable names are considered duplicates, for example:

```
var test01 = function(a,b){
  return (a*b)
}

var test01 = function(a,b){
  return (a*b)
}
```

– Anonymize Functions

Ctrl+Shift+A

Use this dialog to find the exact RGB, HSB and hex values of any color component.

**ItemDescription**

---

	Click this eyedropper to navigate to the object and obtain its color RGB or HSB as well as its color hex values.
Color mixer	Use this area to select a color.
Stack of colors	This area displays colors that were last selected.
Brightness	Move the slider upwards to make to colors in the Color mixer area brighter; move the slider down to make colors darker.
Choose	Click this button to select a color from the Color Mixer area, or the Stack of colors .
Cancel	Click this button to omit saving the color information.

In this dialog box, choose the instance of [Composer](#) to use in the current project among all the instances configured in IntelliJ IDEA. For more details, see [Enabling and configuring the use of Composer Dependency Manager in IntelliJ IDEA](#).

**ItemDescription**

---

Path to composer.phar	In this text box, specify the location of the <code>composer.phar</code> archive to use in the current project. Type the path manually or click the Browse button  and choose the desired location in the dialog box that opens. IntelliJ IDEA parses the contents of the specified file for Composer commands.
Click here to download from getcomposer.org	Click this link to have IntelliJ IDEA download <code>composer.phar</code> from the official storage and specify the folder to store the archive in. This instance of Composer will be available in the current project only. To use it in the command line mode, <a href="#">configure it as a command line tool</a> .

Use this dialog to edit the [library](#) name and to manage the library contents.

The set of the available controls depends on whether you are working with a Java or ActionScript/Flex library, or a JavaScript library.

– [Controls for a Java or ActionScript/Flex library](#)

– [Controls for a JavaScript library](#)

## Controls for a Java or ActionScript/Flex library

### ItemDescription

 or  This button may be available for a library that implements a certain framework or technology (e.g. JSF, Spring) in cases when IntelliJ IDEA can make version-specific file replacements in the library.

In such cases, when you click this button, the [Downloading Options dialog](#) opens in which you can select the necessary library version, and also the files to be downloaded.

As a result, the files in the library will be replaced with the downloaded files.

 Use this icon or shortcut to add items (classes, sources, documentation, etc.) to the library. In the [dialog that opens](#), select the necessary files and folders. For a Java library, these may be individual `.class` and `.java` files, directories and archives (`.jar` and `.zip`) containing such files as well as directories with Java native libraries (`.dll`, `.so` or `.jnlib`). For an ActionScript/Flex library, these may be raw ActionScript 3 libraries, `.swc`, `.jar` and `.zip` files, the directories containing such files, and so on.

IntelliJ IDEA will analyze the selected files and folders, and automatically assign their contents to the appropriate library categories (Classes, Sources, Documentation, Native Library Locations, etc.).

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category yourself.

 To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

 Click this icon to make certain library items "excluded" (see [Excluded library items](#)). In the dialog that opens, select the items that you want IntelliJ IDEA to ignore (folders, archives and folders within the archives), and click OK.

 or   :  
– The selected "ordinary" library items are removed from the library.  
– The selected excluded items (see [Excluded library items](#)) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

## Controls for a JavaScript library

### ItemDescription

 Use this icon or shortcut to add items to the library. Select one of the following options:  
– Attach Files or Directories. Select this option to add JavaScript files. In the dialog that opens, select the necessary files and folders. These may be individual JavaScript files and the directories containing such files.  
IntelliJ IDEA will analyze the selected files and folders, and automatically assign the JavaScript files to the appropriate categories. [Minified files](#) will be assigned to the Release category; ordinary (uncompressed) files will be assigned to the Debug category.

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category (Release or Debug) yourself.

– Attach Debug Version(s). Select this option to add a single uncompressed JavaScript file or a directory containing such files.

Note that IntelliJ IDEA won't analyze the contents of the selected files. If you select a [minified JavaScript file](#) or a directory containing minified JavaScript files, the corresponding file or files will still be added to the library.

– Attach Release Version(s). Select this option to add a single [minified JavaScript file](#) or a directory containing such files.

Note that IntelliJ IDEA won't analyze the contents of the selected files. If you select an ordinary (uncompressed) JavaScript file or a directory with such files, the corresponding file or files will still be added to the library.

– Specify Documentation URL. Select this option to make external online documentation available in IntelliJ IDEA. Specify the documentation URL in the dialog that opens.

– Download Documentation. For jQuery: select this option to download and include jQuery documentation in the library.

 Click this icon to make certain library items "excluded" (see [Excluded library items](#)). In the dialog that opens, select the folders that you want IntelliJ IDEA to ignore, and click OK.

 or   :  
– The selected "ordinary" library items are removed from the library.  
– The selected excluded items (see [Excluded library items](#)) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

From the [Database tool window](#) :

Edit | Drop , Drop from the context menu, or  .

---

Click OK to remove the selected item or items, or click  to copy the SQL statement or statements into the [database console](#) .

---

**ItemDescription**

**SQL Preview**    The statement or statements to be run to remove the selected item or items. If necessary, you can edit the statements right in this pane.  
The statements are executed when you click OK .

---

    Copy the statements into the corresponding database console and close the dialog.

Specify the settings for your Java archive (JAR).

**ItemDescription**

---

Module	The module to be packaged.
Main class	The fully qualified name of your main application class, the one with a <code>main()</code> method.
JAR files from libraries	The way the JAR files from the module libraries are processed: <ul style="list-style-type: none"><li>– extract to the target JAR . The JAR contents are decompressed and then packaged together with the module output in a single JAR.</li><li>– copy to the output directory and link via manifest . The JAR files are copied to the artifact output directory as is. The references to the JARs are added to the <code>Class-Path</code> header field of the <code>MANIFEST.MF</code> file that is packaged in the same JAR as the module output.</li></ul>
Directory for META-INF/MANIFEST.MF	The path to the directory in which <code>META-INF/MANIFEST.MF</code> is generated.
Include tests	Include the module's compiled test classes.

Specify the [library](#) name, [level](#) and contents.

#### ItemDescription

---

**Name** Use this field to edit the library name.

---

**Level** Select the [library level](#) (global, project or module).

---

 or  Use this icon or shortcut to add items (classes, sources, documentation, etc.) to the library. In the [dialog that opens](#), select the necessary files and folders. For a Java library, these may be individual `.class` and `.java` files, directories and archives (`.jar` and `.zip`) containing such files as well as directories with Java native libraries (`.dll`, `.so` or `.jnlib`). For an ActionScript/Flex library, these may be raw ActionScript 3 libraries, `.swc`, `.jar` and `.zip` files, the directories containing such files, and so on.

IntelliJ IDEA will analyze the selected files and folders, and automatically assign their contents to the appropriate library categories (Classes, Sources, Documentation, Native Library Locations, etc.).

When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category yourself.

---

 To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.

---

 Click this icon to make certain library items "excluded" (see [Excluded library items](#)). In the dialog that opens, select the items that you want IntelliJ IDEA to ignore (folders, archives and folders within the archives), and click OK.

---

 or  When you click this icon or press `Delete`:

- The selected "ordinary" library items are removed from the library.
- The selected excluded items (see [Excluded library items](#)) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.

Alt+Insert

**ItemDescription**

---

Name	Use this field to modify the method name.
Return type	Use this field to modify the method return type. <a href="#">Code completion</a> ( <code>Ctrl+Space</code> ) is available in this field, in the Type column of the Parameters area, and in the exception type list in the Exceptions area.
Parameters	
Type	Specify the parameter type. Note that <a href="#">code completion</a> works here. As you type, the suggestion list shrinks to show the matching options. Non-existent type is marked as a syntax error.
Name	Specify the parameter name.
Add/Remove	Use these buttons to add/remove parameters.
Move Up/Down	Use these buttons to reorder parameters by moving them up or down in the parameter list.
Visibility	Select one of the options to change visibility scope of the method.
Abstract	If this checkbox is selected, the <code>abstract</code> modifier is added to the method signature.
Exceptions	
Add/Remove	Use these buttons to add/remove exceptions thrown by the method. For each new exception, specify its type.
Move Up/Down	Use these buttons to reorder exceptions by moving them up or down in the list.
Signature Preview	This read-only area shows the draft method signature as you fill in the dialog fields.

Use this dialog to configure generation of PHPUnit test class stubs.

The dialog box is available when the [PHPUnit](http://www.phpunit.de/manual/current/en/installation.html) tool is installed on your machine and enabled in IntelliJ IDEA. For more information, see <http://www.phpunit.de/manual/current/en/installation.html> and [Testing with PHPUnit](#).

#### ItemDescription

---

Class To Test	In this area, specify the production class to generate a test class for. Type the fully qualified name of the class in the Fully Qualified Name text box. The specified name will be used to propose the Test Class Name. To use completion, press Control+Space and choose the relevant production class from the pop-up list.
Test Class	<ul style="list-style-type: none"><li>- Name: in this text box, specify the name of the test class to generate. IntelliJ IDEA automatically composes the name from the production class name as follows: <code>&lt;production class&gt;Test.php</code>.</li><li>- Namespace: in this text box, specify the namespace the test class will belong to. IntelliJ IDEA completes the namespace automatically based on the value of the Directory text box. When the Directory text box is changed, the value of the Namespace text box is changed accordingly. To use completion, press Control+Space and choose the relevant namespace from the pop-up list.</li><li>- Directory: in this text box, specify the directory where the file with the test class will be stored. By default, it is the directory where the production class is stored. To specify another folder, click the Browse button and choose the relevant folder in the dialog box that opens. To use completion, press Control+Space and choose the relevant folder from the pop-up list.</li><li>- File Name: in this text box, specify the name of the file that will be created for the test class definition. By default, the name is the same as the test class name. However, if several production classes are defined in one single file, for each generated test class IntelliJ IDEA will create a separate file.</li></ul>

This dialog lets you create a run/debug configuration for the selected Gradle task. It appears when you right-click the task in the Gradle tool window and select `Create [task-name]`.

#### ItemDescription

Name	This field shows the name of your Gradle project and the Gradle task that you have selected in the <a href="#">Gradle tool window</a> for the configuration.
Share	<p>Select this check box to make the run/debug configuration available to other team members.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea/runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea/workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p> <p>This check box is not available when editing the run/debug configuration defaults.</p>
Single instance only	<p>If this check box is selected, this run/debug configuration cannot be launched more than once.</p> <p>Every time a new run/debug configuration is launched, IntelliJ IDEA checks the presence of the other instances of the same run/debug configuration, and displays a confirmation dialog box. If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.</p> <p>This makes sense when the usage of certain resources can cause conflicts, or when launching two run/debug configurations of the same type consumes too much of the CPU and memory resources.</p> <p>If this check box is not selected, it is possible to launch as many instances of the runner as required. So doing, each runner will start in its own tab of the Run tool window.</p>
Gradle Project	<p>Use this field to specify the location of your Gradle project. You can either enter it manually or click the <a href="#">Browse</a> button and point to the desired location in the <a href="#">dialog that opens</a>.</p> <p>You can also click button to select an available Gradle module from the list of registered Gradle modules in your existing IntelliJ IDEA project. The list has a tree structure that might be useful if you have a Gradle multi-module project.</p>
Tasks	This field shows the selected Gradle task. You can add other tasks to the selected one. Use spaces to separate one task from another.
VM Options	<p>Use this field to specify VM options for your Gradle project.</p> <p>If you need more room to type, click next to the field to access the VM options dialog where the text entry area is larger.</p> <p>When specifying the options, follow these rules:</p> <ul style="list-style-type: none"><li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code>.</li><li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg</code> or <code>"some arg"</code>.</li><li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code>.</li></ul>
Script Parameters	<p>Use this field as the Gradle command line to specify options for Gradle tasks.</p> <p>For the information on the syntax, see <a href="#">Gradle command line options</a>. Please note that some of the Gradle commands options are not supported in IDE. In this case you will receive an error message indicating the problem.</p>
Before launch	Specify which tasks must be performed before applying the run/debug configuration. The specified tasks are performed in the order they appear in the list.

#### ItemKeyboardDescription shortcut

	 Click this icon to add a task to the list. Select the task to be added:
	<ul style="list-style-type: none"><li>– <b>Run External tool.</b> Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see <a href="#">Configuring Third-Party Tools</a> and <a href="#">External Tools</a>.</li><li>– <b>Make.</b> Select this option to have the project or module compiled. The <a href="#">Make Module command</a> will be carried out if a particular module is specified in the run/debug configuration, and the <a href="#">Make Project command</a> otherwise. If an error occurs during the compilation, IntelliJ IDEA won't attempt to start the run/debug configuration.</li><li>– <b>Make, no error check.</b> The same as the Make option but IntelliJ IDEA will try to start the run/debug configuration irrespective of the compilation result.</li><li>– <b>Build Artifacts.</b> Select this option to have an <a href="#">artifact</a> or artifacts built. In the dialog that opens, select the artifact or artifacts that should be built. See also, <a href="#">Working with Artifacts</a>.</li><li>– <b>Run Another Configuration.</b> Select this option to have another run/debug configuration executed. In the dialog that opens, select the configuration to run. This option is available only if you have already at least one run/debug configuration in the current project.</li><li>– <b>Run Ant target.</b> Select this option to have an Ant target run. In the dialog that opens, select the target to be run. For more information, see <a href="#">Ant</a>.</li></ul>

- Run Grunt task. Select this option to run a Grunt task. In the Grunt task dialog box that opens, specify the `Gruntfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Grunt tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `grunt-cli` package.
- Run Gulp task. Select this option to run a Gulp task. In the Gulp task dialog box that opens, specify the `Gulpfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Gulp tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `gulp` package.
- Run npm Script. Select this check box to execute an npm script. In the NPM Script dialog box that opens, specify the `package.json` file where the required script is defined, select the script to execute, choose the command to apply to it, and specify the arguments to execute the script with.  
Specify the location of the Node.js interpreter and the parameters to pass to it.
- Compile TypeScript. Select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:
  - If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.
  - If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.
- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#).
- Run Maven Goal. Select this option to have a Maven goal run. In the dialog that opens, select the goal to be run. For more information, see [Maven](#).
- Run Remote External tool : Add a remote SSH external tool. Refer to the section [Remote SSH External Tools](#) for details.
- Upload files to Remote Host. Select this option to have the application files automatically uploaded to the server according to the [default server access configuration](#). For more information, see [Configuring Synchronization with a Web Server](#) and [Uploading and Downloading Files](#).
- Run Rake task :Add a Rake task to be executed prior to running or debugging. To choose a Rake task, click the browse button , and select the desired task from the list of available tasks.  
Note that [code completion](#) is available here.

To learn more about Rake support, refer to [Rake Support](#) section.

- Run JRuby compiler : choose this option to execute JRuby compiler with the specified target path, compiler process heap size, and command line parameters (if any).

		Click this icon to remove the selected task from the list.
		Click this icon to edit the selected task. Make the necessary changes in the dialog that opens.
		Click this icon to move the selected task one line up in the list.
		Click this icon to move the selected task one line down in the list.
Show this page	<input type="checkbox"/>	Select this check box to have the run/debug configuration settings shown prior to actually starting the run/debug configuration.
Active tool window	<input type="checkbox"/>	Select this option if you want the <a href="#">Run /Debug</a> tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

- [Upper part: GUI](#)
- [SQL Script](#)
- [Options](#)

## Upper part: GUI

The upper part of the dialog provides a GUI for defining the table structure, and associated constraints and indexes.

## SQL Script

The pane under SQL Script shows the statement or statements to be run to achieve the result you have specified using the GUI.

You can use this pane just as a preview. You can also edit the statement or statements right there.

## Options

### ItemDescription

Execute in database	<p>Change data structure in your database by running the statement or statements. Execute. Execute the statements right away. If associated changes in database consoles are possible, the corresponding preview is shown. See <a href="#">Previewing changes</a> .</p> <p>Preview. Preview potential associated changes prior to executing the statements.</p>
Replace existing DDL	<p>Replace the definition (usually, a <code>CREATE</code> statement) in the corresponding database console or SQL file with the statements shown under SQL Script .</p> <p>Replace. Perform the replacement right away. If associated changes are possible, the corresponding preview is shown.</p> <p>Preview. Preview potential associated changes prior to performing the replacement.</p>
Open in editor	<p>Copy the statements into the corresponding database console or SQL file.</p> <ul style="list-style-type: none"> <li>- Modify existing objects. In the generated set of statements, <code>ALTER</code> statements are preferred to <code>CREATE</code> statements.</li> <li>- Create modified objects. The changes you have made using the GUI are translated into a minimal set of <code>CREATE</code> and other statements.</li> <li>- Create all objects. The generated set always includes the <code>CREATE TABLE</code> statement, as if the whole table were created anew.</li> </ul> <p>To Editor. Switch to the corresponding editor tab right away. If associated changes are possible, the corresponding preview is shown prior to copying the statements.</p> <p>Preview. Preview potential associated changes.</p>

Alt+Enter - Create Test

Ctrl+Shift+T - Create New Test

#### ItemDescription

Testing library	Use this drop-down list to select the test framework to use.
Fix	This button is available, when a library for the selected testing framework is missing. Click this button to add the jar archive of the selected testing framework to the list of module dependencies and libraries.
Class name	Enter the name of the test class to be generated, or accept default.
Superclass	For JUnit3, the superclass <code> junit.framework.TestCase </code> is suggested automatically. For the other supported frameworks, this field is blank.
Destination package	Specify the name of the package where the generated test class will be stored. You can select the desired package from the recent history drop-down list, or type it directly in the text field. So doing, if a package with the specified name does not exist, it will be created automatically. Clicking <code> ... </code> enables you to choose one of the existing packages within your project.
Generate	Select these checkboxes to include stub methods for test fixtures and annotations into the generated test class.

`setUp()@Before`

`tearDown()@After`

Show inherited methods	Select this option to show all methods, including the inherited ones.
Generate test methods for	In the table, select the checkboxes next to the methods you want to generate test for.

To access this dialog:

– From any of the table views:

Right-click the table and select Data Extractor | Configure CSV Formats .

– From the [Database tool window](#) :

Right-click the table or view of interest, select Dump Data to File | Configure CSV Formats .

---

This dialog lets you specify the settings for converting table data into delimiter-separated values formats (e.g. CSV, TSV) and vice versa.

When working on the conversion settings, use the preview in the right-hand part of the dialog.

#### ItemDescription

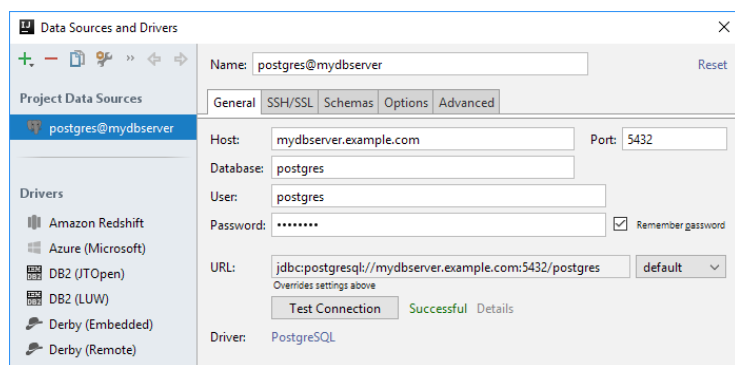

---

Formats	The list of the available delimiter-separated values formats is shown. Each format is a named set of corresponding conversion settings. Select the format whose settings you want to view or edit. Use  ,  ,  and  to create, delete and reorder the formats;  to create a copy of the selected format.
Value separator	Select or type the character for separating individual values.
Row separator	Select or type the character for separating rows.
Null value text	The text to be used as a value if a cell contains <code>null</code> (an unknown value).
Add row prefix/suffix	Row prefix and suffix are character sequences which in addition to the row separator indicate the beginning and end of a row. If necessary, click the link and specify the row prefix and suffix in the fields that appear.
Quotation	Each line in the area under Quotation is a quotation pattern (see <a href="#">Quote values</a> ). A quotation pattern includes: <ul style="list-style-type: none"><li>– The left quotation character, the one inserted before a value.</li><li>– The right quotation character, the one inserted after a value; usually, the same as the left quotation character.</li><li>– An escape method or character for the cases when the quotation character is part of a value. E.g. Escape: duplicate means that if a quotation character occurs within a value, it is doubled. (You can specify your own escape character instead.)</li></ul> <p>If there is more than one pattern, the first of the patterns is used.</p> <p>Use  ,  ,  and  to create, delete and reorder the patterns.</p> <p>To start editing an existing pattern, just click the pattern of interest.</p>
Quote values	Specify in which cases the values should be quoted (i.e. enclosed within quotation characters). <ul style="list-style-type: none"><li>– When needed. A value is quoted only if it contains the value and/or the row separator.</li><li>– Always. Any value is quoted in its text representation.</li></ul>
Trim whitespaces	If this checkbox is not selected, the Unicode whitespace characters that precede and follow the value separators are treated as parts of the corresponding values. If this checkbox is selected, the corresponding whitespace characters are ignored or removed.
First row is header	If this checkbox is selected, the first row is treated as containing column names. The settings that appear under Header Format have the same meanings as the ones above but are applied to the first row.
First column is header	If this checkbox is selected, the first column is treated as containing row names.

To access this dialog from the [Database tool window](#):  or  on the toolbar

## Overview

This dialog lets you manage your [data sources](#) and database drivers.

**Note** A driver here is understood as a collection that includes [database driver](#) files, and also default options and settings for creating a DB data source.

## Left-hand pane

This pane shows your data sources and [drivers](#). When you select an item, its settings appear in the right-hand part of the dialog.

Use the toolbar icons, context menu commands and associated keyboard shortcuts to manage your data sources and drivers, and also to perform other, related tasks.

### Icon and ShortcutDescription command

		Use this icon, command or shortcut to create a new data source or driver. Select: <ul style="list-style-type: none"><li>– Android SQLite to create a data source for an SQLite database located on an Android device or emulator. For this option to be available, there must be an Android application module in your project and/or an Android SDK has to be defined in IntelliJ IDEA. See <a href="#">Android SQLite data source settings</a>.</li><li>– The name of DBMS to create a DB data source associated with the corresponding DBMS. If you have created your own drivers, you can also select a driver to use it as the basis for creating the data source. See <a href="#">DB data source settings</a>.</li><li>– DDL Data Source to create a DDL data source. See <a href="#">DDL data source settings</a>.</li><li>– Database Driver to create a driver. See <a href="#">Driver settings</a>.</li></ul>
		Use this icon, command or shortcut to remove the selected item or items from the list.
		Use this icon, command or shortcut to create a copy of the selected data source or driver.
		Use this icon, command or shortcut to view or edit the settings for the driver associated with the selected DB data source.
		Use this icon or command to move the selected DB data source to the global or project level. Global data sources are available in all your projects.
Change Driver		If more than one driver is available for the selected DB data source, use this command to associate the data source with a different driver.
Reset Changes		Use this command or shortcut to undo the changes made to the selected item.
Load Sources		For the selected DB data source or data sources, IntelliJ IDEA will load source code of database objects for the category of schemas that you select. The alternative way of setting this option - for each data source individually - is by using <a href="#">Load sources for</a> on the <a href="#">Options tab</a> .
Show Driver Usages		Use this command or shortcut to find the DB data sources that use the selected driver. The found data sources are shown in the Used By popup which lets you navigate to anyone of the found data sources.
		Use these icons to switch between the items you've been working with.

## Android SQLite data source settings

Specify the settings for the SQLite database located on an Android device or emulator.

### ItemDescription

Name	Use this field to edit the name of the data source.
Device	Specify where the target database is located. This may be an Android device connected to your computer or a

running Android device emulator.

If [none] is the only option in the list, connect the device to your computer or start the emulator. Unless you do that, you won't be able to configure the data source.

---

Package name	Specify the name of the application package the target database is associated with. For more information about application packages <a href="#">Android documentation</a> . Select a package name suggested by IntelliJ IDEA or type its ID. For the database to be accessible, the corresponding application must be built as debuggable and installed on the device or the emulator.  IntelliJ IDEA run configurations, by default, build Android applications in the debug mode. Alternatively, you can <a href="#">generate the APK in the debug mode</a> .
Storage	Select: – Internal if the database is stored in the internal memory of the device or the emulator. – External if the database is stored in the external memory of the device or the emulator.
Database	If the database is stored in the internal memory, specify the database name. One of the names suggested by IntelliJ IDEA may do. If the database is stored in the external memory, specify the database location relative to the memory root. This may be something like <code>Android/data/&lt;application_ID&gt;/&lt;database_name&gt;</code> .
Download	If the necessary SQLite driver files are missing, you can download them by clicking the Download link in the lower part of the dialog.

---

## DB data source settings

### General tab

Shown on this tab are mainly the database connection settings.

The user interface is adjustable: the set of available controls depends on which option is selected in the list to the right of the [URL field](#) .

#### ItemDescription

---

File	If your database is a local file, specify the path to that file. <input type="button" value="..."/> lets you select an existing database file.  <input type="button" value="+"/> lets you create a new database file.
Path	If your database is a local file or folder, specify the path to that file or folder. <input type="button" value="..."/> lets you select the database file or folder.  Create database. Select this option to create a new database. (This option may be unavailable.)
Host	Specify the hostname (domain name) or the IP address of the computer on which the database is located. If the database is on your local computer, specify <code>localhost</code> or <code>127.0.0.1</code> . If you are using SSH, the database host must be accessible by the specified domain name or IP address from the computer on which the SSH proxy runs. See <a href="#">SSH/SSL tab</a> .
Port	Specify the database port number.
Database	Specify the name of the target database or schema.
User	Specify the name of the database user (i.e. your database user account name).
Password	Specify the password for the <a href="#">database user</a> .
Remember password	Select this checkbox if you want IntelliJ IDEA to remember the password. See <a href="#">Passwords</a> .
URL	Shown in this field is the URL that IntelliJ IDEA will use to connect to the database. The user interface for specifying the URL is different depending on which option is selected in the list to the right: – URL only. This option, generally, is for editing the database connection URL directly. When you select this option, only the following fields are available: <a href="#">User</a> , <a href="#">Password</a> and <a href="#">URL</a> .  You should edit the URL right in the field. Your user name and password, if necessary, are specified in the corresponding fields, or within the URL in the format appropriate for the JDBC driver that you are using. – When using any other of the options (the options are DBMS-specific), IntelliJ IDEA forms the database connection URL automatically using the info in the fields above the URL field. In all such cases, normally, you don't need to edit the URL (though you can if you want).
Test Connection	Click this button to make sure that the database connection settings are correct and IntelliJ IDEA can communicate with the target database.
Driver	Click the <driver name> link to switch to the settings for the associated driver.
Read-only	Select this checkbox if you want to protect the data source from accidental data modifications. As a result, you won't be able to modify the data in the <a href="#">Data editor</a> .  Whether data modifications will be possible by means of the <a href="#">consoles</a> depends on the DBMS: IntelliJ IDEA will try to set the database connection status to read-only. All the rest depends on the database driver, i.e. whether and to which extent the driver supports the read-only status.
Tx	The way transactions are committed: Auto or Manual . The selected option is used by default in the <a href="#">data editors</a> and

---

[database consoles](#) associated with the data source.

- Auto sync
- If this option is off, the view of the data source in the Database tool window is synchronized with the actual state of the database only when you perform the [Synchronize command](#) ( or [Ctrl+Alt+Y](#) ).
- If this option is on, the view of the data source is automatically updated:
- When you change the data source settings. (Technically, when you click OK in the Data Sources and Drivers dialog.)
  - When you run DDL SQL statements in the [database consoles](#) associated with the data source.

Note that auto sync is performed for the overall database and, thus, may be time-consuming. So auto-synchronization is more suitable for "small" databases. If your database is "big", it's recommended that you sync its state manually (e.g. [Ctrl+Alt+Y](#) ), and only for the appropriate database parts such as separate tables.

## SSH/SSL tab

If the target database should be accessed using SSH or SSL, select the corresponding checkbox and specify the associated settings.

– [SSH](#)

– [SSL](#)

### ItemDescription

SSH	
Use SSH tunnel	Select this checkbox to set up and use an SSH tunnel for accessing a remote database via an SSH proxy.
Copy from	If there is already a data source for which the necessary SSH settings are specified, you can copy those settings from that data source. Click the link and select the data source to copy the settings from.
Proxy host	Specify the hostname (domain name) or IP address of the SSH proxy server that you are using. The SSH proxy server host must be accessible by the specified hostname or IP address from your local computer.
Port	Specify the port on which your SSH proxy server accepts SSH connections. The port number <code>22</code> suggested by IntelliJ IDEA is the standard port used by SSH servers. Change this number if your SSH proxy server uses a different port.
Proxy user	Specify the name of the SSH proxy user.
Auth type	Specify the user authentication type used by your SSH proxy. Select: <ul style="list-style-type: none"><li>– Password for password-based authentication.</li><li>– Key pair (Open SSH) for key-based authentication.</li></ul>
Proxy password	For password-based authentication: specify the password for the SSH proxy user. See also, <a href="#">Remember password</a> .
Private key file	For key-based authentication: specify the path to the file where the corresponding private key is stored. Type the path in the field, or click  ( <a href="#">Shift+Enter</a> ) and select the file in the <a href="#">dialog that opens</a> .
Passphrase	For key-based authentication: specify the passphrase for the private key if the key is locked with the passphrase.
Remember password	Select this checkbox if you want IntelliJ IDEA to remember the password or the passphrase. See <a href="#">Passwords</a> .
SSL. All the files specified in this section should be in PEM format. Which of the files you have to specify, depends on the SSL properties of your user account.	
Use SSL	Select the checkbox to use SSL when connecting to the server.
Copy from	If there is already a data source for which the necessary SSL settings are specified, you can copy those settings from that data source. Click the link and select the data source to copy the settings from.
CA file	Specify the path to SSL Certificate Authority (CA) certificate file. If used, this must be the same certificate as used by the server. Type the path in the field, or click  ( <a href="#">Shift+Enter</a> ) and select the file in the <a href="#">dialog that opens</a> .
Client certificate file	Specify the path to your (client) public key certificate file. Type the path in the field, or click  ( <a href="#">Shift+Enter</a> ) and select the file in the <a href="#">dialog that opens</a> .
Client key file	Specify the path to your (client) private key file. Type the path in the field, or click  ( <a href="#">Shift+Enter</a> ) and select the file in the <a href="#">dialog that opens</a> .

## Schemas tab

Select the databases and [schemas](#) to be shown in the Database tool window.

### ItemDescription

	Refresh the list of the databases and schemas.
<input type="text" value="Q test"/>	Specify the text for filtering the list. Only the databases and schemas whose names contain the specified text will be shown.

Pattern An alternative to selecting the databases and schemas by means of the checkboxes. `*.*` would mean all schemas in all databases. To get the info about the syntax to be used, place the cursor into the field and press `Ctrl+Q`.

## Options tab

The settings on this tab relate to filtering database objects, loading source code, etc.

### ItemDescription

Object filter	<p>You can limit the set of tables and other database objects shown in the Database tool window by specifying a filter. The filter is applied to "short" (i.e. unqualified) names of the database objects.</p> <p>Examples:</p> <p><code>f.*</code> Only the objects whose names start with <code>f</code> will be shown.</p> <p><code>table:[gh].*</code> The tables whose names start with <code>g</code> or <code>h</code> and all the objects in other categories will be shown.</p> <p><code>view:new_.*  routine:-[ps].*</code> The views whose names start with <code>new_</code>, the routines whose names start with the letters other than <code>p</code> or <code>s</code>, and all the objects in the categories other than views and routines will be shown.</p>
Plan table	<p>For Oracle: The name of the table that should be used to store the <a href="#">EXPLAIN PLAN</a> output information.</p>
Introspect using JDBC metadata	<p>You may want to select this checkbox (if available) to try to fix the problems with retrieving the database structure information from your database (e.g. when the schemas existing in your database or the database objects below the schema level are not shown in the Database tool window).</p> <p>This option defines which of the following alternative introspectors IntelliJ IDEA is using to retrieve the info about the database objects (DB metadata):</p> <ul style="list-style-type: none"><li>– A native introspector (may be unavailable for certain DBMSs). This introspector uses DBMS-specific tables and views as a source of metadata. In addition to "standard" info, it can retrieve DBMS-specific details and thus produce a more precise picture of your database objects.</li><li>– A JDBC-based introspector (available for all the DBMSs). This introspector uses the metadata provided by the corresponding JDBC driver. It can retrieve only standard info about the database objects and their properties.</li></ul> <p>The JDBC-based introspector should be used only when the native introspector fails (if this is the case, select the checkbox) or is not available (in such a case the checkbox is missing).</p> <p>(The native introspector may fail, for example, when your DB server version is older than the minimum version supported by IntelliJ IDEA, when you are using Amazon Redshift because it "pretends" that it's a Postgres while in fact it isn't, etc.)</p>
Load sources for	<p>IntelliJ IDEA will load source code of database objects for the selected category of schemas.</p> <p>You can change this setting for several data sources at once. To do that, select the data sources of interest in the left-hand pane of the dialog. Then, in the <a href="#">context menu</a>, point to <a href="#">Load Sources</a> and select the necessary option.</p>

## Advanced tab

On this tab, you can configure the database connection properties, and also specify the options and environment variables for the database driver JVM.

### ItemDescription

Name - Value	<p>The set of connection options passed to the database driver as key - value pairs at its start.</p> <p>When you select a cell in the Name column, the description of the corresponding option is shown underneath the table.</p> <p>To find an option of interest, just start typing its name.</p> <p>To start editing a value, click or double-click the corresponding Value field, or press <code>F2</code>.</p> <p>To add a row, start editing the values in the last row, where <code>&lt;user defined&gt;</code> and <code>&lt;value&gt;</code> are shown. A new row will be added to the table automatically.</p>
VM Options	<p>The options for the JVM in which the database driver runs. (The driver is started as a separate process in its own JVM.)</p> <p>Example. For certain Oracle Database versions (e.g. for version 9), there may be connection problems when you and your database server are in different time zones. Specifying the time offset for your timezone may help, e.g. <code>User.timezone=UTC+03:00</code>.</p> <p>Alternatively, you can try setting the variable <code>oracle.jdbc.timezoneAsRegion</code> to <code>false</code> in the <a href="#">Name - Value table</a>.</p>
VM Environment	<p>Environment variables for the database driver JVM.</p> <p>Example. Sometimes, when working with Oracle, your data and/or error messages don't display correctly. Many of such problems are encoding-related and can be solved by appropriately setting the <code>NLS_LANG</code> variable, e.g. <code>NLS_LANG=Russian_CIS.CL8MSWIN1251</code>. For more information, see e.g. <a href="#">Oracle NLS_LANG FAQ</a>.</p> <p>To start editing the variables, click <code>⌘</code>.</p>

For additional information, refer to your DBMS documentation.

## DDL data source settings

A DDL data source is defined by its name, and can reference one or more DDL files and/or another data source (a parent data source).

### ItemDescription

Name	Use this field to edit the data source name.
DDL Files	<p>Use the controls in this area to compose the list of files that contain the necessary DDL definitions.</p> <ul style="list-style-type: none"> <li>+ ( <a href="#">Alt+Insert</a> ). Use this icon or shortcut to add a DDL SQL file or files to the data source definition. In the dialog that opens, select the necessary file or files.</li> <li>- ( <a href="#">Alt+Delete</a> ). Use this icon or shortcut to remove the selected file or files from the list.</li> <li>↑ ( <a href="#">Alt+Up</a> ). Use this icon or shortcut to move the selected file one line up in the list.</li> <li>↓ ( <a href="#">Alt+Down</a> ). Use this icon or shortcut to move the selected file one line down in the list.</li> </ul>
Extend	<p>If necessary, select another data source as a parent. As a result, the data source whose properties you are editing will "inherit" all the DDL definitions from its parent.</p> <p>If the parent data source is not needed, select &lt;none&gt; .</p>

## Driver settings

### Settings tab

Shown on this tab are mainly the defaults for the [General tab](#) .

#### ItemDescription

Class	The fully qualified name of the driver class to be used.
Dialect	<p>The SQL dialect associated with the corresponding data sources. Via the data sources this dialect will "propagate" to the <a href="#">database console</a> .</p> <p>In addition to particular dialects, also the following option is available:</p> <ul style="list-style-type: none"> <li>&lt;Generic SQL&gt;. Basic SQL92-based support is provided including completion and highlighting for SQL keywords, and table and column names. Syntax error highlighting is not available. So all the statements in the input pane are always shown as syntactically correct.</li> </ul>
Tx	Auto or Manual . The default setting for the <a href="#">Tx (transaction control) option</a> .
Auto sync	The default setting for the <a href="#">auto sync option</a> .
Send application info	When connecting to a database server, IntelliJ IDEA sends the info about itself if this checkbox is selected.
JDBC drivers	<p>The <a href="#">JDBC driver</a> to be used to interact with a database. You can download and use a driver from the IntelliJ IDEA driver repository (see <a href="#">Use provided driver</a> ) or specify the driver that you already have available on your computer (see <a href="#">Additional</a> ).</p> <p>Use provided driver. If the checkbox is selected, the driver from the repository is used.</p> <p>To download and use the latest driver version, click the red &lt;driver name&gt; [latest] link. (If the link isn't red, the latest driver version has already been downloaded.)</p> <p>You can also specify that you want to use the latest available driver or the driver with a particular version number. To do that, right-click the link, point to the driver name, and select Latest or the version number. If the selected version has not been yet downloaded, it will be downloaded automatically.</p> <p>Additional. The files specified in this area are used in addition to the downloaded driver if the Use provided driver checkbox is selected, or instead of the downloaded driver otherwise.</p> <p>Say, you want to use the driver that is already available on your computer. In that case, you should clear the Use provided driver checkbox, click + and select the driver files (usually one or more <code>.jar</code> files) in the <a href="#">dialog that opens</a> .</p>
URL templates	<p>The templates used to construct the database URL. The text in curly brackets represents variables, e.g.</p> <ul style="list-style-type: none"> <li>{host} the domain name or IP address of the database host.</li> <li>{port} the database port number.</li> <li>{database} the name of the database or schema.</li> </ul> <p>Optional fragments are in square brackets, e.g. [:{port}] .</p> <p>Template names correspond to the names of the options in the <a href="#">URL options list</a> .</p>

## Advanced tab

Shown on this tab are the default settings for the [Advanced tab](#) .

#### ItemDescription

Name - Value	<p>The default set of connection options passed to the database driver as key - value pairs at its start.</p> <p>To start editing a value, double-click the corresponding Value field.</p> <p>To add a row, start editing the values in the last row, where &lt;user defined&gt; and &lt;value&gt; are shown. A new row will be added to the table automatically.</p>
VM Options	The default options for the JVM in which the database driver runs. (The driver is started as a separate process in its own JVM.)

## Problems

If potential problems are detected, there is a number to the right of Problems . In that case, if you click Problems , you'll see

the list of problems as well as controls for fixing them.

From the [Database tool window](#) :

Select the element or elements of interest, and select Color Settings from the context menu.

Select the [color](#) , and specify how this color should be used (see [Shared](#) and [Override recursively](#) ). Use the checkboxes in the [Appearance Settings](#) section to enable or disable the database colors in various places in the UI.

#### ItemDescription

**Color** Click the color that you want to use for the element or elements selected in the Database tool window.  
If the color that you want is missing, click Custom and specify the color in the dialog that opens.

The color which is currently selected is marked with its name, e.g. Blue .

If you don't want to use any color, click [No Color](#) .

**Shared** Select the checkbox if you want to share the change of color you are about to make with your team. (The database color settings are shared through version control.)

In technical terms, the new color (for the selected element or elements) will be stored in

- `.idea/databaseColors.xml` or the `.ipr` file if the checkbox is selected.
- `.idea/workspace.xml` or the `.iws` file if the checkbox is not selected.

The `workspace.xml` or the `.iws` file, normally, is not shared through version control while the rest of IntelliJ IDEA configuration files are.

For more information on IntelliJ IDEA configuration files and their sharing, see [Configuring projects](#) .

**Override recursively** If the checkbox is selected, the selected color will be applied to the element itself and all its subordinate elements recursively.  
If the checkbox is not selected, the colors set individually for the subordinate elements won't change.

#### Appearance Settings

**Enable database colors** Clear the checkbox to (temporarily) disable the database colors everywhere in the UI.

**In Database tool window** Select the checkbox to use the database colors in the Database tool window.  
When this option is off, the tool window looks like this:

When this option is on, the tool window may look as shown below. (In this example, the blue color is set for the corresponding data source.)

**In editor tabs** Select the checkbox to use the database colors for editor tabs (when working with a data editor and the input pane of a database console).

When this option is off, the tabs look like this:

When this option is on, the tabs have the same color as the corresponding data source or table (e.g. blue):

**In console editors and grids** Select the checkbox to use the database colors for the editing area in database consoles and data editors.  
When this option is off, the editing area looks like this:

When this option is on, the background of the editing area has the same color as the corresponding data source (e.g. blue).

**In toolbars**

Select the checkbox to use the database colors for the toolbars of database consoles and data editors.

When this option is off, the toolbar looks like this:

When this option is on, the toolbar background has the same color as the corresponding data source (e.g. blue).

**No Color**

Click this button, if you don't want to use any color for the selected element or elements.

Project tool window | context menu of a file | Compare File with Editor

Project tool window | context menu of a file | Compare Files

Version Control tool window | Local Changes tab | - 

Version Control tool window | context menu of a folder or file | Show Diff

In this section:

- [Basics](#)
- [Diff & Merge viewer](#)
- [Keyboard shortcuts](#)
- [Context menu commands](#)

## Basics

This dialog is displayed every time you compare two files or two versions of a file (local changes or changes between local files and their revisions in a remote repository). You can compare files of any types, including binaries and `.jar` files.

Note that you can open the differences viewer without running IntelliJ IDEA. To do this, execute the following command:

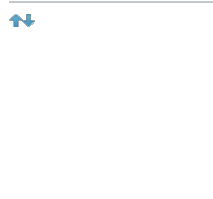

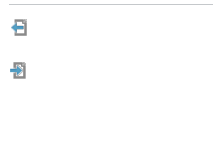

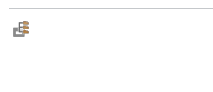

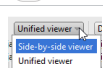

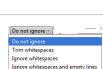

```
<path to IntelliJ IDEA executable file> diff <path_1> <path_2>
```

where `path_1` and `path_2` are paths to the files you want to compare.

The differences viewer provides a powerful editor that enables code completion, live templates, etc.

## Diff & Merge viewer

**Item** **Tooltip** **Description**  
**and**  
**Shortcut**

	<p><b>Previous Difference / Next Difference</b></p> <p>Use these buttons to jump to the next/previous difference. When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons <code>F7</code> / <code>Shift+F7</code> once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a>.</p> <p><code>Shift+F7</code> <code>F7</code></p> <p>This behavior is supported only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.</p>
	<p><b>Compare Previous/Next File</b></p> <p>Click these buttons to compare the local copy of the previous/next file with its update from the server.</p> <p><b>Note</b> These controls are only available if more than one file has been modified locally.</p> <p><code>Alt+Left</code> <code>Alt+Right</code></p>
	<p><b>Go To Changed File</b></p> <p>Click this button to display all changed files in a current change set (and navigate to them).</p> <p><code>Ctrl+N</code></p>
	<p><b>Jump to Source</b></p> <p>Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer.</p> <p><code>F4</code></p>
<b>Viewer type</b>	<p></p> <p>Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only. Both types of viewers enable you to</p> <ul style="list-style-type: none"> <li>- Edit code. Note that one can change text <i>only</i> in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.</li> <li>- Perform the Apply/Append/Revert actions.</li> </ul>
<b>Whitespaces</b>	<p></p> <p>Use this drop-down list to define how the differences viewer should treat white spaces in the text.</p> <ul style="list-style-type: none"> <li>- Do not ignore : white spaces are important, and all differences are highlighted. This</li> </ul>

option is selected by default.

- Trim whitespaces : ( "\t", " " ) , if they appear in the end and in the beginning of a line.
  - If two lines differ in trailing whitespaces only, these lines are considered equal.
  - If two lines are different, such trailing whitespaces are not highlighted in the **By word** mode.
- Ignore whitespaces : white spaces are not important, regardless of their location in the source code.
- Ignore whitespaces and empty lines : the following entities are ignored:
  - all whitespaces (as in the 'ignore whitespaces' option)
  - all added or removed lines consisting of whitespaces only
  - all changes consisting of splitting or joining lines without changes to non-whitespace parts.

For example, changing `a b c` to `a \n b c` is not highlighted in this mode.

- Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).

## Highlighting mode

Select the way differences granularity is highlighted.

The available options are:

- Highlight words : the modified words are highlighted
- Highlight lines : the modified lines are highlighted
- Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.

For example, `A \n B` vs. `A X \n B X` will be treated as two changes instead of one.

- Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.

	Collapse unchanged fragments	Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the Diff & Merge settings page.
	Synchronize scrolling	Click this button to simultaneously scroll both differences panes; if this button is released, each of the panes can be scrolled independently.
	Editor settings	Click this button to invoke the list of available settings. Select or clear this options to show or hide whitespaces, line numbers and indent guides, to use or disable the use of soft wraps, and to set the highlighting level. These commands are also available from the context menu of the differences viewer gutter.
<input type="checkbox"/>	Include into commit <code>Alt+I</code>	This checkbox only appears if you invoke the Differences Viewer from the <a href="#">Commit Changes dialog</a> with multiple changed files (all of which are deselected), and you explore the differences between them and hit the last difference in a file. Select this checkbox if you want to include the file you've reviewed into the commit.
	Move to Another Changelist <code>F6</code>	This button only appears if you invoke the Differences Viewer from the <a href="#">Commit Changes dialog</a> with multiple changed files (all of which are deselected), and you explore the differences between them and hit the last difference in a file. Click this icon to <a href="#">move</a> the file you've reviewed to another changelist.
	Show diff in external tool	Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> settings page. This button only appears on the toolbar when the Use external diff tool option is enabled in the <a href="#">External Diff Tools</a> settings page.
	Help <code>F1</code>	Click this button to show the corresponding help page.
<code>Ctrl+Tab</code>		Use this keyboard shortcut to switch between the panes of the Differences viewer. The active pane has the cursor.
		Use these <b>chevron</b> buttons to apply differences between panes (in case of the side-by-side viewer) or between lines (in case of the unified viewer). The chevron buttons can change their behavior: <ul style="list-style-type: none"><li>- Click  to apply changes. This behavior is the default one.</li><li>- Press <code>Ctrl</code> to change  to  or  and append changes.</li></ul>
<b>Merge actions</b>		
	NA	Click this icon to invoke the list of options allowing you to compare different versions of a file to resolve a conflict. Note that Base refers to the file version that the local and the repository versions originated from (initially displayed in the middle pane), while Middle refers to the resulting version.
	Apply All Non-Conflicting Changes	Click this button to apply all non-conflicting changes. You can also make this behavior automatic, by selecting the checkbox Automatically apply non-conflicting changes in the Diff & Merge page of the Settings/Preferences dialog.

Apply Non-Conflicting Changes from the Left/Right Side

Click these buttons to merge non-conflicting changes from the left/right parts of the dialog.

N/A	Annotate	<p>This option is only available from the context menu of the gutter.</p> <p>Use this option to explore who introduced which changes to the repository version of the file in question, and when. The annotations view lets you see detailed information for each line of code, such as the version from which this line originated, the ID of the user who committed this line, and the commit date.</p> <p>You can <a href="#">configure the amount of information displayed in the annotations pane</a> .</p> <p>For more details on annotations, refer to <a href="#">Viewing Changes Information</a></p>
-----	----------	---

## Keyboard shortcuts

### Keyboard Description shortcut

Ctrl+Shift+D	Use this keyboard shortcut to show the popup menu of the most commonly user diff commands.
Ctrl+Tab	Use this keyboard shortcut to switch between the left and the right panes.
Ctrl+Shift+Tab	Use this keyboard shortcut to select the position obtained by <a href="#">Ctrl+Tab</a> in the opposite pane.
Ctrl+Z / Ctrl+Shift+Z	Use this keyboard shortcut to undo/redo a merge operation. Conflicts will be kept in sync with the text.

## Context menu commands

This context menu is available in the middle of the editor:

### ItemDescription

Show Whitespaces	Select this check command to show whitespaces as the dots in the Differences Viewer .
Show Line Numbers	Select this check command to show line numbers in the Differences Viewer.
Show Indent Guides	Select this check command to have IntelliJ IDEA display vertical lines in the Differences Viewer to indicate positions of indents.
Use Soft Wraps	Select this check command to have IntelliJ IDEA wrap the lines of code, when the dialog box is resized.
Highlighting level	Use this menu item to select the highlighting level in the Differences Viewer. To learn more about the level of highlighting, refer to the description of the <a href="#">Status Bar</a> .
Annotate	Select this check command to <a href="#">annotate</a> the changes.

**Tip** This command is available only for the files under version control.

This context menu is available in both editors:

### ItemDescription

Accept/Append	Select these commands to <a href="#">accept or append</a> the lines shown in the Differences Viewer.
Compare with Clipboard	Select this command to compare the file in the respective pane of the Differences Viewer with the <a href="#">contents of the Clipboard</a> .
Annotate	Select this check command to <a href="#">annotate</a> the changes.

**Tip** This command is available only for the files under version control.

This context menu is available in the right-hand strip of the Differences Viewer:

### ItemDescription

Go to high-priority problems only/Go to next problem	Click one of these radio-buttons to define the way of navigating between the encountered problems.
Customize highlighting level	Click to show the slider to change the <a href="#">highlighting level</a> in the Differences Viewer.
Show code lens on scrollbar hover	Select this checkbox to switch the Differences Viewer to the <a href="#">lens mode</a> .

Project tool window | context menu of a folder | Compare Directory with

Project tool window | context menu of two selected folders | Compare Directories

Project tool window | context menu of a folder | Sync with Deployed to

Remote Host tool window | context menu of a folder | Sync with local

Database tool window | context menu of two selected items | Compare

This window is displayed when you explore the differences between:

- Two local directories
- A remote folder and its local version

This dialog lets you explore the differences and synchronize the folders you are comparing.

**Tip** You can also open the difference viewer without running IntelliJ IDEA. This is done through the following command: `<path to IntelliJ IDEA> executable f11e> diff <path_1> <path_2>` where `path_1` and `path_2` are paths to the folders in question.

## Toolbar

Item	Tooltip and shortcut	Description	Available for
	 	Use these buttons to jump to the next/previous difference. When the last/first difference is hit, IntelliJ IDEA suggests to press  /  once more and compare other files.	Version control
<p><b>Tip</b> This feature becomes available only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.</p>			
	Jump to Source	Click this button to open file in the editor's active tab. The caret will be placed in the same position as in the Differences Viewer.	All
	 Refresh	Click this button to refresh the contents of the differences viewer.	All
	 Show new files on left side	Click this button to display items that are present in the first of the compared directories or database objects and are missing in the second one in the left pane.	All
	Show diff in external tool	Click this button to invoke an external differences viewer, specified in the <a href="#">External Diff Tools</a> page. This button is only available if the Use external diff tool option is selected in the <a href="#">External Diff Tools</a> settings page.	All
	Show difference	Click this button to display items that are present in both folders or database objects but have different contents, timestamp, or size.	All
	Show equal files	Click this button to display items that are present in both directories or objects and have the same contents, timestamp, and size, depending on the parameter set in Compare by drop-down list.	All
	Show new files on right side	Press this toggle button to have IntelliJ IDEA show the items, that are present in the second of the compared directories or database objects and are missing in the first one.	All
Compare by		From this drop-down list, select the parameter to be used for comparison. The available options are: <ul style="list-style-type: none"><li>- Binary Content</li><li>- Text (charset and line separators are ignored)</li><li>- Size</li><li>- Size and Timestamp</li></ul>	Local folders Local-remote folders
	Synchronize Selected	Click this button to have IntelliJ IDEA apply the <a href="#">specified action</a> to the selected pair of	All

		items. Actions to be performed are shown in the * field.	
	Synchronize All	Click this button to have IntelliJ IDEA apply the <a href="#">specified action</a> to all the pairs of items in the list. Actions to be performed are shown in the * field.	All
			
	Hide excluded files	Click this button to suppress showing files <a href="#">excluded from synchronization</a> .	Local-remote folders
Filter		Type the filtering string (for example, file or table name). Use * wildcard to replace any number of arbitrary characters. Note that filter applies on pressing  .	All
Path		These fields show the paths to the folders being compared. To change a directory, click the Browse button  and specify another directory in the <a href="#">dialog that opens</a> .	Local folders Local-remote folders
		These read-only fields show the names of the data sources or tables being compared.	Data sources
	Help	Click this button to show reference page.	All
			

## List of items

The list shows the items from the compared objects that meet the comparison criterion specified in the [Compare by](#) drop-down list and the filtering criteria specified through the [toolbar buttons](#) .

ItemDescription	Available for	
Name	These read-only fields show the names of files, data source tables, or table fields under the object specified in the Path or  fields.	All
Size	These read-only fields show the sizes of files under the folders being compared.	Local folders Local-remote folders
Date	These read-only fields show the timestamps of files under the folders being compared.	Local folders Local-remote folders
*	The icon in this field indicates the action that will be applied to the pair of items in the current line upon clicking the Synchronize Selected  or Synchronize All  toolbar button. To change the currently selected action, click the icon.	All
<b>IconAction</b>		
	Copy the item in the left side to the right side, possibly overwriting the contents of the corresponding target item, if it already exists.	
	Copy the item in the right side to the left side, possibly overwriting the contents of the corresponding target item, if it already exists.	
	The items are treated identical with regard to the selected criterion of comparison. No action will be performed by default.	
	The items differ with regard to the selected criterion of comparison. No action will be performed by default. Explore the differences in the <a href="#">Differences Pane</a> and change the intended action by clicking the icon.	
	The item is present only in one of the folders and will be removed.	

## Differences pane

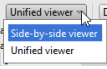

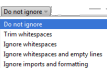

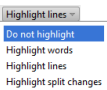

The differences pane is displayed only for files, data source tables, or table fields with the same names, which exist on both sides. For the files and DB objects that exist on one side only, the contents of the selected file/DB object is displayed.

If the files have read-only status, they are not editable in the differences pane.

## Diff viewer

ItemTooltip and Description

## Shortcut

	<p>Previous Difference / Next Difference</p> <p>Shift+F7</p> <p>F7</p>	<p>Use these buttons to jump to the next/previous difference.</p> <p>When the last/first difference is hit, IntelliJ IDEA suggests to click the arrow buttons <b>F7</b> / <b>Shift+F7</b> once more and compare other files, depending on the <a href="#">Go to the next file after reaching last change</a> option in the <a href="#">Differences Viewer settings</a>.</p> <p>This behavior is supported only when the Differences Viewer is invoked from the <a href="#">Version Control</a> tool window.</p>
	<p>Compare Previous/Next File</p> <p>Alt+Left</p> <p>Alt+Right</p>	<p>Click these buttons to compare the local copy of the previous/next file with its update from the server.</p> <p><b>Note</b> These controls are only available if more than one file has been modified locally.</p>
	<p>Go To Changed File</p> <p>Ctrl+N</p>	<p>Click this button to display all changed files in a current change set (and navigate to them).</p>
	<p>Jump to Source</p> <p>F4</p>	<p>Click this button to open the selected file in the active pane in the editor. The caret will be placed in the same position as in the Differences Viewer.</p>
Viewer type		<p>Use this drop-down list to choose the desired viewer type. The side-by-side viewer has two panels; the unified viewer has one panel only.</p> <p>Both types of viewers enable you to</p> <ul style="list-style-type: none"><li>– Edit code. Note that one can change text <b>only</b> in the right-hand part of the default viewer, or, in case of the unified viewer, in the lower ("after") line, i.e. in your local version of the file.</li><li>– Perform the <a href="#">Apply/Append/Revert</a> actions.</li></ul>
Whitespace		<p>Use this drop-down list to define how the differences viewer should treat white spaces in the text.</p> <ul style="list-style-type: none"><li>– Do not ignore : white spaces are important, and all differences are highlighted. This option is selected by default.</li><li>– Trim whitespaces : (" \t", " ") , if they appear in the end and in the beginning of a line.<ul style="list-style-type: none"><li>– if two lines differ in trailing whitespaces only, these lines are considered equal.</li><li>– if two lines are different, such trailing whitespaces are not highlighted in the <a href="#">By word</a> mode.</li></ul></li><li>– Ignore whitespaces : white spaces are not important, regardless of their location in the source code.</li><li>– Ignore whitespaces and empty lines : the following entities are ignored:<ul style="list-style-type: none"><li>– all whitespaces (as in the 'ignore whitespaces' option)</li><li>– all added or removed lines consisting of whitespaces only</li><li>– all changes consisting of splitting or joining lines without changes to non-whitespace parts.</li></ul></li></ul> <p>For example, changing <code>a b c</code> to <code>a \n b c</code> is not highlighted in this mode.</p> <li>– Ignore imports and formatting : changes within import statements and whitespaces are ignored (whitespaces within String literals are respected though).</li>
Highlighting mode		<p>Select the way differences granularity is highlighted.</p> <p>The available options are:</p> <ul style="list-style-type: none"><li>– Highlight words : the modified words are highlighted</li><li>– Highlight lines : the modified lines are highlighted</li><li>– Highlight split changes : if this option is selected, big changes are split into smaller 'atomic' changes.</li></ul> <p>For example, <code>A \n B</code> vs. <code>A X \n B X</code> will be treated as two changes instead of one.</p> <li>– Do not highlight : if this option is selected, the differences are not highlighted at all. This option is intended for significantly modified files, where highlighting only introduces additional difficulties.</li>
	<p>Collapse unchanged fragments</p>	<p>Click this button to collapse all unchanged fragments in both files. The amount of non-collapsible unchanged lines is configurable in the <a href="#">Diff &amp; Merge settings</a> page.</p>
	<p>Synchronize scrolling</p>	<p>Click this button to simultaneously scroll both differences panes; if this button is released, each of the panes can be scrolled independently.</p>
	<p>Editor settings</p>	<p>Click this button to invoke the list of available settings. Select or clear this options to show or hide whitespaces, line numbers and indent guides, to use or disable the use of soft wraps, and to set the highlighting level.</p> <p>These commands are also available from the context menu of the differences viewer gutter.</p>
	<p>Include into commit</p>	<p>This checkbox only appears if you invoke the Differences Viewer from the <a href="#">Commit Changes dialog</a> with multiple changed files (all of which are</p>

Alt+I

deselected), and you explore the differences between them and hit the last difference in a file.

Select this checkbox if you want to include the file you've reviewed into the commit.

 Move to Another Changelist  
 This button only appears if you invoke the Differences Viewer from the [Commit Changes dialog](#) with multiple changed files (all of which are deselected), and you explore the differences between them and hit the last difference in a file. Click this icon to [move](#) the file you've reviewed to another changelist.

F6

 Show diff in external tool  
 Click this button to invoke an external differences viewer, specified in the [External Diff Tools](#) settings page. This button only appears on the toolbar when the Use external diff tool option is enabled in the [External Diff Tools](#) settings page.

 Help  
 Click this button to show the corresponding help page.

F1

Ctrl+Tab

Use this keyboard shortcut to switch between the panes of the Differences viewer. The active pane has the cursor.

 Use these [chevron](#) buttons to apply differences between panes (in case of the side-by-side viewer) or between lines (in case of the unified viewer). The chevron buttons can change their behavior:

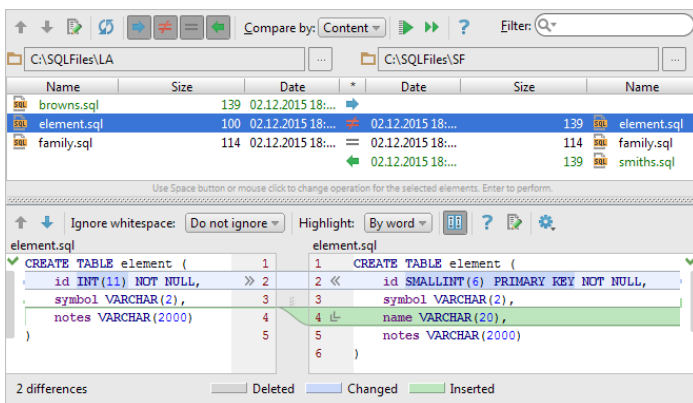

- Click  to apply changes. This behavior is the default one.
- Press  to change  to  or  and append changes.

## Context menu

This menu appears when you right-click an entry in the list of items. The commands in this menu define which action must be taken for the selected entry on clicking [Synchronize Selected](#) or [Synchronize All](#). The selected action appears in the \* column.

### Item IconDescription

Set Copy to Right/Left	 This command sets the specified icons in the * column to copy a file missing from one of the directories. If a file exists on one side, it will be copied; if it doesn't exist, then the file on the other side will not be deleted.
Set Delete	 This command sets the specified icons in the * column to delete file.
Set Do Nothing	Choose this command to remove an action icon.
Set Mirror to Right	 Choose this command to automatically set actions in the * column that will mirror the contents of the left folder in the right folder when you click Synchronize All.
Set Mirror to Left	 Choose this command to automatically set actions in the * column that will mirror the contents of the right folder in the left folder when you click Synchronize All.
Set Default	Choose this command to set the default action for the entry.
Warn When Delete	Select this option to display a warning when trying to delete a file that is located only in one of the two directories during their merge.

File comparison statuses and intended operations are shown in the column marked with an asterisk (\*). To assign or change an operation, use the context menu associated with the corresponding cell. Alternatively, click the cell or press  one or more times.

Applying operations:

-  () applies the operations to selected files.
-  () applies the operations to all the files.

### IconDescription

 The file exists only in the left-hand folder. The intended operation is to copy the file to the right-hand folder. If a file exists in both folders and you apply this operation, the file in the right-hand folder is overwritten.

---

 For the selected comparison criterion, the files are not identical. No operation is assumed.  
Study the file differences in the lower part of the view. You can choose to overwrite one of the files by assigning and applying the corresponding operation. You can as well modify the file contents.

This may be done by typing or by using the following buttons and context menu commands:

-  or  or Replace . Replace the fragment with the one from the other pane.
-  or  or Insert . Insert the fragment into the other pane.
- Remove . Remove the corresponding fragment.

To undo the changes, use  .

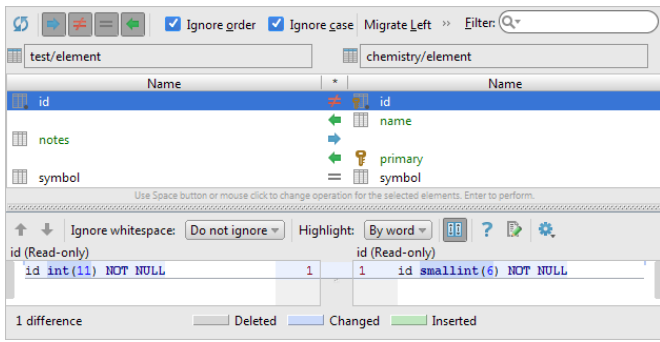

---

 For the selected comparison criterion, the files are identical. No operation is assumed.

 The file exists only in the right-hand folder. The intended operation is to copy the file to the left-hand folder.  
If a file exists in both folders and you apply this operation, the file in the left-hand folder is overwritten.

---

 Delete the file. The operation is not available for files that exist in both folders.

Comparison statuses are shown in the column marked with an asterisk (\*).

#### IconDescription

	The column, constraint or index exists only in the left-hand table.
	The items exist in both tables but their definitions are different. You can study the differences in the lower part of the view.
	The items are identical.
	The item exists only in the right-hand table.

#### Generating ALTER TABLE statements

You can generate a set of `ALTER TABLE` statements for making data definitions in the left-hand and the right-hand parts identical. Use one of the following buttons in the upper part of the view:

- Migrate Left. The statements for the left-hand table or tables are generated.
- Migrate Right. This buttons does the same but for the right-hand table or tables.

The `ALTER TABLE` statements are generated for the items marked , and . If you don't want to generate the statements for some of those items, right click the \* cell and select Set Do Nothing for all such items.

The primary purpose of the differences viewer for tables is to show the differences and similarities of data.

## Detect column insertion

When the tables have different number of columns, "extra columns" in the table with more columns are ignored. If the Detect column insertion option is on, the most different columns are ignored. On the following picture, the first column in the second table is the most different and so it is ignored. As a result, the second row is shown as containing the same data.

browns			smiths		
name	relation		member_id	name	relation
Emily	mother	1	1	Chloe	mother
Harry	father	2	2	Harry	father
Dylan	brother	3			

If the option is off, ignored are the last of the columns. On the following picture, the last column in the second table is ignored. So all the rows are shown as containing different data.

browns			smiths		
name	relation		member_id	name	relation
Emily	mother	1	1	Chloe	mother
Harry	father	2	2	Harry	father
Dylan	brother	3			

## Tolerance

Tolerance is how many columns may be different. With zero tolerance on the following picture, the first row is shown as containing different data.

browns			smiths		
name	relation		member_id	name	relation
Emily	mother	1	1	Chloe	mother
Harry	father	2	2	Harry	father
Dylan	brother	3			

With the tolerance of one on the following picture, the first row is shown as containing about the same data.

browns			smiths		
name	relation		member_id	name	relation
Emily	mother	1	1	Chloe	mother
Harry	father	2	2	Harry	father
Dylan	brother	3			

For this dialog to be available, the Docker integration plugin must be installed and enabled.

---

Specify your [Docker](#) image repository user account settings.

---

**ItemDescription**

---

Name	The name for this set of settings.
Address	The image repository service URL, e.g. – registry.hub.docker.com for <a href="#">Docker Hub</a> – quay.io for <a href="#">Quay</a>
Username	The user name for your user account.
Password	Your password.
Email	The email address that you specified when creating your user account.
Server	The associated <a href="#">Docker configuration</a> (used to connect to the service to check that your user account settings are correct).

Select which library files you want to download. Specify the destination directory and also other settings such as the library name and [level](#) .

**ItemDescription**

Version	If available: select the library version you want to download. Note that your selection affects the set of files you can choose from (shown under <a href="#">Files to download</a> ).
Name	If necessary, edit the library name.
Level	If available: select the <a href="#">level</a> which the library should be assigned to (global, project or module).
Files to download	Use the checkboxes in this area to select the library files to be downloaded.
Download sources	If available: select this checkbox to download the source code for the library files.
Download javadocs	If available: select this checkbox to download Javadoc documentation for the library files.
Copy downloaded files to	Specify the path to the destination directory. To change the default path, click  and select the directory in the <a href="#">dialog that opens</a> .

If a text file containing [delimiter-separated values](#) (e.g. CSV, TSV) is open in the editor, this dialog opens when you select the Edit as Table command.

---

Specify how your delimiter-separated values should be converted into table format.

When working on the conversion settings, use the table preview in the right-hand part of the dialog.

#### ItemDescription

---

Formats	Select your file format and check the table preview. If you haven't achieved the desired result yet, adjust the settings.  If you have changed the settings and want to save the changes, click this icon and select one of the following: <ul style="list-style-type: none"><li>– Save Changes. The settings are saved "under the same name", without creating a new format. (A format, in fact, is a named set of settings.)</li><li>– Save As. The settings are saved "under a different name": a new format is created and you can specify the name for that new format.</li></ul>
---------	--

---

Value separator	Select or type the character used for separating individual values.
-----------------	---

---

Row separator	Select or type the character that should be treated as a row separator.
---------------	---

---

Null value text	The text to be used as a value if a cell contains <code>null</code> (an unknown value).
-----------------	---

---

Add row prefix/suffix	Row prefix and suffix are character sequences which in addition to the row separator indicate the beginning and end of a row. If necessary, click the link and specify the row prefix and suffix in the fields that appear.
-----------------------	--

---

Quotation	Each line in the area under Quotation is a quotation pattern (see <a href="#">Quote values</a> ). A quotation pattern includes: <ul style="list-style-type: none"><li>– The left quotation character, the one inserted before a value.</li><li>– The right quotation character, the one inserted after a value; usually, the same as the left quotation character.</li><li>– An escape method or character for the cases when the quotation character is part of a value. E.g. Escape: duplicate means that if a quotation character occurs within a value, it is doubled. (You can specify your own escape character instead.)</li></ul>
-----------	---

If there is more than one pattern, the first of the patterns is used.

Use  ,  ,  and  to create, delete and reorder the patterns.

To start editing an existing pattern, just click the pattern of interest.

---

Quote values	Specify in which cases the values should be quoted (i.e. enclosed within quotation characters). <ul style="list-style-type: none"><li>– When needed. A value is quoted only if it contains the value and/or the row separator.</li><li>– Always. Any value is quoted in its text representation.</li></ul>
--------------	--

---

Trim whitespaces	If this checkbox is not selected, the Unicode whitespace characters that precede and follow the value separators are treated as parts of the corresponding values. If this checkbox is selected, the corresponding whitespace characters are ignored or removed.
------------------	--

---

First row is header	If this checkbox is selected, the first row is treated as containing column names. The settings that appear under Header Format have the same meanings as the ones above but are applied to the first row.
---------------------	--

---

First column is header	If this checkbox is selected, the first column is treated as containing row names.
------------------------	--

Use this dialog to change or delete the existing macros. Note that the dialog is not available, when there are no macros.

**ItemDescription**

---

Existing macros list The left-hand pane of the dialog shows the list of existing macros.

---

 Click this button to delete a recorded macro.

---

 Click this button to change name of a recorded macro in the Rename Macro dialog.

---

Actions list The right-hand pane shows the list of actions recorded for each macro. The list of actions for each macro is editable - you can remove unnecessary actions.

---

 Click this button to delete an action from the macro.

Edit the [library](#) name and contents.

#### ItemDescription

Name	Use this field to edit the library name.
Change Version	<p>This button may be available for a library that implements a certain framework or technology (e.g. JSF, Spring) in cases when IntelliJ IDEA can make version-specific file replacements in the library.</p> <p>In such cases, when you click this button, the <a href="#">Downloading Options dialog</a> opens in which you can select the necessary library version, and also the files to be downloaded.</p> <p>As a result, the files in the library will be replaced with the downloaded files.</p>

 or 	<p>Use this icon or shortcut to add items (classes, sources, documentation, etc.) to the library.</p> <p>In the <a href="#">dialog that opens</a> , select the necessary files and folders. For a Java library, these may be individual <code>.class</code> and <code>.java</code> files, directories and archives (<code>.jar</code> and <code>.zip</code> ) containing such files as well as directories with Java native libraries (<code>.dll</code> , <code>.so</code> or <code>.jnlib</code> ). For an ActionScript/Flex library, these may be raw ActionScript 3 libraries, <code>.swc</code> , <code>.jar</code> and <code>.zip</code> files, the directories containing such files, and so on.</p> <p>IntelliJ IDEA will analyze the selected files and folders, and automatically assign their contents to the appropriate library categories (Classes, Sources, Documentation, Native Library Locations, etc.).</p> <p>When IntelliJ IDEA cannot guess the category (e.g. when you select an empty folder), a dialog will be shown, in which you will be able to specify the category yourself.</p>
--	--

	To be able to use external documentation available online, click this icon and specify the URL of the external documentation in the dialog that opens.
--	--

	Click this icon to make certain library items "excluded" (see <a href="#">Excluded library items</a> ). In the dialog that opens, select the items that you want IntelliJ IDEA to ignore (folders, archives and folders within the archives), and click OK .
--	--

 or 	<p>When you click this icon or press  :</p> <ul style="list-style-type: none"><li>- The selected "ordinary" library items are removed from the library.</li><li>- The selected excluded items (see <a href="#">Excluded library items</a> ) become "ordinary" items, i.e. their excluded status is cancelled. The items themselves will stay in the library.</li></ul>
--	---

The dialog box opens when you click  next to the Path Mappings field in various cases (for example, in the [Run/Debug Configuration: Node.js](#) dialog , or when you configure a remote interpreter ).

If in the current run/debug configuration you use an interpreter accessible through SFTP connection or located on a Vagrant instance, the mappings are automatically retrieved from the corresponding deployment configuration or `Vagrantfile` and listed in the dialog box. The mappings are read-only.

- To add a custom mapping, click  and specify the path in the project and the corresponding path on the remote runtime environment in the Local Path and Remote Path fields respectively. Type the paths manually or click  and select the relevant files or folders in the dialog box that opens.
- To remove a custom mapping, select it in the list and click  .

Alt+F8

Use this dialog box to calculate values of expressions or code fragments during the debugging session.

**ItemDescription**

Expression	Use this field to edit the expression to be evaluated. If an expression is selected in the editor, this field displays selection. <b>Tip</b> This field is available in the Expression Mode .
Language	Choose Java or Groovy from the drop-down list, to enable recognition of the respective syntax of expressions. <b>Tip</b> This field is available only for Groovy scripts.
Statements to Evaluate	Type the group of statements to be evaluated. If a code fragment is selected in the editor, this field displays selection. <b>Tip</b> This field is available in the Code Fragment Mode .
Result	Here the results are displayed.
Evaluate	Click this button to evaluate the current expression or code fragment.
Close	Click this button to close the dialog box.
Code Fragment Mode	Click this button to toggle to the Code Fragment Mode .
Expression Mode	Click this button to toggle to the Expression Mode .

## ItemDescription

---

Modules to export	This area shows the list of modules that have not been converted and switched to use the Eclipse format yet (the modules that have the IntelliJ IDEA module format <code>.iml</code> ). Select the modules you want to export by selecting the corresponding check-boxes.
Switch selected modules to Eclipse-compatible format	If this checkbox is selected, the modules selected in the Modules to export area, will be switched to the Eclipse-compatible format.
Export non-module libraries	If this checkbox is selected, IntelliJ IDEA creates a User Library configuration file for Eclipse ( <code>*.userlibraries</code> ), containing definitions of all external libraries, used in the project.  If this checkbox is not selected, the Path to resulting <code>.userlibraries</code> field is disabled.
Path to resulting <code>.userlibraries</code>	Specify the path to the generated <code>*.userlibraries</code> file. Note that this field is only available when the Export non-module libraries option is selected.

Use this dialog to save selected files in HTML format.

**ItemDescription**

---

File <name>	Click this radio button to print the file currently selected in the Project view, or open in the editor.
Selected text	Click this radio button to print the text selected in the editor.
All files in the directory	Click this radio button to print all files in the current directory.
Include subdirectories	Select this checkbox to print the files in the subdirectories of the current directory.
Output directory	Specify fully qualified path to the directory, where the resulting HTML file will be stored.
Show line numbers	Select this checkbox to include line numbers in the resulting HTML file.
Generate hyperlinks to classes	Select this checkbox to replace class names with the hyperlinks to the respective classes.
Open generated HTML in browser	Select this checkbox to show HTML file in the default browser after export.

An external process has changed a file, opened and unsaved in IntelliJ IDEA, which results in two conflicting versions of a file. Resolve this conflict using the following options.

**ItemDescription**

---

**Load FS Changes** Click this button to load the file version produced outside of IntelliJ IDEA, and overwrite your local changes.

---

**Keep Memory Changes** Click this button to preserve the version produced in IntelliJ IDEA and stored in cache.

---

**Show Difference** Click this button to invoke the [differences viewer](#) that shows the version in the file system to the left, and IntelliJ IDEA version to the right. You can merge differences as required and load the desired version to IntelliJ IDEA. By default, the cache version is saved.

 or 

In the [Project tool window](#) and [Navigation Bar](#) : Find in Path or Replace in Path from the context menu for a directory.

Specify what you want to find and where. In the Replace in Path window, also specify the replacement text or pattern.

Use  and  to switch between the find and replace modes.

## Search pattern and replacement text options

### ItemDescription

Match case	Select this check box to have IntelliJ IDEA distinguish between upper and lowercase letters while searching.
Preserve case	<p>If you select this check box IntelliJ IDEA retains the case of the first letter and the case of the initial string in general. For example, <i>MyTest</i> will be replaced with <i>Yourtest</i> if you specify <i>yourtest</i> as the replacement. This check box is disabled, if the Case sensitive or Regular expressions check box is selected.</p> <p>This field is available only in the Replace in Path dialog.</p>
Words	<p>Select this check box to have IntelliJ IDEA search for whole words or their parts, (character strings separated with spaces, tabs, punctuation, or special characters). This check box is disabled, if the Regex check box is selected.</p>
Regex	<p>Select this check box if the specified search pattern should be treated as a <a href="#">regular expression</a> .</p> <div style="background-color: #ffff00; padding: 5px;"> <p> Click the ? mark next to the check box to view reference on regular expressions syntax. For more information on regular expressions and their syntax, refer to documentation for <a href="#">java.util.regex</a> .</p> </div>
	<p>Use this drop-down list to confine the search to a certain context, for example:</p> <ul style="list-style-type: none"> <li>– anywhere - select this option to search everywhere.</li> <li>– in comments - select this option to confine search to comments, ignoring the other occurrences.</li> <li>– In string literals - select this option to confine search to string literals, ignoring the other occurrences</li> <li>– Except... - select one of the exception options to perform search avoiding comments, string literals or both.</li> </ul>
File mask	<p>Select this checkbox to narrow down the search scope through file masks. In the drop-down list, select the desired mask or specify a new one using wildcards.</p> <ul style="list-style-type: none"> <li>– Wildcards can include: <ul style="list-style-type: none"> <li>– * to substitute a set of any characters,</li> <li>– ? to substitute a single character,</li> <li>– ! to exclude files. Mind that ! should go first in a particular file name pattern, for example, <code>!*.gant</code></li> </ul> </li> </ul> <p>You can specify multiple file masks, delimited with commas (for example, <code>*.xml,a?c.sql,!*.html</code> ).</p> <p>Note also, that negated pattern (for example, <code>!*.min.js</code> ) has implicit inclusion pattern <code>*</code> . This allows avoiding such constructs as <code>*,!*.min.js</code> for every file except minified javascript).</p> <p>If <a href="#">text to find is not entered</a> , and this checkbox is selected, then IntelliJ IDEA find all files matching the specified mask, regardless of their contents.</p>
Search field	<p>In this field, specify the search pattern. Type the text manually or select one of the previously specified patterns from the drop-down list.</p> <ul style="list-style-type: none"> <li>– If you specify the search pattern through a regular expression, use the <code>\$n</code> format in back references (to refer to a previously found and saved pattern).</li> <li>– This field can be left empty. If there is no text to find, but the <a href="#">File mask</a> checkbox is selected, then search results include only the files matching the specified mask.</li> </ul> <p>Click  icon to see the list of recent search entries.</p>
Replace field	<p>In this field, specify the replacement text. Type the text manually or click  icon to select one of the previously specified replace entries from the drop-down list.</p> <ul style="list-style-type: none"> <li>– If you specify the replacement text through a regular expression, use the <code>\$n</code> format in back references.</li> <li>– To use a backslash character <code>\</code> in a regular expression, escape the meaningful backslashes by inserting <b>three extra backslashes</b> before them: <code>\\ \\ \</code> .</li> </ul> <p>This field is available only in the Replace in Path dialog.</p>
In Project	Select this option to search through the entire project.
Module	Select this option to search through a module within the project. IntelliJ IDEA displays a field with the name of the current module. If you have more than one module you can switch to another module using the drop-down list.
Directory	<p>Select this option to perform search within the specified directory. By default, the text area already contains the directory name where a file currently opened in the editor is located (if you call the dialog from the editor), or where a file selected in the tool window is located (if you call the dialog from the tool window), or the directory name selected in the tool window.</p> <p>Pressing the ellipsis button opens the <a href="#">Select Path</a> dialog, where you can select the necessary directory.</p>
	This icon is only available for the directory search. Select it to set the search to be performed in the chosen directory and its subdirectories.

Scope Select this option to search in a [scope](#) .  
You can choose one of the scopes from the drop-down list, or click the ellipsis button, and define a new scope in the [Scopes dialog](#) .

## Preview area

Use this area to check the preview of your search target.

You can press [Up](#) or [Down](#) keys to navigate between entries in the preview area without leaving the search field. You can press [F4](#) to get to the selected entry in the editor. You can also edit your entry right in the preview area. IntelliJ IDEA opens an editor for each search result so you can edit the result without leaving the Find in Path or Replace in Path window. Press [F3](#) to skip to the next matched entry in the preview editor. You can also press [Ctrl+F](#) to search through the current file or [Ctrl+R](#) to replace text in the current file.

### ItemDescription

- Click the down arrow to reveal the result presentation options.
  - Skip results tab with one usage - Select this checkbox to be navigated directly to the found string in the editor, when only one usage is found.  
The checkbox is available only in the Find in Path dialog box.
  - Open in new tab - If selected, sets the search results to be displayed in a separate tab.
- Open in Find Window
  - When you click this button in the Find in Path dialog box, IntelliJ IDEA displays the encountered occurrences of the search string in the [Find tool window](#) , selects the first occurrence and opens the file with this occurrence in the editor and moves the focus to it.
  - When you click this button in the Replace in Path dialog box, IntelliJ IDEA displays the encountered occurrences of the search string in the [Find tool window](#) , selects the first occurrence and opens the file with this occurrence in the editor and moves the focus to it.  
At the same time, IntelliJ IDEA opens the Replace Usage dialog box, with the full path to the encountered occurrence in the title bar:

Do one of the following:

- To have the selected occurrence replaced, click [Replace](#) .
- To preserve the selected occurrence and move to the next one, click [Skip](#) .
- To have all the occurrences of the search string in the currently active tab replaced, click [Replace All in This File](#) .
- To preserve the occurrences of the search string in the currently active tab (any) and move to the next file, click [Skip to Next File](#) .
- To have all the detected occurrences replaced, click [All Files](#) .
- To switch to the manual mode, click [Preview](#) . The [Replace Usage](#) dialog box closes and the focus moves to the [Find tool window](#). Do one of the following:
  - Browse through the list of detected occurrences, select the ones you want to replace and then click [Replace Selected](#) .
  - To have all the occurrences changed click [Replace All](#) .

In this section:

- [Find Usages](#)
- [Find Usages. Class Options](#)
- [Find Usages. Method Options](#)
- [Find Usages. Package Options](#)
- [Find Usages. Throw Options](#)
- [Find Usages. Variable Options](#)

Alt+F7

The dialog also opens when you click  in the Show Usages pop-up window which lists all the occurrences of the symbol at caret.

Use this dialog to configure the search procedure and scope when looking for occurrences of the following data:

- Fields, variables and parameters
- Classes, tags, attributes, and references in the HTML, XML, and CSS files
- Symbols at caret.
- Elements of \*.gsp files in the Grails views.

The search results are displayed in the [Find tool window](#).

#### ItemDescription

Skip results tab with one usage	Select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.
Scope	Specify the search <a href="#">scope</a> . Select a pre-defined scope from the drop-down list or click  to define a custom scope in the <a href="#">Scopes dialog</a> .
Open in new tab	Select this checkbox to have the results of each search shown on a separate tab of the Find tool window. If the checkbox is not selected, the search results will be shown on the current tab.

Alt+F7

This section describes the controls for specifying Class Usage Search and Interface Usage Search options in the Find Usages dialog box.

The dialog opens when you click  in the Show Usages pop-up window which lists all the occurrences of the symbol at caret.

#### ItemDescription

---

Find	<p>In this area, specify the objects to search.</p> <ul style="list-style-type: none"><li>– Usages - if this checkbox is selected, the search is performed for all references of the class by its name.</li><li>– Usages of methods - if this checkbox is selected, the search is performed for all calls of the selected class methods.</li><li>– Usages of fields - if this checkbox is selected, the search is performed for usages of selected class fields.</li><li>– Derived classes - if this checkbox is selected, the search is performed for all classes that extend the selected class.</li></ul> <p><b>Tip</b> The checkbox is available for class usage search only.</p> <ul style="list-style-type: none"><li>– Implementing classes - if this checkbox is selected, the search is performed for all classes that implement the selected interface.</li></ul> <p><b>Tip</b> The checkbox is available for interface usage search only.</p> <ul style="list-style-type: none"><li>– Derived interfaces - if this checkbox is selected, the search is performed for all interfaces that extend the selected interface.</li></ul> <p><b>Tip</b> The checkbox is available for interface usage search only.</p>
Options	<p>In this area, configure the search procedure using the following controls:</p> <ul style="list-style-type: none"><li>– Search for text occurrences - if this checkbox is selected, the search is performed in files registered in IntelliJ IDEA.</li><li>– Skip results tab with one usage - select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.</li></ul>
Scope	<p>In this area, specify the <a href="#">scope</a> of search. Select a pre-defined scope from the drop-down list or click the Browse button  to open the <a href="#">Scopes</a> dialog box, where you can define a custom scope.</p>
Open in new tab	<p>Select this checkbox to have the results of each search shown in a separate tab of the Find Results window. If the checkbox is cleared, the search results will overwrite the contents of the current tab.</p>

Alt+F7

This section describes the controls for specifying Method Usage Search options in the Find Usages dialog box.

The dialog opens when you click  in the Show Usages pop-up window which lists all the occurrences of the symbol at caret.

#### ItemDescription

---

Find	<p>In this area, specify the objects to search.</p> <ul style="list-style-type: none"><li>- Usages - if this checkbox is selected, the search is performed for all references of the method by its name.</li><li>- Overriding methods - if this checkbox is selected, the search is performed for all methods that override the selected method.</li><li>- Implementing methods - if this checkbox is selected, the search is performed for all methods that implement the selected method.</li></ul>
Search for text occurrences	Select this checkbox to have text contents and comments involved in searching.
Skip results tab with one usage	Select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.
Scope	In this area, specify the scope of search. Select a pre-defined scope from the drop-down list or click the Browse button  to open the <a href="#">Scopes</a> dialog box, where you can define a custom scope.
Open in new tab	Select this checkbox have the results of each search shown in a separate tab of the Find Results window. If the checkbox is cleared, the search results will overwrite the contents of the current tab.

Alt+F7

This section describes the controls for specifying Package Usage Search options in the Find Usages dialog box.

#### ItemDescription

---

Find	<p>In this area, specify the objects to search.</p> <ul style="list-style-type: none"><li>- Usages - if this checkbox is selected, the search is performed for all references of the package by its name in the source code.</li><li>- Usages of classes and interfaces - if this checkbox is selected, the search is performed for all references of classes and interfaces from the selected package by their names in the source code.</li></ul>
Options	<p>In this area, configure the search procedure using the following controls:</p> <ul style="list-style-type: none"><li>- Search for text occurrences - if this checkbox is selected, the search is performed in files registered in IntelliJ IDEA.</li><li>- Skip results tab with one usage - select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.</li></ul>
Scope	<p>In this area, specify the <a href="#">scope</a> of search. Select a pre-defined scope from the drop-down list or click the Browse button  to open the <a href="#">Scopes</a> dialog box, where you can define a custom scope.</p>
Open in new tab	<p>Select this checkbox have the results of each search shown in a separate tab of the Find Results window. If the checkbox is cleared, the search results will overwrite the contents of the current tab.</p>

Alt+F7

Use this dialog box to find throw usages in the specified scope.

**ItemDescription**

Search for text occurrences	Select this checkbox to have text contents and comments involved in searching.
Skip results tab with one usage	Select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.
Scope	In this area, specify the <a href="#">scope</a> of search. Select a pre-defined scope from the drop-down list or click the Browse button  to open the <a href="#">Scopes</a> dialog box, where you can define a custom scope.
Open in new tab	Select this checkbox have the results of each search shown in a separate tab of the Find Results window. If the checkbox is cleared, the search results will overwrite the contents of the current tab.

Alt+F7

This section describes Field, Variable, or Parameter usage search options in the Find Usages dialog.

The dialog opens when you click  in the Show Usages pop-up window which lists all the occurrences of the symbol at caret.

#### ItemDescription

---

**Skip results tab with one usage** Select this checkbox to be navigated directly to the found usage without the Find tool window displayed, when only one usage is found.

---

**Scope** In this area, specify the [scope](#) of search. Select a pre-defined scope from the drop-down list or click the [Browse](#) button  to open the [Scopes](#) dialog box, where you can define a custom scope.

---

**Open in new tab** Select this checkbox have the results of each search shown in a separate tab of the Find Results window. If the checkbox is cleared, the search results will overwrite the contents of the current tab.

---

Use this dialog box to configure the Ant build generation procedure.

**ItemDescription**

---

Generate multiple-file ant build (requires ant 1.6 or later to execute)	Click this option to generate separate build files for every module plus one main file. The generated build files for the modules are stored in the directories that correspond to the <code>.iml</code> files, and the main file is stored under the project root.
Generate single-file ant build	Click this option to generate one build file for the whole project. This file is stored under the project root.
Backup previously generated files	Click this option to create backup copies of the previously generated Ant build files.
Overwrite previously generated files	Click this option to overwrite the previously generated Ant build files with the new ones.
Output file name	Use this field to enter the name of the output file.
Enable UI forms compilation (requires <code>javac2</code> ant task from IntelliJ IDEA distribution)	Select this checkbox, if you have used IntelliJ IDEA UI forms and need them to be created during the build process.
Use JDK definitions from project files	Select this checkbox to specify using particular Java SDK's for every module when building a project, as defined in the project settings. Clear the checkbox to have the Ant script use the Java SDK it runs on.
Inline runtime classpaths	This checkbox affects Ant build generation for the dependent modules. <ul style="list-style-type: none"><li>– If this checkbox is cleared (by default), then the generated runtime classpath will contain references to the runtime libraries of the dependency module.</li><li>– If this checkbox is selected, then the generated runtime classpath will contain copies of references to the libraries of the dependency module.</li></ul>
Use current IntelliJ IDEA instance for <code>idea.home</code> property	If this checkbox is selected, the <code>idea.home</code> property, referring to the current IntelliJ IDEA installation, is added to the file <code>&lt;project&gt;.properties</code> .

Use this wizard to generate equals() and hashCode() methods.

#### ItemDescription

##### Page 1

**Template** Use this drop-down list to select a predefined velocity template or click  to use [Templates Dialog](#) .

**Accept subclasses as parameter to equals() method** While generally in compliant to Object.equals() specification, accepting subclasses might be necessary for generated method to work correctly with frameworks, which generate Proxy subclasses, like Hibernate.

**Use getters during code generation** If this checkbox is selected, the getters are used in `equals()` instead of direct fields access: `getField()` vs `field` .  
Click Next to open the next page.

##### Page 2

**Choose fields to be included in equals()** Select the fields that should be used to determine equality. Each of the selected field's values will be compared, and objects will be considered equal only if all the field values specified here are equivalent.  
Click Next to open the next page.

##### Page 3

**Choose fields to be included in hashCode()** Select the fields to generate hash code. Note that only the fields that were included in the equals() method, can participate in creating hash code. All these fields are selected by default, but you can deselect them, if necessary.  
Click Next to open the next page.

##### Page 4

**Select all non-null fields** This page appears if any of the chosen fields are of non-primitive type in order to avoid generation of unnecessary checks. In other words, if a checkbox for any of these fields is selected, it is presumed that such field never has a null value and such check will not be included into generated methods.

Click Finish to complete the wizard and create equals() and hashCode() methods.

Use this page to select an existing velocity template from the list of available templates or create a custom template.

**ItemDescription**

	Click this icon to add a new custom template.
	Click this icon to delete a created custom template.
	Click this icon to copy the existing template.
Equals Template	This area displays a code sample for <code>equals()</code> of the selected template.
HashCode Template	This area displays a code sample for <code>hashCode()</code> of the selected template.

**ItemDescription**

---

Input directory	In this text box, specify the fully qualified path to the directory with the sources to generate documentation for.
Output directory	In this text box, type the fully qualified path to the directory where the generated documentation will be stored. Alternatively, click  to open the <a href="#">dialog</a> , in which you can select the desired path or create a new directory by clicking  .
Private	Select this checkbox to set the <code>private</code> attribute to <code>true</code> .
Use	Select this checkbox to set the <code>use</code> attribute to <code>true</code> .
Source packages	Use the buttons  and  to create and manage the list of packages containing source files.
Open generated documentation in browser	Select this checkbox if you want IntelliJ IDEA to automatically open the generated documentation in the browser.

This dialog invokes [JavaDoc](#) utility. The controls of the dialog box correspond to the options and tags of this utility.

#### ItemDescription

Generate JavaDoc scope	Use this area to specify the subset of files, folders, packages etc. for which JavaDoc should be generated. This <a href="#">scope</a> can be the whole project, uncommitted files (when VCS is enabled), current file, custom scope etc.
Include test sources	Select this checkbox to have the documentation comments for the test files included in the generated JavaDoc.
Include JDK and library sources in <input type="text" value="sourcepath"/>	If this checkbox is selected, then paths to the JDK and library sources will be passed to the JavaDoc utility. Refer to <a href="#">documentation</a> for details.
Include link to JDK documentation	If this checkbox is selected, the references to the classes, packages etc. from JDK will turn into links, which corresponds to using the <a href="#">-link</a> option of the JavaDoc utility. This checkbox is only enabled when a link to the online documentation is specified in the Documentation Paths tab of the <a href="#">SDK</a> settings.  Refer to <a href="#">JavaDoc</a> documentation for details.
Output directory	In this text box, specify the fully qualified path to the directory where the generated documentation will be stored. Type the path manually or click the Browse button <input type="button" value="..."/> to open the Select Path dialog box where you can select the desired location. The specified value is passed to the <a href="#">-d</a> parameter of the JavaDoc utility. If the specified directory does not exist in your system, you will be prompted to create it. Note that unless the output directory is specified, the OK button is disabled.
Slider	In this area, specify the visibility level of members to be included in the generated documentation. The available options are: <ul style="list-style-type: none"> <li>– Private - select this level to have all classes and members included. The level corresponds to the <a href="#">-private</a> JavaDoc parameter.</li> <li>– Package - select this level to have all classes and members except private ones included. The level corresponds to the <a href="#">-package</a> JavaDoc parameter.</li> <li>– Protected - select this level to have only public and protected classes and members included. The level corresponds to the <a href="#">-protected</a> JavaDoc parameter.</li> <li>– Public - select this level to have only public classes and members included. The level corresponds to the <a href="#">-public</a> JavaDoc parameter.</li> </ul>
Generate hierarchy tree	Select this checkbox to have the class hierarchy generated. If this checkbox is cleared, the <a href="#">-notree</a> parameter is passed to JavaDoc.
Generate navigator bar	Select this checkbox to have the navigator bar generated. If this checkbox is cleared, the <a href="#">-nonavbar</a> parameter is passed to JavaDoc.
Generate index	Select this checkbox to have the documentation index generated. If this checkbox is cleared, the <a href="#">-noindex</a> parameter is passed to JavaDoc.
Separate index per letter	Select this checkbox to have a separate index file for each letter generated. If this checkbox is cleared, the <a href="#">-splitindex</a> parameter is passed to JavaDoc. The checkbox is available only if the Generate index checkbox is selected.
@use	Select this checkbox to have the use of class and package documented. When selected, the checkbox corresponds to the <a href="#">-use</a> JavaDoc parameter.
@author	Select this checkbox to have the <a href="#">@author</a> paragraphs included. When selected, the checkbox corresponds to the <a href="#">-author</a> JavaDoc parameter.
@version	Select this checkbox to have the <a href="#">@version</a> paragraphs included. When selected, the checkbox corresponds to the <a href="#">-version</a> JavaDoc parameter.
@deprecated	Select this checkbox to have the <a href="#">@deprecated</a> information included. When the checkbox is cleared, the <a href="#">-nodeprecated</a> parameter is passed to JavaDoc.
deprecated list	Select this checkbox to have the deprecated list generated. When the checkbox is cleared, the <a href="#">-nodeprecatedlist</a> parameter is passed to JavaDoc. The checkbox is available only if the @deprecated checkbox is selected.
Locale	In this text box, type the desired locale.
Other command line arguments	In this text box, type additional arguments to be passed to JavaDoc. Use the command line syntax.
Maximum heap size (Mb)	In this text box, type the maximum heap size in Mb to be used by Java VM for running JavaDoc.
Open generated documentation in browser	Select this checkbox to have the generated JavaDoc automatically opened in the browser.

**ItemDescription**

Template	Click this drop-down list to choose the template to use.
Settings	Click this button to show <a href="#">Generate toString() Settings Dialog</a> and set up the behavior and templates of the Generate toString() function.
Toolbar	
	Click this button to represent the fields in ascending or descending alphabetical order.
	Click this button to show classes.
	Click this button to expand all class nodes.
	Click this button to collapse all class nodes.
Class members tree view	Click the members to be included in the generated <code>toString()</code> method.
Insert @Override	If this checkbox is selected, the generated code is prepended with the annotation <code>@Override</code> .
OK	Click this button to generate the <code>toString()</code> method with the specified settings and close the dialog.
Select None	Click this button to generate the <code>toString()</code> method that consists of the method declaration and return statement only.
Cancel	Click this button to discard all changes and close the dialog.

On this page:

- [Settings tab](#)
- [Templates tab](#)
  - [Templates toolbar](#)
  - [Variables used in Velocity templates](#)

## Settings tab

### ItemDescription

Use fully qualified class name in code generation (\$classname)	If this checkbox is selected, the dumped classnames will include their package names. (The <code>\$classname</code> variable in the <a href="#">Velocity templates</a> )
Enable getters in code generation (\$method)	If this checkbox is selected, the code generator will have <code>\$methods</code> variable in the Velocity Macro Language. See <a href="#">example 2</a> .
Move caret to the generated method	If this checkbox is selected, the caret scrolls to the generated <code>toString()</code> method.
Sort elements	If this checkbox is selected, the members are sorted in the selected order (ascending or descending).
When method already exists	<p>In this section, choose the default conflict resolution policy:</p> <ul style="list-style-type: none"> <li>– Ask : Choose this option to ask for confirmation, if a <code>toString()</code> method already exists. IntelliJ IDEA shows the dialog box <code>Replace existing toString method</code> .</li> </ul> <p>The answer Yes results in generating the new <code>toString()</code> method in place of the existing one; the answer No results in creating a duplicate method.</p> <ul style="list-style-type: none"> <li>– Replace existing : Choose this option to automatically replace the existing <code>toString()</code> code.</li> <li>– Generate duplicating method : Choose this option to create a duplicate <code>toString()</code> method; so doing, the new method will have the name <code>toString()</code> ; the existing code will not be erased.</li> </ul>
Where to insert?	<p>In this section, choose the place to insert the generated <code>toString()</code> method. The possible options are:</p> <ul style="list-style-type: none"> <li>– At caret .</li> <li>– After equals() and hashCode() : the generated <code>toString()</code> method will be inserted after the equals/hashCode, if present in the Java class; otherwise, the new method will be inserted at the current caret position.</li> <li>– At the end of class : the generated <code>toString()</code> method will be inserted as the last method.</li> </ul>
Exclude	<p>In this section, select the checkboxes next to the elements to be excluded from the <code>toString()</code> method generation:</p> <ul style="list-style-type: none"> <li>– Exclude constant fields : If this checkbox is selected, then any constants won't be a part of the available fields for the code generator.</li> <li>– Exclude static fields : If this checkbox is selected, then any fields that have static modifiers won't be part of available fields for the code generator.</li> <li>– Exclude transient fields : If this checkbox is selected, then any fields with transient modifiers won't be part of the available fields for the code generator.</li> <li>– Exclude enum fields : If this checkbox is selected, then any fields of the type <code>enum</code> (JDK1.5) will not be part of available fields for the code generator.</li> <li>– Exclude logger fields (Log4j, JDK Logging, Jakarta Common Logging): If this checkbox is selected, then any field that is a either a Log4j Logger, Java JDK Logger or a Jakarta Commons Logger will not be part of the available fields for the code generator.</li> <li>– Exclude fields by name (reg exp) : If this checkbox is selected, then IntelliJ IDEA performs a regular expression matching on the field name. If the result is true , then the field will not be part of the available fields for the code generator.</li> <li>– Exclude fields by type name (reg exp) : If this checkbox is selected, then IntelliJ IDEA performs a regular expression matching on the field type name (fully qualified name). If the result is true , the field will not be part of the available fields for the code generator.</li> <li>– Exclude methods by name (reg exp) : If this checkbox is selected, then IntelliJ IDEA performs a regular expression matching on the method name. If the result is true , the method will not be part of the available methods for the code generator.</li> <li>– Exclude methods by return type name (reg exp) : If this checkbox is selected, then IntelliJ IDEA performs a regular expression matching on the method return type name (fully qualified name). If the result is true , the method will not be part of the available methods for the code generator.</li> </ul>

## Templates tab

Use this page to view and manage the list of Velocity templates to be used for the `toString()` method generation.

## Templates toolbar

### ItemDescription

	Click this button to create a new entry to the list of available templates. When the new entry is added, create the corresponding template.
	Click this button to delete the selected user-created entry from the list of available patterns. Note that pre-defined templates cannot be deleted.
	Click this button to create a copy of an existing template.

## Variables used in Velocity templates

### Variable>ReturnsDescription

Variable	Returns	Description
<code>\$classname</code>	String	The name of a class (can be qualified classname, if this is selected in the settings).
<code>\$FQClassname</code>	String	@deprecated (use <code>\$class.qualifiedName</code> ) - The fully qualified name of the class
<code>\$fields</code>	java.util.List	List of FieldElement objects
<code>\$methods</code>	java.util.List	List of MethodElement objects
<code>\$members</code>	java.util.List	List of both FieldElement and MethodElement objects
<code>\$member</code>	Element	The Element object
<code>\$member.accessor</code>	String	The accessor of a field or method. For a field it is <code>\$field.name</code> and for a method it is <code>\$method.methodName</code> .
<code>\$member.typeName</code>	String	The classname of the type (Object, String, List etc.)
<code>\$member.typeQualifiedName</code>	String	The qualified classname of the type (java.lang.Object, java.lang.String, java.util.List etc.)
<code>\$member.array</code>	boolean	Checks if the type is an array type (either a primitive array or object array).
<code>\$member.primitiveArray</code>	boolean	Checks if the type is a primitive array type (int[], short[], float[] etc.)
<code>\$member.objectArray</code>	boolean	Checks if the type is an Object array type (Object[], String[] etc.).
<code>\$member.stringArray</code>	boolean	Checks if the type is a String array type (String[])
<code>\$member.collection</code>	boolean	Checks if the type is assignable from java.util.Collection.
<code>\$member.list</code>	boolean	Checks if the type is assignable from java.util.List
<code>\$member.map</code>	boolean	Checks if the type is assignable from java.util.Map
<code>\$member.set</code>	boolean	Checks if the type is assignable from java.util.Set
<code>\$member.primitive</code>	boolean	Checks if the type is a primitive type (int, char, float etc.)
<code>\$member.modifierStatic</code>	boolean	Does the type have a static modifier?
<code>\$member.modifierPublic</code>	boolean	Does the type have a public modifier?
<code>\$member.modifierProtected</code>	boolean	Does the type have a protected modifier?
<code>\$member.modifierPackageLocal</code>	boolean	Does the type have a package-local modifier?
<code>\$member.modifierPrivate</code>	boolean	Does the type have a private modifier?
<code>\$member.modifierFinal</code>	boolean	Does the type have a final modifier?
<code>\$member.string</code>	boolean	Is the type assignable from java.lang.String?
<code>\$member.numeric</code>	boolean	Is the type assignable from java.lang.Numeric or a primitive type of byte, short, int, long, float, double?
<code>\$member.object</code>	boolean	Is the type assignable from java.lang.Object?
<code>\$member.date</code>	boolean	Is the type assignable from java.util.Date?
<code>\$member.calendar</code>	boolean	Is the type assignable from java.util.Calendar?
<code>\$member.boolean</code>	boolean	Is the type assignable from java.lang.Boolean or a primitive boolean?
<code>\$field</code>	FieldElement	The FieldElement object
<code>\$field.name</code>	String	The name of a field.
<code>\$field.modifierTransient</code>	boolean	Does the field have a transient modifier?
<code>\$field.modifierVolatile</code>	boolean	Does the field have a volatile modifier?
<code>\$field.constant</code>	boolean	Is the field a constant type? (has static modifier and its name is in UPPERCASE only)
<code>\$field.matchName(regex)</code>	boolean	Performs a regular expression matching on a field name.
<code>\$field.enum</code>	boolean	Is this field a enum type?
<code>\$method</code>	MethodElement	The MethodElement object
<code>\$method.name</code>	String	This variable returns one of the following: – The name of the field this getter method covers – The name of the method 'getFoo' when the method does not cover a field
<code>\$method.methodName</code>	String	The name of the method (getFoo).
<code>\$method.fieldName</code>	String	The name of the field this getter method covers - null if the method is not a getter for a field
<code>\$method.modifierAbstract</code>	boolean	Is this method an abstract method?
<code>\$method.modifierSynchronized</code>	boolean	Is this method a synchronized method?
<code>\$method.returnTypeVoid</code>	boolean	Is this method a void method (does not return anything) ?
<code>\$method.getter</code>	boolean	Is this a getter method?

\$method.matchName(regex)	boolean	Performs a regular expression matching on the method name.
\$method.deprecated	boolean	Is this method deprecated?
\$class	ClassElement	The ClassElement object
\$class.name	String	The name of the class
\$class.matchName(regex)	boolean	Performs a regular expression matching on the classname.
\$class.qualifiedName	String	The fully qualified name of the class
\$class.hasSuper	boolean	Does the class have a superclass? (extends another class - note extending java.lang.Object is not considered having a superclass)
\$class.superName	String	The name of the superclass (empty if no superclass)
\$class.superQualifiedName	String	The fully qualified name of the superclass (empty if no superclass)
\$class.isImplements("interfaceName")	boolean	Checks if the class implements the given interface. Checking names of several interfaces can be done by separating the names with commas.
\$class.implementNames	String[]	Returns the class names of the interfaces the class implements. An empty array is returned, if the class does not implement any interfaces.
\$class.isExtends("className")	boolean	Checks if the class extends any of the given class names. Chcecking several class names can be done by separating the names with commas.
\$class.exception	boolean	Is this class an exception class (extends Throwable)?
\$class.deprecated	boolean	Is this class deprecated?
\$class.enum	boolean	Is this class an enum class?
\$class.abstract	boolean	Is this class abstract?
Output variables		The output variables are possible in the Velocity Template (variables are stored in the Velocity Context); Output parameters will be available for the Generate action after the Velocity context has been executed and act upon.
\$autoImportPackages	String	Packagenames that should automatically be imported. Use comma to separate packagenames.

**ItemDescription**

Getter template	Click this drop-down list to choose the template to use. You can click  to open the <a href="#">Template Dialog</a> and add a new getter template or select an existing one.
Setter template	Click this drop-down list to choose the template to use. You can click  to open the <a href="#">Template Dialog</a> and add a new setter template or select an existing one.
	Click this button to represent the fields in ascending or descending alphabetical order.
	Click this button to show classes.
	Click this button to expand all class nodes.
	Click this button to collapse all class nodes.

Use this page to select an existing velocity template from the list of available templates or create a custom template.

**ItemDescription**

	Click this icon to add a new custom template.
	Click this icon to delete a created custom template.
	Click this icon to copy the existing template.
Getter Template	This area displays the selected velocity template and a code sample for <code>getter</code> .
Setter Template	This area displays the selected velocity template and a code sample for <code>setter</code> of the selected template.

**ItemDescription**

---

Template Click this drop-down list to choose the template to use. You can click  to open the [Template Dialog](#) and add a new getter template or select an existing one.

---

 Click this button to represent the fields in ascending or descending alphabetical order.

---

 Click this button to show classes.

---

 Click this button to expand all class nodes.

---

 Click this button to collapse all class nodes.

**ItemDescription**

Template	Click this drop-down list to choose the template to use. You can click  to open the <a href="#">Template Dialog</a> and add a new getter template or select an existing one.
	Click this button to represent the fields in ascending or descending alphabetical order.
	Click this button to show classes.
	Click this button to expand all class nodes.
	Click this button to collapse all class nodes.

Use this dialog to add an external module to a project.

#### ItemDescription

---

Please select the modules/data to include in the project

Use this area to view the list of available external modules or data for your current project.

---

Click this icon to select all the modules from the list.

---

Click this icon to clear the list of selected modules.

---

Click this icon to see only selected modules.

---

 **Select Required**

If you click this icon, IntelliJ IDEA selects the appropriate modules in case you are unsure about dependencies between the modules.

Use this dialog box to extract a hardcoded string literal to the specified `.properties` file. This intention action becomes available, when the Hard-Coded Strings inspection is enabled.

#### ItemDescription

Properties file	In this text box, specify the <code>.properties</code> file to store the extracted string literal in. Type the path to the file manually or click the Browse button  to open the Choose Properties File dialog, where you can select the desired location using the project tree view or through a search by name. As you type the search string, the suggestion list shrinks to show the matching properties files only.
Update all properties files in resource bundle	Select this checkbox to have all properties files in the target bundle updated.
Property key	By default, this text box displays the suggested key name, based on the value of the string to be extracted. Accept the default name or type the desired one.
Property value	By default, this field displays the value of the string to be extracted. Accept the default value or type the desired one.
Resource bundle expression	By default, this field displays a resource bundle expression from the resource bundle declaration in the source code. If the resource bundle is not declared in the source code, the field shows an invalid value in red. To improve the situation, define the desired expression. Do one of the following: <ul style="list-style-type: none"><li>– Enter an expression of the <code>ResourceBundle</code> type, as described in the section <a href="#">Extracting Hard-Coded String Literals using <code>java.util.ResourceBundle</code></a> utility class.</li><li>– Use your own <a href="#">custom</a> utility class.</li></ul>
<div style="background-color: #ffff00; padding: 5px;"><b>Tip</b> Basic code completion (<code>Ctrl+Space</code>) is available in this field.</div>	
Edit i18n template	Click this link to open the File and Code Templates dialog box, where you can change the I18nized Expression template to point to the method of a custom utility class that will be used to access a resource bundle. A changed file template is a global setting that affects all projects. If you want to restore defaults, open the <a href="#">File and Code Templates</a> dialog box, find the I18nized Expression template in the Code tab, and click the Reset button  .
Preview	This read-only field displays the results of applying the I18nize hard-coded string literal intention action.

This dialog opens when [importing delimiter-separated values \(e.g. CSV, TSV\) into a database](#) .

In the left-hand part, specify how your delimiter-separated values should be converted into table format. In the right-hand part, specify the settings for the target table in your database.

- [Conversion settings](#)
- [Table name, structure and data mappings](#)
- [Data and DDL previews](#)
- [Encoding, Write errors to file and Insert inconvertible values as null](#)

## Conversion settings

When working on the conversion settings, use the table preview in the right-hand part of the dialog underneath the table settings.

### ItemDescription

**Formats** Select your file format and check the table preview. If you haven't achieved the desired result yet, adjust the settings.  
 If you have changed the settings and want to save the changes, click this icon and select one of the following:

- Save Changes. The settings are saved "under the same name", without creating a new format. (A format, in fact, is a named set of settings.)
- Save As. The settings are saved "under a different name": a new format is created and you can specify the name for that new format.

**Value separator** Select or type the character used for separating individual values.

**Row separator** Select or type the character that should be treated as a row separator.

**Null value text** The text to be used as a value if a cell contains `null` (an unknown value).

**Add row prefix/suffix** Row prefix and suffix are character sequences which in addition to the row separator indicate the beginning and end of a row.  
If necessary, click the link and specify the row prefix and suffix in the fields that appear.

**Quotation** Each line in the area under Quotation is a quotation pattern (see [Quote values](#) ). A quotation pattern includes:

- The left quotation character, the one inserted before a value.
- The right quotation character, the one inserted after a value; usually, the same as the left quotation character.
- An escape method or character for the cases when the quotation character is part of a value. E.g. Escape: duplicate means that if a quotation character occurs within a value, it is doubled. (You can specify your own escape character instead.)

If there is more than one pattern, the first of the patterns is used.

Use  ,  ,  and  to create, delete and reorder the patterns.

To start editing an existing pattern, just click the pattern of interest.

**Quote values** Specify in which cases the values should be quoted (i.e. enclosed within quotation characters).

- When needed. A value is quoted only if it contains the value and/or the row separator.
- Always. Any value is quoted in its text representation.

**Trim whitespaces** If this checkbox is not selected, the Unicode whitespace characters that precede and follow the value separators are treated as parts of the corresponding values. If this checkbox is selected, the corresponding whitespace characters are ignored or removed.

**First row is header** If this checkbox is selected, the first row is treated as containing column names. The settings that appear under Header Format have the same meanings as the ones above but are applied to the first row.

**First column is header** If this checkbox is selected, the first column is treated as containing row names.

## Table name, structure and data mappings

### ItemDescription

**Table** The name of the table.

**Comment** The table comment.

**Columns / Keys etc.** Data mappings for columns, and the definitions of the columns, constraints and indexes.

- To start editing the information for a column, double-click the corresponding line in the list of columns.  
Note the Mapped to field. This field lets you specify which data column in the file being imported should be used as a source of data for the corresponding column in the database. If you clear this field, no data will be added to the target column in the database.
- To remove a column, select the corresponding line and click  .

## Data and DDL previews

### ItemDescription

**Data preview** The preview of data you are about to import.

DDL preview      The statement or statements that will be run. You can edit the statements right in the preview pane.

## Encoding, Write errors to file and Insert inconvertible values as null

### ItemDescription

---

Encoding	The character encoding for your data in the source file.
Write errors to file	If you select the checkbox, the errors that occurred during the import are written to the specified text file. For each of the errors the place where it occurred is indicated.
Insert inconvertible values as null	If you select the checkbox, NULLs will be inserted into the table for the data that cannot be converted.

This dialog opens when [exporting delimiter-separated values from a table editor to a database](#) .

- [Table name, structure and data mappings](#)
- [DDL preview](#)
- [Encoding, Write errors to file and Insert inconvertible values as null](#)

## Table name, structure and data mappings

### ItemDescription

Table	The name of the table.
Comment	The table comment.
Columns / Keys etc.	Data mappings for columns, and the definitions of the columns, constraints and indexes. <ul style="list-style-type: none"><li>- To start editing the information for a column, double-click the corresponding line in the list of columns. Note the Mapped to field. This field lets you specify which data column in the file being imported should be used as a source of data for the corresponding column in the database. If you clear this field, no data will be added to the target column in the database.</li><li>- To remove a column, select the corresponding line and click  .</li></ul>

## DDL preview

The statement or statements that will be run. You can edit the statements right in this pane.

## Encoding, Write errors to file and Insert inconvertible values as null

### ItemDescription

Encoding	The character encoding for your data in the source file.
Write errors to file	If you select the checkbox, the errors that occurred during the import are written to the specified text file. For each of the errors the place where it occurred is indicated.
Insert inconvertible values as null	If you select the checkbox, NULLs will be inserted into the table for the data that cannot be converted.

This dialog opens when exporting data from one table to another one, or when exporting a table to another database or schema.

---

Specify the data mapping info and the settings for the destination table.

- [Table name, structure and data mappings](#)
- [Data and DDL previews](#)
- [Write errors to file and Insert inconvertible values as null](#)

## Table name, structure and data mappings

### ItemDescription

---

Table	The name of the destination table.
Comment	The table comment.
Columns / Keys etc.	Data mappings for columns, and the definitions of the columns, constraints and indexes. <ul style="list-style-type: none"><li>- To start editing the information for a column, double-click the corresponding line in the list of columns. Note the Mapped to field. This field lets you specify which column in the table being imported should be used as a source of data for the corresponding column in the destination table. If you clear this field, no data will be added to the target column.</li><li>- To remove a column, select the corresponding line and click .</li></ul>

## Data and DDL previews

### ItemDescription

---

Data preview	The preview of data you are about to import. This tab is not available if you started the import by using the Export to Database command (  ) in a data editor or in the Result pane of a database console.
DDL preview	The statement or statements that will be run. You can edit the statements right in the preview pane.

## Write errors to file and Insert inconvertible values as null

### ItemDescription

---

Write errors to file	If you select the checkbox, the errors that occurred during the import are written to the specified text file. For each of the errors the place where it occurred is indicated.
Insert inconvertible values as null	If you select the checkbox, NULLs will be inserted into the table for the data that cannot be imported.

The dialog is available only when the PHP plugin is enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#) .

The dialog box opens when you initiate a **Zero-Configuration** debugging session without previously configuring a **Debug Server** with **path mappings** , so the debugger cannot set correspondence between the scripts in the running application and the files in your IntelliJ IDEA project.

The upper part of the dialog box is read-only and shows the host and port where the script is executed, the path to the script relative to the **server document root** , and the absolute path to the script on the server.

In this dialog box, either specify the path mappings manually or import them from the relevant **deployment configuration** . Learn more at [Creating a PHP Debug Server Configuration](#) , [Configuring Synchronization with a Web Server](#) , and [Zero-Configuration Debugging](#) .

To continue debugging with the imported or manually specified configuration settings, click **Accept** .

#### ItemDescription

---

Import mappings from deployment	<p>Choose this option to use the mappings specified in a <b>server access configuration</b> ( <b>deployment configuration</b> . ).</p> <ul style="list-style-type: none"><li>- Project: this read-only field shows the name of the current IntelliJ IDEA project.</li><li>- Deployment: from this drop-down list, choose the deployment configuration to import the mappings from. If IntelliJ IDEA detects a deployment configuration which seems relevant, the configuration is preselected in the Deployment drop-down list.</li></ul> <p>If IntelliJ IDEA does not detect a relevant configuration:</p> <ol style="list-style-type: none"><li>1. Choose the most suitable configuration from the drop-down list or click  and create a new configuration in the <a href="#">Deployment</a> dialog box that opens, whereupon the new configuration is added to the list.</li><li>2. In the Deployment root text box, type the absolute path to the server root folder.</li></ol> <ul style="list-style-type: none"><li>- Preview: this area shows the absolute path to the project file which corresponds to the currently executed script according to the mappings from the selected configuration.</li></ul>
Manually choose local file or project	<p>When you select this option, IntelliJ IDEA displays the project tree view where you can select a project file and map the currently executed script to it. You can also select and map the entire project.</p>

To open this dialog: Register on the [Welcome screen](#) or [Help | Register](#) .

---

You can evaluate IntelliJ IDEA Ultimate for 30 days. After that period, you need to buy IntelliJ IDEA and activate your license.

The upper part of the dialog reflects your IntelliJ IDEA usage status (e.g. Free evaluation ) and, if appropriate, provides related controls (e.g. Buy IntelliJ IDEA ).

The license activation options are in the lower part of the dialog under Activate new license via .

– [IntelliJ IDEA usage status-related controls](#)

– [License activation options](#)

## IntelliJ IDEA usage status-related controls

### ItemDescription

---

Buy IntelliJ IDEA	Click this button to go to the JetBrains Web site to study the IntelliJ IDEA purchasing options and to buy a license.
-------------------	---

---

Evaluate for free for 30 days	Click this button to start evaluating IntelliJ IDEA.
-------------------------------	--

## License activation options

### ItemDescription

---

License key	Select this option if you have a license key. Specify your user name (or company name) and the key. (The corresponding information is in your license certificate email.) The recommended way of entering the name and the key is by copying the information from the certificate email and then pasting it into the fields (  /  ).
-------------	---

If IntelliJ IDEA rejects the license information, see [The key is not accepted](#) for a possible solution.

---

License server	Select this option if there is the <a href="#">IntelliJ IDEA License Server</a> on your company's intranet. Specify the server URL in the License server address field. For the address to be entered automatically, click the Discover server button. To find out if your company is using the License Server and what its URL should be, contact your system administrator.
----------------	--

---

JetBrains Account	Select this option if your IntelliJ IDEA license is linked with your <a href="#">JetBrains Account</a> . Specify your JetBrains Account access credentials.
-------------------	---

This dialog appears when IntelliJ IDEA tries to decompile the code.

---

**ItemDescription**

---

Accept	Click this button if you decide to agree to the specified terms and conditions. In this case, the dialog will not be displayed in the future and the appropriate code will be automatically decompiled.
Decline and restart	Click this button if you do not agree to the specified terms and conditions. In this case, Java Bytecode Decompiler plugin will be disabled and you will need to restart IntelliJ IDEA to implement the change.
Decide later	Click this button if you want to postpone your decision. In this case, the dialog and a window with the decompiled code will close. However, you will be prompted again with the same dialog when IntelliJ IDEA tries to decompile another source code.

The upper part of the dialog box shows a list of your project templates. When you select a template, its description is shown in the bottom area of the dialog box.

To delete an unnecessary template, select it and click  or press `Alt+Delete` .

Specify a URI and select a local XSD or DTD file for the specified URI. (If an XML file references the specified URI, it's validated according to a selected local file.)

#### ItemDescription

---

URI Use this field to edit the URI. This may be a URL of an XSD or DTD file (e.g. `http://www.example.org/xsds/example.xsd` ) or a namespace URI (e.g. `http://www.example.org` ).

---

Schemas This tab lists XSD and DTD files available in your project, libraries, SDKs and IntelliJ IDEA installation.

---

Explorer This tab implements a [file browser](#) .

This dialog appears when you try to edit non-project files (e.g, library sources, external sources etc.), and protects them from accidental modifications.

**ItemDescription**

These files do not belong to the project	This area displays a non-project file that you are trying to edit.
I want to edit this file anyway	Select this option to disable protection for the listed files.
I want to edit all files in this directory	Select this option to disable protection for the listed files and all files in the same directory.
I want to edit any non-project file in the current session	Select this option to disable protection completely.

All options are effective during current session, once the IDE restarted, protection will be reenabled.

Alt+Insert

Use this dialog to create a new action with the specified identifier, and optionally bind it with a keyboard shortcut that can consist of one or two keystrokes.

#### ItemDescription

ActionId	In this text field, type the identifier of the new action.
Class name	In this text field, specify the name of the class where the new action will be defined. The created stub class contains import statements, and extends <code>AnAction</code> .
Name	Specify the name that will identify the new action in the UI.
Add to Group	In this section, select a group where the action will belong ( Groups section), and specify its position ( Anchor ) relative to the other actions in this group ( Actions ).
Keyboard shortcuts	In the two text fields below, specify the optional primary and secondary keyboard shortcuts, by pressing keyboard keys and their combinations.

**Warning!** If you opt to specify the keyboard shortcuts, it is important to use the mouse pointer for clearing the keyboard shortcuts text fields, applying changes and closing the dialog box, because any keystroke will be interpreted as a shortcut.

Ctrl+Alt+O

Note that this dialog box appears when you select a `Optimize Imports` action on the directory.

---

In this dialog box, specify where you want IntelliJ IDEA to remove unused import statements from, in order to optimize the import procedure.

#### Item Description

---

**Only VCS changed files** If this checkbox is selected, then reformatting will apply only to the files that have been [changed locally](#), but not yet checked in to the repository.

This checkbox is only available for the files under version control.

The dialog box opens when you click the Server paths mappings button in the Debug area of the [Run/Debug Configuration: PHP Web Application](#) or [Run/Debug Configuration: PHPUnit by HTTP](#) dialog box.

Use this dialog box to map folders on your local machine with folders on the server. These mappings are used during remote debugging and testing as the basis for switching between a test or a stack trace of an exception or assertion and the corresponding source code.

**Tip** IntelliJ IDEA detects these mappings automatically but still provides you with this possibility to specify them manually.

#### ItemDescription

Local Path on Client	In this text box, specify the absolute path to the desired local folder. Type the path manually or click the Browse button  and select the desired folder in the <a href="#">dialog that opens</a> .
Local Path on Server	In this text box, specify the path to the corresponding folder on the server according to the file system used on the server.
Add	Click this button to have a new line added to the list of mappings.
Remove	Click this button to remove the selected mapping from the list.

The Tools | Play with Playframework command and the Play Configuration dialog are available only under the following conditions:

- The Playframework Support [plugin](#) is enabled. See [Enabling and Disabling Plugins](#) .
- A Play application is currently open in IntelliJ IDEA. (In technical terms, the directory `<play_dir>\framework\lib` and the file `<play_dir>\framework\play-<version>.jar` are included in the [dependencies](#) of the [module](#) that represents your Play application.)

Additionally, the Play Configuration dialog is not shown if the [Show on console run option](#) is off in the [Play framework settings](#) .

Use this dialog for specifying the [Play framework](#) settings such as the Play framework installation directory and the working directory for the `play` command-line utility (the Play console).

**ItemDescription**

Download	Click this link to open the <a href="#">Play framework downloads page</a> which lets you select and download the necessary version of the Play framework. (See <a href="#">which versions are supported</a> by IntelliJ IDEA.)
Home	Specify the Play framework installation directory. Type the path in the field, or click  (  ) and select the directory in the <a href="#">dialog that opens</a> .
Working directory	Specify the directory from which commands of the <code>play</code> command-line utility are to be run. Usually, this is a root directory of your Play application. Type the path in the field, or click  (  ) and select the directory in the <a href="#">dialog that opens</a> .
Show on console run	Select this checkbox to be able to see and modify the Play framework settings discussed above each time you access the <code>play</code> command-line utility in IntelliJ IDEA.

---

Use this dialog box to specify the text to print and configure the print layout.

In this section:

- [Scope](#)
- [Settings](#)
- [Header and Footer](#)
- [Advanced](#)

## Scope

### ItemDescription

File <name>	Select this option to print the file, which is currently selected in the Project view or opened in the editor.
Selected text	Select this option to print the text selected in the editor.
All files in the directory	Select this option to print all files in the current directory.
Include subdirectories	Select this checkbox to have the files in the subdirectories of the current directory printed as well.

## Settings

In this tab, specify the basic print layout settings.

### ItemDescription

Paper size	From this drop-down list, select the desired paper size.
Font	From the drop-down lists in this area, select the desired font style and size.
Show line numbers	Select this checkbox to have line numbers printed.
Draw border	Select this checkbox to have a border printed.
Orientation	In this area, specify the paper orientation. The available options are: <ul style="list-style-type: none"><li>– Landscape</li><li>– Portrait</li></ul>
Style	In this area, specify the style of the printout by selecting the relevant checkboxes. The available options are: <ul style="list-style-type: none"><li>– Color printing</li><li>– Syntax printing</li><li>– Print as graphics</li></ul>

## Header and Footer

In this tab, specify the contents and placement of the header and footer.

### ItemDescription

Text line	In this text box, specify the contents of the header or footer. If necessary, combine plain text with print keywords. By default, IntelliJ IDEA suggests to print the name of a file <code>\$FILE\$</code> in the header and the current page number <code>\$PAGE\$</code> of all pages <code>\$TOTALPAGES\$</code> in the footer. The following print keywords are recognized: <ul style="list-style-type: none"><li>– <code>\$FILE\$</code> prints fully qualified file name.</li><li>– <code>\$PAGE\$</code></li><li>– <code>\$DATE\$</code></li><li>– <code>\$TIME\$</code></li><li>– <code>\$FILENAME\$</code> prints file name without path.</li><li>– <code>\$TOTALPAGES\$</code></li></ul>
Placement	Use this drop-down list to specify whether the above line will be printed in the header or in the footer.
Alignment	From this drop-down list, select the desired alignment.
Font	In this area, specify the desired font style and size to print the header and footer text.

## Advanced

### ItemDescription

Wrapping	In this area, configure text wrapping. The available options are: <ul style="list-style-type: none"><li>– No wrap</li><li>– Wrap at word breaks</li></ul>
Margins	Use the text boxes in this area to specify the margins in inches.

The Productivity Guide shows usage statistics for IntelliJ IDEA features.

The table in the upper part lists the features. Select a feature to see its description in the lower part.

To sort the information, click a cell in the header row.

**ItemDescription**

---

Feature	The name of the feature.
Group	The group to which the feature belongs.
Used	How many times you used the feature.
Last used	When the feature was last used.

Use the **PSI viewer** to explore internal structure of the various files or fragments of source code, as they are interpreted by IntelliJ IDEA. The dialog box is non-modal and enables you to keep on working with IntelliJ IDEA while being opened.

---

**ItemDescription**

---

Show PSI structure for	Use this drop-down list to specify file type, or language constructs to be explored. The set of recognized file types depends on the supported languages and installed plugins.
Show PsiWhiteSpace	If this checkbox is selected, the generated tree view will contain <code>PsiWhiteSpace</code> nodes, corresponding to the spaces in the source code. When you select of clear this checkbox, the tree view of the PSI structure changes accordingly.
Show Tree Nodes	
Dialect	This drop down list becomes available for the languages that support dialects, for example, SQL, JavaScript etc.
Text	Use this pane to enter source code to be explored. IntelliJ IDEA suggests the following ways to supply code: <ul style="list-style-type: none"><li>– Type immediately within the text area.</li><li>– Paste from clipboard. If you have copied some text from the editor, and then open the PSI viewer, the previous contents of the Text pane is selected, which enables you to overwrite it from the clipboard using <code>Ctrl+V</code>, or <code>Ctrl+Shift+V</code>.</li></ul> <p>Note that some editing features are also available: removing line at caret <code>Ctrl+Y</code>, duplicating text <code>Ctrl+D</code>, and adding line with <code>Shift+Enter</code>.</p>
PSI Structure	This read-only pane displays the PSI structure tree view, generated on clicking the Build PSI Tree button, according to the file type selected in the Show PSI structure for drop-down list. Navigating through the tree view highlights the corresponding fragments of source code in the Text pane. If currently selected tree node has references, they are also displayed in the References pane.
References	This read-only field shows references to the nodes of the PSI Structure tree view (if any). Unresolved references are shown red; the corresponding fragments of source code are also highlighted with a red frame.
Build PSI Tree	Click this button to generate PSI structure tree view of the code in Text pane, according to the file type selected in the Show PSI structure for drop-down list. If source code in the Text pane has been modified, use this button to refresh the tree view.

For this dialog to be available, the Docker integration plugin must be installed and enabled.

---

Specify the settings for pulling an image from a [Docker](#) image repository such as [Docker Hub](#) or [Quay](#) .

---

**ItemDescription**

---

Registry	The URL of the image repository service or a Docker Registry configuration: <ul style="list-style-type: none"><li>– If pulling an image doesn't assume logging on to the corresponding server, specify the repository service URL. E.g. registry.hub.docker.com corresponds to public repositories on <a href="#">Docker Hub</a> .</li><li>– Otherwise, specify the corresponding Docker Registry configuration. Click New to create such a configuration.</li></ul>
New	Click this button to create a Docker Registry configuration. The <a href="#">Docker Registry dialog</a> will open. (A Docker Registry configuration in IntelliJ IDEA represents your Docker image repository user account.)
Repository	The name of the repository (image) to be pulled, e.g. <code>centos</code> , <code>jboss/wildfly</code> .
Tag	The tag of the image to be pulled.

For this dialog to be available, the Docker integration plugin must be installed and enabled.

---

Specify the settings for pushing an image to a [Docker](#) image repository such as [Docker Hub](#) or [Quay](#) .

---

**ItemDescription**

---

Registry	Select the Docker Registry configuration to be used. Click New to create such a configuration.
New	Click this button to create a Docker Registry configuration. The <a href="#">Docker Registry dialog</a> will open. (A Docker Registry configuration in IntelliJ IDEA represents your Docker image repository user account.)
Repository	The name of the repository (image) you are pushing.
Tag	The tag for the repository (image) you are pushing.

---

View | Recent Changes

Shift+Alt+C

---

In the Recent Changes popup, use the arrow keys to move in the list, and the **Enter** key to see details and, if necessary, to revert to the previous state.

All refactoring dialogs provide similar controls to preview results and perform the refactoring.

Specific options and controls are described in the following topics:

- [Change Class Signature Dialog](#)
- [Change Signature Dialog for Java](#)
- [Change Signature Dialog for ActionScript](#)
- [Change Signature Dialog for JavaScript](#)
- [Convert Anonymous to Inner Dialog](#)
- [Convert to Instance Method Dialog](#)
- [Copy Dialog](#)
- [Encapsulate Fields Dialog](#)
- [Extract Dialogs](#)
- [Generify Dialog](#)
- [Inline Dialogs](#)
- [Inline Method](#)
- [Invert Boolean Dialog](#)
- [Inline Super Class](#)
- [Make Static Dialogs](#)
- [Move Dialogs](#)
- [Package and Class Migration Dialog](#)
- [Pull Members Up Dialog](#)
- [Push Members Down Dialog](#)
- [Rename Dialogs](#)
- [Replace Constructor with Builder Dialog](#)
- [Replace Constructor with Factory Method Dialog](#)
- [Replace Inheritance with Delegation Dialog](#)
- [Replace Method Code Duplicates Dialog](#)
- [Replace Temp with Query Dialog](#)
- [Safe Delete Dialog](#)
- [Type Migration Preview](#)
- [Use Interface Where Possible Dialog](#)
- [Wrap Return Value Dialog](#)

Ctrl+F6

Use the Change Class Signature dialog to perform the [Change Class Signature](#) refactoring in Java.

Manage the formal type parameters using the available controls (see the table that follows). You can add and remove parameters as well as change their order.

Click Refactor to perform the refactoring right away. Click Preview to see the potential changes prior to actually performing the refactoring. (These will be shown in the [Find tool window](#).)

**IconShortcutDescription**

		Use this icon or shortcut to add a parameter. Specify the parameter name and default type in the Name and the Default Value fields respectively.
		Use this icon or shortcut to remove the selected parameter.
		Use this icon or shortcut to move the selected parameter one line up in the list.
		Use this icon or shortcut to move the selected parameter one line down in the list.

**Ctrl+F6**

Use the Change Signature dialog to perform the [Change Method Signature in Java](#) refactoring.

Use the available controls to make changes to the method signature. Specify how the method calls should be handled.

Optionally, select the calling methods that the added parameters and exceptions (if any) should be propagated to.

Click Refactor to perform the refactoring right away. Click Preview to see the potential changes prior to actually performing the refactoring. (These will be shown in the [Find tool window](#).)

– [Parameters tab](#)

– [Exceptions tab](#)

#### ItemDescription

Visibility	Select the method visibility scope (access level modifier) from the list.
Return type	Use this field to modify the method return type. <a href="#">Code completion</a> ( <b>Ctrl+Space</b> ) is available in this field, and also in other fields used for specifying the types.
Name	Use this field to modify the method name.
Parameters	See the description of the <a href="#">Parameters tab</a> .
Exceptions	See the description of the <a href="#">Exceptions tab</a> .
Method calls	Select one of the following options to specify how the method calls should be handled: <ul style="list-style-type: none"> <li>– Modify. The existing method calls are modified so that the method with the new signature is called.</li> <li>– Delegate via overloading method. The existing method calls don't change. A new overloading method with the old signature is created. This new method calls the method with the new signature.</li> </ul>
Signature Preview	In this area, the current method signature is shown. (The information in this area is synchronized with the changes you are making to the method signature.)

## Parameters tab

Use the Parameters tab to manage the method parameters.

The available controls let you add new parameters, remove the existing ones, reorder the parameters and also propagate new parameters to the calling methods (see the descriptions that follow).

In addition to that, you can change the type and name for the existing parameters.

To start editing a parameter, just click it. Alternatively, use the **Up** and **Down** arrow keys to navigate to the parameter of interest and **Enter** to start modifying it.

#### ItemTooltip and shortcut

<b>+</b>	Add	Use this icon or shortcut to start adding a new parameter. Specify the type, name, and default value in the corresponding fields. (The default parameter value is the value (or the expression) to be passed to the method in the method calls.)  If necessary, select the Use Any Var option. As a result, IntelliJ IDEA will search for a variable of the corresponding type near the method call. If such a variable is found, it will be placed in the method call instead of the default value.  If more than one variable is found, or the Use Any Var option is not selected, IntelliJ IDEA will use the default value in the call.  You can also <a href="#">propagate</a> the parameters you have added to the calling methods.
<b>-</b>	Remove	Use this icon or shortcut to delete the selected parameter.
<b>↑</b>	Up	Use this icon or shortcut to move the selected parameter one line up in the list of parameters.
<b>↓</b>	Down	Use this icon or shortcut to move the selected parameter one line down in the list of parameters.
<b>⚡</b>	Propagate Parameters	Use this icon or shortcut to propagate the added parameters to the calling methods. You can propagate the changes made to the method parameters to any method that directly or indirectly calls the method whose signature you are changing.

(There may be the methods that call the current method. These, in their turn, may be called by other methods. You can propagate the changes to any of the methods in such sequences.)

In the dialog that opens, select the methods you want the changes to be propagated to.

Note that only the selected calling methods and the method calls within them will be affected. That is, the default values will be added into other method calls.

#### Create and initialize class properties

The checkbox is available only in the PHP context when the **Change signature** refactoring is invoked from the constructor of a class.

– When this checkbox is selected, the newly added parameter is initialized as a field. IntelliJ IDEA creates a protected field with the same name as this parameter and adds a line with the following assignment:

```
$this-><parameter_name> = <parameter_name>;
```

– When the checkbox is cleared, a parameter is added without initialization.

For example, you have the following constructor:

```
class ChangeSignatureNewParam {
    function __construct() {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
    }
}
```

If you invoke the **Change signature** refactoring from the `__construct()` method and add a new `$q` parameter, the result will depend on whether you select or clear the **Create and initialize class properties** checkbox:

– The **Create and initialize class properties** checkbox is selected:

```
class ChangeSignatureNewParam {
    private $q;
    function __construct($q) {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
        $this->q = $q;
    }
}
```

– The **Create and initialize class properties** checkbox is cleared:

```
class ChangeSignatureNewParam {
    function __construct($q) {
        $a = "Constructor in ChangeSignatureNewParam";
        print $a;
    }
}
```

## Exceptions tab

Use the Exceptions tab to manage the exceptions thrown by the method.

The available controls let you add new exceptions, remove the existing ones, reorder the exceptions and also propagate new exceptions to the calling methods (see the descriptions that follow).

In addition to that, you can edit the existing exceptions.

To start editing an exception, just click it.

#### ItemDescription

 or  Use this icon or shortcut to add a new exception.  
Start typing in the field and then select the required exception type from the suggestion list.

Note that you can [propagate](#) the exceptions you have added to the calling methods.

 or  Use this icon or shortcut to delete the selected exception.

 or  Use this icon or shortcut to move the selected exception one line up in the list of exceptions.

 or  Use this icon or shortcut to move the selected exception one line down in the list of exceptions.

 or  Use this icon or shortcut to propagate the added exceptions to the calling methods.  
You can propagate the exceptions you have added to any method that directly or indirectly calls the method whose signature you are changing.

(There may be the methods that call the current method. These methods, in their turn, may be called by other methods. You can propagate the changes to any of the methods in such sequences.)

In the dialog that opens, select the methods you want the exceptions to be propagated to.

Ctrl+F6

Use this dialog to [change the function signature](#) and to perform other, related tasks.

#### ItemDescription

Return type	Use this field to modify the function return type. <b>Note</b> Code completion is available in this field and also in certain fields of the table that contains the function parameters.
Name	Use this field to modify the function name. Use the table and the <a href="#">controls</a> to the right of it to manage the function parameters and their <a href="#">properties</a> .
Type	Use this field to specify the type of a parameter.
Name	Use this field to specify the name of a parameter.
Initializer	A value (or an expression) specified in this field is added to the function definition as the default parameter value.
Default value	A value (or an expression) passed to the function in the function calls.
+ or Alt+Insert	Use this icon or shortcut to start adding a new parameter. Specify the parameter <a href="#">type</a> , <a href="#">name</a> , <a href="#">initializer</a> , and the <a href="#">default value</a> .  Note that you can <a href="#">propagate</a> the parameters you have added to the calling methods.
- or Alt+Delete	Use this icon or shortcut to delete the selected parameter.
↑ or Alt+Up	Use this icon or shortcut to move the selected parameter one line up in the list of parameters.
↓ or Alt+Down	Use this icon or shortcut to move the selected parameter one line down in the list of parameters.
🔗 or Alt+G	Use this icon or shortcut to propagate the added parameters to the calling methods. You can propagate new function parameters to any function that directly or indirectly calls the function whose signature you are changing.  (There may be the functions that call the current function. These functions, in their turn, may be called by other functions. You can propagate new parameters to any of the functions in such sequences.)  In the left-hand pane of the Select Methods to Propagate New Parameters dialog, expand the necessary nodes and select the checkboxes next to the functions you want the new parameters to be propagated to.
Signature Preview	In this area, the current function signature is shown. (The information in this area is synchronized with the changes you are making to the function signature.)
Refactor	Click this button to perform the refactoring right away.
Preview	Click this button to see the expected changes prior to actually performing the refactoring.

Ctrl+F6

Use this dialog to [change the function signature](#) and to perform other related tasks.

**ItemDescription**

**Name** Use this field to modify the function name.

Use the table and the [controls](#) to the right of it to manage the function parameters and their [properties](#) .

**Name** Use this field to specify the name of a parameter.

**Value** A parameter value.  
If the parameter is a required one, the specified value (or expression) will be passed to the function in the function calls. If the parameter is an optional one, this value will be used in the function body to initialize the parameter.

**Optional** Select this checkbox if the parameter is optional. Your selection will define how the [parameter value](#) is used.

 or Use this icon or shortcut to start adding a new parameter.  
 Specify the parameter [name](#) and [value](#) . Also, specify whether the parameter is [optional](#) .

Note that you can [propagate](#) the parameters you have added to the calling methods.

 or Use this icon or shortcut to delete the selected parameter.

 or Use this icon or shortcut to move the selected parameter one line up in the list of parameters.

 or Use this icon or shortcut to move the selected parameter one line down in the list of parameters.

 . Use this icon or shortcut to propagate the added parameters to the calling methods.  
You can propagate new function parameters to any function that directly or indirectly calls the function whose signature you are changing.

(There may be the functions that call the current function. These functions, in their turn, may be called by other functions. You can propagate new parameters to any of the functions in such sequences.)

In the left-hand pane of the Select Methods to Propagate New Parameters dialog, expand the necessary nodes and select the checkboxes next to the functions you want the new parameters to be propagated to.

**Signature Preview** In this area, the current function signature is shown. (The information in this area is synchronized with the changes you are making to the function signature.)

**Refactor** Click this button to perform the refactoring right away.

**Preview** Click this button to see the expected changes prior to actually performing the refactoring.

**ItemDescription**

---

Class name	Specify here the name for the new inner class.
Make class static	Use this option to make the new class static.
Constructor Parameters	In this area select the variables, that will be used as parameters to the inner class constructor.
Move Up/Down	Use these buttons to reorder parameters.

**ItemDescription**

---

Select an instance parameter    Select the class you want the method to belong to after the conversion. All the usages of this class inside the method are replaced with `this`.

---

Visibility    In this area you can change the visibility scope of the converted method. By default the converted method will have no scope declaration (equivalent to `public`).

---

Use this dialog to specify the settings for the [Copy refactoring](#).

**ItemDescription**

---

New name	Specify the name of the class, file, package or directory to be created.
To directory	Specify the directory where to create a copy. Select the destination directory from the list, or click <input type="button" value="..."/> ( <input type="button" value="Shift+Enter"/> ) and select the directory in the Select target directory dialog that opens. (If necessary, you can create a new directory.)
Destination package	When creating a copy of a class: specify in which package the new class should be created. Select the package from the list, or click <input type="button" value="..."/> ( <input type="button" value="Shift+Enter"/> ) and select the destination package in the Choose Destination Package dialog that opens. (If necessary, you can create a new package.)
Target destination directory	When creating a copy of a class: if there is more than one source root in your module (e.g. one source and one test source root), you have an option of selecting in which of the source roots the new class should be created. Select the destination source root from the list, or click <input type="button" value="..."/> ( <input type="button" value="Shift+Enter"/> ) and select the source root in the Choose Destination Directory dialog that opens.  If the specified destination package doesn't exist in the selected source root, it will be created automatically.
Open copy in editor	Select this checkbox to automatically open a file, directory or package after it is copied. If you clear this checkbox, then the file, directory or package that you have copied will not be opened.

**ItemDescription**

Fields to encapsulate	<p>In this area select the fields you want to create accessors for. You can accept the default method names or change them at will.</p> <p>If a method with the same signature is already present in the class to be refactored, the Method icon  appears to the left of the accessor name, along with the corresponding visibility icon. No new accessor method will be created in this case. The existing method will not be changed and, generally, nothing else will be additionally checked. In this case you have to be attentive whether the existing method actually functions as an accessor. Otherwise, you might need either to choose another name for the accessor or to go back to the editor, change the existing method and only then invoke the Encapsulate Fields refactoring again. If the existing method overrides/implements a parent class' method it will also be marked with the Overrides method  or Implements method  icon.</p> <p>If the accessor method does not exist in the class to be refactored but, if created it would override/implement a method of the parent class such method will be marked with the Overrides method  or Implements method  icon only to the left of the accessor name. A new accessor method will be generated. However, this newly created accessor method will actually override or implement the method of the parent class, that might not exactly be what you planned it for. In this case, you might need either to choose another name for the accessor or to go back to the editor, change the existing method and only then invoke the Encapsulate Fields refactoring again.</p>
Get access/Set access	<p>Use this option group to select which accessor methods (Getter, Setter or both) will be created for the selected fields. If one of the checkboxes is cleared, the entire corresponding column (Getter or Setter) in the Fields to Encapsulate table is disabled.</p>
Encapsulated Fields' Visibility	<p>Here you can specify the new visibility scope for the selected fields</p>
Options	<p>Select whether you want to use accessors even when field is accessible or not. If the option Use accessors even when the field is accessible is not checked, the references to the desired fields, when the fields are directly accessible, will not change.</p> <p>Otherwise, all references to the desired fields will be replaced with the accessor calls. It also depends on your selection in the options group Encapsulated Fields' Visibility .</p> <p>For example, if you uncheck the option Use accessors even when the field is accessible , and select the private visibility for the fields, the usages of the fields outside the class will change, but within the class they will remain the same.</p>
Accessors' Visibility	<p>In this area select the visibility scope for the created accessor methods.</p>

- [Extract Variable Dialog](#)
- [Extract Variable Dialog for Sass](#)

Ctrl+Alt+C

**ItemDescription**

Constant of type	IntelliJ IDEA automatically determines the field type.
Name	Specify here the name for the new constant.
Introduce to class	Select the class in which the constant will be introduced.
Introduce as enum constant	If you've selected an enum class in the Introduce to class field, you can use this option to select, whether you want to introduce this constant as an enum constant, or as a usual field. Otherwise, this option is naturally disabled and does not affect anything.
Visibility	Select the visibility scope for the new field.
Replace all occurrences	Check this option to automatically replace all the occurrences of the selected expression (if the selected expression is found more than once in the class).
Delete variable declaration	Check this option to delete variable declaration.
Annotate field as @NotNull	Check this option to avoid changes during localization.

**Tip** – This field is only available if the project is configured to use annotations, that is, the library `annotation.jar` is added to the project or module. If annotations are not available, this option does not appear in the dialog.

– The project language level should be 5.0 to support annotations.

Specify the settings for the [extract delegate refactoring](#) .

**ItemDescription**

---

Name for new class	Specify the name of the class to be created.
Package name	Specify the name of the destination package for the new class.
Members to extract	Select the fields and methods to be extracted to the new class.

Ctrl+Alt+F

---

**ItemDescription**

---

Field of type/ Name	In this text box, specify the name of the new field.
Initialize in	In this area select where the new field will be initialized in.
Visibility	In this area, specify the <a href="#">visibility scope</a> for the new field. The available options are: <ul style="list-style-type: none"><li>– Public - if you select this option, the new field will be accessible from anywhere.</li><li>– Private - if you select this option, the new field will be accessible only from the current class.</li><li>– Protected - if you select this option, the new field will be accessible from the current class as well as from its inherited and parent classes.</li><li>– Package local - if you select this option, the new field will be accessible from the classes of the current package only.</li></ul>
Replace all occurrences	Select this checkbox to have IntelliJ IDEA automatically replace all the occurrences of the selected expression. The checkbox is enabled only if the selected expression is used more than once in the class. All the found occurrences of the expression are highlighted.
Declare final	Check this option to create a final field.
Delete variable declaration	Check this option to delete variable declaration.

**ItemDescription**

---

Name for extracted include file      In this text box, specify the name of the include file to extract the selected source code to.

**Tip** No extension is allowed.

---

Extract to directory      In this field, specify the directory to create the include file in. Either accept the predefined directory, or type another one manually, or click the Browse button  and choose the desired folder in the [dialog that opens](#) .

**ItemDescription**

Extract interface from	This read-only field shows the name of the source package that contains the class to extract an interface from.
Extract interface	When this option is selected, IntelliJ IDEA extracts a new interface but does not use it immediately and the source code is not changed.
Interface name	In this text box, type the name for the new interface. The text box is available if the Extract interface option is selected.
Extract interface and use it where possible	Select this option to have an interface extracted and immediately applied to the source code, with the suggested changes displayed in the dedicated tab of the <a href="#">Find</a> tool window.
Rename original class and use interface where possible	Use this option to rename the original class and make it an implementation of the newly created interface.
Rename implementation class to	In this text box, type the new name for the original class. The text box is available if the Rename original class and use interface where possible option is selected.
Package for new interface	In this drop-down list, specify the package for the new interface. If necessary, click the Browse button  and choose the target package in the <a href="#">dialog that opens</a> .
Members to Form Interface	In this area, specify the methods of the class, as well as final static fields (constants) to be included in the new interface. To have an element included in the interface, select the checkbox next to it.
JavaDoc/ASDoc	In this area, specify the action to be applied to the inline documentation. The available options are: <ul style="list-style-type: none"><li>– As is - select this option to have the inline documentation left where it is.</li><li>– Copy - select this option to have the inline documentation copied to the extracted interface without removing it from its current location.</li><li>– Move - select this option to have the inline documentation moved to the extracted interface and delete it from its current location.</li></ul>

Ctrl+Alt+M

**ItemDescription**

**Name** In this text box, specify the name of the function or method to be generated on the basis of the selected source code.

**Visibility** In this area, specify the visibility scope of the method to be generated.

**Declare static** Select this checkbox to have a static method created.

**Tip** If the new method cannot be declared as static, or, vice-versa, can be created only as a static method, the Declare Static checkbox is disabled.

**Declare varargs** Select this option if you want to declare varargs instead of the array.

**Fold parameters** Select this option to fold the parameters, for example, if you have an array, like `int[] a = new int[i]`, and you want `a[i]` to be passed as a whole to the newly created method.

**Extract chained constructor** Use this option to extract chained constructor from the constructor body, replacing the original code with `this`.

**Output variable(s)** This read-only text box displays the name of the variable through which the output of the new method/function will be passed to the calling method/function. Depending on your choice in the [Return output variable\(s\) through](#) area, this variable either will be used in a `return` statement or will be declared as the passed by reference parameter of the new method/function.

**Return output variable(s) through** In this area, specify the way in which the new method or function will [return the output variables](#) to the callee.

- Return statement - select this option to have the output variables returned by value. If the Output variable(s) read-only field shows exactly one output variable, it will be used as the return value. If the selection outputs several variables, these variables will be returned as an array.
- Parameter(s) passed by reference - select this option to have the output variables returned by reference. IntelliJ IDEA will generate a method/function without a return statement. Instead, the output variables will be added to the set of input parameters in the method/function declaration. The names of these variables will be prepended with an ampersand `&`.

**Note** The area is available only when refactoring is invoked in the PHP context.

**Parameters** In this area, select parameters to be passed to the new method/function.

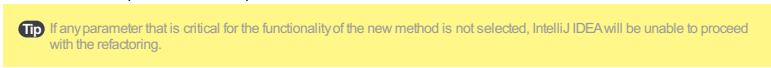

**Tip** If any parameter that is critical for the functionality of the new method is not selected, IntelliJ IDEA will be unable to proceed with the refactoring.

**Move Up/Down** Use these buttons to change the order of the parameters.

**Signature preview** In this read-only field, view the declaration of the new method.

Ctrl+Alt+M

**ItemDescription**

Visibility	In this area, specify the visibility scope of the method to be generated.
Name	In this text box, specify the name of the function or method to be generated on the basis of the selected source code.
Specify return type explicitly	This checkbox is available if you invoke refactoring from the method of a Groovy class. Select this checkbox to return a data type of the value explicitly.
Use explicit return statement	This checkbox is active if the method returns a value. You can omit <code>return</code> keyword if it is the last return statement in the method. If you select this checkbox the keyword is returned.
Parameters	In this area, select parameters to be passed to the new method/function. 
Move Up/Down	Use these buttons to change the order of the parameters.
Signature preview	In this read-only field, view the declaration of the new method/function.

Use this refactoring to extract method object, when Extract Method refactoring is not applicable, because of multiple return values.

**ItemDescription**

---

**Create inner class**      Select this option, if you want to extract method object to an inner class. All the local variables will become fields on that class. Specify also name for the class and visibility scope. You can make the class static, if needed.

---

**Create anonymous class**      Select this option to an object with the corresponding method.

---

**Parameters**      In this area select the variables that will be used as a parameters. Use Move Up / Move Down buttons to reorder parameters/

**ItemDescription**

**Extract module from** This read-only field displays the name of Ruby class, from which a module should be extracted.

**Module name** In this text field, type the name of the target module. The module name should a proper Ruby constant.

**Directory for new module** In this text field, specify the path to the target directory, where the new module will be stored.

**Context to form module** Click one of the radio buttons ( Instance or Static ) to define the way the new module will be used in a Ruby class.

**Members to form module** This area displays the list of members detected in the original class. Select the checkboxes next to the members to be included in the new module.

Note that static methods are disabled when Instance context is selected, and vice versa.

Ctrl+Alt+P

---

Use this dialog to specify the options and settings related to the [Extract Parameter refactoring in ActionScript](#).

**ItemDescription**

---

Type	Specify the type of the new parameter. Usually, you don't need to change the type suggested by IntelliJ IDEA.
Name	Specify the name for the new parameter.
Value	The expression to be replaced with the new parameter. Initially, this field contains the expression that you have selected. Normally, this initial value does not need to be changed.
Optional parameter	If you want the new parameter to be an optional parameter, select this checkbox. For information about required and optional parameters, see the discussion of function parameters in <a href="#">Flex/ActionScript documentation</a> .

---

Replace all occurrences	Select this option to replace all the occurrences of the selected expression within the function.
-------------------------	---

Ctrl+Alt+P

Ctrl+Shift+Alt+P

Specify the settings for extracting a parameter. See [Extract Parameter in Java](#) and [Extract Functional Parameter](#) .

**ItemDescription**

Parameter of type	Specify the type of the new parameter. Usually, you don't need to change the type suggested by IntelliJ IDEA.
Name	Specify the name for the new parameter.
Replace all occurrences	Select this option to replace all the occurrences of the selected expression within the method.
Declare final	Select this option to declare the parameter <code>final</code> .
Delegate via overloading method	Select this option to keep the existing method calls unchanged. As a result, a new overloading method will be created and the new parameter will be added to the definition of this method. The method with the old signature will be kept. The call to the new method will be added to the old method. The necessary value (or expression) will be passed to the new method in this call.

The following options are available if the expression contains a direct call to a class field that has a getter.

Do not replace	Select this option to use a direct call to the field regardless of the scope context.
Replace fields inaccessible in usage context	Select this option to use a call to the getter only where a field is directly inaccessible.
Replace all fields	Select this option to use a call to the getter.

The following options are available when the refactored expression contains local variables.

Delete variable definition	Select this option to remove the definition of a local variable.
Use variable initializer to initialize parameter	Select this option to use the default value of the selected variable in the corrected method calls. <b>Warning!</b> It is strongly recommended that you select both checkboxes. Otherwise, the code may become uncompileable.

Ctrl+Alt+P

Use this dialog to specify the options and settings related to the [Extract Parameter refactoring in Groovy](#).

**ItemDescription**

Type	Specify the type of the new parameter. Usually, you don't need to change the type suggested by IntelliJ IDEA.
Name	Specify the name for the new parameter.
Declare final	Select this option to declare the parameter <code>final</code> .
Delegate via overloading method	Select this option to keep the existing method calls unchanged. As a result, a new overloading method will be created and the new parameter will be added to the definition of this method. The method with the old signature will be kept. The call to the new method will be added to the old method. The necessary value (or expression) will be passed to the new method in this call.
Remove parameter <name> no longer used	Select this checkbox to remove a parameter.
Use explicit return statement	This checkbox is active if the method returns a value. You can omit <code>return</code> keyword if it is the last return statement in the method. If you select this checkbox the keyword is returned.
Parameters	In this area, select parameters to be passed to the new method/function. <div style="background-color: #ffff00; padding: 5px;"><b>Tip</b> If any parameter that is critical for the functionality of the new method is not selected, IntelliJ IDEA will be unable to proceed with the refactoring.</div>
Move Up/Down	Use these buttons to change the order of the parameters.
Signature preview	In this read-only field, view the declaration of the new method/function.

Ctrl+Alt+P

Use this dialog to specify the options and settings related to the [Extract Parameter refactoring in JavaScript](#).

**ItemDescription**

Type	Specify the type of the new parameter. Usually, you don't need to change the type suggested by IntelliJ IDEA.
Name	Specify the name for the new parameter.
Value	The expression to be replaced with the new parameter. Initially, this field contains the expression that you have selected. Normally, this initial value does not need to be changed.
Optional parameter	<p>If this option is selected, the new parameter is assigned a value in the function body. The value corresponds to that currently set in the Value field. The calls to the function do not change.</p> <p>If this option is not selected, all the function calls change according to the new function signature. The value specified in the Value field is added to the function calls and thus is passed to the function. No explicit value assignment for the new parameter is added to the function body.</p>
Replace all occurrences	Select this option to replace all the occurrences of the selected expression within the function.

---

Use this refactoring to create a wrapper class around some selected parameters of a method, or use a compatible existing class as a wrapper.

**ItemDescription**

---

Method to extract parameters from	This read-only field shows the name of the selected method.
Parameter Class	Use this section to specify whether you want to create a new wrapper class or use an existing one.
Create new class	Click this radio-button to move parameters of a method to a new class. If this option is selected, specify the class and destination package name in the fields below. By default, current package name is displayed. You can type a different package name in the text field, or click the ellipsis button and select the destination package from the tree view. If the desired package doesn't exist, click  to create a new one.
Create inner class	Click this radio-button to move parameters of a method to an inner class. If this option is selected, specify the class name in the field below.
Use existing class	Click this radio-button to move parameters of a method to an existing class of your choice. You can type the fully-qualified class name in the text field, or click the ellipsis button and choose the desired class in the Select parameter class dialog box. Note that you can select the desired wrapper class both from the project and non-project classes.
Parameters to extract	Use checkboxes in this section to select which parameters of a method should be extracted into separate object.
Move Up / Move Down	Use these buttons to move the selected reorder parameters in the list.
Keep method as delegate	If this checkbox is selected, the original method will be preserved as a delegate to the newly created method.

Use this dialog to create a partial view file from the selected fragment of HTML code in a view. The selection must be valid and contain matching opening and closing tags.

## Prerequisites

Before you start working with Ruby, make sure that Ruby plugin is [installed and enabled](#) . The plugin is not bundled with IntelliJ IDEA.

Also make sure that the following prerequisites are met:

- Ruby SDK is downloaded and installed on your machine.
- The required framework SDKs are downloaded and installed on your machine.

Refer to their respective download and installation pages for details:

- [Ruby](#)
- [Ruby on Rails](#)

## ItemDescription

---

Name	Type the string from which IntelliJ IDEA will generate the resulting partial view name in accordance with the Rails naming conventions. The entered string should not contain extension and the leading underscore.
------	---

Ctrl+Alt+V

---

This refactoring is only available for `pom.xml` files.

**ItemDescription**

---

**Name** In this field, specify the name you want to assign to a new property. You can either type this name manually, or select one of the values suggested by IntelliJ IDEA.

---

**Project** Select the `pom.xml` where the new property will be declared.

**ItemDescription**

Extract superclass from	This read-only field shows the name of the source package that contains the class to extract a superclass from.
Extract superclass	When this option is selected, IntelliJ IDEA extracts a new superclass but does not use it immediately and the source code is not changed.
Superclass name	In this text box, type the name for the new superclass. The text box is available if the Extract superclass option is selected.
Extract superclass and use it where possible	Select this option to have a superclass extracted and immediately applied to the source code, with the suggested changes displayed in the dedicated tab of the <a href="#">Find</a> tool window.
Rename original class and use superclass where possible	Use this option to rename the original class and make it an implementation of the newly created superclass.
Rename original class to	In this text box, type the new name for the original class. The text box is available if the Rename original class and use superclass where possible option is selected.
Package for new superclass	In this drop-down list, specify the package for the new superclass. If necessary, click the Browse button  and choose the target package in the <a href="#">dialog that opens</a> .
Members to Form Superclass	In this area, specify the members of the class to be moved or delegated to the new superclass. To have an element included in the interface, select the checkbox next to it.
Make Abstract	Select this option to leave the method implementation within the current class, and declare it abstract in the extracted superclass.
JavaDoc/ASDoc for abstracts	In the JavaDoc /ASDoc area, specify the action to be applied to the inline documentation. The available options are: <ul style="list-style-type: none"><li>- As is - select this option to have the inline documentation left where it is.</li><li>- Copy - select this option to have the inline documentation copied to the extracted superclass without removing it from its current location.</li><li>- Move - select this option to have the inline documentation moved to the extracted superclass and delete it from its current location.</li></ul>

`Ctrl+Alt+V`

Generally, this dialog is used to extract new variables. Depending on the language, there may be additional options, for example:

- In Java, you can declare the new variable `final` .  
To make this dialog accessible for Java, you have to disable [in-place refactoring in the editor settings](#) .
- In JavaScript, you can select to extract a (global) variable or a constant. For JavaScript 1.7, JavaScript 1.8.5, ES5, and ES6, there is also an option of extracting a local variable.
- In ActionScript, you can choose to extract a constant rather than a variable, and specify the variable type.

Item	Description	Language
Type	Select the type of the new variable.	ActionScript
Name	Specify the name for the new variable.	All
Replace all occurrences	Select this option to replace all the occurrences of the selected expression (if more than one occurrence of the selected expression is found).	All
Declare final	Select this option to declare the new variable <code>final</code> .	Java
Var kind	Choose to extract a (global) variable, a constant, or a local variable: <ul style="list-style-type: none"><li>- extract var - select this option to extract a global variable.</li><li>- extract constant - select this option to extract a constant.</li><li>- extract local variable - select this option to extract a local variable.</li></ul> The extract local variable option is available only for JavaScript 1.7, JavaScript 1.8.5, ES5, and ES6.	JavaScript
Make constant	Select this option to extract a constant rather than a variable.	ActionScript

Ctrl+Alt+V

Use this dialog box to replace a Sass expression with a variable.

**ItemDescription**

---

Name	Specify the name for the new variable.
Place for declaration	Select the place in the source code, where the new variable will be declared. The declaration can be global (a variable is declared in the beginning of a Sass file and is available throughout the whole file), or local (a variable is declared immediately before use, and is available in the current block only).
Replace all occurrences	Select this option to replace all the occurrences of the selected expression (if more than one occurrence of the selected expression is found).

**ItemDescription**

Drop obsolete casts	If this option is checked, IntelliJ IDEA analyzes whether the parameter cast cases are changed by refactoring. If the resulting parameter type is similar to the obsolete one, the cast statement is removed.
Leave Object-parameterized types raw	Check this option to make objects, that have <code>java.lang.Object</code> as a parameter, raw.
Perform exhaustive search	Check this option to perform search in all nodes.
Generify Objects	Check this option to transform the <code>java.lang.Object</code> objects into the type, they are actually used for.
Produce wildcard types	Check this option to produce wildcard types where possible (expressions like <code>List&lt;? extends String&gt;</code> ).
Preserve raw arrays	If this checkbox is selected, the arrays are not changed to the arrays with parameterized types. Otherwise, the arrays will be transformed to parameterized type. Clearing this checkbox can be risky and result in uncompileable code.

`Ctrl+Alt+N`[- Inline Variable dialog](#)[- Inline to Anonymous Class dialog](#)

## Inline Variable dialog

The Inline Variable refactoring allows you to replace a redundant variable with its value. See [examples](#) .

To access the Inline Variable dialog box through a menu item or the keyboard shortcut, position the cursor at the variable to be inlined. The dialog box does not contain any controls but just displays the following message:

```
Inline variable <variable name>? (<the number of variable occurrences>)
```

## Inline to Anonymous Class dialog

### ItemDescription

All references and remove the class	Select this radio button to replace all the class references with its code and remove the class.
-------------------------------------	--

This reference only and keep the class	Use this option to replace only the current class reference.
--	--

Search in comments and strings	Select this checkbox to display the usages of methods in comments and strings in the Refactoring Preview tool window.
--------------------------------	---

**Note** This option will force the Refactoring Preview tool window to open even if you click the Refactor button instead of the Preview button.

Search for text occurrences	Check this option to apply the changes to non-java files (such as documentation, HTML, JSP and other files included in the project).
-----------------------------	--

[Inline Method](#) refactoring results in placing method's body into the body of its caller(s). You can opt to:

- inline all occurrences of the method, and delete the method
- inline only a single occurrence, and retain the method

#### ItemDescription

---

Inline all invocations and remove the method      Select this radio button to replace all the method calls with its code and remove the method.

---

Inline this invocation only and keep the method      Use this option to replace only the current method call.

---

Search in comments and strings      Select this checkbox to display the usages of methods in comments and strings in the Refactoring Preview tool window.

**Note** This option will force the Refactoring Preview tool window to open even if you click the Refactor button instead of the Preview button.

---

Search for text occurrences      Check this option to apply the changes to non-java files (such as documentation, HTML, JSP and other files included in the project).

**ItemDescription**

---

Name of inverted method/field

Specify the name for the inverted method or field.

[Inline Super Class](#) refactoring results in pushing superclass' methods into the class where they are used, and removing the superclass.

**ItemDescription**

---

JavaDoc for inlined members	<p>In this area you can select an action that can be applied to JavaDoc.</p> <p>You can choose from the following options:</p> <ul style="list-style-type: none"><li>- As is - lets you leave the inline documentation where it is.</li><li>- Copy - lets you copy the inline documentation to the destination superclass without removing it from its current location.</li><li>- Move - lets you move the inline documentation to the destination superclass and delete it from its current location.</li></ul>
Inline all references and remove the class	Select this radio button to replace all the super class references with its code and remove the super class.
Inline this reference only and keep the super class	Select this radio button to replace only the current super class reference.

Use this refactoring to convert an inner class or an instance method into a static one.

– [Make Class Static dialog](#)

– [Make Method Static dialog](#)

## Make Class Static dialog

### ItemDescription

---

Replace instance qualifiers with class references	Specify whether you want to replace instance qualifiers with class references or not.
---	---

## Make Method Static dialog

### ItemDescription

---

Add object as a parameter with name	Select this checkbox, if you want to pass the whole referenced object as a parameter to the method, then specify the name for the parameter in the field below.
-------------------------------------	---

Add parameters for fields	Select this checkbox to pass the referenced fields/variables as parameters to the method, then select the appropriate fields in the list.
---------------------------	---

Move Up/Move Down	Use this buttons to reorder parameters in the list.
-------------------	---

Replace instance qualifiers with class references	Specify whether you want to replace instance qualifiers with class references or not. This checkbox is available, if the method does not contain any references to fields or instance variables.
---	---

In this section:

- [Move Class Dialog](#)
- [Move Directory Dialog](#)
- [Move Package Dialog](#)
- [Move Instance Method Dialog](#)
- [Move Inner to Upper Level Dialog for Java](#)
- [Move Inner to Upper Level Dialog for ActionScript](#)
- [Move Members Dialog](#)
- [Move File Dialog](#)
- [Move Namespace Dialog](#)

The Move Class refactoring dialog box is invoked for the classes selected in the Project view, or opened in the editor.

#### ItemDescription

To package	Specify the destination package. Click the ellipsis button, and select the target package in the Choose Destination Package dialog that shows a tree view of all packages within the project.
Make inner class of	If you want to make your class inner, specify the target class. Click the ellipsis button and select the target class in the Choose Class dialog. This option is not available for ActionScript.
Search in comments and strings	Select this option to apply the changes to comments and strings.
Search for text occurrences	Select this option to apply the changes to documentation, HTML, JSP and other files included in your project.
Search for references	Select this checkbox to have the changes applied to the references to the file in question. This option is available only for Move File or Move Package refactorings.
Move to another source folder	If this option is selected, you can select the target root, where the destination package will be located. If the option is not selected, only the current root is used. This option is disabled for the modules that contain a single source root.
Target destination directory	<p>When the dialog box opens, the field shows the path to the folder where the file that implements the class to move is currently stored.</p> <p>The path is displayed in the format <code>...\&lt;project root folder&gt;\&lt;path to the current namespace folder relative to the project root&gt;</code>. The path is updated automatically as you specify the namespace to move the class to. However, if you are going to move a class to a non-existing namespace under another parent namespace, IntelliJ IDEA will not suggest the proper folder unless you appoint a root folder for your namespace structure by marking the relevant folder as Sources on the Directories page of the Settings dialog box.</p> <p>Do one of the following:</p> <ul style="list-style-type: none"> <li>- Accept the preselected path displayed in the field.</li> <li>- Choose another path from the list. All of them are evaluated from the namespace root or from the current directory, so it is safe to choose any of them.</li> <li>- Click  and select a folder in the dialog box that opens.</li> <li>- Press  and edit the preselected path. Keep in mind that this may cause problems with automatic loading in the future.</li> </ul>
Open moved in editor	Select this checkbox to open the moved class in the editor.

The Refactor | Move menu command invokes the Move Directory dialog box when a directory is selected in the Project tool window.

**ItemDescription**

---

To directory	Specify the destination directory. Type the path manually or click  and select the target directory in the <a href="#">dialog that opens</a> .
Search for references	Select the checkbox to find and update the references to the directory being moved.
Open moved files in editor	Select this checkbox to see the files of the moved directory in the editor.

---

**ItemDescription**

---

Select refactoring Specify which action you want to perform: [move package to another package](#) , [move directory to another source root](#) , or [to another directory](#) .

---

This dialog box opens when Move package to another package option has been selected.

---

To package Specify the destination package. Click the ellipsis button, and select the target package in the Choose Destination Package dialog that shows a tree view of all packages within the project.

---

Search in comments and strings Select this option to apply the changes to comments and strings.

---

Search for text occurrences Select this option to apply the changes to documentation, HTML, JSP and other files included in your project.

---

Search for references Select this checkbox to have the changes applied to the references to the file in question. This option is available only for Move File or Move Package refactorings.

---

Move to another source folder If this option is selected, you can select the target root, where the destination package will be located. If the option is not selected, only the current root is used. This option is disabled for the modules that contain a single source root.

---

This dialog box opens when Move directory to another source root option has been selected.

---

Select source root Choose the target source root from a tree view of source roots configured in your project.

---

This dialog box opens when Move directory to another directory option has been selected.

---

To directory Use this field to specify the destination directory. Click the ellipsis button, and select the target directory in the Select Path dialog box.

F6

**ItemDescription**

---

Select an instance parameter

Select the target class.

---

Visibility

Select visibility scope for the method to be moved.

---

Move Inner Class refactoring dialog box is invoked for inner classes selected in the Structure view or opened in the editor.

**ItemDescription**

---

Class name	Use this field to rename the moved inner class, if needed.
Package name	Specify the name of the package for the class to be moved to.
Pass outer class' instance as a parameter	Select this checkbox, if you want the moved class to preserve access rights to its former outer class.
Parameter name	Specify here the name for the outer class' instance passed as a parameter.
Search in comments and strings	Select this option to apply the changes to comments and strings.
Search for text occurrences	Select this option to apply the changes to documentation, HTML, JSP and other files included in your project.
Search for references	Select this checkbox to have the changes applied to the references to the file in question. This option is available only for Move File or Move Package refactorings.

---

This dialog opens when moving an out-of-package class, function, variable, constant or namespace into a package. You can specify the destination package and other, associated settings.

The out-of-package entities being moved are referred to in the dialog as **inner** entities, for example, an inner class, an inner function, etc.

This dialog can be accessed from:

- The editor when the cursor is within the item (class, function, etc.) that you are going to move.
- The Structure tool window when the corresponding item is selected there.

#### ItemDescription

---

<Entity> name	If necessary, change the name of the entity (class, function, etc.) that you are moving.
Package name	Specify the destination package. Select the package from the list, or click  and select the package in the Select Destination Package dialog.
Search in comments and strings	Select this option to apply the changes to comments and strings.
Search for text occurrences	Select this option to apply the changes to documentation, HTML, JSP and other files included in your project.
Move to another source folder	If this option is selected, you can select the target root, where the destination package will be located. If the option is not selected, only the current root is used. This option is disabled for the modules that contain a single source root.

Move Member refactoring dialog box is invoked for static members selected in the Structure view, or in the editor.

### ItemDescription

**Move members from** This read-only field displays the fully qualified name of the source class containing members to be moved.

**To (fully qualified name)** Specify the fully qualified name of the target class.

**Move as enum constant if possible** This option is useful when moving constants ( `static final` fields) to an `enum` type in cases when the `enum` type has a constructor with one parameter of the suitable type. Say, we are moving `MOUSE_EVENT` from the class `Events`

```
class Events {
    public static final String MOUSE_EVENT = "mouseEvent";
}
```

to the enum `ActionType`

```
enum ActionType {
    ;
    String typeName;
    ActionType(String name) {
        typeName = name;
    }
}
```

If the option is on, we'll get the following result:

```
enum ActionType {
    MOUSE_EVENT("mouseEvent");
    String typeName;
    ...
}
```

If the option is off, the result will be:

```
enum ActionType {
    ;
    public static final String MOUSE_EVENT = "mouseEvent";
    String typeName;
    ...
}
```

**Members to be moved (static only)** This table shows all static members detected in the specified class. Select checkboxes next to the members you want to move.

**Visibility** Specify visibility level. You can either specify it explicitly, or select Escalate to automatically raise it to a necessary level.

---

The Refactor | Move menu command invokes one of the following dialog boxes depending on the selected item to be moved:

- The Move File dialog box is invoked when a file is selected in the [Project](#) tool window or opened in the editor.
- The Move File dialog box is invoked when a file opened in the editor.

**ItemDescription**

---

To package	Specify the destination package. Type the path manually or click <input type="checkbox"/> and select the target package in the <a href="#">dialog that opens</a> .
Search in comments and strings	Select the checkbox to find and update the comments and strings to the file being moved.
Open moved in editor	Select this checkbox to see the moved file in the editor.

The dialog box is available only if the PHP plugin is installed and enabled. The plugin is not bundled with IntelliJ IDEA, but it can be installed from the [JetBrains plugin repository](#) as described in [Installing, Updating and Uninstalling Repository Plugins](#) and [Enabling and Disabling Plugins](#).

The dialog box opens when you select a PHP namespace to be moved and choose Refactor | Move on the main menu or on the context menu of the selection.

IntelliJ IDEA supposes that the namespaces in your project are arranged in compliance with the [PSR0 standard](#) and enforces you to retain the folder structure and the namespace hierarchy in accordance with this standard when moving namespaces.

When you specify a namespace to move a namespace to, IntelliJ IDEA automatically updates the Target Destination Directory field, which shows the path to the folder that corresponds to the namespace in question.

#### ItemDescription

**New Namespace Name** When the dialog box opens, the field shows the fully qualified name of the selected namespace. Specify the new namespace name. Use only backslashes ( \ ) as namespace separators.

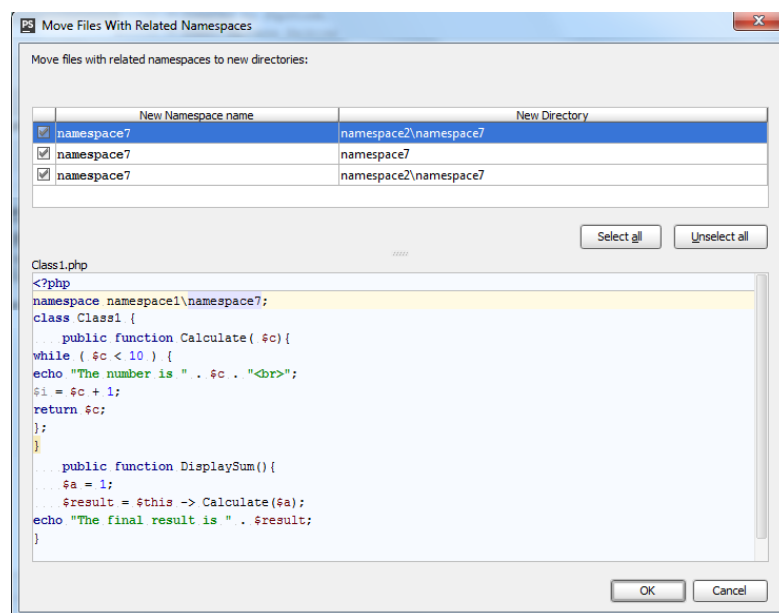

**Target Destination Directory** When the dialog box opens, the field shows the path to the folder which corresponds to the current namespace. The path is displayed in the format `...\<project root folder>\<path to the current namespace folder relative to the project root>`. The path is updated automatically as you specify the new namespace name. However, if you are going to move a namespace to another parent namespace, IntelliJ IDEA will not suggest the proper folder unless you appoint a root folder for your namespace structure by marking the relevant folder as Sources on the Directories page of the Settings dialog box.

Do one of the following:

- Accept the preselected path displayed in the field.
- Choose another path from the list. All of them are evaluated from the namespace root or from the current directory, so it is safe to choose any of them.
- Click  and select a folder in the dialog box that opens.
- Press **F2** and edit the preselected path. Keep in mind that this may cause problems with automatic loading in the future.

**Refactor** Click this button to open the Move Files with Related Namespaces dialog box and specify the classes and files to be moved to the new namespace and the new folder.

The upper pane of the dialog box lists the destination namespaces and folders for classes and files related to the namespace in question. Each item in the list corresponds to a class/file. When you move the cursor to an item, the bottom pane shows the contents of the file related with it.

- To have a class and the corresponding file moved to the destination namespace and the destination folder, select the checkbox next to the namespace/folder.
- To add all the items to the list or remove all of them from the list, click Select All or Unselect All respectively.

**ItemDescription**

---

Select migration map	Select the desired migration map from the drop-down list. By default, only Swing 1.0.3.to 1.1 migration map is present.
Edit	Click this button to change the selected migration map, using the Edit Migration Map dialog.
New	Click this button to create your own migration map, using the Edit Migration Map dialog.
Remove	Click this button to delete the selected migration map from the list.

Use this dialog to pull selected members up to the selected superclass or an interface, or interface to a superinterface.

**ItemDescription**

---

Pull Up Members of <class_name> to	Select the destination object (superclass or interface).
Members to be pulled up	In this area, select the members you want to move.
Make abstract	Select this checkbox to move the selected method as abstract.
JavaDoc for abstracts	In this area, select the action to be applied on the JavaDoc. <ul style="list-style-type: none"><li>- To leave it where it is, select the As is option.</li><li>- To copy it to the destination superclass (subclass) or interface (subinterface), select the Copy option.</li><li>- To move it to the destination subclass or subinterface, select the Move option.</li></ul>

Use this dialog to push selected members down to immediate subclass.

**ItemDescription**

---

Members to be pushed down      In this area, select the members you want to move.

---

Keep abstract      Select this checkbox to preserve moved method as abstract.

---

JavaDoc for abstracts      In this area, select the action to be applied on the JavaDoc.  
- To leave it where it is, select the As is option.  
- To copy it to the destination superclass (subclass) or interface (subinterface), select the Copy option.  
- To move it to the destination subclass or subinterface, select the Move option.

Shift+F6

The Rename dialogs let you perform the [Rename refactoring](#) for various entities such as classes, fields, methods, packages, etc. You can select where the changes to occurrences of the entity name are required and where not.

- [Rename Dialog for a Class or an Interface](#)
- [Rename Dialog for a Directory](#)
- [Rename Dialog for a Field](#)
- [Rename Dialog for a File](#)
- [Rename Dialog for a Method](#)
- [Rename Dialog for a Package](#)
- [Rename Dialog for a Parameter](#)
- [Rename Dialog for a Table or Column](#)
- [Rename Dialog for a Variable](#)

Shift+F6

Use this dialog to rename a class or an interface.

In addition to renaming the class or the interface itself, IntelliJ IDEA can also look for the usages of the class or the interface name. If found, the changes you are making to the class or the interface name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

#### ItemDescription

Rename <class or interface> and its usages to

**Search in comments and strings** If this checkbox is selected, IntelliJ IDEA will look for occurrences of the class or the interface name within comments and string literals in your source code files.

**Search for text occurrences** If this option is on, IntelliJ IDEA will look for occurrences of the class or the interface name in the files that don't contain source code. These may be the text files, properties files, HTML files, documentation files, etc.

**Rename variables** If this option is on, IntelliJ IDEA will look for occurrences of the class or the interface name in the names of variables. Note that only the variables that have the type of the class or the interface you are renaming will be taken into account.

To illustrate, let's assume that you are renaming the class `MyClass` and there are the variables `MyClass myclass`, `MyClass myclass20`, `MyClass m` and `YourClass myclass25`. In such a case, IntelliJ IDEA will suggest to rename the first and the second of the variables but won't suggest to rename the third and the fourth.

**Rename inheritors** If this option is on, IntelliJ IDEA will look for occurrences of the class or the interface name in the names of its inheritors:

- if you are renaming a class, IntelliJ IDEA will search the hierarchies of the classes that extend this class.
- if you are renaming an interface, IntelliJ IDEA will search the hierarchies of the interfaces that extend this interface and the hierarchies of the classes that implement this interface.

**Rename tests** If this option is on, IntelliJ IDEA will look for occurrences of the class name in the names of the test classes.

**Rename bound forms** This option is available if the class you are renaming has an associated GUI form. Select this checkbox to rename the associated form.

Shift+F6

---

Use this dialog to rename a directory.

In addition to renaming the directory itself, IntelliJ IDEA can also look for the usages of the directory name. If found, the changes you are making to the directory name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

**ItemDescription**

---

Rename <directory> and its usages to Specify a new name for the directory.

---

Search for references If this option is on, IntelliJ IDEA will look for occurrences of the directory name in directory references in source code files.  
Whether or not a string literal is a reference is defined by the (programming) language used in a source file.

---

Search in comments and strings If this checkbox is selected, IntelliJ IDEA will look for occurrences of the directory name within comments and string literals in your source code files.

Shift+F6

---

Use this dialog to rename a field.

In addition to renaming the field itself, IntelliJ IDEA can also look for the usages of the field name. If found, the changes you are making to the field name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

---

**ItemDescription**

---

Rename <field> and its usages to	Specify a new name for the field.
-------------------------------------	-----------------------------------

---

Search in comments and strings	If this checkbox is selected, IntelliJ IDEA will look for occurrences of the field name within comments and string literals in your source code files.
--------------------------------------	--

---

Search for text occurrences	If this option is on, IntelliJ IDEA will look for occurrences of the field name in the files that don't contain source code. These may be the text files, properties files, HTML files, documentation files, etc.
--------------------------------	---

Shift+F6

---

Use this dialog to rename a file.

In addition to renaming the file itself, IntelliJ IDEA can also look for the usages of the file name. If found, the changes you are making to the file name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

**ItemDescription**

---

Rename <file> and its usages to Specify a new name for the file.

---

Search for references If this option is on, IntelliJ IDEA will look for occurrences of the file name in file references in source code files. Whether or not a string literal is a reference is defined by the (programming) language used in a source file.

---

Search in comments and strings If this checkbox is selected, IntelliJ IDEA will look for occurrences of the file name within comments and string literals in your source code files.

Shift+F6

---

Use this dialog to rename a method.

In addition to renaming the method itself, IntelliJ IDEA can also look for the usages of the method name. If found, the changes you are making to the method name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

---

**ItemDescription**

---

Rename <method> and its usages to Specify a new name for the method.

---

Search in comments and strings If this checkbox is selected, IntelliJ IDEA will look for occurrences of the method name within comments and string literals in your source code files.

---

Search for text occurrences If this option is on, IntelliJ IDEA will look for occurrences of the method name in the files that don't contain source code. These may be the text files, properties files, HTML files, documentation files, etc.

Shift+F6

---

Use this dialog to rename a package.

In addition to renaming the package itself, IntelliJ IDEA can also look for the usages of the package name. If found, the changes you are making to the package name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

**ItemDescription**

---

Rename <package> and its usages to	Specify a new name for the package.
Search in comments and strings	If this checkbox is selected, IntelliJ IDEA will look for occurrences of the package name within comments and string literals in your source code files.
Search for text occurrences	If this option is on, IntelliJ IDEA will look for occurrences of the package name in the files that don't contain source code. These may be the text files, properties files, HTML files, documentation files, etc.

Shift+F6

---

Use this dialog to rename a parameter.

In addition to renaming the parameter itself, IntelliJ IDEA can also look for the usages of the parameter name. If found, the changes you are making to the parameter name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

---

**ItemDescription**

---

Rename <parameter> and its usages to	Specify a new name for the parameter.
--------------------------------------	---------------------------------------

---

Search in comments and strings	If this checkbox is selected, IntelliJ IDEA will look for occurrences of the parameter name within comments and string literals in your source code files.
--------------------------------	--

Shift+F6

---

Use this dialog to rename a table or column.

In addition to renaming the table or column itself, IntelliJ IDEA can also look for the usages of the table or column name. If found, the changes you are making to the table or column name can also be applied to these usages.

**Item**

Description	
Rename <table or column> and its usages to	Specify a new name for the table or column.
Search in comments and strings	If this checkbox is selected, IntelliJ IDEA will look for occurrences of the table or column name within comments and string literals in your source code files.
SQL Script	The statement to be run to rename the table or column. If necessary, you can edit the statement right in this pane.
Refactor	Execute the statement and make associated changes right away.
Preview	Preview potential associated changes prior to executing the statement. See <a href="#">Previewing changes</a> .

Shift+F6

---

Use this dialog to rename a variable.

In addition to renaming the variable itself, IntelliJ IDEA can also look for the usages of the variable name. If found, the changes you are making to the variable name can also be applied to these usages.

The usages are assigned to different categories which correspond to the options which you can turn on and off.

Note that regardless of the options selected, the search scope (that is, the places where the name occurrences are looked for) is always limited to the current entity (file, class, etc) and the entities that the current one depends on.

---

**ItemDescription**

---

Rename <variable> and its usages to	Specify a new name for the variable.
-------------------------------------	--------------------------------------

---

Search in comments and strings	If this checkbox is selected, IntelliJ IDEA will look for occurrences of the variable name within comments and string literals in your source code files.
--------------------------------	---

The Replace Constructor with Builder refactoring helps hide a constructor, replacing its usages with the references to a newly generated builder class, or to an existing builder class.

#### ItemDescription

---

### Parameters to pass to the builder

Parameter	This column shows the list of parameters detected in the constructor, which will be replaced with the builder fields.
Field name	This editable column shows the list of suggested field names in the builder.
Setter name	This editable column shows the list of suggested setter names in the builder.
Default value	Use this editable column to initialize the fields with the default values.
Optional setter	If the specified default value of a field matches the parameter value in the constructor invocation, then selecting this checkbox results in omitting setter method for this field in the builder invocation.  If this checkbox is not selected, the corresponding setter method will be shown anyway.

### Builder name and location

Create new	Click this radio button to generate a new builder class, with the specified name and destination package.
Builder class name	This editable field shows the suggested name of the new builder class to be generated. You can accept default, or type a new one.
Package for new builder	Type the name of the destination package, or click the browse button, and locate it in the Choose Destination Package dialog box.  If the desired package doesn't exist, click  to create a new one.
Use existing	Click this radio button to specify an existing builder class.
Builder class name	Type here the fully qualified name of the desired builder class that already exists in your project, or click the browse button and find it either by name, or in the project tree view.

**ItemDescription**

---

Factory method name	Specify here the name for the factory method.
In (fully qualified name)	Specify here the class, where the method will be created.

**ItemDescription**

Replace with delegation inheritance from	Select here the parent object, inheritance to which will be replaced.
Field name	Specify the name for the field of the new inner class.
Inner class name	In this field specify the name for the inner class definition.
Delegate members	In this area, select the members of the parent class, that will be delegated through the inner class.
Generate getter for delegated component	Check this option to create a getter for the inner class.

The Replace Method Code Duplicates allows you to find code repetitions similar to the selected method, and replace them with calls to the method.

**ItemDescription**

---

Name	Specify the name for the extracted method.
Declare static	Check this option to declare the method static. This option is enabled when the initial expression is static itself.
Parameters	In this area, select the parameters you want to be used in the extracted method. The parameters are all checked by default. If unchecked, the appropriate value will be used as a local variable in the extracted method.
Move Up/Down	Use this buttons to reorder parameters in the list.
Visibility	Here you can change the method's visibility scope.

Alt+Delete

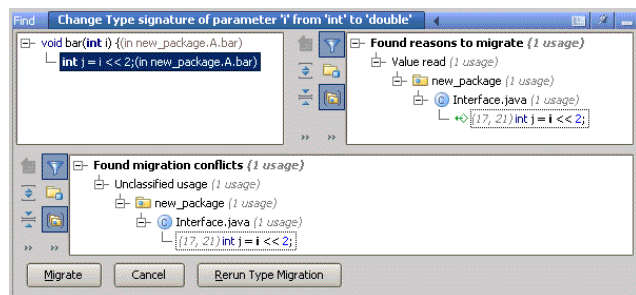

Use this dialog to define the scope of the [Safe delete](#) refactoring.

**ItemDescription**

---

Search in comments and strings	Select this checkbox to display the usages of the specified symbol in comments and strings in the Refactoring Preview tool window.
Search for text occurrences	Select this checkbox to apply the changes text files within the project (such as documentation, HTML, JSP, etc.)

This view allows you to review type migration results and correct the scope of changes by excluding/including items from/to the refactoring.

The view consists of the following panes:

- The upper left pane displays the tree view of the items to be refactored. The root item in this tree view is the one you meant to refactor. Nodes represent all pieces of code that depend on this type.
- The upper right pane is a common Find Usages view.
- The bottom pane shows conflicts found.

Toolbar options for both upper right and bottom panes are similar to those of the [Find](#) tool window.

Here context menu options for the upper left pane are described.

#### Item ShortcutDescription

Exclude	Delete	Select to exclude the item from the refactoring. It won't be changed.
Include	Insert	Select to include item to the refactoring.
Jump to Source	F4	Opens in the editor the file that contains the selected code fragment, and places the caret at the type.

**ItemDescription**

---

Change usages	Select the parent class or interface, which will replace the usages of the current class.
Use interface/superclass in <code>instanceof</code>	If this option is checked, IntelliJ IDEA scans the source code for the presence of the <code>instanceof</code> statements for the selected superclass or interface, and change it, if found.

---

Use this refactoring to create a wrapper class around the return values of a method, or use a compatible existing class as a wrapper.

**ItemDescription**

---

Method to wrap returns from	This read-only field shows the name of the selected method.
Create new class	Click this radio-button to create a new wrapper class. If this option is selected, specify the class and destination package name in the fields below.
Class name	Type the name of the new wrapper class.
Package name	By default, the current package name is displayed. You can type a different package name in the text field, or click the ellipsis button and select the destination package from the tree view. If the desired package doesn't exist, click  to create a new one.
Target destination directory	<p>Use this field to select the target destination directory. By default, the current destination directory is displayed. You usually choose the target destination based on a current package. If this package exists in multiple roots, you can click arrow button and select Leave in same source root from the list. In this case, wrapper would be placed near the initial class.</p> <p>You can click the ellipsis button to open Choose Destination Directory window.</p> <p>You can choose Directory Structure tab to select another destination directory or choose Choose By Neighbor Class tab to place a wrapper near the neighbor class if, for example, you want to put the wrapper in <code>util</code> directory near your Pair or Triple classes and you do not remember the exact package, putting wrapper near the Pair class would save you time.</p>
Use existing class	Click this radio-button to use an existing class of your choice as a wrapper.
Name	<p>Specify the name of the desired wrapper class. Note that such class should contain a constructor with a parameter of the same type as the return value in question.</p> <p>You can type the fully-qualified class name in the text field, or click the ellipsis button and choose the desired class in the Select parameter class dialog box. Note that you can select the desired wrapper class both from the project and non-project classes.</p>
Wrapper field	Select the field that will store the return value, from the drop-down list of fields, encountered in the specified wrapper class.
Inner class	Click this radio-button to create an inner class. You might want to do that if, for example, you have a private method. In this case you can leave everything in the same class.
Name	Specify the name of the inner class.

Shift+Alt+F10

Shift+Alt+F9

Use this dialog box to create, edit, or remove run/debug configurations, and configure the default settings that will apply to all newly created run/debug configurations.

Click [here](#) for the description of the options that are common for all run/debug configurations.

The default settings are grouped under the Defaults node in the left-hand part of the dialog box.

## Toolbar

### ItemShortcutDescription

	Alt+Insert	Click this button to add a new configuration to the list.
	Alt+Delete	Click this button to remove the selected configuration from the list.
	Ctrl+D	Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	Alt+Up or Alt+Down	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of a new run/debug configuration. This field is not available for the <a href="#">default run/debug configurations</a> .
Defaults	This node in the left-hand pane contains the default run/debug configuration settings. Select configuration to modify its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	<p>Select this check box to make the run/debug configuration available to other team members.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate .xml file in the <code>.idea/runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea/workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p> <p>This check box is not available when editing the run/debug configuration defaults.</p>

**Before launch** Use the controls in this area to specify which tasks must be performed before applying the run/debug configuration. The tasks are performed in the order they appear in the list. The following options are available:

- ( Alt+Insert ): click this icon to add a task to the list. Select one of the following task types:
  - Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see [Configuring Third-Party Tools](#) and [External Tools](#) .
  - Run Another Configuration : select this option to execute one on the existing run/debug configuration. Choose a configuration to execute from the dialog box that opens.
  - Make : select this option to have the project or the module compiled. The [Make Module command](#) will be executed if a particular module is specified in the run/debug configuration, or the [Make Project command](#) if no modules are specified.
  - Make, no error check : this option is the same as Make , the only difference being is that IntelliJ IDEA will start the run/debug configuration irrespective of the compilation result.
  - Build Artifacts : select this option to build [artifacts](#) . Select the artifact(s) you want to build in the dialog that opens. For more information, see [Working with Artifacts](#) .
  - Run Ant target : select this option to execute an Ant target. In the dialog that opens select a target that you want to build. For more information, see [Ant](#) .
  - Run Maven goal : select this option to run a Maven goal. In the dialog that opens, select a goal that you want to

- run. For more information, see [Maven](#) .
- Run Gradle task : select this option to run a Gradle task. In the dialog that opens, select a task that you want to run. For more information, see [Gradle](#)
  - Compile TypeScript : select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:
    - If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.
    - If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.
  - Run File Watcher : select this option to run the File Watchers that are active in the current project. For more information, see [Using File Watchers](#) .
  - Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#) .
  - Run Remote External tool : select this option to run a remote SSH external tool. In the dialog that opens, specify the SSH external tool that you want to run. For more information, see [Remote SSH External Tools](#) .
-  ( Alt+Delete ) : click this icon to remove the selected task from the list.
  -  ( Enter ) : click this icon to modify the selected task. Edit the task settings in the dialog that opens.
  -  ( Alt+Up ) : click this icon to move the selected task up in the list.
  -  ( Alt+Down ) : click this icon to move the selected task down in the list.
- Show this page : select this check box if you want to display the run/debug configuration settings before applying it.
  - Active tool window : select this option if you want the Run /Debug tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

## Defaults

### ItemDescription

Confirm rerun with process termination	<p>The behavior of this checkbox depends on whether the Single instance only checkbox is selected for a particular run/debug configuration.</p> <ul style="list-style-type: none"> <li>- If this checkbox is selected, then, in case of a single instance, launching a new process (for example, by clicking  on the main toolbar) while another process is still running, results in showing a dialog box prompting to terminate the current process before launching a new one.</li> <li>- If this checkbox is not selected (or in case of multiple instances), IntelliJ IDEA starts the new process silently.</li> </ul>
Temporary configurations limit	Specify here the maximum number of temporary configurations to be stored and shown in the Select Run/Debug Configuration drop-down list.

Use this dialog box to create configurations used to run or debug Android applications and activities on actual or virtual devices.

This dialog box consists of three tabs:

- [General](#)
- [Miscellaneous](#)
- [Profiling](#)

The dialog also provides a [toolbar](#) and the [options that are common](#) to all run/debug configuration types.

## General Tab

### ItemDescription

Module	From this drop-down list, select a module to which this configuration will be applied.
Installation Options	<p>Use this area to configure the following settings:</p> <ul style="list-style-type: none"><li>- Deploy - use this drop-down list to appoint the <code>.apk</code> file that will be deployed to the target virtual or physical device. You can select one of the following options:<ul style="list-style-type: none"><li>- Default APK - select this option to have IntelliJ IDEA upload the <code>.apk</code> built from the module specified in the Module drop-down list above. The <code>.apk</code> is built automatically, no preliminary artifact configuration is required from your side.</li><li>- Custom Artifact - select this option to have IntelliJ IDEA upload the <code>.apk</code> built from the code and resources appointed in a manually configured artifact. Select an artifact from the drop-down list which shows all manually created artifact definitions for the selected module. See <a href="#">Working with Artifacts</a> for details.</li><li>- Nothing - select this option to suppress uploading data to the device. This approach may be helpful if you have already deployed your application manually outside IntelliJ IDEA.</li></ul></li><li>- Install Flags - use this field to specify options for the <code>pm install</code> command.</li></ul> <p>For more information, see the <a href="#">package manager</a> page.</p>
Launch Options	<p>In this area, appoint the activity that will be launched on the application start.</p> <ul style="list-style-type: none"><li>- Launch - use this drop-down list to specify the following launch settings:<ul style="list-style-type: none"><li>- Default Activity - select this option to have IntelliJ IDEA automatically launch the <a href="#">activity marked as start-up</a>.</li><li>- Nothing - select this option to connect to an already running application provided that you have chosen Nothing in the Installation Options area. Executing a run configuration with these settings is the same as clicking the Attach debugger to Android process button  on the toolbar.</li><li>- Specified Activity - select this option to have IntelliJ IDEA launch an activity of your choice upon the application start. This option may be helpful when you want to run or debug a part of your application and have already chosen the Custom Artifact option in the Installation Options area. Type the activity name manually or click the Browse button  and select it in the Select Activity Class dialog box that opens. The list of available activities is determined by the choice of the module.</li><li>- URL - select this option to launch a browser when you run your application. You can specify the URL address in the URL field.</li></ul></li><li>- Launch Flags - use this field to specify additional options for the <code>am start</code> command.</li></ul> <p>For more information, see the <a href="#">activity manager</a> page.</p>
Deployment Target Options	<p>In this area, select the type of device to run/debug the application on. The available options are:</p> <ul style="list-style-type: none"><li>- Show Device Chooser Dialog: select this option to have IntelliJ IDEA display the <a href="#">Choose Device</a> dialog box upon the application start. If you want to automatically use the device chosen through the Choose Device dialog in the future, select the Use same device for future launches option.</li><li>- USB Device: select this option to have IntelliJ IDEA detect a plugged-in USB device upon the application start.</li></ul> <div data-bbox="193 1464 976 1529" style="background-color: #ffff00; padding: 5px;"><p><b>Note</b> Selecting the Show Device Chooser Dialog or USB Device option may be helpful if you are going to run the application on a physical device which will be plugged in later and therefore the set of available devices cannot be foreseen.</p></div> <ul style="list-style-type: none"><li>- Emulator: select this option to use one of the configured device emulators. From the Prefer Android Virtual Device drop-down list, select a virtual device that will be used to run/debug the specified activity. If you want to add/edit a virtual device configuration, click the Browse button  to launch the Android Virtual Device (AVD) Manager (see <a href="#">Managing Virtual Devices</a> for details).</li></ul>

## Miscellaneous Tab

In this tab, configure the scope of log data shown during a run/debug session.

### ItemDescription

Logcat	<p>Use this area to configure logcat settings for your Android run/debug configuration:</p> <ul style="list-style-type: none"><li>- Show logcat automatically : select this checkbox to show logcat automatically every time an application is deployed and launched successfully.</li><li>- Clear log before launch : select this checkbox if you want data from previous sessions to be removed from the log file before starting the application.</li></ul>
Installation Options	<p>Use this area to configure the installation options for running or debugging your Android application:</p> <ul style="list-style-type: none"><li>- Skip installation if APK has not changed : select this checkbox to skip APK installation when you run your application if the APK has not changed.</li><li>- Force stop running application before launching activity : select this checkbox to stop running an already launched application before you start running the activity from IntelliJ IDEA.</li></ul>

## Profiling Tab

In this tab, specify the Graphic Trace options.

### ItemDescription

Disable precompiled shaders and programs	Select this checkbox if you want to disable precompiled shaders and programs and compile them at the runtime instead.
--	---

## Toolbar

### ItemShortcutDescription

		Click this button to add a new configuration to the list.
		Click this button to remove the selected configuration from the list.
		Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	 or 	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of a new run/debug configuration. This field is not available for the <a href="#">default run/debug configurations</a> .
Defaults	This node in the left-hand pane contains the default run/debug configuration settings. Select configuration to modify its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	Select this check box to make the run/debug configuration available to other team members. If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate .xml file in the <code>.idea/runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea/workspace.xml</code> file otherwise.  If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.  This check box is not available when editing the run/debug configuration defaults.

Before launch Use the controls in this area to specify which tasks must performed before applying the run/debug configuration. The tasks are performed in the order they appear in the list. The following options are available:

-   : click this icon to add a task to the list. Select one of the following task types:
  - Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see [Configuring Third-Party Tools](#) and [External Tools](#) .
  - Run Another Configuration : select this option to execute one on the existing run/debug configuration. Choose a configuration to execute from the dialog box that opens.
  - Make : select this option to have the project or the module compiled. The [Make Module command](#) will be executed if a particular module is specified in the run/debug configuration, or the [Make Project command](#) if no modules are specified.
  - Make, no error check : this option is the same as Make , the only difference being is that IntelliJ IDEA will start the run/debug configuration irrespective of the compilation result.
  - Build Artifacts : select this option to build [artifacts](#) . Select the artifact(s) you want to build in the dialog that opens. For more information, see [Working with Artifacts](#) .
  - Run Ant target : select this option to execute an Ant target. In the dialog that opens select a target that you want to build. For more information, see [Ant](#) .
  - Run Maven goal : select this option to run a Maven goal. In the dialog that opens, select a goal that you want to run. For more information, see [Maven](#) .
  - Run Gradle task : select this option to run a Gradle task. In the dialog that opens, select a task that you want to run. For more information, see [Gradle](#) .
  - Compile TypeScript : select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:
    - If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.
    - If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.

- Run File Watcher : select this option to run the **File Watchers** that are active in the current project. For more information, see [Using File Watchers](#) .
- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#) .
- Run Remote External tool : select this option to run a remote SSH external tool. In the dialog that opens, specify the SSH external tool that you want to run. For more information, see [Remote SSH External Tools](#) .
-  ( [Alt+Delete](#) ) : click this icon to remove the selected task from the list.
-  ( [Enter](#) ) : click this icon to modify the selected task. Edit the task settings in the dialog that opens.
-  ( [Alt+Up](#) ) : click this icon to move the selected task up in the list.
-  ( [Alt+Down](#) ) : click this icon to move the selected task down in the list.
- Show this page : select this check box if you want to display the run/debug configuration settings before applying it.
- Active tool window : select this option if you want the [Run /Debug](#) tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

Use this dialog box to configure testing of Android applications and activities on actual or virtual devices.

The dialog box consists of three tabs:

- [General](#)
- [Emulator](#)
- [Logcat](#)

The dialog also provides a [toolbar](#) and the [options that are common](#) to all run/debug configuration types.

## General Tab

### ItemDescription

Module	From this drop-down list, select the module to which this configuration will be applied.
Test	<p>In this area, specify the location of tests that you want to apply:</p> <ul style="list-style-type: none"><li>– All in module : select this option if you want to launch all tests from the selected module.</li><li>– All in package : select this option if you want to launch all tests from a specific package. In the Package text box, specify the package where tests are located. Type the package name manually or click the Browse button  and select the desired package in the dialog that opens.</li><li>– Class : select this option if you want to launch tests of a specific class. In the Class text box, specify the required class. Type the class name manually or click the Browse button  and select the desired class in the dialog that opens.</li><li>– Method : select this option if you want to launch a specific test method. In the Class text box, specify the class to which this method belongs. In the Method text box, specify the desired method. Type the names manually or click the Browse button  and select the desired class and method in the dialog that opens.</li></ul>

Specific instrumentation runner	In this text box, specify the location of the desired <a href="#">instrumentation runner</a> . Type the path manually or click the Browse button  and select the location in the dialog that opens.
---------------------------------	--

Deployment Target Options	<p>In this area, select the type of device to run/debug the application on. The available options are:</p> <ul style="list-style-type: none"><li>– Show Device Chooser Dialog: select this option to have IntelliJ IDEA display the <a href="#">Choose Device</a> dialog box upon the application start. If you want to automatically use the device chosen through the Choose Device dialog in the future, select the Use same device for future launches option.</li><li>– USB Device: select this option to have IntelliJ IDEA detect a plugged-in USB device upon the application start.</li></ul>
---------------------------	--

**Note** Selecting the Show Device Chooser Dialog or USB Device option may be helpful if you are going to run the application on a physical device which will be plugged in later and therefore the set of available devices cannot be foreseen.

- Emulator: select this option to use one of the configured device emulators. From the Prefer Android Virtual Device drop-down list, select a virtual device that will be used to run/debug the specified activity. If you want to add/edit a virtual device configuration, click the Browse button  to launch the Android Virtual Device (AVD) Manager (see [Managing Virtual Devices](#) for details).

## Emulator Tab

In this tab, specify additional configuration settings for launching the Android emulator.

### ItemDescription

Network Speed	From this drop-down list, select the <a href="#">network transfer rate</a> to be emulated.
Network Latency	<p>Use this drop-down list to specify the time delay between the initial input and the output. You can select between the following <a href="#">latency levels</a> :</p> <ul style="list-style-type: none"><li>– None : no latency</li><li>– GPRS : GPRS (min 150, max 550 milliseconds)</li><li>– EDGE : EDGE/EGPRS (min 80, max 400 milliseconds)</li><li>– UMTS : UMTS/3G (min 35, max 200 milliseconds)</li></ul>
Wipe user data	Select this checkbox to have the contents of the user-data image copied to the new user-data disk image while resetting the image. By default, the <code>&lt;system&gt;/userdata.img</code> is copied.
Disable boot animation	Select this checkbox if you do not want an animated boot screen displayed upon the emulator start-up.
Additional command line options	In this text box, type the additional options to be passed to the emulator via the command line. For lengthy command lines, click the  button and type the text in the Emulator Additional Command Line Options dialog that opens.

## Logcat Tab

### ItemDescription

Clear log before launch	Select this checkbox if you want data from previous sessions to be removed from the log before starting the application.
-------------------------	--

## Toolbar

### ItemShortcutDescription

		Click this button to add a new configuration to the list.
		Click this button to remove the selected configuration from the list.
		Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	 or 	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of a new run/debug configuration. This field is not available for the <a href="#">default run/debug configurations</a> .
Defaults	This node in the left-hand pane contains the default run/debug configuration settings. Select configuration to modify its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	<p>Select this check box to make the run/debug configuration available to other team members.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate .xml file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p> <p>This check box is not available when editing the run/debug configuration defaults.</p>
Before launch	<p>Use the controls in this area to specify which tasks must be performed before applying the run/debug configuration. The tasks are performed in the order they appear in the list. The following options are available:</p> <ul style="list-style-type: none"> <li>-  ( ): click this icon to add a task to the list. Select one of the following task types: <ul style="list-style-type: none"> <li>- Run External tool: Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see <a href="#">Configuring Third-Party Tools</a> and <a href="#">External Tools</a> .</li> <li>- Run Another Configuration : select this option to execute one on the existing run/debug configuration. Choose a configuration to execute from the dialog box that opens.</li> <li>- Make : select this option to have the project or the module compiled. The <a href="#">Make Module command</a> will be executed if a particular module is specified in the run/debug configuration, or the <a href="#">Make Project command</a> if no modules are specified.</li> <li>- Make, no error check : this option is the same as Make , the only difference being is that IntelliJ IDEA will start the run/debug configuration irrespective of the compilation result.</li> <li>- Build Artifacts : select this option to build <a href="#">artifacts</a> . Select the artifact(s) you want to build in the dialog that opens. For more information, see <a href="#">Working with Artifacts</a> .</li> <li>- Run Ant target : select this option to execute an Ant target. In the dialog that opens select a target that you want to build. For more information, see <a href="#">Ant</a> .</li> <li>- Run Maven goal : select this option to run a Maven goal. In the dialog that opens, select a goal that you want to run. For more information, see <a href="#">Maven</a> .</li> <li>- Run Gradle task : select this option to run a Gradle task. In the dialog that opens, select a task that you want to run. For more information, see <a href="#">Gradle</a> .</li> <li>- Compile TypeScript : select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected: <ul style="list-style-type: none"> <li>- If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.</li> <li>- If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.</li> </ul> </li> <li>- Run File Watcher : select this option to run the <a href="#">File Watchers</a> that are active in the current project. For more information, see <a href="#">Using File Watchers</a> .</li> <li>- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see <a href="#">CoffeeScript</a> .</li> <li>- Run Remote External tool : select this option to run a remote SSH external tool. In the dialog that opens, specify the SSH external tool that you want to run. For more information, see <a href="#">Remote SSH External Tools</a> .</li> </ul> </li> <li>-  ( ): click this icon to remove the selected task from the list.</li> <li>-  ( ): click this icon to modify the selected task. Edit the task settings in the dialog that opens.</li> <li>-  ( ): click this icon to move the selected task up in the list.</li> <li>-  ( ): click this icon to move the selected task down in the list.</li> <li>- Show this page : select this check box if you want to display the run/debug configuration settings before applying it.</li> <li>- Active tool window : select this option if you want the <a href="#">Run /Debug</a> tool windows to be activated automatically when</li> </ul>

you run/debug your application. This option is enabled by default.

This feature is only supported in the Ultimate edition.

**Warning!** The following is only valid when Python Plugin is installed and enabled!

Use this dialog box to create a run/debug configuration for App Engine server .

## Configuration tab

### ItemDescription

Port	In this text box, specify the port number where the server will start.
Additional options	In this field, type the additional options to be passed to the server. Refer to the following resources for details: <ul style="list-style-type: none"><li>– Google App Engine <a href="#">command line arguments</a></li><li>– Django server <a href="#">command line arguments</a></li></ul>
Run browser	Select this check box, if you want your Google App Engine application to open in the default browser. In the text field below, enter the IP address where your application will be opened.
Environment	
Project	Click this drop-down list to select one of the projects, <a href="#">opened in the same IntelliJ IDEA window</a> , where this run/debug configuration should be used. If there is only one open project, this field is not displayed.
Environment variable	This field shows the list of environment variables. If the list contains several variables, they are delimited with semicolons.  To fill in the list, click the browse button, or press <code>Shift+Enter</code> and specify the desired set of environment variables in the Environment Variables dialog box.  To create a new variable, click <code>+</code> , and type the desired name and value.
Python Interpreter	
Interpreter options	In this field, specify the string to be passed to the interpreter. If necessary, click <code>+</code> , and type the string in the editor.
Working directory	Specify a directory to be used by the running task. <ul style="list-style-type: none"><li>– When a default run/debug configuration is created by the keyboard shortcut <code>Ctrl+Shift+F10</code> , or by choosing Run on the context menu of a script, the working directory is the one that contains the executable script. This directory may differ from the project directory.</li><li>– When this field is left blank, the <code>bin</code> directory of the IntelliJ IDEA installation will be used.</li></ul>
Path mappings	This field appears, if a remote interpreter has been selected in the field Python interpreter .  Click the browse button <code>...</code> to define the required mappings between the local and remote paths. In the Edit Path Mappings dialog box, use <code>+</code> / <code>-</code> buttons to create new mappings, or delete the selected ones.
Add content roots to PYTHONPATH	Select this check box to add all <a href="#">content roots</a> of your project to the environment variable PYTHONPATH;
Add source roots to PYTHONPATH	Select this check box to add all <a href="#">source roots</a> of your project to the environment variable PYTHONPATH;

**Warning!** This field only appears when [Docker-based remote interpreter](#) has been selected for a project.

**Note** Speaking about the correspondence of settings with some options (`--net` , `--link` , etc.), note that these options come from [Docker command line arguments](#) .

Click `...` to open the dialog and specify the following settings:

- Disable networking : select this checkbox to have the networking disabled. This corresponds to `--net="none"` , which means that inside a container the external network resources are not available.
- Network mode : corresponds to the other values of the option `--net` .
  - `bridge` is the default value. An IP address will be allocated for container on the bridge's network and traffic will be routed though this bridge to the container.

Containers can communicate via their IP addresses by default. To communicate by name, they must be linked.

- `host` : use the host's network stack inside the container.
- `container:<name|id>` : use the network stack of another container, specified via its name or id .

Refer to the [Network settings](#) documentation for details.

- Links : Use this section to link the container to be created with the other containers. This is applicable to `Network mode = bridge` and corresponds to the `--link` option.
- Publish all ports : This corresponds to the option `--publish-all` .
- Port bindings : Use this field to specify the
- Extra hosts : This corresponds to the `--add-host` option. Refer to the page [Managing /etc/hosts](#) for details.
- Volume bindings : Use this field to specify the bindings between the special folders- volumes and the folders of the computer, where the Docker daemon runs. This corresponds to the `-v` option.

See [Managing data in containers](#) for details.

- Environment variables : Use this field to specify the list of environment variables and their values. This corresponds to the `-e` option. Refer to the page [ENV \(environment variables\)](#) for details.

Click  to expand the tables. Click ,  or  to make up the lists.

## Logs tab

Use this tab to specify which log files generated while running or debugging should be displayed in the console, that is, on the dedicated tabs of the [Run](#) or [Debug tool window](#).

### ItemDescription

Is Active	Select check boxes in this column to have the log entries displayed in the corresponding tabs in the <a href="#">Run tool window</a> or <a href="#">Debug tool window</a> .
Log File Entry	The read-only fields in this column list the log files to show. The list can contain: <ul style="list-style-type: none"><li>– Full paths to specific files.</li><li>– <a href="#">Ant patterns</a> that define the range of files to be displayed.</li><li>– Aliases to substitute for full paths or patterns. These aliases are also displayed in the headers of the tabs where the corresponding log files are shown. If a log entry pattern defines more than one file, the tab header shows the name of the file instead of the log entry alias.</li></ul>
Skip Content	Select this check box to have the previous content of the selected log skipped.
Save console output to file	Select this check box to save the console output to the specified location. Type the path manually, or click the browse button and point to the desired location in the <a href="#">dialog that opens</a> .
Show console when a message is printed to standard output stream	Select this check box to activate the output console and bring it forward if an associated process writes to Standard.out.
Show console when a message is printed to standard error stream	Select this check box to activate the output console and bring it forward if an associated process writes to Standard.err.
	Click this button to open the <a href="#">Edit Log Files Aliases dialog</a> where you can select a new log entry and specify an alias for it.
	Click this button to edit the properties of the selected log file entry in the <a href="#">Edit Log Files Aliases dialog</a> .
	Click this button to remove the selected log entry from the list.
	Click this button to edit the selected log file entry. The button is available only when an entry is selected.

## Toolbar

### ItemShortcutDescription

		Click this button to add a new configuration to the list.
		Click this button to remove the selected configuration from the list.
		Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	 or 	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of the current run/debug configuration. This field does not appear for the default run/debug configurations.
Defaults	This node in the left-hand pane of the dialog box contains the default run/debug configuration settings. Select the desired configuration to change its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	Select this check box to make the run/debug configuration available to other team members. If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate .xml file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.  If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.  This check box is not available when editing the run/debug configuration defaults.

Single instance only If this check box is selected, this run/debug configuration cannot be launched more than once. Every time a new run/debug configuration is launched, IntelliJ IDEA checks the presence of the other instances of the same run/debug configuration, and displays a confirmation dialog box. If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.

This makes sense when the usage of certain resources can cause conflicts, or when launching two run/debug configurations of the same type consumes too much of the CPU and memory resources.

If this check box is not selected, it is possible to launch as many instances of the runner as required. So doing, each runner will start in its own tab of the Run tool window.

Before launch Specify which tasks must be performed before applying the run/debug configuration. The specified tasks are performed in the order they appear in the list.

**ItemKeyboardDescription  
shortcut**

+	Alt+Insert	Description
		<p>Click this icon to add a task to the list. Select the task to be added:</p> <ul style="list-style-type: none"> <li>- Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. ## Configuration settings specific for App Engine for PHP

### ItemDescription

Name	In this text box, specify the name of the run/debug configuration.
Share	Select this check box to make the run/debug configuration available to other team members. If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.  If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.  This check box is not available when editing the run/debug configuration defaults.
Host	In this field, specify the host to run the development server and the application on (the default is <code>localhost</code> ).
Port	In this field, specify the port through which IntelliJ IDEA will communicate with the development server (the default port is <code>8888</code> ).

## Command Line area

In this area, specify the settings for running and debugging your application on the PHP development server in the command-line mode.

### ItemDescription

Interpreter options	In this field, specify the options to be passed to the PHP executable file of the built-in PHP interpreter, see <a href="#">Command-Line Arguments</a> for details.
Yaml files	In this field, specify the <code>.yaml</code> configuration files to use. This field is optional, use it when your application consists of several modules and therefore several <code>.yaml</code> configuration files are used.
Custom working directory	In this text box, specify the location of the files that are outside the folder with your sources and are referenced through relative paths. Type the path manually or click the Browse button  and select the desired folder in the <a href="#">dialog that opens</a> .
Environment variables	In this field, specify the environment variables be passed to the built-in server. See <a href="#">Environment Variables in Apache</a> for details.

## Toolbar

### ItemShortcutDescription

		Click this button to add a new configuration to the list.
		Click this button to remove the selected configuration from the list.
		Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	 or 	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

#### ItemKeyboardDescription shortcut

Alt+Insert

- Click this icon to add a task to the list. Select the task to be added:
- Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see [Configuring Third-Party Tools](#) and [External Tools](#).
  - Make. Select this option to have the project or module compiled. The [Make Module command](#) will be carried out if a particular module is specified in the run/debug configuration, and the [Make Project command](#) otherwise.  
If an error occurs during the compilation, IntelliJ IDEA won't attempt to start the run/debug configuration.
  - Make, no error check. The same as the Make option but IntelliJ IDEA will try to start the run/debug configuration irrespective of the compilation result.
  - Build Artifacts. Select this option to have an [artifact](#) or artifacts built. In the dialog that opens, select the artifact or artifacts that should be built.  
See also, [Working with Artifacts](#).
  - Run Another Configuration. Select this option to have another run/debug configuration executed. In the dialog that opens, select the configuration to run.  
This option is available only if you have already at least one run/debug configuration in the current project.
  - Run Ant target. Select this option to have an Ant target run. In the dialog that opens, select the target to be run. For more information, see [Ant](#).
  - Run Grunt task. Select this option to run a Grunt task. In the Grunt task dialog box that opens, specify the `Gruntfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Grunt tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `grunt-cli` package.
  - Run Gulp task. Select this option to run a Grunt task. In the Gulp task dialog box that opens, specify the `Gulpfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Gulp tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `gulp` package.
  - Run npm Script. Select this check box to execute an npm script. In the NPM Script dialog box that opens, specify the `package.json` file where the required script is defined, select the script to execute, choose the command to apply to it, and specify the arguments to execute the script with.  
Specify the location of the Node.js interpreter and the parameters to pass to it.
  - Compile TypeScript. Select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:
    - If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.
    - If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.

- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#) .
- Run Maven Goal. Select this option to have a Maven goal run. In the dialog that opens, select the goal to be run. For more information, see [Maven](#) .
- Run Remote External tool : Add a remote SSH external tool. Refer to the section [Remote SSH External Tools](#) for details.
- Upload files to Remote Host. Select this option to have the application files automatically uploaded to the server according to the default [server access configuration](#) . For more information, see [Configuring Synchronization with a Web Server](#) and [Uploading and Downloading Files](#) .
- Run Rake task :Add a Rake task to be executed prior to running or debugging. To choose a Rake task, click the browse button  , and select the desired task from the list of available tasks. Note that [code completion](#) is available here.

To learn more about Rake support, refer to [Rake Support](#) section.

- Run JRuby compiler : choose this option to execute JRuby compiler with the specified target path, compiler process heap size, and command line parameters (if any).

		Click this icon to remove the selected task from the list.
		Click this icon to edit the selected task. Make the necessary changes in the dialog that opens.
		Click this icon to move the selected task one line up in the list.
		Click this icon to move the selected task one line down in the list.
<b>Show this page</b>	<input type="checkbox"/>	Select this check box to have the run/debug configuration settings shown prior to actually starting the run/debug configuration.
<b>Active tool window</b>	<input type="checkbox"/>	Select this option if you want the <a href="#">Run /Debug</a> tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

An applet run/debug configuration enables you to run Java applets using an applet viewer or a Web page and your local browser.

This section provides descriptions of the [configuration-specific items](#) , as well as the [toolbar](#) and [options](#) that are common for all run/debug configurations.

#### ItemDescription

Name	In this text box, specify the name of the current run/debug configuration.
Applet Class	Choose this option to create a configuration profile for running an applet via an applet class.
URL	Choose this option to create a configuration profile for running an applet via a Web page.
Applet Class	Use the controls in the area to specify the applet implementation class and the applet size. <ul style="list-style-type: none"> <li>– Applet Class - in this text box, specify the fully qualified name of the applet class to run. Type the name manually or click the Browse button  to open the Choose Applet Class dialog box and select the path there.</li> <li>– Width - in this text box, type the desired width of the applet.</li> <li>– Height - in this text box, type the desired height of the applet.</li> </ul> <p>The area is available after the Applet Class option is chosen.</p>
Applet Parameters	In this area, specify a set of applet parameters. <ul style="list-style-type: none"> <li>– Add - click this button to add a new entry to the list.</li> <li>– Remove - click this button to delete the selected entry from the list.</li> <li>– Name - in this text bos, specify the name of the applet parameter.</li> <li>– Value - in this text bos, specify the parameter value.</li> </ul> <p>This area is available after the Applet Class option is chosen.</p>
URL	In the URL/HTML File text box, specify the file to invoke the applet from. Type the path to the file manually or click the Browse button  and select the file in the <a href="#">dialog that opens</a> . This area is available after the URL option is chosen.
Policy File	In this text box, specify the location of the <code>appletviewer.policy</code> file. Because this file is distributed with IntelliJ IDEA, the text box is by default filled in with the standard location. To specify another location, click the Browse button  and choose the desired location in the <a href="#">dialog that opens</a> .
VM Options for Applet Viewer	In this text box, specify the string to be passed to the VM for executing the applet viewer. Usually this string contains the options such as <code>-mx</code> , <code>-verbose</code> , etc. If necessary, click  and type the desired string in the VM Options dialog.  When specifying the options, follow these rules: <ul style="list-style-type: none"> <li>– Use spaces to separate individual options, for example, <code>-client -ea -Xmx1024m</code> .</li> <li>– If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, <code>some "arg</code> or <code>"some arg"</code> .</li> <li>– If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, <code>-Dmy.prop=\"quoted_value\"</code> .</li> </ul> <p>The <code>-classpath</code> option specified in this field overrides the classpath of the module.</p>
Use Classpath Module	From this drop-down list, select one of the modules configured in your project. The classpath and JDK of this module will be used to run the applet with the current run configuration.
Use Alternative JRE	Select this checkbox to enable defining another JRE than the JRE used by the current project / module.

## Toolbar

#### ItemShortcutDescription

		Click this button to add a new configuration to the list.
		Click this button to remove the selected configuration from the list.
		Click this button to create a copy of the selected configuration.
	Edit defaults	Click this button to edit the default configuration templates. The defaults are used for newly created configurations.
	 or 	Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.
	Move into new folder / Create new folder	Use this button to <a href="#">create a new folder</a> . If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.  Move run/debug configurations to a folder using drag-and-drop, or the  buttons.
	Sort configurations	Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of the current run/debug configuration. This field does not appear for the default run/debug configurations.
Defaults	This node in the left-hand pane of the dialog box contains the default run/debug configuration settings. Select the desired configuration to change its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	<p>Select this check box to make the run/debug configuration available to other team members.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p> <p>This check box is not available when editing the run/debug configuration defaults.</p>
Single instance only	<p>If this check box is selected, this run/debug configuration cannot be launched more than once.</p> <p>Every time a new run/debug configuration is launched, IntelliJ IDEA checks the presence of the other instances of the same run/debug configuration, and displays a confirmation dialog box. If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.</p> <p>This makes sense when the usage of certain resources can cause conflicts, or when launching two run/debug configurations of the same type consumes too much of the CPU and memory resources.</p> <p>If this check box is not selected, it is possible to launch as many instances of the runner as required. So doing, each runner will start in its own tab of the Run tool window.</p>
Before launch	Specify which tasks must be performed before applying the run/debug configuration. The specified tasks are performed in the order they appear in the list.

### ItemKeyboardDescription shortcut

Alt+Insert

Click this icon to add a task to the list. Select the task to be added:

- Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see [Configuring Third-Party Tools](#) and [External Tools](#).
- Make. Select this option to have the project or module compiled. The [Make Module command](#) will be carried out if a particular module is specified in the run/debug configuration, and the [Make Project command](#) otherwise.  
If an error occurs during the compilation, IntelliJ IDEA won't attempt to start the run/debug configuration.
- Make, no error check. The same as the Make option but IntelliJ IDEA will try to start the run/debug configuration irrespective of the compilation result.
- Build Artifacts. Select this option to have an [artifact](#) or artifacts built. In the dialog that opens, select the artifact or artifacts that should be built.  
See also, [Working with Artifacts](#).
- Run Another Configuration. Select this option to have another run/debug configuration executed. In the dialog that opens, select the configuration to run.  
This option is available only if you have already at least one run/debug configuration in the current project.
- Run Ant target. Select this option to have an Ant target run. In the dialog that opens, select the target to be run. For more information, see [Ant](#).
- Run Grunt task. Select this option to run a Grunt task. In the Grunt task dialog box that opens, specify the `Gruntfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Grunt tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `grunt-cli` package.
- Run Gulp task. Select this option to run a Gulp task. In the Gulp task dialog box that opens, specify the `Gulpfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Gulp tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `gulp` package.
- Run npm Script. Select this check box to execute an npm script. In the NPM Script dialog box that opens, specify the `package.json` file where the required script is defined, select the script to execute, choose the command to apply to it, and specify the arguments to execute the script with.  
Specify the location of the Node.js interpreter and the parameters to pass to it.
- Compile TypeScript. Select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:

- If the Check errors checkbox is selected, the compiler will show all the errors and the run configuration will not start.
- If the Check errors checkbox is cleared, the compiler will show all the detected errors but the run configuration still will be launched.
- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#).
- Run Maven Goal. Select this option to have a Maven goal run. In the dialog that opens, select the goal to be run. For more information, see [Maven](#).
- Run Remote External tool : Add a remote SSH external tool. Refer to the section [Remote SSH External Tools](#) for details.
- Run Rake task :Add a Rake task to be executed prior to running or debugging. To choose a Rake task, click the browse button , and select the desired task from the list of available tasks. Note that [code completion](#) is available here.

To learn more about Rake support, refer to [Rake Support](#) section.

- Run JRuby compiler : choose this option to execute JRuby compiler with the specified target path, compiler process heap size, and command line parameters (if any).

		Click this icon to remove the selected task from the list.
		Click this icon to edit the selected task. Make the necessary changes in the dialog that opens.
		Click this icon to move the selected task one line up in the list.
		Click this icon to move the selected task one line down in the list.
Show this page	<input type="checkbox"/>	Select this check box to have the run/debug configuration settings shown prior to actually starting the run/debug configuration.
Active tool window	<input type="checkbox"/>	Select this option if you want the <a href="#">Run /Debug</a> tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

This dialog lets you create a run/debug configuration for the selected Ant target.

#### ItemDescription

Name	This field shows the name of your Ant target that you have selected in the <a href="#">Ant Build tool window</a> .
Share	<p>Select this check box to make the run/debug configuration available to other team members.</p> <p>If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea\runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea\workspace.xml</code> file otherwise.</p> <p>If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.</p> <p>This check box is not available when editing the run/debug configuration defaults.</p>
Single instance only	<p>If this check box is selected, this run/debug configuration cannot be launched more than once.</p> <p>Every time a new run/debug configuration is launched, IntelliJ IDEA checks the presence of the other instances of the same run/debug configuration, and displays a confirmation dialog box. If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.</p> <p>This makes sense when the usage of certain resources can cause conflicts, or when launching two run/debug configurations of the same type consumes too much of the CPU and memory resources.</p> <p>If this check box is not selected, it is possible to launch as many instances of the runner as required. So doing, each runner will start in its own tab of the Run tool window.</p>
Before launch	Specify which tasks must be performed before applying the run/debug configuration. The specified tasks are performed in the order they appear in the list.

#### ItemKeyboardDescription shortcut

	<p><b>Alt+Insert</b> Click this icon to add a task to the list. Select the task to be added:</p> <ul style="list-style-type: none"><li>– Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. ---	--

- Generate CoffeeScript Source Maps. Select this option to have the source maps for your CoffeeScript sources generated. In the dialog that opens, specify where your CoffeeScript source files are located. For more information, see [CoffeeScript](#) .
- Run Maven Goal. Select this option to have a Maven goal run. In the dialog that opens, select the goal to be run. For more information, see [Maven](#) .
- Run Remote External tool : Add a remote SSH external tool. Refer to the section [Remote SSH External Tools](#) for details.
- Upload files to Remote Host. Select this option to have the application files automatically uploaded to the server according to the [default server access configuration](#) . For more information, see [Configuring Synchronization with a Web Server](#) and [Uploading and Downloading Files](#) .
- Run Rake task :Add a Rake task to be executed prior to running or debugging. To choose a Rake task, click the browse button  , and select the desired task from the list of available tasks. Note that [code completion](#) is available here.

- To learn more about Rake support, refer to [Rake Support](#) section.
- Run JRuby compiler : choose this option to execute JRuby compiler with the specified target path, compiler process heap size, and command line parameters (if any).

	<input type="button" value="Alt+Delete"/>	Click this icon to remove the selected task from the list.
	<input type="button" value="Enter"/>	Click this icon to edit the selected task. Make the necessary changes in the dialog that opens.
	<input type="button" value="Alt+Up"/>	Click this icon to move the selected task one line up in the list.
	<input type="button" value="Alt+Down"/>	Click this icon to move the selected task one line down in the list.
Show this page	<input type="checkbox"/>	Select this check box to have the run/debug configuration settings shown prior to actually starting the run/debug configuration.
Active tool window	<input type="checkbox"/>	Select this option if you want the <a href="#">Run /Debug</a> tool windows to be activated automatically when you run/debug your application. This option is enabled by default.

The **application** run/debug configuration enables you running or debugging applications via the `main()` method .

The dialog box consists of the following tabs:

- [Configuration tab](#)
- [Code Coverage tab](#)
- [Logs tab](#)

Click [here](#) for the description of the options that are common for all run/debug configurations.

## Configuration tab

### ItemDescription

**Main class** In this text box, specify the fully qualified name of the class to be executed (passed to the JRE). Type the class name manually or click the Browse button  to open the Choose Main Class dialog box, where you can find the desired class by name or search through the project.

**VM options** In this text box, specify the string to be passed to the VM for launching an application. Usually this string contains the options such as `-mx` , `-verbose` , etc.  
If necessary, click  and type the desired string in the VM Options dialog.

When specifying the options, follow these rules:

- Use spaces to separate individual options, for example, `-client -ea -Xmx1024m` .
- If an option includes spaces, enclose the spaces or the argument that contains the spaces in double quotes, for example, `some "arg or "some arg"` .
- If an option includes double quotes (e.g. as part of the argument), escape the double quotes by means of the backslashes, for example, `-Dmy.prop="\quoted_value\"` .

The `-classpath` option specified in this field overrides the classpath of the module.

**Program arguments** In this text box, type a list of arguments to be passed to the program in the format you would use in the command line. If necessary, click the  button and type the desired arguments in the Program Parameters dialog box. Use the same rules as for specifying the [VM options](#) .

**Working directory** In this text box, specify the current directory to be used by the running application. This directory is the starting point for all relative input and output paths. By default, the field contains the directory where the project file resides. To specify another directory, click the Browse button  select the directory in the [dialog that opens](#) .  
Click this  icon to view the list of available [path variables](#) that you can use as a path to your working directory.

**Note** The list of the path variables may vary depending on the enabled plugins.

**Environment variables** Click the Browse button  to open the Environment Variables dialog box, where you can create variables and specify their values.  
Note that you can copy-paste the contents of the Environment variables field without having to open the Environment Variables dialog box.

**Use classpath of module** Select the module whose classpath should be used to run the application.

**JRE** By default, the newest JDK from the module dependencies is used to run the application. If you want to specify an alternative JDK or JRE here, select it from the drop-down list.

**Enable capturing form snapshots** Select this check box to enable the [GUI Designer](#) to [take snapshots of the GUI components](#) , that can be afterwards converted into a form.

## Code Coverage tab

Use this tab to configure [code coverage](#) monitoring options.

### ItemDescription

**Choose code coverage runner** Select the desired code coverage runner.  
By default, IntelliJ IDEA uses its own coverage engine with the Sampling mode. You can also choose [JaCoCo](#) or [Emma](#) for calculating coverage.

**Sampling** Select this option to measure code coverage with minimal slow-down.

**Tracing** Select this option to collect accurate branch coverage. This mode is available for the IntelliJ IDEA code coverage runner only.

**Track per test coverage** Select this check box to detect lines covered by one test and all tests covering line. If this check box is selected,  becomes available on the toolbar of the coverage statistic pop-up window.

**Note** This option is only available for the Tracing mode of code coverage measurement for the testing run/debug configurations.

Refer to the section [Viewing Code Coverage Results](#) .

**Merge data with previous results** When you run your unit testing or application configuration several times, use this item to calculate statistics in the Project View , taking into account the statistics of each time you have run the configuration.

**Tip** Finally, the line is considered *covered* if it is covered at least once.

---

Packages and classes to record code coverage data

Click  and  buttons to specify classes and packages to be measured. You can also remove classes and packages from the list by selecting them in the list and clicking the  button.

 Click this button to define the scope of code coverage analysis. In the Add Pattern dialog box that opens, type the comma-delimited list of Ruby regular expressions, and specify whether the matching files should be included into or excluded from code coverage analysis. The patterns defining files to be included into code coverage analysis, are marked with + ; the ones to be excluded are marked with - .

Each pattern can be enabled or disabled. To do that, select or clear the check box next to a pattern. By default, all newly created patterns are enabled.

 Click this button to delete the selected pattern from the list.

 Click this button to change the selected code coverage pattern.

Do not use the optimized C runtime Select this check box to enable the option `--no-rcovrt` . Use this option with discretion, since it significantly slows down performance.

Enable coverage in test folders. If this check box is selected, the folders marked as test  are included in the code coverage analysis.

Use bundled coverage.py If this check box is selected, IntelliJ IDEA will use the bundled `coverage.py` .

If this check box is not selected, IntelliJ IDEA will use the coverage tool included in the selected Python interpreter. Refer to the section [Code Coverage](#) for details.

## Logs tab

Use this tab to specify which log files generated while running or debugging should be displayed in the console, that is, on the dedicated tabs of the [Run](#) or [Debug tool window](#) .

### ItemDescription

Is Active Select check boxes in this column to have the log entries displayed in the corresponding tabs in the [Run tool window](#) or [Debug tool window](#) .

Log File Entry The read-only fields in this column list the log files to show. The list can contain:

- Full paths to specific files.
- [Ant patterns](#) that define the range of files to be displayed.
- Aliases to substitute for full paths or patterns. These aliases are also displayed in the headers of the tabs where the corresponding log files are shown. If a log entry pattern defines more than one file, the tab header shows the name of the file instead of the log entry alias.

Skip Content Select this check box to have the previous content of the selected log skipped.

Save console output to file Select this check box to save the console output to the specified location. Type the path manually, or click the browse button and point to the desired location in the [dialog that opens](#) .

Show console when a message is printed to standard output stream Select this check box to activate the output console and bring it forward if an associated process writes to Standard.out.

Show console when a message is printed to standard error stream Select this check box to activate the output console and bring it forward if an associated process writes to Standard.err.

 Click this button to open the [Edit Log Files Aliases dialog](#) where you can select a new log entry and specify an alias for it.

 Click this button to edit the properties of the selected log file entry in the [Edit Log Files Aliases dialog](#) .

 Click this button to remove the selected log entry from the list.

 Click this button to edit the select log file entry. The button is available only when an entry is selected.

## Toolbar

### ItemShortcutDescription

  `Alt+Insert` Click this button to add a new configuration to the list.

  `Alt+Delete` Click this button to remove the selected configuration from the list.

  `Ctrl+D` Click this button to create a copy of the selected configuration.

 Edit defaults Click this button to edit the default configuration templates. The defaults are used for newly created configurations.

 or   or  `Alt+Up` or `Alt+Down` Use these buttons to move the selected configuration or folder up and down in the list. The order of configurations or folders in the list defines the order in which configurations appear in the Run/Debug drop-down list on the main toolbar.

 Move into new Use this button to [create a new folder](#) .

folder / Create new folder If one or more run/debug configurations are in focus, the selected run/debug configurations are automatically moved to the newly created folder. If only a category is in focus, an empty folder is created.

Move run/debug configurations to a folder using drag-and-drop, or the  buttons.

Sort configurations Click this button to sort configurations in alphabetical order.

## Common options

### ItemDescription

Name	In this text box, specify the name of the current run/debug configuration. This field does not appear for the default run/debug configurations.
Defaults	This node in the left-hand pane of the dialog box contains the default run/debug configuration settings. Select the desired configuration to change its default settings in the right-hand pane. The defaults are applied to all newly created run/debug configurations.
Share	Select this check box to make the run/debug configuration available to other team members. If the <a href="#">directory-based project format</a> is used, the settings for a run/debug configuration are stored in a separate <code>.xml</code> file in the <code>.idea/runConfigurations</code> folder if the run/debug configuration is shared, or in the <code>.idea/workspace.xml</code> file otherwise.  If the <a href="#">file-based format</a> is used, the settings are stored in the <code>.ipr</code> file for shared configurations, or in the <code>.iws</code> file otherwise.  This check box is not available when editing the run/debug configuration defaults.
Single instance only	If this check box is selected, this run/debug configuration cannot be launched more than once. Every time a new run/debug configuration is launched, IntelliJ IDEA checks the presence of the other instances of the same run/debug configuration, and displays a confirmation dialog box. If you click OK in the confirmation dialog box, the first instance of the runner will be stopped, and the next one will take its place.  This makes sense when the usage of certain resources can cause conflicts, or when launching two run/debug configurations of the same type consumes too much of the CPU and memory resources.  If this check box is not selected, it is possible to launch as many instances of the runner as required. So doing, each runner will start in its own tab of the Run tool window.
Before launch	Specify which tasks must be performed before applying the run/debug configuration. The specified tasks are performed in the order they appear in the list.

### ItemKeyboardDescription shortcut

Alt+Insert

Click this icon to add a task to the list. Select the task to be added:

- Run External tool. Select this option to run an application which is external to IntelliJ IDEA. In the dialog that opens, select the application or applications that should be run. If the necessary application is not defined in IntelliJ IDEA yet, add its definition. For more information, see [Configuring Third-Party Tools and External Tools](#).
- Build Artifacts. Select this option to have an [artifact](#) or artifacts built. In the dialog that opens, select the artifact or artifacts that should be built.  
See also, [Working with Artifacts](#).
- Run Another Configuration. Select this option to have another run/debug configuration executed. In the dialog that opens, select the configuration to run.  
This option is available only if you have already at least one run/debug configuration in the current project.
- Run Ant target. Select this option to have an Ant target run. In the dialog that opens, select the target to be run. For more information, see [Ant](#).
- Run Grunt task. Select this option to run a Grunt task. In the Grunt task dialog box that opens, specify the `Gruntfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Grunt tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `grunt-cli` package.
- Run Gulp task. Select this option to run a Gulp task. In the Gulp task dialog box that opens, specify the `Gulpfile.js` where the required task is defined, select the task to execute, and specify the arguments to pass to the Gulp tool.  
Specify the location of the Node.js interpreter, the parameters to pass to it, and the path to the `gulp` package.
- Run npm Script. Select this check box to execute an npm script. In the NPM Script dialog box that opens, specify the `package.json` file where the required script is defined, select the script to execute, choose the command to apply to it, and specify the arguments to execute the script with.  
Specify the location of the Node.js interpreter and the parameters to pass to it.
- Compile TypeScript. Select this option to run the built-in TypeScript compiler and thus make sure that all the changes you made to your TypeScript code are reflected in the generated JavaScript files. In the TypeScript Compile Settings dialog that opens, select or clear the Check errors checkbox to configure the behaviour of the compiler in case any errors are detected:
